Abstract

We provide several notions of confluence in processes and we show how these relate to τ-inertness, i.e. if $s \xrightarrow{\tau} s'$, then s and s' are equivalent. Using deterministic linear processes we show how these notions can conveniently be used to reduce the size of state spaces and simplify the structure of processes while preserving equivalence.

1 Introduction

In his seminal book [12] Milner devotes a chapter to the notions strong and observation confluence in process theory. Many other authors have confirmed the importance of confluence. E.g. in [13, 9, 5] the notion is used for on the fly reduction of finite state spaces and in [12, 15] it has been used for the verification of protocols.

We feel that a more general treatment of the notion of confluence is in order. The first reason for this is that the treatment of confluence has always been somewhat ad hoc in the setting of process theory. This strongly contrasts with for instance term rewriting [10], where confluence is one of the major topics. In particular, we want to clarify the relation with *τ-inertness*, which says that if $s \xrightarrow{\tau} s'$, then s and s' are equivalent in some sense.

The second reason is that we want to develop systematic ways to prove distributed systems correct in a precise and formal fashion. In this way we want to provide techniques to construct fault free distributed systems. For this purpose the language μCRL is designed, being process algebra extended with data [7]. In [6] a proof theory has been developed and in [14] it has been shown how correctness proofs can be checked using proof checkers, giving us the means to deliver descriptions of distributed systems with the highest thinkable level of correctness. In order to show the applicability of the techniques several protocols have been verified [11, 8, 3], both from theoretical and practical perspectives. Experience with these protocols gave rise to the development of new and the adaption of existing techniques to make systematic verification possible [4, 3]. Employing confluence also belongs to these techniques. It appears to enable easier verification of distributed systems, which in essence boils down to the application of τ-inertness.

In the first part of the paper we address the relationship between confluence and τ-inertness. The notions proposed in [12] all imply τ-inertness. We come up with a more general notion, namely weakly $\sim$-confluence where $\sim$ is some equivalence. For several notions of equivalence

we show that weakly $\sim$-confluence and τ-inertness with respect to $\sim$ coincide (especially for weak and branching bisimulation), provided the process is τ-well founded (there are no infinite τ-paths).

However, there are many protocols, where there are infinite τ-paths, for instance communication protocols over unreliable channels. Therefore, we introduce the distinction between progressing and non progressing τ's and show that weakly progressing confluence is enough to guarantee τ-inertness. Contrary to what one would expect, weakly $\sim$-progressing confluence does not imply τ-inertness.

In the second part of this paper we direct our attention to establishing confluence. It does hardly make sense to establish confluence directly on transition systems, because these are generally far too large to be represented. Therefore, we try to establish confluence on Linear Processes [4] which represent large transition systems symbolically in a compact way.

In the third part we show how we can use τ-inertness to reduce state spaces and carry out verifications on linear processes. We provide two examples illustrating that the application of confluence often reduces the size of state spaces considerably and simplifies the structure of distributed systems, while preserving branching bisimulation. This is in general a very profitable preprocessing step before analysis, testing or simulation of a distributed system.

Acknowledgements. We thank Marc Bezem for discussion in an early phase of the project and Frits Vaandrager for demonstrating the importance of confluence in the verification of a leader election protocol. Furthermore we thank Jaco van de Pol and Wan Fokkink for comments on a draft version of this paper.

2 Preliminary definitions

Let S and S' be sets. A binary relation R on S and S' is a subset of $S \times S'$. We write xRy for $(x,y) \in R$. If $S \equiv S'$ we say that R is a binary relation on S. We write $xRyRz$ for $xRy \wedge yRz$ and R^* for the reflexive, transitive closure of R. The symmetric closure of R is denoted by R°. We write $R^\circledast$ for $(R^\circ)^*$. This relation is an equivalence relation, since symmetry is preserved[1] by $(-)^*$. Finally, we write Δ_R for the diagonal-relation on R, i.e. $\Delta_R = \{(x,x) \mid x \in R\}$.

Definition 2.1. *A binary relation R on S is called well-founded iff there is no infinite sequence $\{s_i\}_{i=0}^{\infty}$ such that $s_{i+1} R s_i$ for all $i \in \mathbb{N}$.*

Let Act be an arbitrary set of actions, containing a distinguished element τ. Throughout this paper we fix this set of actions, except that from Section 5 we distinguish progressing τ-steps (denoted by $\tau_>$) and non-progressing τ-steps (denoted by $\tau_<$).

Definition 2.2. *A transition system is a pair $(S, \longrightarrow\!\!\triangleright)$ with S a set and $\longrightarrow\!\!\triangleright \subseteq S \times \text{Act} \times S$. We write $s \xrightarrow{a}\!\!\triangleright\, t$ instead of $\longrightarrow\!\!\triangleright\, (s,a,t)$.*

Note that this definition implies that we exclude transition systems that have more than one a-step from s to s'.

[1] The converse does not hold, $(R^*)^\circ$ is not necessarily transitive.

Convention 2.3. *We introduce the following notations* ($a \in \text{Act}, \sigma \in \text{Act}^\star$)*:*

- $s \xrightarrow{a^*} t$ *means* $s \equiv u_1 \xrightarrow{a} \cdots \xrightarrow{a} u_n \equiv t$ *for some* $u_1, \ldots, u_n$ *with* $n \geq 1$,
- $s \xrightarrow{\sigma a} t$ *means* $s \xrightarrow{\sigma} u \xrightarrow{a} t$ *for some* u,
- $s \stackrel{a}{\Longrightarrow} t$ *means* $s \xrightarrow{\tau^*} u_1 \xrightarrow{a} u_2 \xrightarrow{\tau^*} t$ *for some* u_1, u_2.
- $s \stackrel{a}{\Longrightarrow} t$ *means* $s \stackrel{a}{\Longrightarrow} t \ \vee \ (a \equiv \tau \wedge s \xrightarrow{\tau^*} t)$.

Definition 2.4. *A relation* $R \subseteq S \times S'$ *is called a weak bisimulation on* $(S, \longrightarrow)$ *and* $(S', \longrightarrow)$ *iff*

$$sRs' \Longrightarrow \begin{cases} s \xrightarrow{a} t & \Longrightarrow \quad \exists t'.\ s' \stackrel{a}{\Longrightarrow} t' \ \wedge \ tRt' \\ s' \xrightarrow{a} t' & \Longrightarrow \quad \exists t.\ s \stackrel{a}{\Longrightarrow} t \ \wedge \ tRt' \end{cases}$$

for all $s \in S$ *and for all* $s' \in S'$.

We say that R is a weak bisimulation on $(S, \longrightarrow)$ iff R is a weak bisimulation on $(S, \longrightarrow)$ and $(S, \longrightarrow)$.

Let $\{R_i\}_{i \in I}$ be a collection of weak bisimulations on $(S, \longrightarrow)$ and $(S', \longrightarrow)$, then $\bigcup_{i \in I} R_i$ is also a weak bisimulation on $(S, \longrightarrow)$ and $(S', \longrightarrow)$. Consequently there exists a maximal weak bisimulation on $(S, \longrightarrow)$ and $(S', \longrightarrow)$, namely the union of all weak bisimulations on $(S, \longrightarrow)$ and $(S', \longrightarrow)$. This maximal weak bisimulation is denoted as $\leftrightarrows_w$. If $s \leftrightarrows_w t$ then we say that s and t are *weakly bisimular*. $\leftrightarrows_w$ is an equivalence relation.

Definition 2.5. *A transition system* $(S, \longrightarrow)$ *is called* a*-well-founded iff* $\{(s,t) \mid t \xrightarrow{a} s\}$ *is a well-founded relation on* S*, i.e. there is no infinite sequence of the form*

$$s_1 \xrightarrow{a} s_2 \xrightarrow{a} s_3 \xrightarrow{a} \cdots\cdots$$

Let $\mathcal{O}$ be the class of ordinals.

Definition 2.6. *Let* $R \subseteq S \times S$ *be a well-founded relation on* S*. We define a mapping* $d_R : S \longrightarrow \mathcal{O}$ *as follows:*

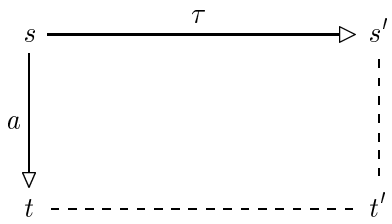
$$d_R(t) = \sup\{1 + d_R(s) \mid sRt\}.$$

If $R = \{(x,y) \mid y \xrightarrow{a} x\}$ *then we write* d_a *instead of* d_R*.* $d_a(t)$ *is the length of the longest chain of* a*-steps starting from* t.

3 Confluence and τ-inertness

In this section we introduce three different notions of *confluence*, namely strong confluence, weak confluence and weak $\leftrightarrows_w$-confluence. These three notions have in common that they express that

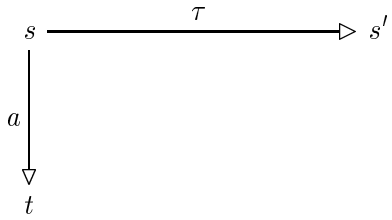
two 'diverging' steps $s \xrightarrow{a} t$ and $s \xrightarrow{\tau} s'$ can be brought together in some sense. In a diagram we can picture this as follows:



We investigate whether or not the different notions of confluence are strong enough to serve as a condition for

$$s \xrightarrow{\tau} t \Longrightarrow s \leftrightarrows_w t \tag{1}$$

to hold. It is obvious that (1) is not valid in general. A simple counterexample is

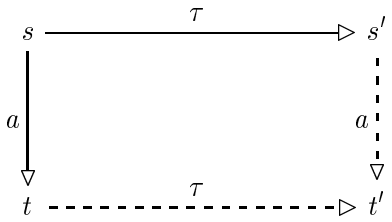


(2)

where a is not a τ-step. Transition systems that satisfy (1) are called *τ-inert with respect to $\leftrightarrows_w$*.

3.1 Strong confluence

Definition 3.1. *A transition system $(S, \longrightarrow)$ is called strongly confluent for a iff for each pair $s \xrightarrow{a} t$ and $s \xrightarrow{\tau} s'$ of different steps there exists a state t' such that $t \xrightarrow{\tau} t'$ and $s' \xrightarrow{a} t'$. In a diagram:*



A transition system $(S, \longrightarrow)$ is called strongly confluent iff it is strongly confluent for a, for all $a \in$ Act.

Omitting the word 'different' in Definition 3.1 would give a stronger notion:

is strongly confluent, but would not be strongly confluent if the word 'different' was omitted.

Theorem 3.2. *Strongly confluent transition systems are τ-inert with respect to $\leftrightarrows_w$.*

Proof. Let $(S, \longrightarrow\!\!\triangleright)$ be a strongly confluent transition system. Consider

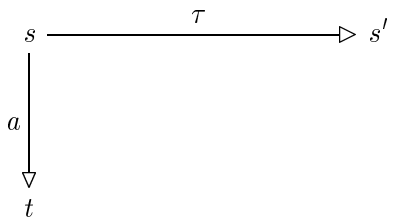
$$R = \{(x, y) \mid x \xrightarrow{\tau} y\} \cup \Delta_S.$$

It suffices to prove that R is a weak bisimulation on $(S, \longrightarrow\!\!\triangleright)$, as in that case, by definition, $R \subseteq \leftrightarrows_w$. So $s \xrightarrow{\tau} t \Longrightarrow sRt \Longrightarrow s \leftrightarrows_w t$. Assume sRs'. We have to prove:

(i) $s \xrightarrow{a} t \Longrightarrow \exists t'.\ s' \overset{a}{\Longrightarrow} t' \ \wedge \ tRt'$
(ii) $s' \xrightarrow{a} t' \Longrightarrow \exists t.\ s \overset{a}{\Longrightarrow} t \ \wedge \ tRt'$

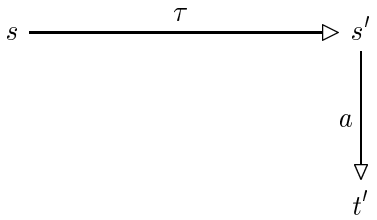
If $s \equiv s'$ then we are trivially done. So assume $s \xrightarrow{\tau} s'$.

Proof of (i): Assume $s \xrightarrow{a} t$. The situation is now as follows:



If these two transitions are different, then there exists a state t' such that $s' \xrightarrow{a} t'$ and $t \xrightarrow{\tau} t'$, by the definition of strong confluence. If $t \xrightarrow{\tau} t'$ then tRt' so (i) is satisfied. If these two transitions are identical, we have $t \equiv s'$ and $a \equiv \tau$, so tRs' by $\Delta_S \subseteq R$. Again, (i) is satisfied.

Proof of (ii): Assume $s' \xrightarrow{a} t'$. The situation is then as follows:

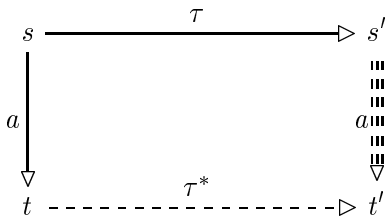


Now take $t \equiv t'$. This does the job, since $s \xrightarrow{\tau a} t'$ and $t'Rt'$ since $\Delta_S \subseteq R$. ❑

The converse of Theorem 3.2 is obviously not valid. A transition system that is τ-inert with respect to $\leftrightarrows_w$, is not necessarily strongly confluent. As a counter example one can take (2) with $a \equiv \tau$. This counter example means that strong confluence is actually a stronger notion than we need since we are primarily interested in τ-inertness (wrt. $\leftrightarrows_w$). Hence we introduce a weaker notion of confluence, which differs from strong confluence in that we allow τ-steps in the paths from t to t' and from s' to t'.

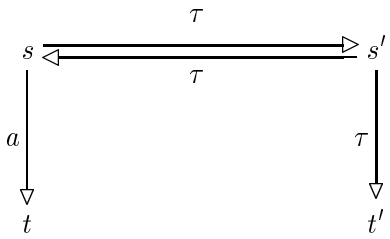
3.2 Weak confluence

Definition 3.3. *A transition system $(S, \longrightarrow\!\!\triangleright)$ is called weakly confluent for a iff for each pair $s \xrightarrow{a} t$ and $s \xrightarrow{\tau} s'$ of different steps there exists a state t' such that $s' \stackrel{a}{\Longrightarrow} t'$ and $t \xrightarrow{\tau^*} t'$. In a diagram:*



A transition system $(S, \longrightarrow\!\!\triangleright)$ is called weakly confluent iff it is weakly confluent for a, for all $a \in$ Act.

The following example (due to Roland Bol) shows that weak confluence is too weak to serve as a condition for (1) to hold, i.e. weak confluent transition systems are not necessarily τ-inert with respect to $\leftrightarrows_w$.

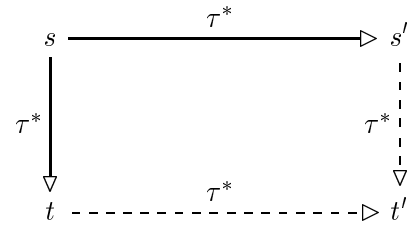


(3)

This transition system is weakly confluent but $s' \xrightarrow{\tau} t'$ does not connect bisimilar states if $a \not\equiv \tau$. Note that (3) is not τ-well-founded. In Theorem 3.6 we prove that τ-well-founded, weakly confluent transition systems are τ-inert with respect to $\leftrightarrows_w$. This means that we can not replace (3) by a τ-well-founded counter example.

The following lemma is very useful and frequently used in the remaining of the paper.

Lemma 3.4. *Let $(S, \longrightarrow\!\!\triangleright)$ be τ-well-founded and weakly confluent for τ. Let $s \xrightarrow{\tau^*} s'$ and $s \xrightarrow{\tau^*} t$, then there exists a t' such that $s' \xrightarrow{\tau^*} t'$ and $t \xrightarrow{\tau^*} t'$. In a diagram:*



Proof. We use induction on $d_\tau(s)$. Note that the lemma is trivial if $s \equiv s'$ or $s \equiv t$. (In particular, the lemma is trivial for $d_\tau(s) = 0$.) Suppose that $s \not\equiv s'$ and $s \not\equiv t$, say $s \xrightarrow{\tau} u \xrightarrow{\tau^*} t$ and $s \xrightarrow{\tau} u' \xrightarrow{\tau^*} s'$. Assume that the lemma holds for all x satisfying $d_\tau(x) < d_\tau(s)$. We distinguish two cases:

- $s \xrightarrow{\tau} u$ and $s \xrightarrow{\tau} u'$ are identical. We can draw the following picture:

  $t \xrightarrow{\tau^*} t'$ and $s' \xrightarrow{\tau^*} t'$ exist because the lemma holds (by induction) in u.

- $s \xrightarrow{\tau^*} u$ and $s \xrightarrow{\tau^*} u'$ are different. Now we can draw the following picture:

  The upper-left part of the diagram is given by weak confluence for τ. The other parts are given by induction hypotheses for u, u' and u''.

❑

We can not omit 'τ-well-foundedness' as a condition in Lemma 3.4. As a counter example take (3) with $a \equiv \tau$.

The following relations form the core of all our 'confluence implies τ-inertness' proofs.

$$\begin{aligned} \mathcal{T} &\triangleq \{(x,y) \mid x \xrightarrow{\tau} y\} \\ B_w &\triangleq \{(x,y) \mid x \xrightarrow{\tau} y \ \vee \ x \leftrightarrows_w y\}. \end{aligned}$$

Lemma 3.5. *Let $(S, \longrightarrow)$ be τ-well-founded and weakly confluent, then*

$$\mathcal{T}^* \text{ is a weak bisimulation on } (S, \longrightarrow). \tag{4}$$

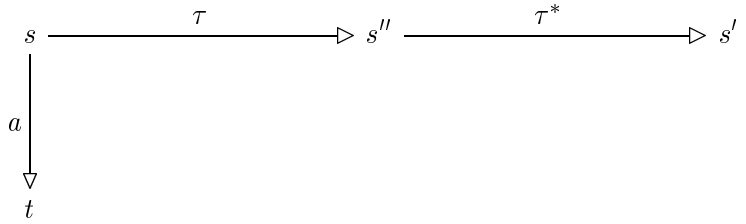
Proof. Let $s\mathcal{T}^*s'$, i.e. $s \xrightarrow{\tau^*} s'$, then we have to show:

(i) $s \xrightarrow{a} t \Longrightarrow \exists t'.\ s' \overset{a}{\Longrightarrow} t' \ \wedge \ t\mathcal{T}^*t'$

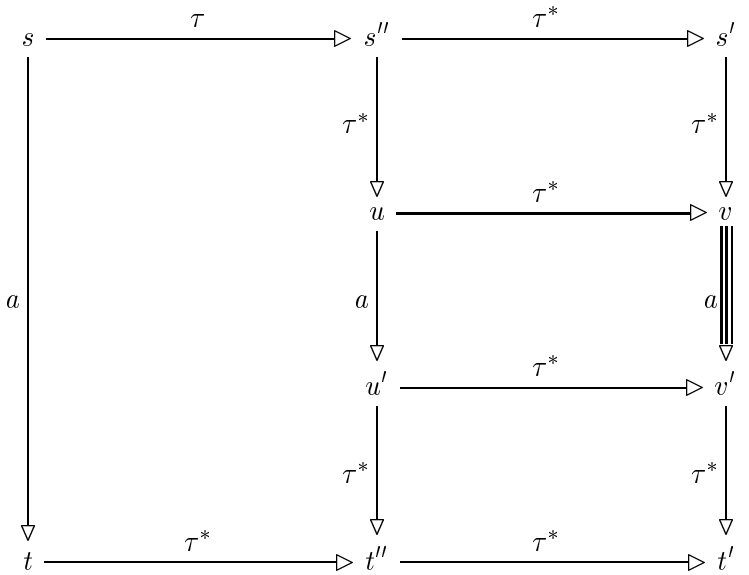
(ii) $s' \xrightarrow{a} t' \Longrightarrow \exists t.\ s \overset{a}{\Longrightarrow} t \ \wedge \ t\mathcal{T}^*t'$

(ii) is easy, take $t \equiv t'$ then $s \overset{a}{\Longrightarrow} t$ since $s \xrightarrow{\tau^*} s' \xrightarrow{a} t'$. Furthermore $t\mathcal{T}^*t'$ holds by reflexivity of $\mathcal{T}^*$.

By induction to $d_\tau(s)$ we show that (i) holds. If $s \equiv s'$ (and in particular, if $d_\tau(s) = 0$) the lemma is trivial: take $t' \equiv t$. Assume that (i) holds for all states x with $d_\tau(x) < d_\tau(s)$. Let $s \xrightarrow{\tau} s'' \xrightarrow{\tau^*} s'$. We are in the following situation:



In case $a \equiv \tau$ then we apply Lemma 3.4. If $a \not\equiv \tau$ then we can draw the following diagram:



The left part of the diagram is given by weak confluence. The upper-right part is given by Lemma 3.4. The middle-right part is given by applying the induction hypothesis on $u\mathcal{T}^*v$ and $u \xrightarrow{a} u'$, using that $d_\tau(u) < d_\tau(s)$. Finally the lower-right part of the diagram is given by applying Lemma 3.4 again. We are done because $t\mathcal{T}^*t'$ and $s' \stackrel{a}{\Longrightarrow} t'$. ❑

Theorem 3.6. *Weakly confluent transition systems are τ-inert with respect to $\leftrightarrows_w$.*

Proof. $\mathcal{T}^* \subseteq \leftrightarrows_w$ by Lemma 3.5. Now $s \xrightarrow{\tau} t \Longrightarrow s\mathcal{T}^*t \Longrightarrow s \leftrightarrows_w t$. ❑

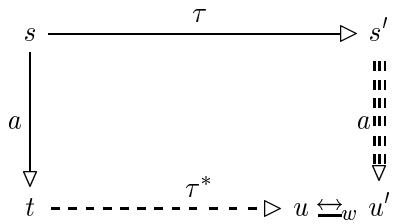
On page 5 we mentioned that τ-inertness with respect to $\leftrightarrows_w$ does not imply strong confluence. The same (τ-well-founded) counter example[2] illustrates that τ-inertness with respect to $\leftrightarrows_w$ does not even imply weak confluence. So weak confluence and τ-inertness with respect to $\leftrightarrows_w$ are independent notions. If we restrict ourselves to the τ-well-founded transition systems we have strict inclusion of the weakly confluent transition systems into the transition systems that are τ-inert with respect to $\leftrightarrows_w$.

[2]Diagram (2) with $a \equiv \tau$, on page 4

3.3 Weak bisimulation confluence

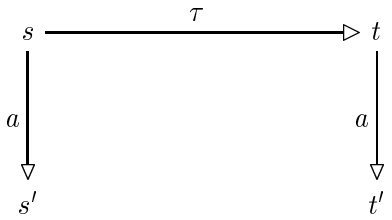
In the definition below we introduce yet another notion of confluence. This thirth notion is optimal in the sense that it is equivalent with τ-inertness with respect to $\leftrightarrows_w$ for τ-well-founded systems.

Definition 3.7. *A transition system $(S, \longrightarrow)$ is called weakly $\leftrightarrows_w$-confluent for a iff for each pair $s \xrightarrow{a} t$ and $s \xrightarrow{\tau} s'$ of different steps there exists states u and u' such that $u \leftrightarrows_w u'$, $s' \stackrel{a}{\Longrightarrow} u'$ and $t \xrightarrow{\tau^*} u$. In a diagram:*



A transition system $(S, \longrightarrow)$ is called weakly $\leftrightarrows_w$-confluent iff it is weakly $\leftrightarrows_w$-confluent for a, for all $a \in$ Act.

We want to prove that in τ-well-founded transition systems 'weak $\leftrightarrows_w$-confluence' implies 'τ-inertness with respect to $\leftrightarrows_w$'. In order to prove this we can not simply 'copy' the proof of Lemma 3.5, since $\mathcal{T}^*$ is not necessarily a weak bisimulation on weakly $\leftrightarrows_w$-confluent transition systems, as the following example shows:

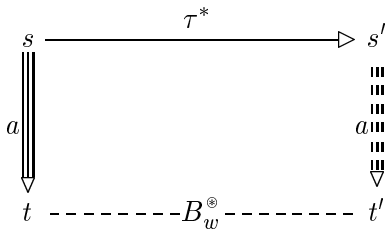


(5)

Here $\mathcal{T}^* = \{(s,s),(s',s'),(s,t),(t,t),(t',t')\}$ is not a weak bisimulation although the transition system is weakly $\leftrightarrows_w$-confluent since $s' \xrightarrow{\tau^*} s' \leftrightarrows_w t'$. The diagram above is also an example of a transition system that is weakly $\leftrightarrows_w$-confluent but not weakly confluent.

The following lemma is used in the proof of 3.9.

Lemma 3.8. *Let $(S, \longrightarrow)$ be τ-well-founded and weakly $\leftrightarrows_w$-confluent. Let $s \xrightarrow{\tau^*} s'$ and $s \stackrel{a}{\Longrightarrow} t$. There exists a state t' such that $tB_w^{\circledast}t'$ and $s' \stackrel{a}{\Longrightarrow} t'$. In a diagram:*



Proof. We use induction on $d_\tau(s)$. If $s \equiv s'$ (and in particular if $d_\tau(s) = 0$) then the lemma is trivial. Suppose that $s \xrightarrow{\tau} s'' \xrightarrow{\tau^*} s'$ and assume that the lemma holds for all states x such that $d_\tau(x) < d_\tau(s)$. If $a \equiv \tau$ then $t' \equiv s'$ satisfies the required properties, namely $tB_w^{\circledast}t'$ since $t \xleftarrow{\tau^*} s \xrightarrow{\tau} s'$ and $s' \overset{\tau}{\Longrightarrow} t'$ by reflexivity of $\overset{\tau}{\Longrightarrow}$.

Assume that $a \not\equiv \tau$. Say $s \xrightarrow{\tau^*} v \xrightarrow{a} u \xrightarrow{\tau^*} t$. We distinguish two cases:

- $v \equiv s$. We can draw the following picture:

  The left-part of the diagram is given by weak confluence and the right-part of the diagram follows from applying the induction hypothesis on s'', which is allowed since $d_\tau(s'') < d_\tau(s)$. Now $tB_w^{\circledast}t'$ and $s' \overset{a}{\Longrightarrow} t'$ so t' satisfies the required properties.

- $v \not\equiv s$. We are in the following situation:

  The upper-part of the diagram follows directly from Lemma 3.4 and the lower-part of the diagram is given by application of the induction hypothesis on v, which is allowed since $d_\tau(v) < d_\tau(s)$. We are done because $tB_w^{\circledast}t'$ and $s' \overset{a}{\Longrightarrow} t'$.

❑

Lemma 3.9. *Let $(S, \longrightarrow)$ be τ-well-founded and weakly $\leftrightarrows_w$-confluent, then the equivalence relation $B_w^{\circledast}$, defined on page 7, is a weak bisimulation on $(S, \longrightarrow)$.*

Proof. As $sB_w^{\circledast}s'$, we may assume that there exists an $n \geq 0$ such that

$$s \equiv x_0 B_w^{\circ} x_1 B_w^{\circ} \cdots\cdots B_w^{\circ} x_{n-1} B_w^{\circ} x_n \equiv s'.$$

We have to show:

(i) $s \xrightarrow{a} t \Longrightarrow \exists t'.\ s' \stackrel{a}{\Longrightarrow} t' \ \wedge \ tB_w^{\circledast}t'$

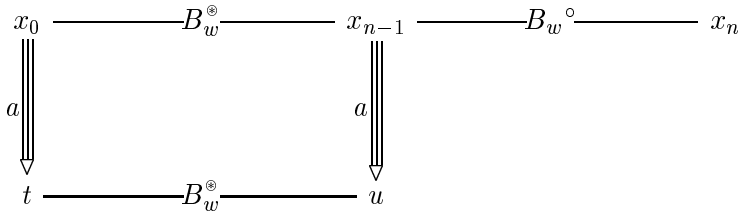
(ii) $s' \xrightarrow{a} t' \Longrightarrow \exists t.\ s \stackrel{a}{\Longrightarrow} t \ \wedge tB_w^{\circledast}t'$

Since $B_w^{\circledast}$ is symmetric we have (i)$\Longleftrightarrow$(ii). We prove (i).

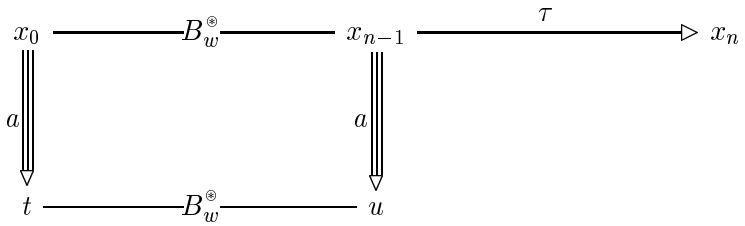
Proof of (i): We prove the following slightly stronger result by induction to n:

$$s \stackrel{a}{\Longrightarrow} t \Longrightarrow \exists t'.\ s' \stackrel{a}{\Longrightarrow} t' \ \wedge \ tB_w^{\circledast}t'. \qquad (\mathrm{i}')$$

For $n = 0$ the validity of (i′) is trivial. Let $n > 0$ and assume that the lemma holds for $n - 1$. Consider the following diagram:



u is given by the induction hypothesis. We distinguish three cases for $x_{n-1}B_w^{\circ}x_n$:



Applying Lemma 3.8 gives a state t' satisfying the right properties. If $x_{n-1} \leftrightarrows_w x_n$ then use the definition of weak bisimulation and if $x_{n-1} \xleftarrow{\tau} x_n$ then simply take $t' \equiv u$. ❑

Theorem 3.10. *Let $(S, \longrightarrow)$ be τ-well-founded. Then $(S, \longrightarrow)$ is weakly $\leftrightarrows_w$-confluent iff $(S, \longrightarrow)$ is τ-inert with respect to $\leftrightarrows_w$.*

Proof. Let $(S, \longrightarrow)$ be τ-well-founded.

($\Longrightarrow$) By Lemma 3.9, the equivalence relation $B_w^{\circledast}$, defined on page 7, is a weak bisimulation. Since $\leftrightarrows_w$ is the union of all weak bisimulations, we have $B_w^{\circledast} \subseteq \leftrightarrows_w$. Now $s \xrightarrow{\tau} t \Longrightarrow sB_w^{\circledast}t \Longrightarrow s \leftrightarrows_w t$.

($\Longleftarrow$) Let $s \xrightarrow{a} t$ and $s \xrightarrow{\tau} s'$. Then $s \leftrightarrows_w s'$ since $(S, \longrightarrow)$ satisfies (1). Now, by definition, there exists a state t' such that $s' \stackrel{a}{\Longrightarrow} t'$ and $t \leftrightarrows_w t'$, so we are done. ❑

Note that we need the τ-well-foundedness of $(S, \longrightarrow\!\!\triangleright)$ only in the proof from left to right (it allows us to apply Lemma 3.9).

We conclude this section with an overview of the results, which have been depicted in Figure 1. Below the horizontal line we have the τ-well-founded transition systems. We see that strong confluence always implies τ-inertness with respect to $\leftrightarrows_w$. The other two notions of confluence do not imply τ-inertness with respect to $\leftrightarrows_w$. However, the counter examples are all τ-non-well-founded (above the horizontal line). Finally, we see that weak $\leftrightarrows_w$-confluence and τ-inertness with respect to $\leftrightarrows_w$ coincide for τ-well-founded transition systems (below the horizontal line).

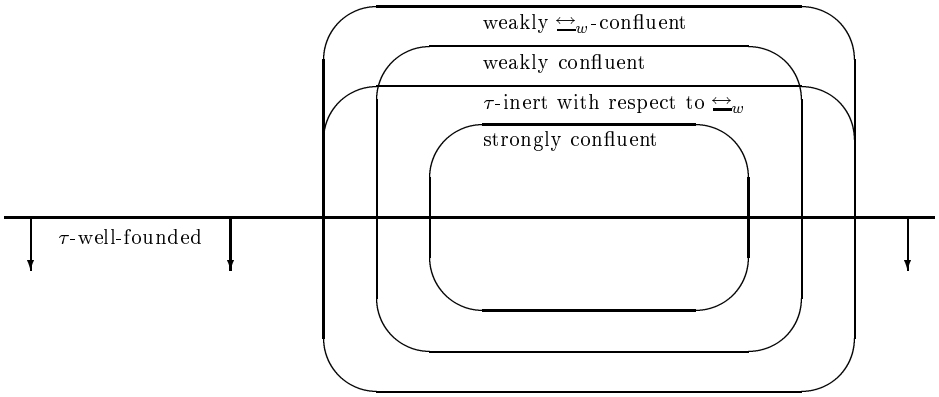


Figure 1: The transition sytems in a diagram

4 Other graph equivalences

In this section we study the consequences of replacing $\leftrightarrows_w$ in Section 3 by other process equivalences. From the large variety of equivalences, that have been proposed to capture the behavioural aspects of processes (see e.g. [16]), we chose *strong bisimulation, branching bisimulation* and *finite trace equivalence*. This choice is motivated by the fact that these three equivalences are frequently used in the field of process theory.

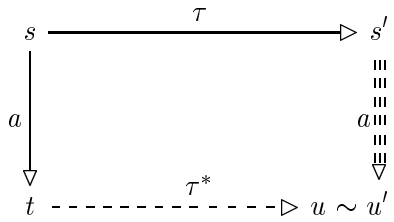
4.1 Two definitions generalised

We generalise those notions of Section 3 that assume an equivalence relation on S.

Definition 4.1. *Let $\sim \subseteq S \times S$ be an equivalence relation. A transition system $(S, \longrightarrow\!\!\triangleright)$ is called a-inert with respect to $\sim$ iff*

$$s \xrightarrow{a}\!\!\triangleright\, t \Longrightarrow s \sim t \quad \textit{for all } s, t \in S$$

Definition 4.2. *A transition system $(S, \longrightarrow\!\!\triangleright)$ is called weakly $\sim$-confluent for a iff for each pair $s \xrightarrow{a} t$ and $s \xrightarrow{\tau} s'$ of different steps there exists states u and u' such that $u \sim u'$, $s' \stackrel{a}{\Longrightarrow} u'$ and $t \xrightarrow{\tau^*} u$. In a diagram:*



A transition system $(S, \longrightarrow\!\!\triangleright)$ is called weakly $\sim$-confluent iff it is weakly $\sim$-confluent for a, for all $a \in$ Act.

4.2 Strong bisimulation

Definition 4.3. *A relation $R \subseteq S \times S'$ is called a strong bisimulation on $(S, \longrightarrow\!\!\triangleright)$ and $(S', \longrightarrow\!\!\blacktriangleright)$ iff*

$$sRs' \Longrightarrow \begin{cases} s \xrightarrow{a} t & \Longrightarrow \quad \exists t'.\ s' \xrightarrow{a} t' \ \wedge \ tRt' \\ s' \xrightarrow{a} t' & \Longrightarrow \quad \exists t.\ s \xrightarrow{a} t \ \wedge \ tRt' \end{cases}$$

for all $s \in S$ and for all $s' \in S'$.

We say that R is a strong bisimulation on $(S, \longrightarrow\!\!\triangleright)$ iff R is a strong bisimulation on $(S, \longrightarrow\!\!\triangleright)$ and $(S, \longrightarrow\!\!\triangleright)$. Similar to weak bisimulation we have that the union of any collection $\{R_i\}_{i \in I}$ of strong bisimulations on $(S, \longrightarrow\!\!\triangleright)$ and $(S', \longrightarrow\!\!\blacktriangleright)$ is again a strong bisimulation on $(S, \longrightarrow\!\!\triangleright)$ and $(S', \longrightarrow\!\!\blacktriangleright)$. The maximal strong bisimulation on $(S, \longrightarrow\!\!\triangleright)$ and $(S', \longrightarrow\!\!\blacktriangleright)$ is denoted by $\leftrightarrows$. If $s \leftrightarrows_s t$ then we say that s and t are *strongly bisimilar*. The relation $\leftrightarrows$ is an equivalence relation.

About the state of affairs, in case we replace $\leftrightarrows_w$ in Section 3 by $\leftrightarrows$, we can be short. Non of the notions of confluence, presented in this section, is strong enough to imply τ-inertness with respect to $\leftrightarrows$. This follows immediately from the (trivial) fact that even a strongly confluent transition system is not necessarily τ-inert with respect to $\leftrightarrows$, e.g.

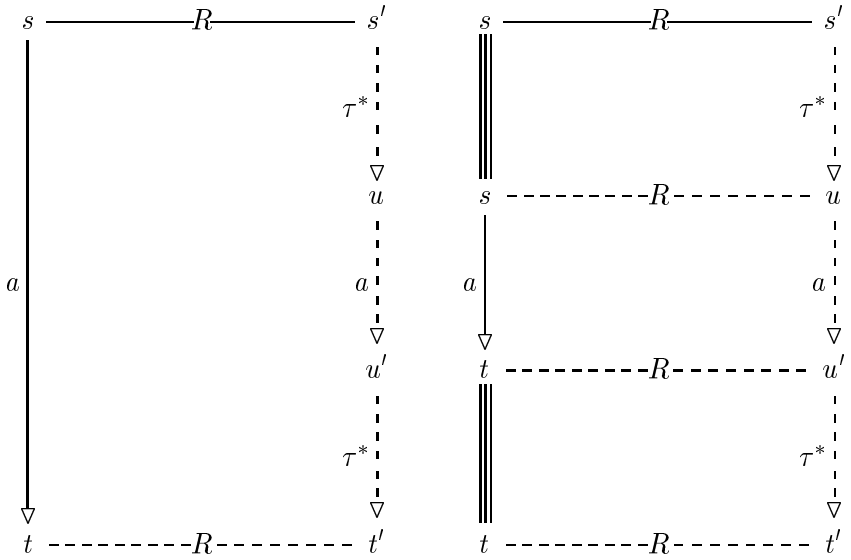
$$s \xrightarrow{\tau} t \xrightarrow{a} u$$

with $a \not\equiv \tau$, is strongly confluent but not τ-inert with respect to $\leftrightarrows$.

4.3 Branching bisimulation

In the previous subsection we explained that non of the notions of confluence implies τ-inertness with respect to $\leftrightarrows$. Even stronger graph equivalences than $\leftrightarrows$ of course give the same result and are therefore not interesting for us to analyse here.

Branching bisimulation, which we study in this subsection, however, is weaker than strong bisimulation (and stronger than weak bisimulation). We briefly explain the difference between weak- and branching bisimulation:



For weak bisimulation (see the left diagram above) it is not required that the states that are passed *before* the a-step are related to s and that the states, that are passed *after* the a-step, are related to t. This means that in the simulation $s' \stackrel{a}{\Longrightarrow\!\triangleright} t'$ of $s \stackrel{a}{\longrightarrow\!\triangleright} t$ there may be states in which other steps were enabled. In other words: the branching structure is not preserved in the simulation. The basic idea behind branching bisimulation is that this branching structure is preserved in a simulation, by relating the intermediate states as depicted in the right diagram above.

Definition 4.4. *A relation $R \subseteq S \times S'$ is called a branching bisimulation on $(S, \longrightarrow\!\triangleright)$ and $(S', \longrightarrow\!\triangleright')$ iff*

$$sRs' \Longrightarrow \begin{cases} s \stackrel{a}{\longrightarrow\!\triangleright} t \implies [a \equiv \tau \ \wedge tRs'] \ \vee \\ \qquad\qquad [\exists u, u' \,.\, s' \stackrel{\tau^*}{\longrightarrow} u \stackrel{a}{\longrightarrow} u' \ \wedge \ sRu \ \wedge \ tRu'] \\ s' \stackrel{a}{\longrightarrow} t' \implies [a \equiv \tau \ \wedge sRt'] \ \vee \\ \qquad\qquad [\exists u, u' \,.\, s \stackrel{\tau^*}{\longrightarrow\!\triangleright} u \stackrel{a}{\longrightarrow\!\triangleright} u' \ \wedge \ s'Ru \ \wedge \ t'Ru'] \end{cases}$$

for all $s \in S$ and for all $s' \in S'$.

We say that R is a branching bisimulation on $(S, \longrightarrow\!\triangleright)$ iff R is a weak bisimulation on $(S, \longrightarrow\!\triangleright)$ and $(S, \longrightarrow\!\triangleright)$. The union of all branching bisimulations is denoted as $\leftrightarroweq_b$.

Observe that Definition 4.4 is not the relation we informally described above, since we do not enforce the extra relation-requirements for *all* the intermediate states. Only the states immediately before and after the a-step are subject to this extra requirements. Allthough the informal description above Definition 4.4 is a strictly stronger notion, the union of all such relations (and the union is what actually interests us) equals $\leftrightarroweq_b$ [17].

Note that the existence of t', as depicted in the diagram above, is always trivially satisfied since we can take $t' \equiv u'$. Therefore, this requirement is omitted in Definition 4.4.

We provide the same theorems as for the weak bisimulation case. The proofs are analogous to the corresponding weak bisimulation versions of those theorems. Only a number of extra conditions must be checked. We omit those proofs.

Theorem 4.5. *Strongly confluent transition systems are τ-inert with respect to $\leftrightarrows_b$.*

Theorem 4.6. *Weakly confluent, τ-well-founded transition systems are τ-inert with respect to $\leftrightarrows_b$.*

Theorem 4.7. *Let $(S, \longrightarrow\!\!\triangleright)$ be τ-well-founded, then $(S, \longrightarrow\!\!\triangleright)$ is weakly $\leftrightarrows_b$-confluent iff $(S, \longrightarrow\!\!\triangleright)$ is τ-inert with respect to $\leftrightarrows_b$.*

4.4 Finite trace equivalence

In this subsection we study the consequences of replacing $\leftrightarrows_w$ in Section 3 by *finite trace equivalence*, which is denoted as $\approx$ in this paper. In order to define $\approx$ we introduce some notations first.

Notations. Let $A^\star$ denote the set of words over A. The empty word is denoted by ε. Concatenation of words is denoted by juxta-position. $\ell(w)$ denotes the length of word w.

$$\begin{aligned} \ell(\varepsilon) &= 0 \\ \ell(a\ w) &= 1 + \ell(w) \quad \text{for all } a \in A, w \in A^\star \end{aligned}$$

For the rest of this subsection we fix the transition system $(S, \longrightarrow\!\!\triangleright)$.

Definition 4.8. *Let $s \in S$. The set* $\textsc{Traces}(s)$ *of traces starting from s, is the smallest set of words over* Act, *satisfying*

$$\textsc{Traces}(s) = \bigcup_{a,t} \{ ext(a)\ \sigma \mid s \xrightarrow{a}\!\!\triangleright\ t \ \wedge\ \sigma \in \textsc{Traces}(t) \} \cup \{\varepsilon\}$$

where $ext : \textsc{Act} \longrightarrow \textsc{Act}^\star$ *is defined by*

$$ext(a) = \begin{cases} \varepsilon & \text{if } a \equiv \tau \\ a & \text{if } a \not\equiv \tau \end{cases}$$

Furthermore, we define $\textsc{Traces}(S) = \bigcup_{s \in S} \textsc{Traces}(s)$.

Definition 4.9. *Let $s, s' \in S$ then $s \approx s'$ iff* $\textsc{Traces}(s) = \textsc{Traces}(s')$.

It is a well-known fact that $\leftrightarrows_w \subseteq \approx$ so statements like

Weakly/strongly -confluent systems are τ-inert with respect to $\approx$

are trivial consequences of 3.2 and 3.6. However, a $\approx$-version of Theorem 3.10 (from left to right) is not trivially implied by 3.10, since the equivalence $\approx$ also appears in the notion of confluence. So not only the proof obligation but also the premise is weakened.

Let $\textsc{Traces}_n(s) = \{x \mid x \in \textsc{Traces}(s) \ \wedge \ \ell(x) \leq n\}$. $\textsc{Traces}_n(s)$ is the set of traces, starting from s, with length less or equal to n. Now

$$\textsc{Traces}(s) = \bigcup_{n \in \mathbb{N}} \textsc{Traces}_n(s)$$

and $s \approx s'$ iff $\textsc{Traces}_n(s) = \textsc{Traces}_n(s')$ for all $n \in \mathbb{N}$. We write $s \approx_n t$ iff $\textsc{Traces}_n(s) = \textsc{Traces}_n(t)$. A trace $\sigma \in \textsc{Traces}_n(s) \setminus \textsc{Traces}_n(s')$ is called an *n-distinguishing trace for* (s, s').

Definition 4.10. *Let $s \in S$. The set* $\textsc{Execs}(s)$ *of executions starting from s, is the smallest set, satisfying*

$$\textsc{Execs}(s) = \bigcup_{a,t} \{s \xrightarrow{a} \rhd \sigma \mid s \xrightarrow{a} \rhd t \ \wedge \ \sigma \in \textsc{Execs}(t)\} \cup \{s\}$$

Furthermore we define $\textsc{Execs}(S) = \bigcup_{s \in S} \textsc{Execs}(s)$.

We also write $\ell(\sigma)$ for the length[3] of σ for all $\sigma \in \textsc{Execs}(s)$.

Theorem 4.11. *τ-well-founded, weakly $\approx$-confluent transition systems are τ-inert with respect to $\approx$.*

Proof. We have to prove that

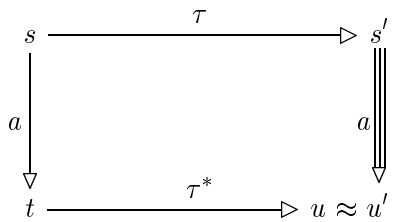
$$x \xrightarrow{\tau} \rhd y \Longrightarrow x \approx y \quad \text{for all } x, y \in S. \tag{6}$$

Assume that (6) does not hold in general, i.e. there exist triples $(x, y, z) \in S \times S \times \mathbb{N}$ such that $x \xrightarrow{\tau} \rhd y$ and $x \not\approx_z y$. Let (s, s', n) be such a triple, and assume that n is minimal, i.e.

$$\left(x \xrightarrow{\tau} \rhd y \ \wedge \ x \not\approx_z y\right) \Longrightarrow z \geq n \quad \text{for all triples } (x, y, z). \tag{7}$$

Since $\textsc{Traces}(s') \subseteq \textsc{Traces}(s)$, which follows immediately from $s \xrightarrow{\tau} \rhd s'$, and since $\textsc{Traces}_n(s) \neq \textsc{Traces}_n(s')$, there is an n-distinguishing trace for (s, s'). Note that $n > 0$ because $\textsc{Traces}_0(u) = \varepsilon$ for all $u \in S$. Let $\sigma \equiv ext(a)\ \sigma'$ with $s \xrightarrow{a} \rhd t$ and $\sigma' \in \textsc{Traces}(t)$ be such a trace.

Assume that $a \not\equiv \tau$. Now $\ell(\sigma) = 1 + \ell(\sigma')$ so $\sigma' \in \textsc{Traces}_{n-1}(t)$. Applying weak $\approx$-confluence on $s \xrightarrow{a} \rhd t$ and $s \xrightarrow{\tau} \rhd s'$ gives



[3] the number of *steps* of σ, not the number of *states*

Since $\sigma' \in \textsc{Traces}_{n-1}(u')$ implies $\sigma \in \textsc{Traces}_n(s')$, we conclude that $\sigma' \notin \textsc{Traces}_{n-1}(u')$. Moreover, $\sigma' \notin \textsc{Traces}_{n-1}(u)$ because $u \approx u'$.

Let $t \equiv x_0 \xrightarrow{\tau} \rhd \ldots \xrightarrow{\tau} \rhd x_m \equiv u$. Combining $x_i \xrightarrow{\tau} \rhd x_{i+1}$ with (7) gives that $x_i \approx_{n-1} x_{i+1}$ for all $i \in \{0, \ldots, m-1\}$. Now, transitivity of $\approx_{n-1}$ leads to $t \approx_{n-1} u'$, contradicting that $\sigma' \in \textsc{Traces}_{n-1}(t) \setminus \textsc{Traces}_{n-1}(u')$.

We conclude that $a \equiv \tau$. In other words: the first step, corresponding to an n-distinguishing trace, must be a τ-step. Now $\sigma = ext(\tau)\,\sigma' = \varepsilon\,\sigma' = \sigma'$ so $\ell(\sigma') = \ell(\sigma) = n$ and $\sigma' \in \textsc{Traces}_n(t)$. Moreover, we have that $\sigma' \notin \textsc{Traces}_n(u)$ because $\sigma \notin \textsc{Traces}_n(s')$. From the transitivity of $\approx_n$ it now follows that $x_i \not\approx_n x_{i+1}$ for some $i \in \{0, \ldots, m-1\}$. Thus, we have constructed another minimal triple (x_i, x_{i+1}, n) on which we can apply the same argument. However, since $s \xrightarrow{\tau} \rhd t \equiv x_0 \xrightarrow{\tau} \rhd \ldots \xrightarrow{\tau} \rhd x_i$ we know that $d_\tau(x_i) < d_\tau(s)$, which means that we find an infinite decreasing sequence of 'counter-examples' for (6). This contradicts the τ-well-foundedness of $(S, \longrightarrow\rhd)$, so the assumption that (6) is not generally valid is violated. ❑

5 Transition systems that are not τ-well-founded

Most of the results in Sections 3 and 4 rely on τ-well-foundedness of the transition system in question. However, many realistic examples of protocol specifications correspond to transition systems that are not τ-well-founded. As soon as a protocol internally consists in some kind of correction mechanism (e.g. retransmissions in a data link protocol) the specification of that protocol will contain a τ-loop. In Section 8.2 we see an example of this phenomenon.

Since we feel applicability to realistic examples is important, we considered the requirement that the transition system has to be τ-well-founded a serious drawback. Therefore, we distinguish what we will call *progressing* τ-steps and *non-progressing* τ-steps. This enables us to formulate a slightly more subtle notion of confluence, which is sufficiently strong for our purposes and only relies on well-foundedness of the *progressing* τ-steps.

5.1 Progressing and non-progressing τ-steps

Convention 5.1. *We use the following notations:*

- $s \xrightarrow{\tau_>} \rhd\ t$ *for a progressing* τ*-step from* s *to* t,
- $s \xrightarrow{\tau_<} \rhd\ t$ *for a non-progressing* τ*-step from* s *to* t,
- $s \xrightarrow{\tau} \rhd\ t$ *for* $s \xrightarrow{\tau_>} \rhd\ t$ *or* $s \xrightarrow{\tau_<} \rhd\ t$,
- $s \xRightarrow{a} \rhd\ t$ *for* $s \xrightarrow{\tau_>^*} \rhd\ s' \xrightarrow{a} \rhd\ t' \xrightarrow{\tau_>^*} \rhd\ t$.
- $s \xRightarrow{a} \rhd\ t$ *for* $s \xRightarrow{a} \rhd\ t \quad \vee \quad (a \equiv \tau \wedge s \xrightarrow{\tau_>^*} \rhd\ t)$.

Transition systems where the τ-steps are labeled with $>$ or with $<$ are called *τ-labeled transition systems*. Instead of τ-inertness with respect to $\sim$, we try to prove $\tau_>$-inertness with respect to $\sim$. In a formula:

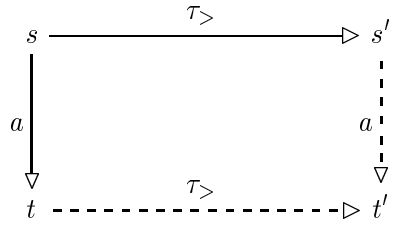
$$s \xrightarrow{\tau_>} \rhd\ t \Longrightarrow s \sim t \tag{8}$$

Definition 2.4 of 'weak bisimulation' remains unchanged for τ-labeled transition systems. Combined with Convention 5.1(iii) this means that the τ-steps mentioned in 2.4 may either be progressing or not.

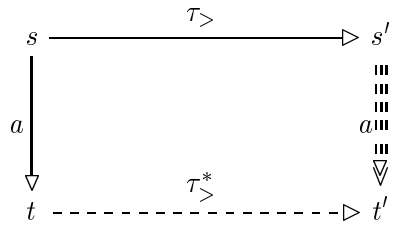
5.2 Progressing confluence

For each notion of confluence, introduced in Section 3 as well as each notion introduced in Section 4, we can define a progressing version. Those progressing versions are given below in definitions 5.2, 5.3 and 5.4. As we will see, only the first two notions (definitions 5.2 and 5.3) are useful to us. The notion of confluence, defined in Definition 5.4, does not imply $\tau_>$-inertness and is therefore not interesting. A counter example is given in Proposition 5.9.

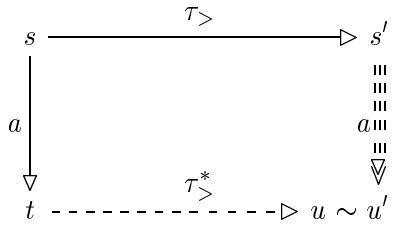
Definition 5.2. *A τ-labeled transition system $(S, \longrightarrow\!\triangleright)$ is called strongly $>$-confluent (pronounce: strongly progressing confluent) iff for each pair $s \xrightarrow{\tau_>} s'$ and $s \xrightarrow{a} t$ of different steps there exists a state t' such that $t \xrightarrow{\tau_>} t'$ and $s' \xrightarrow{a} t'$. In a diagram:*



Definition 5.3. *A τ-labeled transition system $(S, \longrightarrow\!\triangleright)$ is called weakly $>$-confluent (pronounce: weakly progressing confluent) iff for each pair $s \xrightarrow{\tau_>} s'$ and $s \xrightarrow{a} t$ of different steps there exists a state t' such that $t \xrightarrow{\tau_>^*} t'$ and $s' \xRightarrow{a} t'$. In a diagram:*



Definition 5.4. *A τ-labeled transition system $(S, \longrightarrow\!\triangleright)$ is called weakly $>$-$\sim$-confluent (pronounce: weakly progressing $\sim$-confluent) iff for each pair $s \xrightarrow{\tau_>} s'$ and $s \xrightarrow{a} t$ of different steps there exist states u and u' such that $t \xrightarrow{\tau_>^*} u$, $s' \xRightarrow{a} u'$ and $u \sim u'$. In a diagram:*

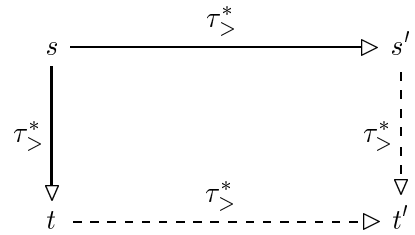


Theorem 3.2 and Theorem 3.6 have a progressing counterpart, stating that the progressing version of the confluence notion in question implies $\tau_>$-inertness with respect to $\sim$.

Theorem 5.5. *Strongly $>$-confluent transition systems are $\tau_>$-inert with respect to $\sim$, for $\sim \in \{\leftrightarrows_w, \leftrightarrows_b, \approx\}$.*

Proof. Analogous to the corresponding proofs in sections 3 and 4. ❑

Lemma 5.6. *Let $(S, \longrightarrow\!\triangleright)$ be $\tau_>$-well-founded and weakly $>$-confluent for $\tau_>$. Let $s \xrightarrow{\tau_>^*} s'$ and $s \xrightarrow{\tau_>^*} t$, then there exists a t' such that $s' \xrightarrow{\tau_>^*} t'$ and $t \xrightarrow{\tau_>^*} t'$. In a diagram:*



Proof. Analogously to the proof of Lemma 3.4. ❑

Lemma 5.7. *Let $(S, \longrightarrow\!\triangleright)$ be $\tau_>$-well-founded and weakly $>$-confluent, then*

$$\mathcal{T}_> = \{(x, y) \mid x \xrightarrow{\tau_>^*} y\}$$

is a weak bisimulation.

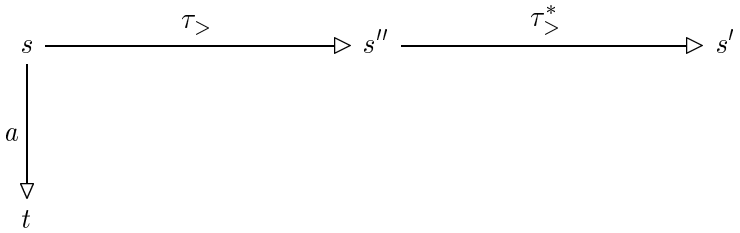
Proof. Let $s \mathcal{T}_>^* s'$, i.e. $s \xrightarrow{\tau_>^*} s'$, then we have to show:

(i) $s \xrightarrow{a} t \Longrightarrow \exists t'.\ s' \overset{a}{\Longrightarrow} t' \ \wedge\ t \mathcal{T}_>^* t'$

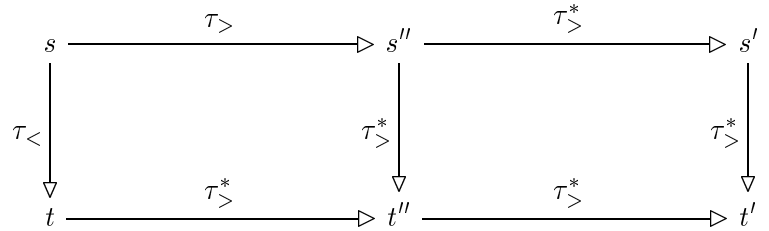
(ii) $s' \xrightarrow{a} t' \Longrightarrow \exists t.\ s \overset{a}{\Longrightarrow} t \ \wedge\ t \mathcal{T}_>^* t'$

(ii) is easy, take $t \equiv t'$ then $s \overset{a}{\Longrightarrow} t$ since $s \xrightarrow{\tau^*} s' \xrightarrow{a} t'$. Furthermore $t \mathcal{T}_>^* t'$ holds by reflexivity of $\mathcal{T}_>^*$.

By induction to $d_{\tau_>}(s)$ we show that (i) holds. If $s \equiv s'$ (and in particular, if $d_{\tau_>}(s) = 0$) the lemma is trivial: take $t' \equiv t$. Assume that (i) holds for all states x with $d_{\tau_>}(x) < d_{\tau_>}(s)$. Let $s \xrightarrow{\tau_>} s'' \xrightarrow{\tau_>^*} s'$. We are in the following situation:



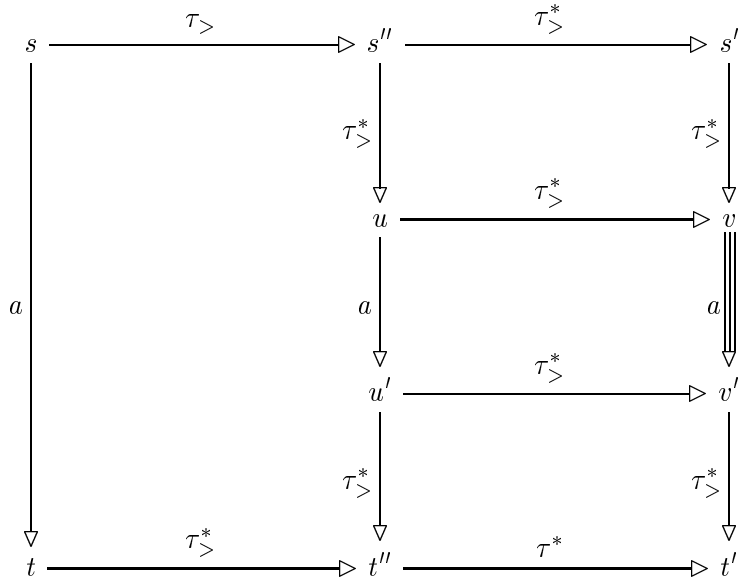
In case $a \equiv \tau_>$ then we apply Lemma 5.6. If $a \equiv \tau_<$ then there exists (by weak $>$-confluence) a state t' such that $t \xrightarrow{\tau_>^*} t'$ and $s' \overset{\tau_<}{\Longrightarrow} t'$. If $s' \xrightarrow{\tau_>^*} t'$ then we can draw the following diagram:



The right-part of the diagram is given by Lemma 5.6.

The case $s' \xrightarrow{\tau_>^*} u \xrightarrow{\tau_<} u' \xrightarrow{\tau_>^*} t'$ is treated like the general case $a \not\equiv \tau$.

If $a \not\equiv \tau$ then we can draw the following diagram:



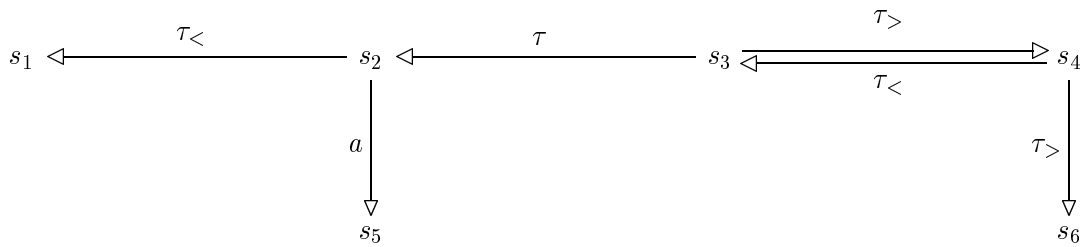
The left part of the diagram is given by weak $>$-confluence. The upper-right part is given by Lemma 5.6. The middle-right part is given by applying the induction hypothesis on $u\mathcal{T}_>^* v$ and $u \xrightarrow{a} u'$, using that $d_{\tau_>}(u) < d_{\tau_>}(s)$. Finally the lower-right part of the diagram is given by applying Lemma 5.6 again. We are done because $t\mathcal{T}_>^* t'$ and $s' \xRightarrow{a} t'$. ❑

Theorem 5.8. *Weakly $>$-confluent, $\tau_>$-well-founded transition systems are $\tau_>$-inert with respect to $\sim$, for $\sim \in \{\leftrightarrows_w, \leftrightarrows_b, \approx\}$.*

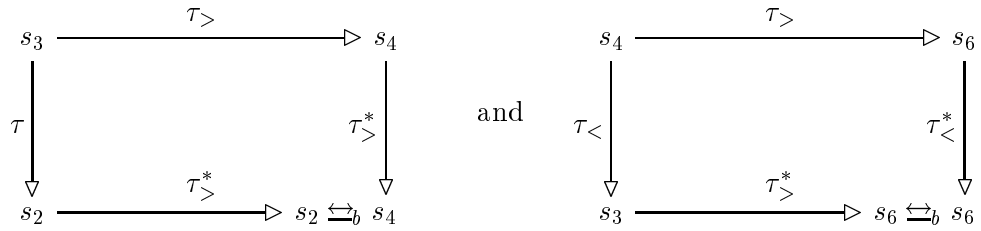
Proof. $\mathcal{T}_> \subseteq \leftrightarrows_w$ by Lemma 5.7. Now $s \xrightarrow{\tau_>} t \Longrightarrow s\mathcal{T}_> t \Longrightarrow s \leftrightarrows_w t$, which proves the theorem for $\sim \equiv \leftrightarrows_w$ (and hence also for $\sim \equiv \approx$). In order to prove the theorem for $\sim \equiv \leftrightarrows_b$ some extra conditions have to be checked. ❑

Proposition 5.9. *Let $(S, \longrightarrow)$ be weakly $<$-$\sim$-confluent and $\tau_>$-well-founded then $(S, \longrightarrow)$ is not necessarily $\tau_>$-inert with respect to $\sim$, for $\sim \in \{\leftrightarrows_w, \leftrightarrows_b, \approx\}$.*

Proof. Let $a \not\equiv \tau$. The following transition system is not $\tau_>$-inert with respect to $\sim$ since $s_4 \xrightarrow{\tau_>} s_6$ and $s_4 \not\sim s_6$. However, weak $<$-$\sim$-confluence holds.



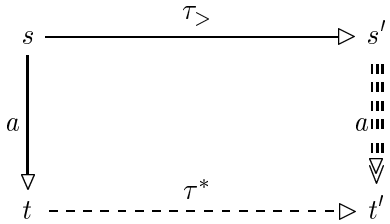
Suppose $R \subseteq S \times S$ is defined by $s_1 R s_5 R s_6$ and $s_2 R s_3 R s_4$, then one easily verifies that $R^{\circledast}$ is a branching bisimulation on S. Now $(S, \longrightarrow\!\triangleright)$ is weakly $>$-$\leftrightarrows_b$-confluent because



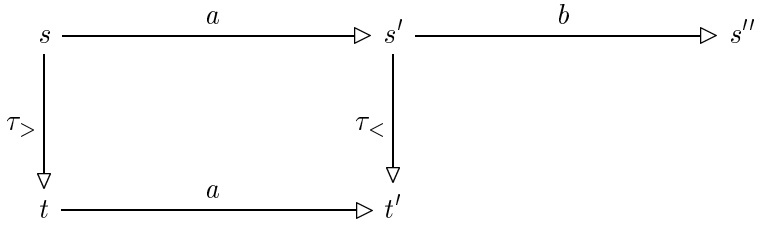
Since $\leftrightarrows_b \subseteq \leftrightarrows_w \subseteq \approx$ we know that the transition system is also weakly $>$-$\leftrightarrows_w$-confluent and weakly $>$-$\approx$-confluent so we are done. ❑

So far, we showed that weak $>$-confluence is useful to us and weak $>$-$\sim$-confluence is not. One might wonder whether there are other ways to relax the notion of weak $>$-confluence. The obvious way to do this is to allow non-progressing τ-steps in either the path $t \xrightarrow{\tau}\!\triangleright\, t'$ or the path $s' \overset{a}{\Longrightarrow}\!\!\triangleright\, t'$. We show that the notions of confluence, thus obtained (weak $>$-confluence$_1$ and weak $>$-confluence$_2$), do both not imply $\tau_>$-inertness and are therefore not useful to us.

Definition 5.10. *A system $(S, \longrightarrow\!\triangleright)$ is called weakly $>$-confluent$_1$ iff for each pair $s \xrightarrow{a}\!\triangleright\, t$ and $s \xrightarrow{\tau_>}\!\triangleright\, s'$ of different steps there exists a state t' such that $t \xrightarrow{\tau^*}\!\triangleright\, t'$ and $s' \overset{a}{\Longrightarrow}\!\!\triangleright\, t'$. In a diagram:*



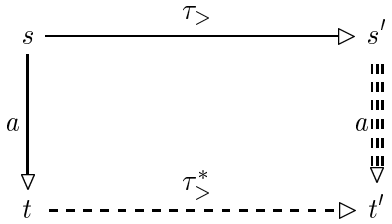
Now the following transition system is weakly $>$-confluent$_1$ but not $\tau_>$-inert with respect to $\sim$, for $\sim \in \{\leftrightarrows_w, \leftrightarrows_b, \approx\}$.



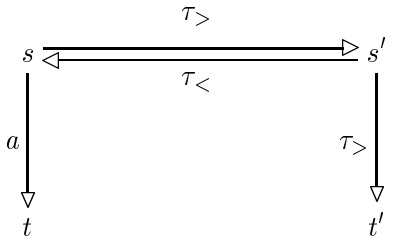
(9)

$s \not\leftrightarrows_w t$ although they are connected by a progressing τ-step. It is essential in this example that the τ-step from s' to t' is non-progressing. It relieves us from the obligation to add a state t'' satisfying $t' \overset{b}{\Longrightarrow}\!\!\triangleright\, t''$ and $s'' \xrightarrow{\tau^*}\!\triangleright\, t''$. Note that (9) is not weakly $>$-confluent since the τ-step from s' to t' is non-progressing.

Definition 5.11. *A system $(S, \longrightarrow\!\triangleright)$ is called weakly $>$-confluent$_2$ iff for each pair $s \xrightarrow{a} t$ and $s \xrightarrow{\tau_>} s'$ of different steps there exists a state t' such that $t \xrightarrow{\tau_>^*} t'$ and $s' \xRightarrow{a} t'$. In a diagram:*

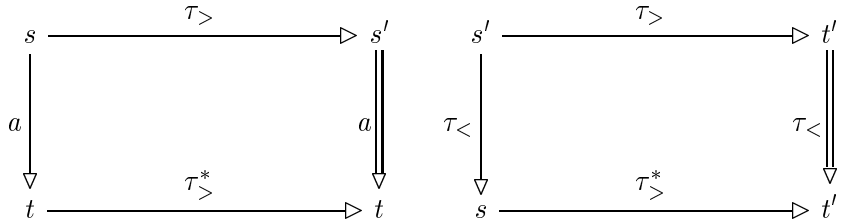


The following transition system is weakly $>$-confluent$_2$ but not $\tau_>$-inert with respect to $\sim$, for $\sim \in \{\leftrightarrows_w, \leftrightarrows_b, \approx\}$.



(10)

The progressing τ-step from s' to t' does not connect weakly bisimilar states. (10) is weakly $>$-confluent$_2$ because the following properties hold:



6 Confluence of linear processes

We want to use the notion confluence to verify the correctness of processes. In order to do so, we must be able to determine whether a transition system is confluent. This is in general not possible, because the transition systems belonging to distributed systems are often too large to be handled as plain objects. In order to manipulate with large state spaces (*Deterministic*) *Linear Process* ((*D-*)*LP*s) [4] can be used as in these D-LPs the state space is compactly encoded using data parameters. Moreover, processes that are described using the common process algebra operators, including parallelism, can straightforwardly be transformed to a D-LP, maintaining strong bisimulation.

In this section we describe how a D-LP can be shown to be confluent. In the next section we show how confluence is used to reduce the size of state spaces.

6.1 Linear processes

Definition 6.1. *Let $Act \subseteq$ Act be a finite set of actions. A deterministic linear process equation*

is an expression of the form

$$p(d) = \sum_{a \in Act} \sum_{e_a : E_a} a(f_a(d, e_a)) \cdot p(g_a(d, e_a)) \lhd b_a(d, e_a) \rhd \delta$$

for data sorts D, E_a and F_a and functions $f_a : D \times E_a \longrightarrow F_a$, $g_a : D \times E_a \longrightarrow D$ and $b_a : D \times E_a \longrightarrow \mathbb{B}$ where $\mathbb{B}$ is the predefined sort of booleans. We assume that the internal action τ ($\tau_>$ and $\tau_<$ if progressing and non-progressing τ's are distinguished) has no data parameter.

In [4] summands without a recursive call are also allowed in the definition of a linear process. We omit these summands here.

It is straightforward to see how a linear process equation determines a transition system. The process $p(d)$ can perform an action $a(f_a(d, e_a))$ for every $a \in Act$ and every data element e_a of sort E_a, provided the condition $b_a(d, e_a)$ holds. The process then continues as $p(g_a(d, e_a))$. Hence, the notions defined in the previous sections carry over directly.

It is well-known that modulo strong bisimulation a deterministic linear process equation has a unique solution p which is called a *deterministic linear process* (*D-LP*).

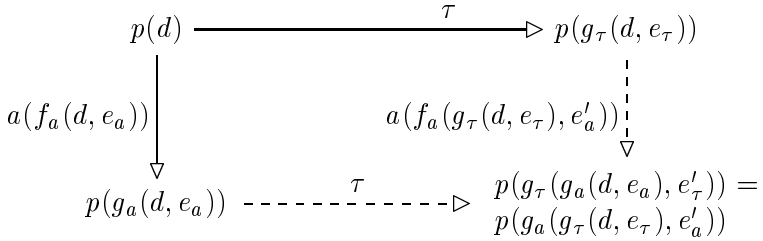
A linear process is called *convergent* iff the corresponding transition system is τ-well-founded. If we distinguish progressing and non-progressing τ's, we use the notion convergence with respect to the progressing τ's (i.e. $\tau_>$).

Definition 6.2. *A linear process as defined in definition 6.1 is called $>$-convergent iff there is a well-founded ordering $<$ on D such that for all $d : D$ and $e_{\tau_>} : D_{\tau_>}$ if $b_{\tau_>}(d, e_{\tau_>})$, then $g_{\tau_>}(d, e_{\tau_>}) < d$.*

The $>$ symbol in '$>$-convergent' refers to 'progressing' and not to the ordering on D. However, the ordering on D and the labeling on τ-steps are closely related. Typically, the τ-steps that are labeled with $>$ are precisely those τ-steps $p(d) \xrightarrow{\tau} p(d')$ satisfying $d' < d$. So after each performence of a progressing τ-step one is moved towards a state with a value that is strictly smaller with respect to some well-founded ordering. Thus, the progressing τ-steps express progression in that sense that progression is made in the execution of internal activity.

6.2 A condition for strong confluence

We provide sufficient criteria for p to be strongly confluent. Let p be a deterministic linear process as defined in Definition 6.1. The criteria can best be understood via the following diagram.



Note that in this diagram $p(g_a(d, e_a))$ and $p(g_\tau(d, e_\tau))$ are supposed to be different if $a = \tau$. We summarise the conditions in the following theorem.

Theorem 6.3. *The process p as defined in Definition 6.1 is strongly confluent if for all $a \in Act$, $e_1 : E_a,\ e_2 : E_\tau$ such that*

(i) $a = \tau \Rightarrow g_a(d, e_1) \neq g_\tau(d, e_2)$

(ii) $b_a(d, e_1)\ \wedge\ b_\tau(d, e_2)$

the following property holds:

$$\exists e_3 : E_a, e_4 : E_\tau \left\{ \begin{array}{l} f_a(d, e_1) = f_a(g_\tau(d, e_2), e_3)\ \wedge \\ b_a(g_\tau(d, e_2), e_3)\ \wedge \\ b_\tau(g_a(d, e_1), e_4)\ \wedge \\ g_a(g_\tau(d, e_2), e_3) = g_\tau(g_a(d, e_1), e_4). \end{array} \right.$$

6.3 A condition for weak progressing confluence

In this section we derive a condition to establish that a D-LP is weakly confluent. This is more involved, because we must now speak about sequences of transitions.

In order to keep notation compact, we introduce some convenient abbreviations. Let $\sigma, \sigma', \ldots$ range over lists of pairs $\langle a, e_a \rangle$ with $a \in Act$ and $e_a : E_a$. We define $\mathcal{G}_d(\sigma)$ with $d \in D$ by induction over the length of σ:

$$\mathcal{G}_d(\lambda) = d \qquad\qquad \mathcal{G}_d(\sigma\langle a, e_a \rangle) = g_a(\mathcal{G}_d(\sigma), e_a)$$

Each σ determines an execution fragment:

$$\underbrace{p(d) \longrightarrow\!\triangleright\ p(\mathcal{G}_d(\sigma))}_{\text{determined by } \sigma} \xrightarrow{a(f_a(\mathcal{G}_d(\sigma), e_a))}\!\triangleright\ p(\mathcal{G}_d(\sigma\langle a, e_a \rangle))$$

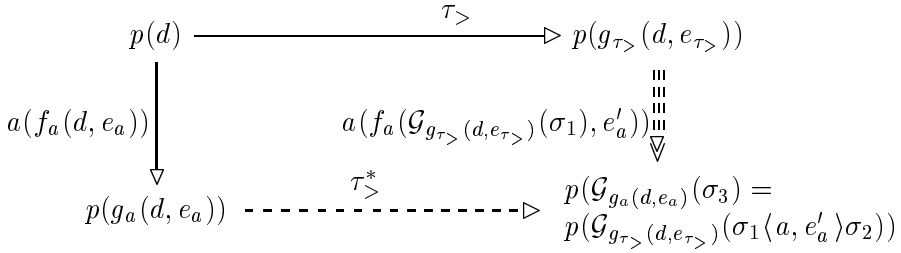
is the execution fragment determined by $\sigma\langle a, e_a \rangle$. This execution fragment is allowed for $p(d)$ iff the conjunction $\mathcal{B}_d(\sigma)$ of all conditions associated to the actions in σ evaluates to *true*. The boolean $\mathcal{B}_d(\sigma)$ is also defined by induction to the length of σ:

$$\mathcal{B}_d(\lambda) = true \qquad\qquad \mathcal{B}_d(\sigma\langle a, e_a \rangle) = \mathcal{B}_d(\sigma) \wedge b_a(\mathcal{G}_d(\sigma), e_a)$$

We write $\pi_1(\sigma)$ for the sequence of actions that is obtained from σ by applying the first projection to all its elements.

$$\begin{array}{rcl} \pi_1(\lambda) & = & \lambda \\ \pi_1(\sigma\langle a, e_a \rangle) & = & \pi_1(\sigma)a \end{array}$$

The diagram for weak $>$-confluence can be redrawn instantiated for D-LPs as shown below. The actions in the (possibly empty) sequences σ_1, σ_2 and σ_3 must all be progressing τ-steps, that is: $\pi_1(\sigma_i) = \tau_>^*$ for all $i = 1, 2, 3$.



We summarise this diagram in the following theorem. Due to its generality the theorem looks rather complex. However, in those applications that we considered, the lists that are existentially quantified were mainly empty, which trivialises major parts of the theorem.

Theorem 6.4. *The process p as defined in Definition 6.1 is weakly $>$-confluent if p is $>$-convergent and for all $e_1 : E_a,\ e_2 : E_{\tau_>}$ such that*

(i) $a = \tau_> \Rightarrow g_a(d, e_1) \neq g_{\tau_>}(d, e_2)$

(ii) $b_a(d, e_1) \wedge b_{\tau_>}(d, e_2)$

the following property holds:

$$\exists \sigma_1, e_3, \sigma_2, \sigma_3 \begin{cases} \pi_1(\sigma_i) = \tau_>^* \text{ for all } i = 1, 2, 3 \ \wedge \\ f_a(d, e_1) = f_a(\mathcal{G}_{g_{\tau_>}(d,e_2)}(\sigma_1), e_3) \ \wedge \\ \mathcal{B}_{g_a(d,e_1)}(\sigma_3) \ \wedge \\ \mathcal{B}_{g_{\tau_>}(d,e_2)}(\sigma) \ \wedge \\ \mathcal{G}_{g_a(d,e_1)}(\sigma_3) = \mathcal{G}_{g_{\tau_>}(d,e_2)}(\sigma) \end{cases}$$

where $\sigma = \sigma_1 \langle a, e_3 \rangle \sigma_2$, or $a = \tau$ and $\sigma = \sigma_1 \sigma_2$.

7 State space reduction

Here we employ the results about confluence and τ-inertness that we have obtained thus far to achieve state space reductions and to simplify the behaviour of processes. In this section we work in the setting of branching bisimulation, but the results apply to weak bisimulation as well. First we present the results on transition systems in general, and then on linear processes. This is done as for transition systems the results are easy to understand. However, as argued in the previous section, the results can be applied more conveniently in the setting of linear processes.

Definition 7.1. *Let $T_1 = (S, \longrightarrow\!\!\triangleright)$ and $T_2 = (S, \longrightarrow\!\!\blacktriangleright)$ be τ-labeled transition systems. We call T_2 a τ-Prioretised-reduction (TP-reduction) of T_1 iff*

(i) $\longrightarrow\!\!\blacktriangleright \subseteq \longrightarrow\!\!\triangleright$,

(ii) *for all $s, s' \in S$ if $s \xrightarrow{a}\!\!\triangleright\ s'$ then $s \xrightarrow{a}\!\!\blacktriangleright\ s'$ or $s \xrightarrow{\tau_>}\!\!\blacktriangleright\ s''$ for some s''.*

Clearly, T_2 can be obtained from T_1 by iteratively removing transitions from states as long as these keep at least one outgoing progressing τ-step. It does not need any comment that this may considerably reduce the state space of T_1, especially because large parts may become unreachable.

The following theorem states that if T_1 is $\tau_>$-inert with respect to $\leftrightarrows_w$, then a TP-reduction maintains weak bisimulation. As confluence implies τ-inertness, this theorem explains how confluence can be used to reduce the size of transition systems.

Theorem 7.2. *Let $T_1 = (S, \longrightarrow\!\!\triangleright)$ and $T_2 = (S, \longrightarrow\!\!\blacktriangleright)$ be τ-labeled transition systems. Let $\leftrightarrows_b$ be the maximal branching bisimulation on T_1 and T_2. If T_1 is $\tau_>$-inert with respect to $\leftrightarrows_b$ and T_2 is a τ-well founded TP-reduction of T_1 then $s \leftrightarrows_b s$ for each state $s \in S$.*

Proof. Let R denote the union of all branching bisimulations on T_1. Since T_1 is $\tau_>$-inert with respect to $\leftrightarrows_b$ we have (by definition) that

$$s \xrightarrow{\tau_>} s' \implies sRs' \tag{11}$$

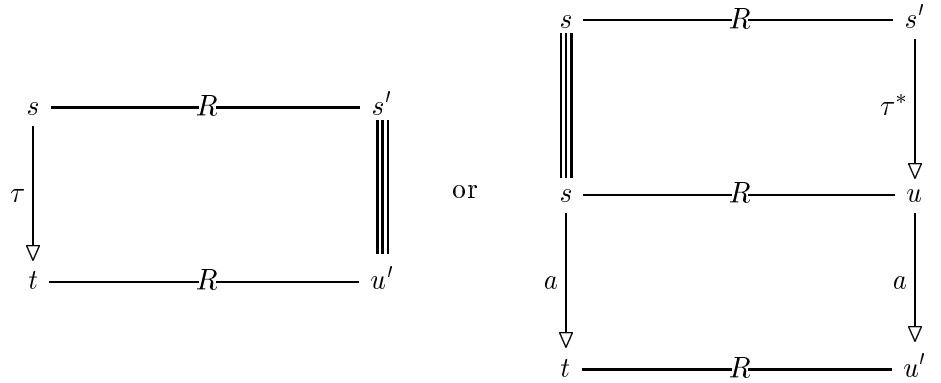
holds. We prove that R is a branching bisimulation on T_1 and T_2. Then, by definition, $R \subseteq \leftrightarrows_b$ and the theorem follows immediately since sRs for all $s \in S$.

Let sRs'. We have to prove:

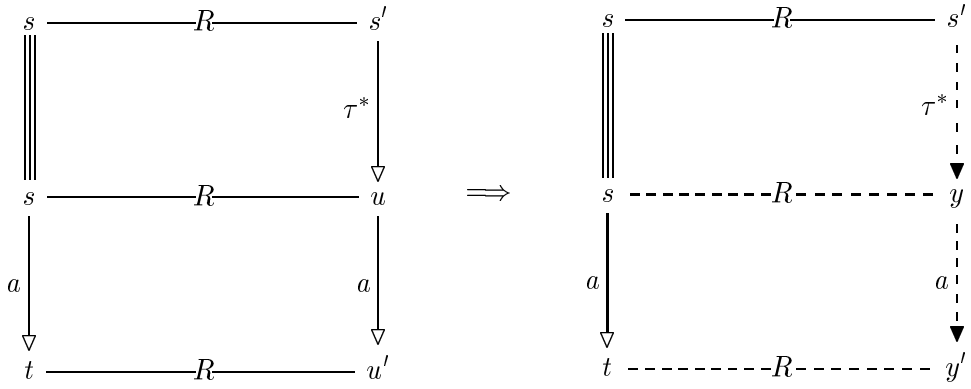
(i) $s \xrightarrow{a} t \implies [a \equiv \tau \ \wedge tRs'] \ \vee \ [\exists u, u' \,.\, s' \xrightarrow{\tau^*} u \xrightarrow{a} u' \ \wedge \ sRu \ \wedge \ tRu']$

(ii) $s' \xrightarrow{a} t' \implies [a \equiv \tau \ \wedge sRt'] \ \vee \ [\exists u, u' \,.\, s \xrightarrow{\tau^*} u \xrightarrow{a} u' \ \wedge \ s'Ru \ \wedge \ t'Ru']$

We first prove (i). Suppose $s \xrightarrow{a} t$. We are in one of the following situations:



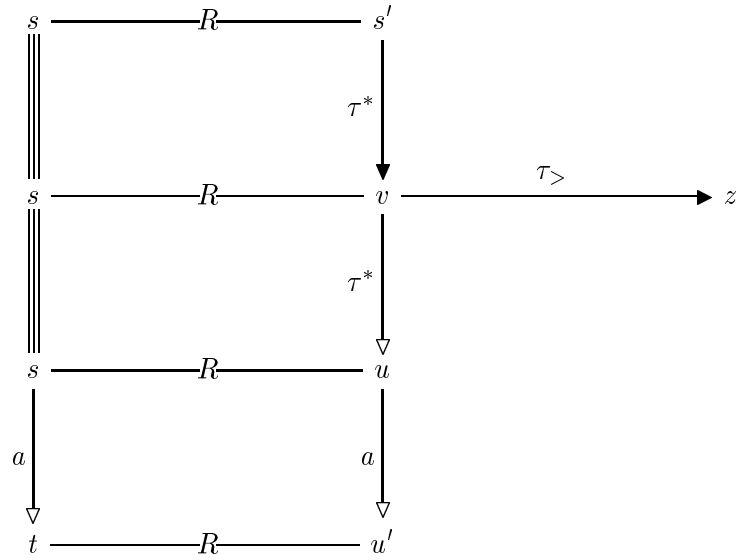
The existence of u and u' as depicted above is given by the definition of R. If all transitions of $s' \longrightarrow\!\!\!\!\triangleright\!\!\triangleright u'$ occur in T_2 (and in particular if $s' \equiv u'$) then we are done. To settle (i) in the other case — i.e. the case that not all transitions of $s' \longrightarrow\!\!\!\!\triangleright\!\!\triangleright u'$ occur in T_2 (and in particular $s' \not\equiv u'$) — we prove that the following property holds:



We use induction on $d_\tau(s')$. Here, d_τ is defined with respect to T_2, i.e. $d_\tau(x)$ equals the number of $\xrightarrow{\tau}$-steps that can be executed from x.

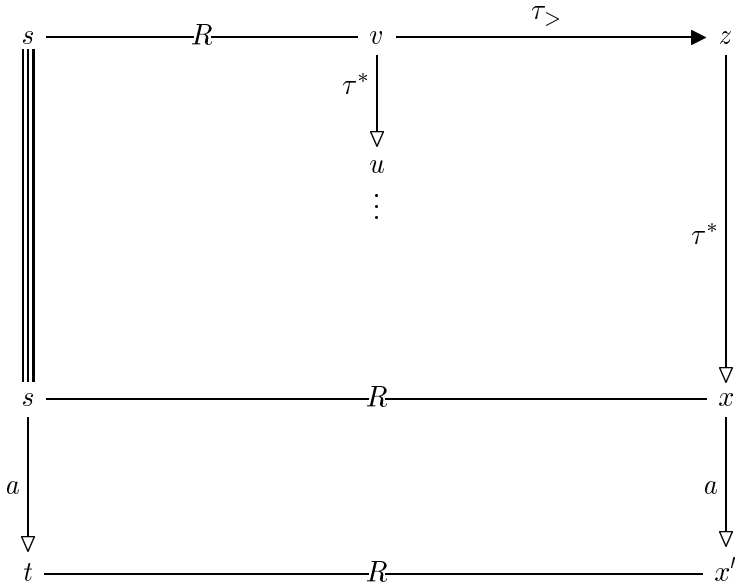
Let v and v' be those states occurring in the path $s' \xrightarrow{\tau^*} u \xrightarrow{a} u'$ of T_1, such that $s' \xrightarrow{\tau^*} v \not\longrightarrow v'$. Id est, $v \longrightarrow\!\!\triangleright v'$ is the first transition of $s' \xrightarrow{\tau^*} u \xrightarrow{a} u'$ that does not

occur in T_2. We can draw the following diagram:

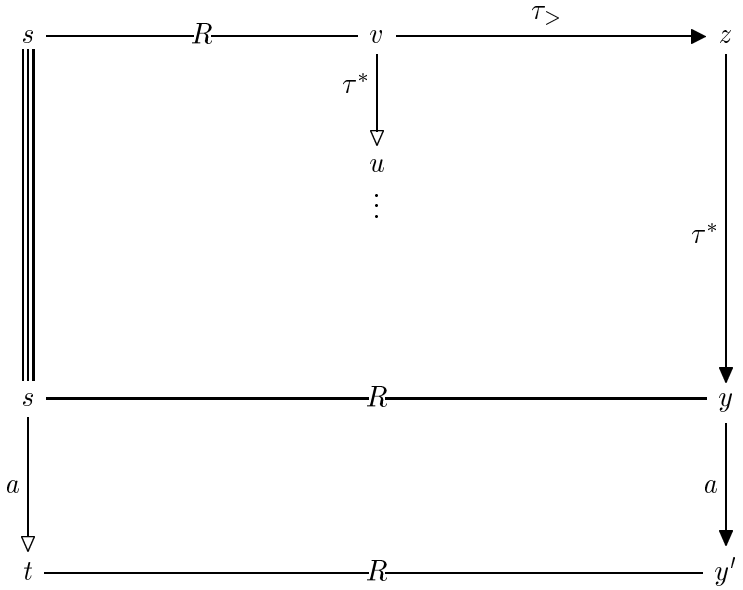


If $s' \equiv v$ then $v \longrightarrow\!\!\triangleright\ v'$ is the first transition of $s' \stackrel{\tau^*}{\longrightarrow\!\!\triangleright}\ u \stackrel{a}{\longrightarrow\!\!\triangleright}\ u'$, if $v \equiv u$ then $v \longrightarrow\!\!\triangleright\ v'$ is the last transition of $s' \stackrel{\tau^*}{\longrightarrow\!\!\triangleright}\ u \stackrel{a}{\longrightarrow\!\!\triangleright}\ u'$ and otherwise $v \longrightarrow\!\!\triangleright\ v'$ is an intermediate transition of $s' \stackrel{\tau^*}{\longrightarrow\!\!\triangleright}\ u \stackrel{a}{\longrightarrow\!\!\triangleright}\ u'$.

The transition $v \stackrel{\tau_>}{\longrightarrow} z$ exists because T_2 is a TP-reduction of T_1. Since $\longrightarrow\ \subseteq\ \longrightarrow\!\!\triangleright$ we can conclude vRz, using (11). Furthermore sRz (by transitivity of R) and $d_\tau(z) < d_\tau(s')$. Since R is a branching bisimulation on T_1 there exist states x and x' as depicted below:

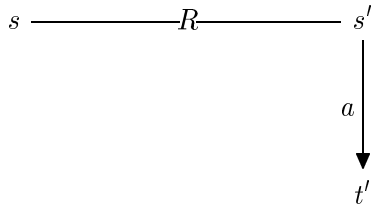


Now, by the induction hypothesis, there exist states y and y' such that

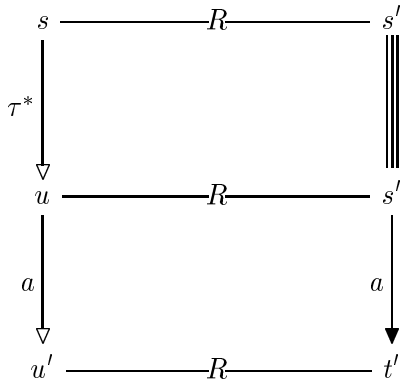


and we are done because y and y' satisfy the required properties.

The validity of (ii) is easy. Suppose $s' \xrightarrow{a} t'$. We are in the following situation:



Since $\longrightarrow \subseteq \longrightarrow\!\!\triangleright$ we have that $s' \xrightarrow{\tau} t'$. Now there exist states u and u' as depicted below since R is a branching bisimulation on T_1.



so we are done. ❑

As has been shown in the previous section, weak $>$-confluence can relatively easy be determined on Linear Processes. We provide a way to reduce the complexity of a Linear Process. Below we reformulate the notion of a TP-reduction on linear processes. We assume that p is a linear process according to definition 6.1 and that the data sort E_τ is ordered by some total ordering $\prec$, which assigns priority among τ-actions in the TP-reduction.

Definition 7.3. *The TP-reduction of p is the linear process*

$$p_r(d) = \sum_{a \in Act} \sum_{e_a : E_a} a(f_a(d, e_a))\, p_r(g_a(d, e_a)) \lhd b_a(d, e_a) \land c_a(d, e_a) \rhd \delta$$

where

$$c_a(d, e_a) \equiv \begin{cases} \neg\exists e_{\tau_>} : E_{\tau_>}\ b(d, e_{\tau_>}) & \text{if } a \neq \tau_> \\ \neg\exists e_{\tau_>} : E_{\tau_>}\ e_a \prec e_{\tau_>} \land b(d, e_{\tau_>}) & \text{if } a = \tau_> \end{cases}$$

Note that for the sake of conciseness, we use $\exists$ in the condition $c_a(d, e_a)$, which does not adhere to the formal definition of μCRL.

Theorem 7.4. *If the linear process p is $>$-convergent and weakly $>$-confluent, and if p_r is convergent, then for all $d : D$*

$$p(d) \leftrightarrows_b p_r(d)$$

8 Two examples

We illustrate how we apply the theory by means of two examples, where the structure of the processes is considerably simplified by a confluence argument.

8.1 Concatenation of two queues

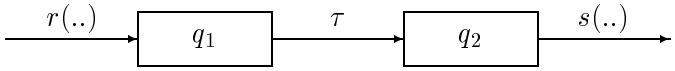
Consider the following linear process $Q(q)$ describing a queue q:

$$Q(q) = \sum_{e_r : E_r} r(e_r) \cdot Q(in(e_r, q)) + s(toe(q)) \cdot Q(untoe(q)) \lhd ne(q) \rhd \delta$$

The boolean expression $ne(q)$ evaluates to *true* iff q is not empty. The function *in* is used to insert an element to a queue and the function *untoe* is used to remove that element of a queue which has been inserted first. The function *toe* returns this first element. Now the following linear process $Q(\langle q_1, q_2 \rangle)$ describes the concatenation of two queues q_1 and q_2:

$$\begin{array}{rcl} Q(\langle q_1, q_2 \rangle) = \sum_{e_r : E_r} r(e_r) & \cdot & Q(\langle in(e_r, q_1), q_2 \rangle) \lhd true \rhd \delta + \\ \tau & \cdot & Q(\langle untoe(q_1), in(toe(q_1), q_2) \rangle) \lhd ne(q_1) \rhd \delta + \\ s(toe(q_2)) & \cdot & Q(\langle q_1, untoe(q_2) \rangle) \lhd ne(q_2) \rhd \delta \end{array}$$

As we can see, the process $Q(\langle q_1, q_2 \rangle)$ can always read a datum and insert it in q_1. If q_2 is not empty then the 'toe' of q_2 can be sent. The internal action τ removes the first element of q_1 and inserts it in q_2.



Using Theorem 6.3 we can straightforwardly prove that $Q(\langle q_1, q_2 \rangle)$ is strongly confluent. For the read action r we find the condition that for all queues q_1, q_2 and $e_r : E_r$

$$ne(q_1) \Rightarrow \exists e'_r : E_r \;\; e_r = e'_r \wedge ne(in(d, q_1)) \;\; \wedge$$
$$\langle in(e'_r, untoe(q_1)), in(toe(q_1), q_2) \rangle = \langle untoe(in(e_r, q_1)), in(toe(in(e_r, q_1)), q_2) \rangle.$$

Similarly, we can formulate the following conditions for the action s. For all queues q_1, q_2

$$(ne(q_2) \wedge ne(q_1)) \Rightarrow$$
$$toe(q_2) = toe(in(toe(q_1), q_2)) \;\; \wedge$$
$$ne(in(toe(q_1), q_2)) \wedge ne(q_1) \;\; \wedge$$
$$\langle untoe(q_1), untoe(in(toe(q_1), q_2)) \rangle = \langle untoe(q_1), in(toe(q_1), untoe(q_2)) \rangle.$$

With the appropriate axioms for queues, the validity of these facts is easily verified.

For the $a = \tau$ we find that the precondition $a = \tau \;\; \Rightarrow \;\; g_a(d, e_1) \neq g_\tau(d, e_2)$ is instantiated to $\tau = \tau \Rightarrow \langle untoe(q_1), in(toe(q_1), q_2) \rangle \neq \langle untoe(q_1), in(toe(q_1), q_2) \rangle$, which is a trivial contradiction.

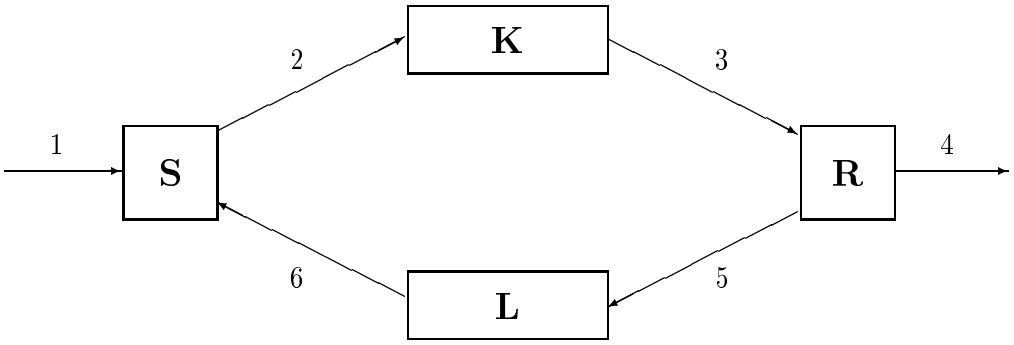
Now, by Theorem 7.4, the following TP-reduced version (see Definition 7.3) of $Q(\langle q_1, q_2 \rangle)$ is branching bisimilar to $Q(\langle q_1, q_2 \rangle)$.

$$\begin{array}{lcllcccl}
Q_r(\langle q_1, q_2 \rangle) = & & & & & & & \\
\sum_{e_r : E_r} r(e_r) & \cdot & Q_r(\langle in(e_r, q_1), q_2 \rangle) & \lhd & true \wedge empty(q_1) & \rhd & \delta & + \\
\tau & \cdot & Q_r(\langle untoe(q_1), in(toe(q_1), q_2) \rangle) & \lhd & ne(q_1) & \rhd & \delta & + \\
s(toe(q_2)) & \cdot & Q_r(\langle q_1, untoe(q_2) \rangle) & \lhd & ne(q_2) \wedge empty(q_1) & \rhd & \delta &
\end{array}$$

Note that after the TP-reduction q_1 never contains more than one element!

8.2 The alternating bit protocol

The alternating bit protocol (ABP) consists of a sender S, a receiver R and two unreliable channels K and L. (See [2], page 108) All these components can straightforwardly be described by a linear process.



The sender

The variables d_s, b_s and n_s are the data parameter, the bit and the state of the sender. If $n_s = 0$ then S can read a fresh datum $r_1(x)$. If $n_s = 1$, it wants to send data to channel K and if $n_s = 2$ then S is waiting for an acknowledgement.

$$\begin{array}{rcrl} S(d_s{:}\mathsf{D}, b_s{:}\mathbb{B}, n_s{:}\mathbb{N}) & = & \sum_{x:\mathsf{D}} r_1(x) \cdot S(x, b_s, 1) & \lhd\, n_s = 0 \,\rhd\ \delta\ + \\ & & s_2(d_s, b_s) \cdot S(d_s, b_s, 2) & \lhd\, n_s = 1 \,\rhd\ \delta\ + \\ & & r_6(\neg b_s) \cdot S(d_s, b_s, 1) & \lhd\, n_s = 2 \,\rhd\ \delta\ + \\ & & r_6(ce) \cdot S(d_s, b_s, 1) & \lhd\, n_s = 2 \,\rhd\ \delta\ + \\ & & r_6(b_s) \cdot S(d_s, \neg b_s, 0) & \lhd\, n_s = 2 \,\rhd\ \delta \end{array}$$

Note that this linear process is not deterministic because the last three summands of this linear process equation all perform the same action $r_6(..)$.

The channels

We provide linear process equations for the channels K and L. Again, the processes are not deterministic. Analogously to the sender, d_k, b_k and n_k are the data parameter, the bit and the state of channel K. If $n_k = 0$ then K can read a datum. If $n_k = 1$ then K can choose to deliver the datum correctly ($n_k := 2$) or to loose the datum and report a checksum error ce ($n_k := 3$). After delivary of either message, K can read again.

$$\begin{array}{rcrl} K(d_k{:}\mathsf{D}, b_k{:}\mathbb{B}, n_k{:}\mathbb{N}) & = & \sum_{x:\mathsf{D}} \sum_{y:\mathbb{B}} r_2(x, y) \cdot K(x, y, 1) & \lhd\, n_k = 0 \,\rhd\ \delta\ + \\ & & i \cdot K(d_k, b_k, 2) & \lhd\, n_k = 1 \,\rhd\ \delta\ + \\ & & i \cdot K(d_k, b_k, 3) & \lhd\, n_k = 1 \,\rhd\ \delta\ + \\ & & s_3(d_k, b_k) \cdot K(d_k, b_k, 0) & \lhd\, n_k = 2 \,\rhd\ \delta\ + \\ & & s_3(ce) \cdot K(d_k, b_k, 0) & \lhd\, n_k = 3 \,\rhd\ \delta \end{array}$$

The linear process equation for channel L is almost identical to the linear process equation for channel K we just gave. The only difference lies in the fact that channel L does not transport any data but only an acknowledging bit.

$$\begin{array}{rcrl} L(b_\ell{:}\mathbb{B}, n_\ell{:}\mathbb{N}) & = & \sum_{y:\mathbb{B}} r_5(y) \cdot L(y, 1) & \lhd\, n_\ell = 0 \,\rhd\ \delta\ + \\ & & i \cdot L(b_\ell, 2) & \lhd\, n_\ell = 1 \,\rhd\ \delta\ + \\ & & i \cdot L(b_\ell, 3) & \lhd\, n_\ell = 1 \,\rhd\ \delta\ + \\ & & s_6(b_\ell) \cdot L(b_\ell, 0) & \lhd\, n_\ell = 2 \,\rhd\ \delta\ + \\ & & s_6(ce) \cdot L(b_\ell, 0) & \lhd\, n_\ell = 3 \,\rhd\ \delta \end{array}$$

The meaning of the parameters of L is exactly the same as the meaning of the corresponding parameters of K.

The receiver

The parameters d_r, b_r and n_r are the data, bit and state of the receiver respectively. If $n_r = 0$ then R is waiting for data to arrive via channel K. If $n_r = 1$ then R wants to send an

acknowledgement via channel L and if $n_r = 2$ then R is ready to execute action $s_4(d_r)$, i.e. deliver a datum.

$$
\begin{array}{lrl}
R(d_r{:}\mathsf{D}, b_r{:}\mathbb{B}, n_r{:}\mathbb{N}) = & \sum_{x:\mathsf{D}} r_3(x, b_r) \cdot R(x, b_r, 1) & \lhd\, n_r = 0 \,\rhd\ \delta\ + \\
& r_3(ce) \cdot R(d_r, b_r, 1) & \lhd\, n_r = 0 \,\rhd\ \delta\ + \\
& \sum_{x:\mathsf{D}} r_3(x, \neg b_r) \cdot R(x, \neg b_r, 2) & \lhd\, n_r = 0 \,\rhd\ \delta\ + \\
& s_5(b_r) \cdot R(d_r, b_r, 0) & \lhd\, n_r = 1 \,\rhd\ \delta\ + \\
& s_4(d_r) \cdot R(d_r, b_r, 1) & \lhd\, n_r = 2 \,\rhd\ \delta
\end{array}
$$

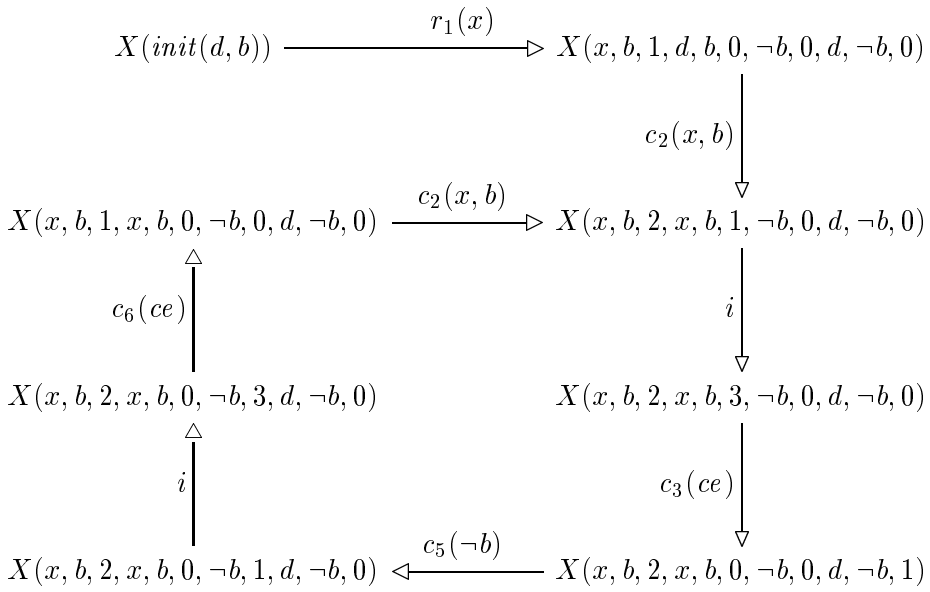
The parallel composition

The parallel composition $\partial_{\{r_i, s_i \mid i=2,3,5,6\}}(S \| K \| L \| R)$ can then be described by the following linear process, that is easily calculated from the four components S, K, L and R. In order to improve the readability we write $X[{}^{a}\!/_{b}]$ for the process that is obtained from $X(..)$ by replacing b by a. E.g. in the linear process equation for the sender we could have written $S[{}^{2}\!/_{n_s}]$ instead of $S(d_s, b_s, 2)$ and so on.

$$
\begin{array}{lcl}
X(d_s, b_s, n_s, d_k, b_k, n_k, b_\ell, n_\ell, d_r, b_r, n_r) = & & \\
\sum_{x:\mathsf{D}} r_1(x) \cdot X[{}^{x}\!/_{d_s}][{}^{1}\!/_{n_s}] & \lhd\ n_s = 0 & \rhd\ \delta\ + \\
c_2(d_s, b_s) \cdot X[{}^{2}\!/_{n_s}][{}^{d_s}\!/_{d_k}][{}^{b_s}\!/_{b_k}][{}^{1}\!/_{n_k}] & \lhd\ n_s = 1 \wedge n_k = 0 & \rhd\ \delta\ + \\
c_6(b_\ell) \cdot X[{}^{0}\!/_{n_s}][{}^{0}\!/_{n_\ell}][{}^{\neg b_s}\!/_{b_s}] & \lhd\ b_\ell = b_s \wedge n_s = 2 \wedge n_\ell = 2 & \rhd\ \delta\ + \\
c_6(b_\ell) \cdot X[{}^{1}\!/_{n_s}][{}^{0}\!/_{n_\ell}] & \lhd\ b_\ell \neq b_s \wedge n_s = 2 \wedge n_\ell = 2 & \rhd\ \delta\ + \\
c_6(ce) \cdot X[{}^{1}\!/_{n_s}][{}^{0}\!/_{n_\ell}] & \lhd\ n_s = 2 \wedge n_\ell = 3 & \rhd\ \delta\ + \\
c_3(d_k, b_k) \cdot X[{}^{d_k}\!/_{d_r}][{}^{1}\!/_{n_r}][{}^{0}\!/_{n_k}] & \lhd\ b_k = b_r \wedge n_r = 0 \wedge n_k = 2 & \rhd\ \delta\ + \\
c_3(d_k, b_k) \cdot X[{}^{d_k}\!/_{d_r}][{}^{2}\!/_{n_r}][{}^{0}\!/_{n_k}][{}^{\neg b_r}\!/_{b_r}] & \lhd\ b_k \neq b_r \wedge n_r = 0 \wedge n_k = 2 & \rhd\ \delta\ + \\
c_3(ce) \cdot X[{}^{1}\!/_{n_r}][{}^{0}\!/_{n_k}] & \lhd\ n_k = 3 \wedge n_r = 0 & \rhd\ \delta\ + \\
c_5(b_r) \cdot X[{}^{0}\!/_{n_r}][{}^{b_r}\!/_{b_\ell}][{}^{1}\!/_{n_\ell}] & \lhd\ n_r = 1 \wedge n_\ell = 0 & \rhd\ \delta\ + \\
s_4(d_r) \cdot X[{}^{1}\!/_{n_r}] & \lhd\ n_r = 2 & \rhd\ \delta\ + \\
i \cdot X[{}^{2}\!/_{n_k}] & \lhd\ n_k = 1 & \rhd\ \delta\ + \\
i \cdot X[{}^{3}\!/_{n_k}] & \lhd\ n_k = 1 & \rhd\ \delta\ + \\
i \cdot X[{}^{2}\!/_{n_\ell}] & \lhd\ n_\ell = 1 & \rhd\ \delta\ + \\
i \cdot X[{}^{3}\!/_{n_\ell}] & \lhd\ n_\ell = 1 & \rhd\ \delta
\end{array}
$$

We assume that initially the alternating bits of S and K are equal and unequal to the alternating bits of L and R. Furthermore we assume that initially all data parameters are equal and that all state parameters are 0. So all initial states are of the form $(d, b, 0, d, b, 0, \neg b, 0, d, \neg b, 0)$. In the sequel we abbreviate this state by $init(d, b)$.

Let $I = \{c_2, c_3, c_5, c_6, i\}$ then $\tau_I(X(init(d,b)))$ is not τ-well-founded. For instance



will, after hiding, result in a τ-loop. This means that we can not use Theorem 3.6 or Lemma 3.9 in order to derive property (1). Theorem 3.2 is also useless since $\tau_I(X(init(d,b)))$ is obviously not strongly confluent. However, if we divide the τ-steps of $\tau_I(X)$ in progressing and non-progressing ones, such that the result is $\tau_>$-well-founded, then we can apply Theorem 6.4. Let Y be the process obtained from $\tau_I(X)$ by labeling those τ-steps that set n_k or n_ℓ to 3, with $<$ and all the other τ-steps with $>$.

$$
\begin{array}{lcccc}
Y(d_s,b_s,n_s,d_k,b_k,n_k,b_\ell,n_\ell,d_r,b_r,n_r) & = & & & \\
\sum_{x:\mathsf{D}} r_1(x)\cdot Y[{}^{x}\!/_{d_s}][{}^{1}\!/_{n_s}] & \lhd & n_s = 0 & \rhd & \delta \;+ \\
\tau_>\cdot Y[{}^{2}\!/_{n_s}][{}^{d_s}\!/_{d_k}][{}^{b_s}\!/_{b_k}][{}^{1}\!/_{n_k}] & \lhd & n_s = 1 \wedge n_k = 0 & \rhd & \delta \;+ \\
\tau_>\cdot Y[{}^{0}\!/_{n_s}][{}^{0}\!/_{n_\ell}][{}^{\neg b_s}\!/_{b_s}] & \lhd & b_\ell = b_s \wedge n_s = 2 \wedge n_\ell = 2 & \rhd & \delta \;+ \\
\tau_>\cdot Y[{}^{1}\!/_{n_s}][{}^{0}\!/_{n_\ell}] & \lhd & b_\ell \neq b_s \wedge n_s = 2 \wedge n_\ell = 2 & \rhd & \delta \;+ \\
\tau_>\cdot Y[{}^{1}\!/_{n_s}][{}^{0}\!/_{n_\ell}] & \lhd & n_s = 2 \wedge n_\ell = 3 & \rhd & \delta \;+ \\
\tau_>\cdot Y[{}^{d_k}\!/_{d_r}][{}^{1}\!/_{n_r}][{}^{0}\!/_{n_k}] & \lhd & b_k = b_r \wedge n_r = 0 \wedge n_k = 2 & \rhd & \delta \;+ \\
\tau_>\cdot Y[{}^{d_k}\!/_{d_r}][{}^{2}\!/_{n_r}][{}^{0}\!/_{n_k}][{}^{\neg b_r}\!/_{b_r}] & \lhd & b_k \neq b_r \wedge n_r = 0 \wedge n_k = 2 & \rhd & \delta \;+ \\
\tau_>\cdot Y[{}^{1}\!/_{n_r}][{}^{0}\!/_{n_k}] & \lhd & n_k = 3 \wedge n_r = 0 & \rhd & \delta \;+ \\
\tau_>\cdot Y[{}^{0}\!/_{n_r}][{}^{b_r}\!/_{b_\ell}][{}^{1}\!/_{n_\ell}] & \lhd & n_r = 1 \wedge n_\ell = 0 & \rhd & \delta \;+ \\
s_4(d_r)\cdot Y[{}^{1}\!/_{n_r}] & \lhd & n_r = 2 & \rhd & \delta \;+ \\

\tau_<\cdot Y[{}^{3}\!/_{n_k}] & \lhd & n_k = 1 & \rhd & \delta \;+ \\
\tau_>\cdot Y[{}^{2}\!/_{n_\ell}] & \lhd & n_\ell = 1 & \rhd & \delta \;+ \\
\tau_<\cdot Y[{}^{3}\!/_{n_\ell}] & \lhd & n_\ell = 1 & \rhd & \delta
\end{array}
$$

In order to proceed we need the following lemma:

Lemma 8.1. *The following invariant properties hold in every state of* $Y(init(d,b))$.

(i) $n_k \neq 0 \mathrel{-\!\!>} (n_s = 2 \wedge d_s = d_k \wedge b_s = b_k)$

(ii) $n_\ell \neq 0 \mathrel{-\!\!>} (n_s = 2 \wedge n_r = 0 \wedge n_k = 0 \wedge b_r = b_\ell)$

(iii) $n_r \neq 0 \mathrel{-\!\!>} (n_k = 0 \wedge n_s = 2)$

(iv) $n_r = 0 \mathrel{-\!\!>} b_r = b_\ell$

(v) $b_s = b_r \mathrel{-\!\!>} (d_s = d_r \wedge n_s \neq 0)$

Proof. Straightforward induction. ❑

Next we show that $Y(init(d,b))$ is weakly $>$-confluent. Since we formulated the conditions for weak $>$-confluence for *deterministic* linear processes (Theorem 6.4) we first formulate a deterministic version Y' of Y.

$$
\begin{array}{l}
Y'(d_s,b_s,n_s,d_k,b_k,n_k,b_\ell,n_\ell,d_r,b_r,n_r) \;=\; \\
\sum_{x:\mathsf{D}} r_1(x)\cdot Y' \quad [x/d_s][1/n_s] \qquad\qquad \lhd \quad n_s = 0 \quad \rhd\ \delta \ + \\
\qquad s_4(d_r)\cdot Y' \quad [1/n_r] \qquad\qquad \lhd \quad n_r = 2 \quad \rhd\ \delta \ + \\
\qquad \sum_{n:\mathsf{N}} \tau_< \cdot Y' \begin{cases} [3/n_k] & \text{if } n = 1 \\ [3/n_\ell] & \text{if } n = 2 \end{cases} \qquad \lhd \quad \left[\begin{array}{c} (n_k = 1 \wedge n = 1) \vee \\ (n_\ell = 1 \wedge n = 2) \end{array}\right] \quad \rhd\ \delta \ + \\

$$

Lemma 8.2. *$Y'(init(d,b))$ is weakly $>$-confluent.*

Proof. Confluence must be checked for all $a \in Act$ and $e_1 : E_a$, with respect to all $e_2 : E_{\tau_>}$. We do this by a straightforward application of Theorem 6.4. We have distinguished 140 cases that have been listed in the table below. For 68 cases, marked with a $\times$ in the table the condition $b_a(d,e_1) \wedge b_{\tau_>}(d,e_2)$ does not hold. In 10 cases, marked with a $\blacksquare$, the condition $a = \tau_> \;\Rightarrow\; g_a(d,e_1) \neq g_{\tau_>}(d,e_2)$ is violated. In 60 of the remaining 62 confluence is immediately clear from the fact that the substitutions do not affect each other (i.e. they are commutative). These cases are marked with a $\circ$ in the table below.

	r_1	s_4	$\tau_< 1$	$\tau_< 2$	$\tau_> 1$	$\tau_> 2$	$\tau_> 3$	$\tau_> 4$	$\tau_> 5$	$\tau_> 6$	$\tau_> 7$	$\tau_> 8$	$\tau_> 9$	$\tau_> 10$
$\tau_> 1$	×	○	×	○	■	×	×	×	×	×	×	○	×	○
$\tau_> 2$	×	○	○	×	×	■	×	×	○	○	○	×	○	×
$\tau_> 3$	×	○	○	×	×	×	■	×	○	○	○	×	○	×
$\tau_> 4$	×	○	○	×	×	×	×	■	○	○	○	×	○	×
$\tau_> 5$	○	×	×	○	×	○	○	○	■	×	×	×	×	○
$\tau_> 6$	○	×	×	○	×	○	○	○	×	■	×	×	×	○
$\tau_> 7$	○	×	×	○	×	○	○	○	×	×	■	×	×	○
$\tau_> 8$	○	×	○	×	○	×	×	×	×	×	×	■	○	×
$\tau_> 9$	○	○		○	×	○	○	○	×	×	×	○	■	○
$\tau_> 10$	○	○	○		○	×	×	×	○	○	○	×	○	■

So, there are 2 cases left. Each case corresponds to the choice of a channel to corrupt the datum or not. We only treat the case $\tau_< 1$ and $\tau_> 9$.

We take σ_2 empty and $\sigma = \sigma_1$ using that $a = \tau_<$. So, e_3 is irrelevant. We distinguish the following two cases

- Assume $b_r = b_s$. We take for $\sigma_1 = \langle \tau_>, 5 \rangle$ and $\sigma_3 = \langle \tau_>, 7 \rangle$. We must now check the three requirements

  $$\mathcal{B}_{g_a(d,e_1)}(\sigma_3), \mathcal{B}_{g_{\tau_>}(d,e_2)}(\sigma) \text{ and } \mathcal{G}_{g_a(d,e_1)}(\sigma_3) = \mathcal{G}_{g_{\tau_>}(d,e_2)}(\sigma)$$

  These boil down to the following three proof obligations, where the trivial ones have been omitted. All obligations follow from the invariant in Lemma 8.1 in a straightforward fashion as we know that $n_k = 1$.

  $$n_r = 0, b_k = b_r \ \wedge \ n_r = 0 \text{ and } d_k = d_r.$$

- In the case that $b_r \neq b_s$, we take σ_1 empty and $\sigma_3 = \langle \tau_>, 7 \rangle \ \langle \tau_>, 8 \rangle \ \langle \tau_>, 10 \rangle \ \langle \tau_>, 3 \rangle \ \langle \tau_>, 1 \rangle \ \langle \tau_>, 9 \rangle$. The three requirements now become

  $$n_r = 0 \wedge n_\ell = 0 \wedge b_r \neq b_s \wedge n_s = 2, true \text{ and}$$
  $$n_s = 2 \wedge b_r = b_\ell \wedge n_\ell = 0 \wedge n_r = 0 \wedge d_s = d_k \wedge b_s = b_k.$$

  These also follow from the invariant and the fact that $n_k = 1$.

❑

The TP-reduction now prescribes that in all states where there is a progressing τ-step all other actions can be removed. In the cases where $n_k = 1$ or $n_\ell = 1$ this is applicable; we can remove the non-progressing τ-steps. By removing all transitions that have become unreachable in this way, we obtain the following simple process of which each state has only one outgoing transition. In particular, the channels have become reliable. One easily verifies that this process is convergent. E.g. the natural number $3 \cdot ((-n_s) \bmod 3) + 3 \cdot ((n_r - 2) \bmod 3) - n_k - n_\ell + 4$ decreases after each τ-step. By Theorem 7.4 this reduced process is branching bisimilar to the alternating bit

protocol.
