Molar heat capacities of the linear alcohols 1-dodecanol ($C_{12}H_{26}O$) and 1-tridecanol ($C_{13}H_{28}O$) were measured from 10 K to 380 K. The alcohols 1-pentadecanol ($C_{15}H_{32}O$) and 1-heptadecanol ($C_{17}H_{36}O$) were measured between 300 K and 370 K. Derived thermodynamic functions were given for the first two alcohols, and correlations for the molar heat capacity of the compounds in the liquid state and for the absolute entropy at 360 K were presented. These correlations were fit by using both these data and earlier published data on the linear alcohols with the number of carbon atoms (*n*) in the chain up to n = 22. The molar heat capacities of the liquid 1-alcohols can be described by $C_{p,l}(n,T) = \{-265.2 + 27.41n + 0.02501nT + 0.96196T\}$ J·K⁻¹·mol⁻¹. The correlation for the absolute entropy is *S*°(360 K, *n*) = $\{111.80 + 38.607n)$ J·K⁻¹·mol⁻¹.

Introduction

This is the second article on the heat capacities and derived thermodynamic properties of the normal 1-alcohols. In the first article¹ heat capacity measurements on the compounds 1-octadecanol, 1-nonadecanol, 1-eicosanol, and 1-docosanol were presented. The object of this study is to extend the available data on the 1-alcohols and to look for relations between the thermodynamic properties. While this group of compounds has both commercial and scientific interest, properties such as accurate heat capacities and entropy values have not been measured previously. Most of the work done on these compounds is by Sirota,² who made precise DSC measurements. Mosselman et al.³ published results on the alcohols with a carbon number between 13 and 16. Their work is of a more qualitative nature; results are derived from heating and cooling curves in an adiabatic semi-microcalorimeter. Watanabe⁴ presented temperature-time curves in the heating and cooling modes of several n-alcohols and also reported X-ray diffraction patterns of pure and mixed alcohols. Meyer and Reid⁵ presented cooling curves from the melt of the alcohols with 10 to 18 carbon atoms. For the liquid state there are a few references: Vasil'ev et al.⁶ reported the heat capacities of liquid 1-nonanol, 1-undecanol, 1-dodecanol, and 1-pentadecanol, Svensson⁷ measured the heat capacities of 1-decanol and 1-dodecanol, and Khasanshin⁸ reported analytical expressions for the heat capacities of the normal alcohols with a carbon number of 11 to 18.

Experimental Section

The compounds were purchased from Fluka Chemica with a stated purity of better than 98%. The compounds were used without further purification; care was taken to avoid contact with the air. The calorimeter vessel was filled in a glovebox under a dry nitrogen atmosphere. 1-Dode-canol and 1-tridecanol were measured in CALV (laboratory design indication).^{9,10} Below 30 K, the reproducibility of this calorimeter is about 1%, between 30 K and 100 K, it is 0.05 to 0.1%, and above 100 K, it is 0.03%. The accuracy of the heat capacity measurements was checked with *n*-heptane and with synthetic sapphire. Deviations larger than 0.2% from the recommended values were not found.

1-Pentadecanol and 1-heptadecanol were measured in Cal8, a scaled down version of Cal V. Cal8 is described in detail in a recent article.¹¹ This calorimeter works with samples of about 0.4 g, and the accuracy is estimated to be 0.5% for heat capacity measurements and 0.2% for latent energy effects such as the enthalpy of fusion. Both calorimeters use a rhodium—iron thermometer calibrated by Oxford Instruments to 0.001 K. The temperature scale used is the ITS-90.¹² Molar masses were calculated using the IUPAC tables of 1991.¹³

The filled vessel was evacuated for half an hour; then a helium pressure of about 1 kPa was admitted before closing, in order to promote the heat exchange within the vessel. Measurements were made in the intermittent mode, using stabilization periods of about 600 s and heat input periods of about 500 s. Between 5 K and 30 K, stabilization and input periods of about 100 to 150 s were used. The temperature increase was generally about 2 to 3 K for each measurement. Each compound was first measured from

room temperature up to about 360 K. Then a slow, controlled cooling curve was measured by setting the inner adiabatic shield and the wire heater about 10 K below the temperature of the vessel. This resulted in a cooling rate outside the crystallization area of about $4 \text{ K} \cdot \text{h}^{-1}$.

After completion of the measurements, all data were combined in one file. The data consist of the mean temperatures, the mean heat capacity over the measurement interval, and the relative enthalpy values. After calculating starting values for the entropy and enthalpy at 10 K, the dataset was interpolated for every degree. The derived properties were calculated by numerical integration. The starting values of S° and $H^{\circ}(T) - H^{\circ}(0)$ were calculated assuming that below 10 K the low-temperature limit of the Debye heat capacity function $C_{\rm p} = \alpha T^3$ holds.

Results and Discussion

1-Dodecanol. From the first melting experiment and the subsequent cooling curve, it was concluded that this compound does not show a solid–solid phase transition. The cooling curve did show an undercooling of the crystallization of 2.6 K. The combined experimental data set is given in Table 1. In the melt, heat capacity values are $> 10^5$ J·K⁻¹·mol⁻¹; these values are not included in Table 1, instead the equilibrium temperatures in the melt and the

^{*a*} The following linear fits of the heat capacity were used to calculate the enthalpy of fusion: $C_p[\text{solid}] = \{-158.30 + 1.7360 T\}$ J·K⁻¹·mol⁻¹ and $C_p[\text{liquid}] = \{78.02 + 1.2203 T\}$ J·K⁻¹·mol⁻¹.

reciprocal of the melted fraction are given in Table 2. In Figure 1 the heat capacity curve is shown. The second derivative of the heat capacity curve of the solid becomes positive around 200 K. This temperature is too low to be explained by impurity effects. To calculate the enthalpy of fusion and the fractional melting curve, a linear function was fitted to the heat capacity of the solid between 250 and 270 K. This fit and a linear fit of the heat capacity of the liquid phase were used to construct the baseline of the enthalpy curve. The results of the two melting experiments and the fits for the used baselines are given in Table 3. The second melting experiment was made with stabiliza-

Figure 2. Equilibrium temperature in the melt of 1-dodecanol versus the reciprocal of the melted fraction. The linear behavior of this plot indicates that the impurity does form a eutectic system with the compound.

tion periods of 1500 s. Equilibrium temperatures in the melt were calculated by exponential extrapolation. The stabilization periods used were sufficiently long to give a correspondence of the calculated extrapolated temperature and the temperature at the end of the stabilization period of 0.001 K. The plot of the equilibrium temperature against the reciprocal of the melted fraction (*F*), as given in Figure 2, is a straight line up to 1/F = 6. This indicates that the impurity does form a eutectic system with the compound and that the van't Hoff law is applicable. The triple point temperature (at 1/F = 0) is 297.30 K; the calculated molar purity is 99.62%.

For the numerical calculation of the enthalpy and the entropy increments from 0 K, the relation $C_p = \alpha T^3$ was used. From the data between 4 K and 6 K, α was calculated to be $3.46 \times 10^{-3} \text{ J} \cdot \text{K}^{-4} \cdot \text{mol}^{-1}$. From 6 K on, the data were interpolated for every degree. The resulting thermodynamic data are given in Table 4. Near the melting point, the heat capacities are extrapolated according to the functions given in Table 3. The result of the second melting experiment is used to calculate the entropy and the enthalpy of the liquid at 297.30 K.

1-Tridecanol. The compound (4.945 g) was loaded as received in the calorimeter. Several measuring series were carried out, followed by a controlled cooling. The first

Figure 3. Molar heat capacity of 1-tridecanol around the solid– solid transition and the melt: (•) the compound as received; (\bigcirc) measurement after cooling from the melting temperature to 294.7 K (in this cooling process the solid–solid transition did not take place); (•) measurement after cooling to 260 K; (\bigtriangledown) measurement after cooling to 4 K. The lines drawn are only intended as a guide for the eye.

measuring series were used to assess the thermal behavior of the compound and were not tabulated. Some of the results are shown in Figure 3, which shows the dependence of the solid-solid transition on the thermal history. In Table 5 the experimental heat capacity data of the series 5 to 8 are given. These measurements form a continuous set from 5 K to 335 K. The measurements in the transition and fusion region are given separately in Table 6. In this table, enthalpy increments are also given. Three measurements were made for the solid-solid transition and the melt. These two effects could not be separated, as the heat capacity between them does remain anomalously high. From the enthalpy curves of series 1 and 2, we estimate the enthalpy of the solid-solid transition to be 1500 J·mol⁻¹. Series 2 was made on the undercooled hightemperature solid phase. The two enthalpy curves, matched to be equal in the liquid phase, are given in Figure 4. The difference at 300 K is assumed to be the enthalpy of the solid-solid transition. The other melting experiments do give a very different ratio between the solid-solid transition and the melt. However, the first experiment was performed on an annealed sample and is probably closest to thermodynamic equilibrium. In Table 7, the linear fits of the heat capacity of the solid and the liquid phase used

to calculate the baseline and the results of the transition and melt experiments are given. The baseline was calculated by extrapolating both fits to the end melting point. No iterative procedure, as is often done in adiabatic calorimetry to calculate a sigmoid baseline, was applied. The end of the fusion is given as T_{end} . The triple point temperature could not be calculated, as the solid–solid transition distorts the plot of the reciprocal of the melted fraction. The sum of the enthalpies of transition and of fusion is, within the margin of uncertainties, the same for the three experiments. This is remarkable, as it was expected that the enthalpy of the solid would be different. In Table 8 the calculated thermodynamic properties at selected temperatures are given.

The cooling curves are given in Figure 5a. As different cooling rates were used (cool1, 2.848 K·h⁻¹, cool2, 4.605 K·h⁻¹, and cool3, 1.01 K·h⁻¹, all calculated between 310 K and 304 K), the time axes of cool1 and cool2 were scaled in order to represent all three curves in one plot on the same temperature scale. The compound does show polymorphic behavior; it crystallizes in a metastable form, which exists only temporally. The temperature at which this crystallization took place was in the range 303.1 K to 303.2 K, depending on the cooling rate. In Figure 5b an enlarged

Figure 4. Enthalpy curves of 1-tridecanol around the melt. The solid line gives the enthalpy curve of the compound as received, and the broken line gives the enthalpy curve of the compound after cooling to 294.7 K; in this cooling process, the solid–solid transition did not occur.

 a The following linear fits of the heat capacity were used to calculate the enthalpy of the transition and the fusion: ${\it C}_p[solid,$ between 275 K and 285 K] = {-281.6 + 2.24226 T} J·K⁻¹·mol⁻¹ and ${\it C}_p[liquid,$ between 310 K and 320 K] = {86.66 + 1.29985 T} J·K⁻¹·mol⁻¹.

view around the crystallization region is shown. When 15 to 30% of the liquid was crystallized, a sudden transition to the stable crystal form took place. There seems to be no relation between the cooling rate and the amount of metastable crystalline material that could be formed. The solid–solid transition does show an undercooling of 8 to 10 K.

1-Pentadecanol. The compound (0.4102 g) was loaded as received in the calorimeter (Cal8). Two measurement

Figure 5. (a) Three controlled cooling curves of 1-tridecanol. The three curves are plotted on one axis by scaling cooling curves 1 and 2 to the time axis of cooling curve 3. Cooling curve 1 was stopped at 294.7 K before the solid-solid transition took place; the encircled part is enlarged in part b. (b) View of a part of the three cooling curves of 1-tridecanol (see Figure 5a); the compound crystallizes in a metastable crystalline form, which transforms spontaneously into the stable high-temperature crystalline form.

series were made. The first series ranged from 297 K to 360 K, with an input time of 600 s and a stabilization time of 1000 s. The actual melting procedure took about 6 h.

Table 9. Experimental Data Series for 1-Pentadecanol

The experimental results are given in Table 9. In this table, the temperatures in the midpoints of the heat inputs, the molar heat capacities, and the relative enthalpy at the aforementioned temperatures are given. A controlled cooling curve gave two thermal arrests. The first arrest, when liquid transformed into the rotator phase, shows hardly any undercooling. The second arrest, when the rotator phase changes to the crystalline phase, does show an undercooling of 4.3 K. The second heat capacity measurement series was made with a stabilization time of 2000 s; it ranged from 299 K to 380 K. Both measurement series do not indicate a metastable form; the drift of the calorimeter in the stabilization periods is within the normal range. The heat capacities of the two series are comparable within the reproducibility limit of the calorimeter (0.03%). This remark should be considered in connection with the results of 1-heptadecanol (in the next section) and 1-nonadecanol;¹ both these compounds crystallize from the liquid in a

Figure 6. Experimental heat capacity curve and enthalpy curve for 1-pentadecanol in the transition and fusion region: (\bullet) heat capacity measurement on the compound as received; (\blacktriangle) heat capacity curve of the once melted sample; (\bigcirc) and (\triangle) give the corresponding enthalpy curves.

Table 10. Melting Experiments of 1-Pentadecanol^a

ovnoriment	$\frac{T_{\text{transition}}}{\kappa}$	$\frac{T_{\text{fus}}}{\kappa}$	ΔH_{total}
experiment	N	К	J-11101
1	315.4	316.9	53 686
2	315.4	316.9	53 551
mean value	315.4	316.9	$53~618\pm100$

^{*a*} The following linear fits of the heat capacity were used to calculate the enthalpies of transition and of fusion together: $C_p[\text{solid}] = \{-622.93 + 3.5084T\}$ and $C_p[\text{liquid}] = \{267.19 + 0.96076T\}$ J·K⁻¹·mol⁻¹.The total enthalpy of transition and of fusion can be divided into 21.4 kJ·mol⁻¹ for the solid–solid transition and 32.1 kJ·mol⁻¹ for the fusion.

metastable form. In Figure 6, the heat capacity curves and the enthalpy curves around the transition and the melt are given. The sum of the enthalpies of transition and of fusion was calculated and is given in Table 10. The solid–solid phase transition is not separated from the melting process. From the enthalpy curve and the cooling curve it was estimated that the enthalpy of transition is about two-thirds of the enthalpy of fusion. So the total enthalpy of transition and of fusion as given in Table 10 can be divided into $21.4 \text{ kJ} \cdot \text{mol}^{-1}$ for the solid–solid transition and $32.2 \text{ kJ} \cdot \text{mol}^{-1}$ for the fusion process.

1-Heptadecanol. The calorimeter was loaded with 0.4473 g. Four measurement series were made; the experimental data are given in Table 11. In this table the relative enthalpies are shifted in such a way that they coincide in the liquid state. In Figure 7, the enthalpy curves of the first two measurements are given. The two linear fits of the enthalpies of the solid phase do show that the enthalpy of the recently melted product is higher than the enthalpy of the product as received, which was annealed by storing at room temperature. The observed difference at 310 K is 1000 J·mol⁻¹ (Table 12).

Liquid State. In a previous article on the *n*-alcohols,¹ we presented a fit of the heat capacities of the liquid state

Figure 7. Enthalpy curves of 1-heptadecanol around the transition and melt: (\triangle) series 1 on the compound as received; (+) series 2 after cooling from the melting temperature.

of 1-octadecanol, 1-nonadecanol, 1-eicosanol, and 1-docosanol. The fit used was given by

$$C_{\text{p,meas}}$$
/J·K⁻¹·mol⁻¹ =
(-450.41 + 36.4968*n* + 1.473177) (1)

where n is the number of carbon atoms in the molecules and T the temperature in Kelvin. Then we combined these

Table 12. Melting Experiments of 1-Heptadecanol^a

	$T_{\text{transition}}$	$T_{ m fus}$	$\Delta H_{\mathrm{total}}$
experiment	K	K	J•mol ^{−1}
1	324.1	327.3	63 043
2	323.2	327.3	63 081
mean value		327.3	$63~062\pm100$

^a The following linear fits of the heat capacity were used to calculate the enthalpy of transition and fusion together: $C_p[solid] = \{-713.81 + 3.9224T\}$ and $C_p[liquid] = \{181.33 + 1.44359T\}$ J·K⁻¹·mol⁻¹.The division of the total enthalpy between the enthalpy of transition and the enthalpy of fusion is about 23.7 kJ·mol⁻¹ for the transition and 39.4 kJ·mol⁻¹ for the fusion.

data with the results in this article. All data for the liquid state were used and combined in a file consisting of temperature–number of carbon atoms–heat capacity triplets. A total of 339 data points (N) were used. Using the same fit-coefficients as in eq 1, a mean percentage deviation,

$$M\% = \frac{\sum_{i=1}^{i=N} \frac{Abs(C_{p,meas} - C_{p,fit})}{C_{p,meas}}}{N}$$
(2)

Table 13. Measured and Correlated Absolute Entropies at 360 \mathbb{K}^a

		$S_{\rm abs}(360 \text{ K}) \text{ meas}$	S _{abs} (360 K) correl	dev
compound	n ^b	J•K ^{−1} •mol ^{−1}	J•K ⁻¹ •mol ⁻¹	%
1-dodecanol	12	574.8	575.1	0.05
1-tridecanol	13	613.6	613.7	0.01
1-octadecanol	18	806.8	806.8	0.00
1-nonadecanol	19	845.8	845.4	0.05
1-eicosanol	20	885.1	884.1	0.12
1-docosanol	22	960.2	961.3	0.12

^{*a*} The correlation is $S_{abs}(360 \text{ K}) = (111.52 + 38.627n) \text{ J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$. ^{*b*} Number of carbon atoms.

of 0.4% was found. This result could be improved significantly by adding one parameter. Fitting the data to the form

$$C_{\rm p,meas}/J\cdot K^{-1}\cdot {\rm mol}^{-1} = (a_0 + a_1n + a_2nT + a_3T)$$
 (3)

resulted in

$$C_{\text{p,meas}}/J\cdot K^{-1}\cdot \text{mol}^{-1} =$$

(-265.2 + 27.41*n* + 0.0250*nT* + 0.96196*T*) (4)

The mean percentage deviation (M%) of this fit was 0.13%, which is on the order of the experimental error, considering that two different calorimeters were used.

Correlation of the Entropy at 360 K. In Table 13 the experimental absolute entropy values at 360 K are given for the *n*-alcohols with the carbon numbers 12, 13, 18, 19, 20, and 22. A linear fit as a function of the number of carbon atoms in the molecules resulted in the correlation

$$S(360 \text{ K}) = (111.80 + 38.607 n) \text{ J} \cdot \text{K}^{-1} \cdot \text{mol}^{-1}$$

The standard deviation of this equation is $0.8 \text{ J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$, and the maximum deviation is 0.12% for n = 22. The

deviations from the linear fit are within the expected experimental uncertainty.
