Multiple period integrals and cohomology

Roelof W. Bruggeman and Youngju Choie

We give a version of the Eichler–Shimura isomorphism with a nonabelian H^1 in group cohomology. Manin has given a map from vectors of cusp forms to a noncommutative cohomology set by means of iterated integrals. We show that Manin’s map is injective but far from surjective. By extending Manin’s map we are able to construct a bijective map and remarkably this establishes the existence of a nonabelian version of the Eichler–Shimura map.

1. Introduction

In the theory of modular forms the Eichler–Shimura isomorphism has played an important role, with many applications. For instance, it gives integrality of eigenvalues for Hecke operators and algebraicity of the critical values of the L -functions of modular forms, which, for example, enables the construction of p -adic L -functions and gives a connection to Iwasawa theory as well as the computational aspects of modular form theory. The Eichler–Shimura isomorphism relates spaces of cusp forms of integral weight to a parabolic cohomology group, namely,

$$S_k(\mathrm{SL}_2(\mathbb{Z})) \oplus \bar{S}_k(\mathrm{SL}_2(\mathbb{Z})) \cong H_{\mathrm{par}}^1(\mathrm{SL}_2(\mathbb{Z}), \mathbb{C}_{k-2}[X, Y]),$$

where $\mathbb{C}_{k-2}[X, Y]$ is the $\mathrm{SL}_2(\mathbb{Z})$ -module of homogeneous polynomials of degree $k - 2$ in the indeterminates X, Y , and where $S_k(\mathrm{SL}_2(\mathbb{Z}))$ (resp. $\bar{S}_k(\mathrm{SL}_2(\mathbb{Z}))$) is the space of holomorphic (resp. antiholomorphic) cusp forms of weight k .

The Eichler–Shimura isomorphism was eventually extended in [Knopp 1974] and [Knopp and Mawi 2010] by establishing a canonical isomorphism between 1-cohomology of cofinite discrete subgroups Γ of $\mathrm{SL}_2(\mathbb{R})$ with appropriate holomorphic coefficients and the space of cusp forms with real weight.

Manin [2005] defined a “nonabelian” H^1 in group cohomology with values in a nonabelian group, and a map from a product of spaces of cusp forms to this cohomology set, in analogy to the Eichler–Shimura map. Manin’s construction uses iterated integrals in the spirit of the multiple zeta values which have proved so useful

Keywords: cusp form, iterated integral, noncommutative cohomology.

in understanding zeta values and mixed Tate motives, for example. Manin’s integrals give a way to express multiple L -values of modular forms and have been studied by the second author [Choie 2014] and independently in the thesis of N. Provost [2014] recently. In [Choie 2014] the period polynomials whose coefficients are multiple L -values were treated as elements in a nonabelian H^1 for the first time.

In a recent talk at ICM, Brown [2014] mentioned a connection between the iterated integrals of Manin and certain mixed motives. He explained how to interpret motivic multiple zeta values as periods of the pro-unipotent fundamental groupoid of the projective line minus three points $X = \mathbb{P}^1 \setminus \{0, 1, \infty\}$ via iterated integral of smooth 1-forms on a differentiable manifold discussed by Chen [1977]. Hain [2015] discussed the relation between Manin’s iterated integrals and the Hodge theory of modular groups. However, it was not clear yet how to relate Manin’s iterated integral and Eichler–Shimura theory. Manin’s map from spaces of cusp forms to cohomology differs in two aspects from the Eichler–Shimura map: the summand $\bar{S}_k(\mathrm{SL}_2(\mathbb{Z}))$ is absent and the map is injective but not surjective.

This paper addresses the second difference by extending Manin’s map to more complicated combinations of spaces of cusp forms to obtain a variant of the Eichler–Shimura isomorphism with values in a nonabelian cohomology H^1 . Our main result (Theorem 6.7) states that there is an extension of Manin’s map that is bijective onto a noncommutative cohomology set. It is remarkable that there exists some nonabelian version of the Eichler–Shimura map.

To obtain our main result we modify Manin’s construction [2005] in several ways in the spirit of a variant Eichler–Shimura isomorphism established in [Knopp 1974; Knopp and Mawi 2010]: first replace the finite-dimensional spaces of polynomials by spaces of functions on the lower half-plane. Secondly, unlike in the classical Eichler–Shimura isomorphism, antiholomorphic modular forms are not considered. Thirdly, we allow automorphic forms for cofinite discrete subgroups Γ of $\mathrm{SL}_2(\mathbb{R})$ with arbitrary real weights and multiplier system. Finally, we collapse the number of variables in the iterated integrals.

To be more precise consider the iterated integral

$$\begin{aligned}
 R_\ell(f_1, \dots, f_\ell; y, x; t_1, \dots, t_\ell) &:= \int_{\tau_1=x}^y f_1(\tau_1)(\tau_1 - t_1)^{w_1} \int_{\tau_2=x}^{\tau_1} f_2(\tau_2)(\tau_2 - t_2)^{w_2} \\
 &\quad \cdots \int_{\tau_\ell=x}^{\tau_{\ell-1}} f_\ell(\tau_\ell)(\tau_\ell - t_\ell)^{w_\ell} d\tau_\ell \cdots d\tau_2 d\tau_1, \quad (1-1)
 \end{aligned}$$

where x, y are in the extended complex upper half-plane and each $t_j, 1 \leq j \leq \ell$, is in the lower half-plane. If the f_j are cusp forms of even integral weight $w_j + 2$, the iterated integral defines a polynomial function in the $t_j, 1 \leq j \leq \ell$, whose coefficients are multiple L -values of f_j . The resulting iterated integral is holomorphic in

(t_1, \dots, t_ℓ) in the product of ℓ copies of the lower half-plane if the f_j are cusp forms of real weight. As the order ℓ of the iterated integral increases, the relations between iterated integrals become more and more complicated. However, the relations between iterated integrals of order ℓ look simple modulo all products of iterated integrals of lower order. Manin [2005; 2006] has shown how to give a neat formulation for all relations among iterated integrals of the type indicated in (1-1). His approach works with formal series in noncommuting variables and can be applied to much more general iterated integrals than studied here.

The factors $(\tau_j - t_j)^{w_j}$ in (1-1) occur also in the definition of cocycles attached to cusp forms. Manin attaches to vectors of cusp forms (f_1, \dots, f_ℓ) a cocycle in a noncommutative cohomology set, and thus gives a generalization of the Eichler-Shimura map. The cohomology has values in a noncommutative subgroup $N(\mathcal{A})$ of the unit group of the noncommutative ring \mathcal{A} of formal power series in noncommuting variables A_1, \dots, A_ℓ with coefficients in spaces of holomorphic functions on the lower half-plane. The variables A_j correspond to spaces of cusp forms $S_{w_j+2}(\Gamma, v_j)$ with positive real weights $w_j + 2$ and corresponding multiplier systems v_j . Then Manin's approach leads to a map

$$\prod_{j=1}^{\ell} S_{w_j+2}(\Gamma, v_j) \longrightarrow H^1(\Gamma; N(\mathcal{A})) \quad (1-2)$$

from a product of finitely many spaces of cusp forms to a noncommutative cohomology set. This (nonlinear) map is far from surjective. In Theorem 6.7 we show that Manin's map can be extended, and that all elements of the cohomology set $H^1(\Gamma; N(\mathcal{A}))$ can be related to combinations of cusp forms by means of iterated integrals. The simplification $t_1 = \dots = t_\ell$ in the iterated integrals is essential for our methods to work.

Sections 2 and 3 have a preliminary nature. We review the approach of Knopp [1974] of associating cocycles to any cusp form of real weight and the definition of the iterated integrals that we use. Sections 4 and 5 discuss Manin's approach of using formal series in noncommuting variables to associate noncommutative cocycles to vectors of cusp forms. In Section 6 we extend this approach in such a way that the resulting map from collections of cusp forms to noncommutative cohomology is bijective.

2. Cusp forms and theorem of Knopp and Mawi

Discrete group. Let Γ be a cofinite discrete subgroup of $\mathrm{SL}_2(\mathbb{R})$ with translations. Without loss of generality we assume that $\begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} \in \Gamma$. For convenience we conjugate Γ into a position for which ∞ is among its cusps and such that the subgroup Γ_∞ of Γ fixing ∞ is generated by $T = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$.

Notation. For $w \in \mathbb{R}$ and v a corresponding *unitary* multiplier system, we denote by $S_{w+2}(\Gamma, v)$ the space of holomorphic cusp forms of weight $w + 2$ and multiplier system v . This is the finite-dimensional space of holomorphic functions f on the upper half-plane satisfying $f(\gamma z) = v(\gamma)(cz + d)^{w+2} f(z)$ for $\gamma \in \Gamma$, with exponential decay upon approach of the cusps. If the weight $w + 2$ is integral, a multiplier system is a character.

Functions with at most polynomial growth. By $V(v, w)$, with $w \in \mathbb{R}$ and v a corresponding multiplier system, we denote the space of holomorphic functions on the lower half-plane \mathfrak{H}^- with at most polynomial growth at the boundary $\mathbb{P}_{\mathbb{R}}^1$ of \mathfrak{H}^- , provided with the action of $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma$ given by

$$f|_{v,-w}\gamma(t) = v(\gamma)(ct + d)^{-w} f(\gamma t). \tag{2-1}$$

The condition that f has polynomial growth on \mathfrak{H}^- can be formulated as

$$|f(t)| \leq C_1 |t|^A + C_2 |\text{Im } t|^{-A} \quad \text{for all } t \in \mathfrak{H}^-, \text{ for some } A, C_1, C_2 \geq 0. \tag{2-2}$$

The action $|_{v,-w}$ of Γ preserves this condition.

Remarks. (a) In [Bruggeman et al. 2014, §1.4] we denoted the representation $V(v, w)$ of Γ by $\mathcal{D}_{v,-w}^{-\infty}$ (actually we used $r = w + 2$ as the main parameter, and wrote $\mathcal{D}_{v,2-r}^{-\infty}$).

(b) The polynomial growth condition in (2-2) can be formulated in terms of an estimate by one function $Q(t) = |\text{Im } t|/|t - i|^2$ as $|f(t)| \leq C Q(t)^{-A}$ for some $A, C \geq 0$. See the discussion in [Bruggeman et al. 2014, §1.5].

Knopp’s cocycles associated to cusp forms. Knopp [1974] associated to cusp forms $f \in S_{w+2}(\Gamma, v)$ a cocycle $\bar{\psi}_f$ given by

$$\bar{\psi}_{f,\gamma}(z) = \overline{\int_{\gamma^{-1}\infty}^{\infty} f(\tau)(\tau - \bar{z})^w d\tau}.$$

This cocycle takes values in the holomorphic functions on the upper half-plane \mathfrak{H} that have at most polynomial growth on \mathfrak{H} in the sense of (2-2) (now with t replaced by $z \in \mathfrak{H}$). We avoid the complex conjugation by taking a cocycle with values in the holomorphic functions on the lower half-plane \mathfrak{H}^- with at most polynomial growth at the boundary:

$$\psi_{f,\gamma}(t) = \int_{\tau=\gamma^{-1}\infty}^{\infty} f(\tau)(\tau - t)^w d\tau. \tag{2-3}$$

So ψ_f has values in the Γ -module $V(v, w)$.

Theorem 2.1 [Knopp and Mawi 2010]. *For real weight $w + 2$ and corresponding unitary multiplier system v , the map $f \mapsto [\psi_f]$ determines a linear bijection*

$$S_{w+2}(\Gamma, v) \longrightarrow H^1(\Gamma; V(v, w)).$$

Knopp [1974] conjectured this result, and proved it for many cases. Finally, the remaining cases were completed in [Knopp and Mawi 2010].

Remarks. (a) A multiplier system v is called *unitary* if $|v(\gamma)| = 1$ for all $\gamma \in \Gamma$.

(b) Since $S_{w+2}(\Gamma, v) = \{0\}$ for $w + 2 \leq 0$, the theorem implies that the cohomology groups vanish as well for $w + 2 \leq 0$.

(c) If $w \in \mathbb{Z}_{\geq 0}$, the cocycles take values in polynomial functions on \mathfrak{H}^- , which for the trivial multiplier system form a submodule of $V(1, w)$ isomorphic to $\mathbb{C}_w[X, Y]$.

If the multiplier system v has values only in $\{1, -1\}$ then conjugation gives cocycles in the same module. The Eichler–Shimura theory gives the parabolic cohomology group with values in polynomial functions of degree at most w as the direct sum of the images of the two maps $f \mapsto [\psi_f]$ and $f \mapsto [\bar{\psi}_f]$. However, in the large module of polynomially growing functions, the cocycles $\bar{\psi}_f$ become coboundaries. Also the cocycles associated to Eisenstein series become coboundaries over the module of functions with at most polynomial growth.

(d) Knopp [1974] shows that the parabolic cohomology group $H_{\text{par}}^1(\Gamma; V(v, w))$ is equal to the cohomology group $H^1(\Gamma; V(v, w))$.

3. Iterated integrals

By taking $t_1 = \dots = t_\ell = t$ we consider the following holomorphic function in t running through the lower half-plane:

$$R_\ell(f_1, \dots, f_\ell; y, x; t) := \int_{\tau_1=x}^y f_1(\tau_1)(\tau_1 - t)^{w_1} \int_{\tau_2=x}^{\tau_1} f_2(\tau_2)(\tau_2 - t)^{w_2} \dots \int_{\tau_\ell=x}^{\tau_{\ell-1}} f_\ell(\tau_\ell)(\tau_\ell - t)^{w_\ell} d\tau_\ell \dots d\tau_2 d\tau_1. \quad (3-1)$$

It is a multilinear form on $\prod_{j=1}^\ell S_{w_j+2}(\Gamma, v_j)$ for ℓ pairs $(v_1, w_1), \dots, (v_\ell, w_\ell)$ of real numbers w_j and corresponding unitary multiplier systems v_j . The parameter t is in the lower half-plane \mathfrak{H}^- . The value of the iterated integral does not depend on the path of integration, provided we take care to approach cusps along geodesic half-lines (for instance, vertically).

The most interesting case is $y = \gamma^{-1}\infty$, $\gamma \in \Gamma$, and $x = \infty$. For $\ell = 1$ this gives the value $\psi_{f_1, \gamma}$ of the cocycle in (2-3). That is why we call $R_\ell(f_1, \dots, f_\ell; \gamma^{-1}\infty, \infty; t)$ a *multiple period integral*.

Functions with at most polynomial growth. The condition of polynomial growth in (2-2) is preserved by the action of Γ given for $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ by

$$\begin{aligned} h|_{v,-w}\gamma(t) &= v(\gamma)^{-1}(ct+d)^w h(\gamma t), \\ v(\gamma) &= v_1(\gamma)v_2(\gamma)\cdots v_\ell(\gamma), \\ w &= w_1 + w_2 + \cdots + w_\ell. \end{aligned} \tag{3-2}$$

By $V(v, w)$ we denote the vector space of holomorphic functions on \mathfrak{H}^- with the action $|_{v,-w}$ given in (3-2). Multiplication of functions gives a bilinear map $V(v; w) \times V(v'; w') \rightarrow V(vv'; w + w')$. The action behaves according to the rule

$$(h|_{v,-w}\gamma)(h'|_{v',-w'}\gamma) = (hh')|_{vv',-w-w'}\gamma. \tag{3-3}$$

Lemma 3.1. *For $f = (f_1, \dots, f_\ell) \in \prod_{j=1}^\ell S_{w_j+2}(\Gamma, v_j)$, the multiple period integral $R_\ell(f; y, x; \cdot)$ defines an element of $V(v, w)$.*

Proof. Each cusp form has at most polynomial growth on \mathfrak{H} , and has exponential decay at cusps when the cusp is approached along a geodesic half-line. This implies that the iterated integral in (3-1) has at most polynomial growth in t and $\tau_{\ell-1}$. Successively this also implies polynomial growth in τ_{j-1} and t of the further integrals. \square

Trivial relation. Directly from the definition we have

$$R_\ell(f; x, x; t) = 0. \tag{3-4}$$

Lemma 3.2. *For $\gamma \in \Gamma$,*

$$R_\ell(f; \gamma^{-1}y, \gamma^{-1}x; t) = R_\ell(f; y, x; \cdot)|_{v,-w}\gamma(t). \tag{3-5}$$

Proof. In the following computation all τ_j are replaced by $\gamma\tau_j$, with $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma$:

$$\begin{aligned} &R_\ell(f; x, y; \cdot)|_{v,-w}\gamma(t) \\ &= \prod_{j=1}^\ell (v_j(\gamma)^{-1}(ct+d)^{w_j}) \int_{\tau_1=x}^y f_1(\tau_1)(\tau_1-\gamma t)^{w_1} \int_{\tau_\ell=x}^{\tau_{\ell-1}} f_\ell(\tau_\ell)(\tau_\ell-\gamma t)^{w_\ell} \\ &\hspace{20em} d\tau_\ell \cdots d\tau_1 \\ &= \prod_{j=1}^\ell (v_j(\gamma)^{-1}(ct+d)^{w_j}) \int_{\tau_1=\gamma^{-1}x}^{\gamma^{-1}y} f_1(\gamma\tau_1) \frac{(\tau_1-t)^{w_1}}{(c\tau_1+d)^{w_1}(ct+d)^{w_1}} \\ &\hspace{10em} \int_{\tau_\ell=\gamma^{-1}x}^{\gamma^{-1}(\tau_{\ell-1})} f_\ell(\gamma\tau_\ell) \frac{(\tau_\ell-t)^{w_\ell}}{(c\tau_\ell+d)^{w_\ell}(ct+d)^{w_\ell}} \frac{d\tau_\ell}{(c\tau_\ell+d)^2} \cdots \frac{d\tau_1}{(c\tau_1+d)^2} \\ &= R_\ell(f; \gamma^{-1}y, \gamma^{-1}x; t). \hspace{10em} \square \end{aligned}$$

Cocycles. For $\ell = 1$ we get the cocycle ψ_f in (2-3):

$$\psi_{f,\gamma}(t) = -R_1(f; \gamma^{-1}\infty, \infty; t). \tag{3-6}$$

Decomposition. It is easy to see that the cocycles in (2-3) satisfy the cocycle relation

$$c_{\gamma\delta} = c_\gamma|_\delta + c_\delta$$

for $\gamma, \delta \in \Gamma$: use the decomposition relation $\int_b^a + \int_c^b = \int_c^a$ for integrals together with the invariance relation in Lemma 3.2.

There are *decomposition relations* for the iterated integrals in (3-1), which can be obtained by application of the decomposition relation for integrals of one variable to the subintegrals in (3-1). For the orders 2 and 3 these relations take the form

$$\begin{aligned} R_2(f_1, f_2; z, y; t) + R_2(f_1, f_2; y, x; t) - R_2(f_1, f_2; z, x; t) \\ = R_1(f_1; z, y; t)R_1(f_2; y, x; t), \end{aligned} \quad (3-7)$$

$$\begin{aligned} R_3(f_1, f_2, f_3; z, y; t) + R_3(f_1, f_2, f_3; y, x; t) - R_3(f_1, f_2, f_2; z, x; t) \\ = -R_1(f_1; z, y; t)R_2(f_2, f_3; y, x; t) + R_2(f_1, f_2; z, y; t)R_1(f_3; y, x; t). \end{aligned} \quad (3-8)$$

We have written these relations in such a way that the quantity on the left should be zero if the standard decomposition would hold. On the right is a correction term consisting of products of iterated integrals of lower order.

Example. The decomposition relations can be used to obtain relations between values of multiple L -functions at special points, as studied in [Choi 2014] and in the thesis by Provost [2014] independently.

Let us take $\Gamma = \mathrm{SL}_2(\mathbb{Z})$, and assume that $v_1 = v_2 = 1$, and $w_1, w_2 \in 2\mathbb{Z}_{\geq 0}$. This implies that the multiple integrals yield polynomial functions in the variable t . We apply (3-7) with $z = x = \infty$ and $y = 0$. With (3-4),

$$R_2(f_1, f_2; \infty, 0; t) + R_2(f_1, f_2; 0, \infty; t) = R_1(f_1; \infty, 0; t)R_1(f_2; 0, \infty; t).$$

Using the binomial theorem, we see that $R_1(f; \infty, 0; t)$ is a polynomial in t with coefficients that can be expressed in values of completed L -functions. In a similar way, $R_2(f_1, f_2; \infty, 0; t)$ is a polynomial in t with coefficients that can be expressed in values of a completed multiple L -function of order 2 as defined in [Choi 2014, (2.6)]. With Lemma 3.2,

$$R_2(f_1, f_2; 0, \infty; \cdot) = R_2(f_1, f_2; \infty, 0; \cdot)|_{-wS},$$

where $S = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. In this way, the decomposition relation (3-7) implies the equality of two polynomials. Comparing coefficients leads to the relation in [Choi 2014, Theorem 3.1].

This account is a simplification. The decomposition relations are valid for the iterated integrals in (1-1), and lead for $w_j \in 2\mathbb{Z}_{\geq 0}$ to polynomials in two variables. Choi [2014] works in that generality.

4. Formal series

Manin [2005; 2006] has indicated a way to give structure to the decomposition relations of any order. His approach works in a general context of iterated integrals associated to cusp forms. The factors $(\tau_j - t)^w$ of the kernel in (3-1) and $(\tau_j - t_j)$ in (1-1) may be replaced by more general factors, for instance, by factors leading to iterated L -integrals as studied in [Choie 2014]. Here we use Manin’s formalism for the iterated integrals in (3-1).

We keep fixed ℓ combinations of a weight $w_j + 2 \in \mathbb{R}$ and a corresponding unitary multiplier system v_j . For a vector $\mathbf{f} = (f_1, \dots, f_\ell) \in \prod_{j=1}^\ell S_{w_j+2}(\Gamma, v_j)$ of length ℓ , we form iterated integrals of arbitrary order

$$R_n(f_{m_1}, f_{m_2}, \dots, f_{m_n}; y, x; t) \tag{4-1}$$

for any choice $m = (m_1, \dots, m_n) \in \{1, \dots, \ell\}^n$, for any $n \geq 0$. For $n = 0$ we define this quantity to be 1. The same f_j may occur several times as f_{m_i} . So we do not get linearity in f_j . The result is a holomorphic function on \mathfrak{H}^- , and has at most polynomial growth by Lemma 3.1.

To formulate the Γ -equivariance, we put for $m = (m_1, m_2, \dots, m_n)$

$$\mathbf{v}(m) := v_{m_1} v_{m_2} \cdots v_{m_n}, \quad \mathbf{w}(m) := w_{m_1} + w_{m_2} + \cdots + w_{m_n}. \tag{4-2}$$

We consider the iterated integral in (4-1) as an element of $V(\mathbf{v}(m), \mathbf{w}(m))$. For the empty sequence $m = ()$ we put $V(\mathbf{v}(), \mathbf{w}()) = \mathbb{C}$ with the trivial action $|_{1,0}$. Multiplication follows the rule in (3-3). Lemma 3.2 can be applied.

Power series in noncommuting variables. We choose ℓ spaces of cusp forms $S_{w_j+2}(\Gamma, v_j)$ with $w_j + 2 > 0$ and unitary multiplier systems v_j , for $1 \leq j \leq \ell$. We indicate this choice by the symbol \mathcal{A} . For this choice \mathcal{A} we take ℓ noncommuting variables A_1, A_2, \dots, A_ℓ .

Let $\mathcal{O}(\mathcal{A})$ be the set of formal power series in the A_j for which the coefficient of the monomial $A_{m_1} A_{m_2} \cdots A_{m_n}$ is in $V(\mathbf{v}(m), \mathbf{w}(m))$ for each $m \in \{1, \dots, \ell\}^n$. The constant term is in $V(\mathbf{v}(), \mathbf{w}()) = \mathbb{C}$. The relation (3-3) implies that $\mathcal{O}(\mathcal{A})$ is a ring.

Formal series associated to vectors of cusp forms. Following Manin we combine all iterated integrals in (4-1) as coefficients of an element of the ring $\mathcal{O}(\mathcal{A})$. Let

$$S_{\mathcal{A}}(\Gamma) = \prod_{j=1}^\ell S_{w_j+2}(\Gamma, v_j). \tag{4-3}$$

For $\mathbf{f} = (f_1, \dots, f_\ell) \in S_{\mathcal{A}}(\Gamma)$ define the formal series $J(\mathbf{f}; y, x; t) \in \mathcal{O}(\mathcal{A})$ by

$$J(\mathbf{f}; y, x; t) = 1 + \sum_{n \geq 1} \sum_{m_1, \dots, m_n \in \{1, \dots, \ell\}} R_n(f_{m_1}, f_{m_2}, \dots, f_{m_n}; y, x; t) A_{m_1} A_{m_2} \cdots A_{m_n}. \tag{4-4}$$

Remarks. (a) $J(\mathbf{f}; z, w; \cdot)$ is an invertible element of $\mathcal{O}(\mathcal{A})$ since it has a nonzero constant term.

(b) The coefficients $R_n(f_{m_1}, \dots, f_{m_n}; y, x; t)$ are continuous functions of $y, x \in \mathfrak{H}^*$, and are holomorphic in $x, y \in \mathfrak{H}$.

(c) The A_j codes for the space $S_{w_j+2}(\Gamma, v_j)$. This approach differs from that in [Manin 2005, §2]. There the formal variables code for linearly independent elements of the space $\prod_j S_{w_j+2}(\Gamma, v_j)$.

Action of Γ . We define an action of Γ on $\mathcal{O}(\mathcal{A})$ by the action $|_{v(m), -w(m)}$ on the coefficient of $A_{m_1} \cdots A_{m_n}$. Lemma 3.2 implies the relation

$$J(\mathbf{f}; \gamma^{-1}y, \gamma^{-1}x; \cdot) = J(\mathbf{f}; y, x; \cdot)|_{\gamma} \quad \text{for each } \gamma \in \Gamma. \quad (4-5)$$

Multiplication properties. These formal series satisfy for $z, y, x \in \mathfrak{H}^*$

$$J(\mathbf{f}; x, x; t) = 1, \quad (4-6)$$

$$J(\mathbf{f}; x, y; t) = J(\mathbf{f}; y, x; t)^{-1}, \quad (4-7)$$

$$J(\mathbf{f}; z, x; t) = J(\mathbf{f}; z, y; t)J(\mathbf{f}; y, x; t). \quad (4-8)$$

We will prove a more general result in Proposition 6.3.

These relations encapsulate infinitely many relations between multiple period integrals. The reader who takes the trouble to compare the coefficients of A_1A_2 in (4-8) obtains the relation (3-7). Similarly, relation (3-8) is given by the coefficient of $A_1A_2A_3$.

Commutative example. In the modular case we may look at $w = N/2 - 2$ for some $N \in \mathbb{Z}_{\geq 1}$. As the corresponding multiplier system we choose $v_{N/2}$ determined by

$$v_{N/2} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = e^{\pi i N/12}, \quad v_{N/2} \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} = e^{-\pi i N/4}. \quad (4-9)$$

For $1 \leq N \leq 24$ the space of cusp forms is one-dimensional, in fact:

$$S_{N/2+2}(\Gamma(1), v_{N/2}) = \mathbb{C}\eta^N,$$

where $\eta(\tau) = q^{1/24} \prod_{n \geq 1} (1 - q^n)$, $q = e^{2\pi i \tau}$, is the Dedekind eta function.

We take $\ell = 1$, with $w_1 = N/2 - 2$ and multiplier system $v_{N/2}$. The ring $\mathcal{O}(\mathcal{A})$ is a commutative ring of formal power series in one variable A . The coefficient of A^m is in the $\Gamma(1)$ -module $V(v_{mN/2}, mN/2 - 2m)$.

If we take $1 \leq N \leq 24$, then with $\mathbf{f} = (\eta^N)$ we get in (4-4)

$$J(\mathbf{f}; y, x; t) = 1 + \sum_{n \geq 1} R_n((\eta^N)^{\times n}; y, x; t)A^n, \quad (4-10)$$

where $(\eta^N)^{\times n}$ means a sequence of n copies of η^N .

If $N > 24$ we still can work with $\mathbf{f} = (f)$, but now f need not be a multiple of η^N .

5. From cusp forms to noncommutative cohomology

Manin uses relation (4-8) to associate a noncommutative cocycle to the vector $\mathbf{f} = (f_1, \dots, f_\ell)$ of cusp forms. We first reformulate Manin’s description [2005, §1] of noncommutative cohomology for a right action, and then determine the map from vectors of cusp forms to noncommutative cohomology.

Noncommutative cohomology. Let G and N be groups, written multiplicatively, and suppose that for each $g \in G$ there is an automorphism $n \mapsto n|g$ of N such that the map $g \mapsto |g$ is an antihomomorphism from G to the automorphism group $\text{Aut}(N)$, i.e., $n|(gh) = (n|g)|h$ for $n \in N$ and $g, h \in G$.

A map $\rho : G \rightarrow N$ is called a 1-cocycle if it satisfies

$$\rho_{gh} = (\rho_g|h)\rho_h \quad \text{for all } g, h \in G. \tag{5-1}$$

The set of such cocycles is called $Z^1(G; N)$. It is not a group. Nevertheless it contains the special element $1 : g \mapsto 1$.

The group N acts on $Z^1(G; N)$ from the left, by $\rho \mapsto {}^n\rho$ defined by

$${}^n\rho_g = (n|g)\rho_g n^{-1}. \tag{5-2}$$

The cohomology set $H^1(G; N)$ is the set of N -orbits in $Z^1(G; N)$ for this action. The orbit of the cocycle $g \mapsto 1$ is called the set of coboundaries $B^1(G; N)$.

Noncommutative cocycles attached to a sequence of cusp forms. As the group N we use the subgroup $N(\mathcal{A})$ of the group of those units in $\mathcal{O}(\mathcal{A})^*$ that have constant term equal to 1. The series $J(\mathbf{f}; y, x; \cdot)$ in (4-4) is an element of $N(\mathcal{A})$.

Following Manin we define for $\mathbf{f} = (f_1, \dots, f_\ell) \in S_{\mathcal{A}}(\Gamma)$ and $x \in \mathfrak{H}^*$

$$\Psi(\mathbf{f})_x^x(t) = J(\mathbf{f}; \gamma^{-1}x, x; t). \tag{5-3}$$

The properties (4-5) and (4-8) imply that this defines a noncommutative cocycle $\Psi(\mathbf{f})^x \in Z^1(\Gamma; N(\mathcal{A}))$, and that its cohomology class $\text{Coh}_{\mathcal{A}}(\mathbf{f}) \in H^1(\Gamma; N(\mathcal{A}))$ does not depend on the choice of the base-point x . We write $\Psi(\mathbf{f}) = \Psi(\mathbf{f})^\infty$.

Proposition 5.1. *The map*

$$\text{Coh}_{\mathcal{A}} : S_{\mathcal{A}}(\Gamma) \rightarrow H^1(\Gamma; N(\mathcal{A})) \tag{5-4}$$

is injective.

Proof. Suppose that the cocycles $\Psi(f_1, \dots, f_\ell)$ and $\Psi(f'_1, \dots, f'_\ell)$ are in the same cohomology class. Then there is an $n \in N(\mathcal{A})$ such that for all $\gamma \in \Gamma$

$$\Psi(f'_1, \dots, f'_\ell)_\gamma = (n|\gamma)\Psi(f_1, \dots, f_\ell)_\gamma n^{-1}. \tag{5-5}$$

We denote the coefficient of A_j in n by $n_j \in V(v_j, w_j)$. In relation (5-5) we consider only the constant term and the term with A_j , and work modulo all other terms:

$$1 - \psi_{f'_j, \gamma} A_j \equiv (1 + n_j A_j)(1 - \psi_{f_j, \gamma} A_j)(1 - n_j A_j).$$

Taking the factor of A_j gives

$$-\psi_{f'_j, \gamma} = n_j |_{v_j, -w_j} \gamma - \psi_{f_j, \gamma} - n_j.$$

In other words, $\psi_{f'_j}$ and ψ_{f_j} differ by a coboundary. We have used the noncommutative relation (5-5) in $N(\mathcal{A})$ to get a commutative relation in $V(v_j, w_j)$.

By the theorem of Knopp and Mawi (Theorem 2.1) we conclude that $f'_j = f_j$ for all j . Hence $\text{Coh}_{\mathcal{A}}$ is injective. □

Remarks. (a) Implicit in the proof is the quotient of \mathcal{A} by the ideal generated by all monomials in the A_j with degree 2. The corresponding quotient of $N(\mathcal{A})$ is isomorphic to the direct sum of the $V(v_j, w_j)$.

(b) The injectivity of the map from cusp forms to cocycles is a point in common for this result, the theorem of Knopp and Mawi, and the classical Eichler–Shimura result. The bijectivity in the theorem of Knopp and Mawi is not shared by the classical result, where conjugates of cocycles also determine cohomology classes. In the next section we will see that the whole group $H^1(\Gamma; N(\mathcal{A}))$ can be described with cusp forms, but in a more complicated way than by the map $\text{Coh}_{\mathcal{A}}$.

Commutative example. Toward the end of page 653 we considered the case $\ell = 1$. Then $N(\mathcal{A})$ is a commutative group, and $H^1(\Gamma; N(\mathcal{A}))$ is a cohomology group.

When $\Gamma = \Gamma(1)$, with the choices and notations indicated on page 653, the cocycle $\Psi(\eta^N)$ vanishes on $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ (hence may be called a parabolic cocycle), and is determined by its value on $S = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$:

$$\Psi(\eta^N)_S(t) = J(\eta^N; 0, \infty; t) = 1 + \sum_{n \geq 1} R_n((\eta^N)^{\times n}; 0, \infty; t) A^n. \tag{5-6}$$

The coefficient of A^n is an iterated period integral of η^N . The cocycle satisfies the well known relations $(\Psi(\eta^N)_S | S) \Psi(\eta^N)_S = 1$ and $\Psi(\eta^N)_S = \Psi(\eta^N)_S | T' \Psi(\eta^N)_S | T$, with $T' = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} = TST$.

6. Noncommutative cocycles and collections of cusp forms

The proof of Proposition 5.1 is based on the fact that the vector of cusp forms \mathbf{f} can be recovered from the terms of degree 1 in the formal series $J(\mathbf{f}; \gamma^{-1}\infty, \infty; t)$. In this section we associate to collections of cusp forms noncommutative cocycles of a more general nature.

We keep fixed the choice \mathcal{A} of positive weights $w_1 + 2, \dots, w_\ell + 2$ and corresponding multiplier systems v_1, \dots, v_ℓ . To each monomial $B = A_{m_1} \cdots A_{m_d}$ in $\mathcal{O}(\mathcal{A})$ we associate the shifted weight $\mathbf{w}(B) := \mathbf{w}(m)$ and the multiplier system $\mathbf{v}(B) := \mathbf{v}(m)$ as defined in (4-2) for $m = (m_1, \dots, m_d) \in \{1, \dots, \ell\}^d$. So $\mathbf{w}(B)$ and $\mathbf{v}(B)$ depend only on the factors A_{m_i} occurring in B , not on their order.

Definition 6.1. We call the *degree* $d(B)$ of the monomial $B = A_{m_1} \cdots A_{m_d}$ the number d of factors A_j ($1 \leq j \leq \ell$) occurring in it.

Let $\mathcal{B}(\mathcal{A})$ be the set of all monomials B in A_1, \dots, A_ℓ with $d(B) \geq 1$ for which $S_{\mathbf{w}(B)+2}(\Gamma, \mathbf{v}(B)) \neq \{0\}$. We put

$$S(\mathcal{A}; \Gamma) := \prod_{B \in \mathcal{B}(\mathcal{A})} S_{\mathbf{w}(B)+2}(\Gamma, \mathbf{v}(B)). \tag{6-1}$$

Remarks. (a) The space of cusp forms $S_{\mathbf{w}(B)+2}(\Gamma, \mathbf{v}(B))$ may be zero. In fact, this is necessarily the case if $\mathbf{w}(B) \leq -2$. For $\mathbf{w}(B) > -2$ it may also happen to be zero, depending on Γ and $\mathbf{v}(B)$.

(b) The set $\mathcal{B}(\mathcal{A})$ is often infinite. We recall that elements of infinite direct sums of vector spaces have zero components at all but finitely many $B \in \mathcal{B}(\mathcal{A})$. Here we use the product. Its elements may have nonzero components for all B .

(c) We denote elements of $S(\mathcal{A}; \Gamma)$ by \mathbf{h} , with component $\mathbf{h}(B)$ in the factor corresponding to the monomial B .

(d) There may be more than one monomial B for which $S_{\mathbf{w}(B)+2}(\Gamma, \mathbf{v}(B))$ is equal to a given space of cusp forms. See (f2) below for an example where this happens for infinitely many monomials.

(e) The space $S_{\mathcal{A}}(\Gamma) = \prod_{j=1}^{\ell} S_{w_j+2}(\Gamma, v_j)$ in (4-3) may be considered as a subspace of $S(\mathcal{A}; \Gamma)$. To do this we define for a given $\mathbf{f} = (f_1, \dots, f_\ell) \in S_{\mathcal{A}}(\Gamma)$ the element $\mathbf{h} \in S(\mathcal{A}; \Gamma)$ by

$$\mathbf{h}(A_j) = f_j, \quad \mathbf{h}(B) = 0, \quad \text{if } d(B) \geq 2.$$

(f) In the *commutative case* $\ell = 1$ we have $\mathcal{B}(\mathcal{A}) \subset \{A^n : n \in \mathbb{Z}_{\geq 1}\}$. We consider three specializations of the example on page 653.

(f1) Take $N = 24$. So $\mathcal{B}(\mathcal{A}) = \{A^n : n \in \mathbb{Z}_{\geq 1}\}$, $\mathbf{w}(B) = 10n$ and $\mathbf{v}(B) = v_{12} = v_0 = 1$. Hence

$$S(\mathcal{A}; \Gamma(1)) = \prod_{n \geq 1} S_{10n+2}(\Gamma(1), 1). \tag{6-2}$$

(f2) Take $N = 4$. So $\mathbf{w}(A^n) = 0$ for all $n \geq 1$ and the space $S_2(\Gamma(1), v_{2n})$ is equal to $\mathbb{C}\eta^4$ if $n \equiv 1 \pmod 6$ and zero otherwise. This implies that

$$\mathcal{B}(\mathcal{A}) = \{A^n \geq 1 : n \equiv 1 \pmod 6\}.$$

Since $v(B) = v_n = v_2$ for $n \equiv 1 \pmod 6$, we obtain

$$S(\mathcal{A}; \Gamma(1)) = \prod_{\substack{n \geq 1 \\ n \equiv 1 \pmod 6}} S_2(\Gamma(1), v_2). \tag{6-3}$$

(f3) Take $N = 1$. So $w(B) = w_1 = -\frac{3}{2}$, and $nw_1 < -2$ for $n \geq 2$. Hence $\mathcal{B}(\mathcal{A}) = \{A\}$, $v(B) = v_{1/2}$, and

$$S(\mathcal{A}; \Gamma(1)) = S_{1/2}(\Gamma(1), v_{1/2}) = \mathbb{C}\eta, \tag{6-4}$$

with $\eta(\tau) = e^{\pi i \tau / 12} \prod_{n \geq 1} (1 - e^{2\pi i n \tau})$.

Lemma 6.2. *For each $\mathbf{h} \in S(\mathcal{A}; \Gamma)$, the series*

$$J(\mathbf{h}; y, x; t) := 1 + \sum_{n \geq 1} \sum_{B_1, \dots, B_n \in \mathcal{B}(\mathcal{A})} R_n(\mathbf{h}(B_1), \mathbf{h}(B_2), \dots, \mathbf{h}(B_n); y, x; t) B_1 B_2 \cdots B_n \tag{6-5}$$

converges and defines an element of $N(\mathcal{A})$.

Proof. The degree of $B_1 B_2 \cdots B_n$ is at least n . For convergence in $\mathcal{O}(\mathcal{A})$ there should be for each $D \geq 0$ only finitely many terms with degree at most D . This restricts n to $n \leq D$, and the B_j to monomials of degree bounded by D , of which there are only finitely many.

The terms with $n \geq 1$ cannot contribute to the constant term, hence we obtain an element of $N(\mathcal{A})$. □

Remarks. (a) If $\mathbf{h}(B_i) = 0$ for some i in the iterated integral in (6-5), then the integral vanishes. In (6-5) we could have restricted the B_i in the sum by the condition $\mathbf{h}(B_i) \neq 0$. In particular, $J(0; y; x; t) = 1$.

(b) Definition (6-5) extends definition (4-4). If $\mathbf{f} \in S_{\mathcal{A}}(\Gamma)$ is considered as an element $\mathbf{h} \in S(\mathcal{A}; \Gamma)$, as in remark (e) to Definition 6.1, then

$$J(\mathbf{f}; y, x; t) = J(\mathbf{h}; y, x; t). \tag{6-6}$$

Proposition 6.3. *For all $\mathbf{h} \in S(\mathcal{A}; \Gamma)$, $\gamma \in \Gamma$, $z, y, x \in \mathfrak{S}^*$,*

$$J(\mathbf{h}; \gamma^{-1}y, \gamma^{-1}x; \cdot) = J(\mathbf{h}; y, x; \cdot)|\gamma, \tag{6-7}$$

$$J(\mathbf{h}; x, x; t) = 1, \tag{6-8}$$

$$J(\mathbf{h}; z, x; t) = J(\mathbf{h}; z, y; t)J(\mathbf{h}; y, x; t), \tag{6-9}$$

$$J(\mathbf{h}; x, y; t) = J(\mathbf{h}; y, x; t)^{-1}. \tag{6-10}$$

Proof. The relations (6-7) and (6-8) follow directly from Lemma 3.2 and (3-1). We will prove relation (6-9) in a sequence of lemmas, and finally will derive relation (6-10) from relation (6-9).

Relation (6-9). This relation holds in a general context of iterated integrals; automorphic properties are not needed. Our proof follows [Manin 2006, Proposition 1.2] closely. We first show relation (6-9) for $x, y, z \in \mathfrak{H}$.

Lemma 6.4. *For $\mathbf{h} \in S(\mathcal{A}; \Gamma)$ put*

$$\Omega(\mathbf{h}; z; t) := \sum_{B \in \mathcal{B}(\mathcal{A})} (z - t)^{w(B)} \mathbf{h}(B; z) dz \cdot B. \tag{6-11}$$

This formal series of $\mathbf{O}(\mathcal{A})$ -valued differential forms converges, and for $z \in \mathfrak{H}$

$$d_z J(\mathbf{h}; z, x; t) = \Omega(\mathbf{h}; z; t) J(\mathbf{h}; z, x; t). \tag{6-12}$$

Proof. The sum in (6-11) is infinite in most cases. The convergence follows from the fact that the number of monomials with a given degree is finite. The differential of a nonconstant term in (6-5) is given by

$$\begin{aligned} d_z R_n(\mathbf{h}(B_1), \mathbf{h}(B_2), \dots, \mathbf{h}(B_n); z, x; t) B_1 B_2 \cdots B_n \\ = \mathbf{h}(B_1; z) (z - t)^{w(B_1)} B_1 R_{n-1}(\mathbf{h}(B_2), \dots, \mathbf{h}(B_n); z, x; t) B_2 \cdots B_n. \end{aligned}$$

With a renumbering in the summation this gives (6-12). □

Lemma 6.5. $d_z J(\mathbf{h}; z, x; t)^{-1} = -J(\mathbf{h}; z, x; t)^{-1} \Omega(\mathbf{h}; z; t)$.

Proof. The inverse is defined by the relation

$$1 = J(\mathbf{h}; z, x; t)^{-1} J(\mathbf{h}; z, x; t).$$

Taking the differential of both sides gives, with (6-12),

$$0 = (d_z J(\mathbf{h}; z, x; t)^{-1}) J(\mathbf{h}; z, x; t) + J(\mathbf{h}; z, x; t)^{-1} \Omega(\mathbf{h}; z; t) J(\mathbf{h}; z, x; t).$$

Right multiplication by $J(\mathbf{h}; z, x; t)$ gives the relation in the lemma. □

Lemma 6.6. *For fixed x and y , put $K(z) = J(\mathbf{h}; z, y; t)^{-1} J(\mathbf{h}; z, x; t)$. Then $K(z) = J(\mathbf{h}; y, x; t)$.*

Proof. With Lemmas 6.4 and 6.5 we find

$$\begin{aligned} d_z K(z) &= -J(\mathbf{h}; z, y; t)^{-1} \Omega(\mathbf{h}; z; t) J(\mathbf{h}; z, x; t) + J(\mathbf{h}; z, y; t)^{-1} \Omega(\mathbf{h}; z; t) J(\mathbf{h}; z, x; t) \\ &= 0. \end{aligned}$$

Hence $K(z)$ is constant. By (6-8), its value is

$$K(y) = J(\mathbf{h}; y, y; t)^{-1} J(\mathbf{h}(y, x; t) = J(\mathbf{h}; y, x; t). \tag{6-8} \quad \square$$

Completion of the proof of relation (6-9). The relation

$$K(z) = J(\mathbf{h}; y, x; t) = J(\mathbf{h}; z, y; t)^{-1} J(\mathbf{h}; z, x; t)$$

implies the desired result for $z, y, x \in \mathfrak{H}$. By continuity it holds for $z, y, x \in \mathfrak{H}^*$.

Relation (6-10). This relation follows from (6-8) and (6-9). This ends the proof of Proposition 6.3. \square

Noncommutative cocycle. From (6-7) and (6-9) it follows that for any $\mathbf{h} \in S(\mathcal{A}; \Gamma)$

$$\Psi(\mathbf{h})_\gamma := J(\mathbf{h}; \gamma^{-1}\infty, \infty; t) \quad (6-13)$$

defines a cocycle $\gamma \rightarrow \Psi(\mathbf{h})_\gamma$ in $Z^1(\Gamma; N(\mathcal{A}))$.

If we replace ∞ in (6-13) by another base-point $x \in \mathfrak{H}^*$ we get a cocycle in the same cohomology class. So $\mathbf{h} \mapsto \Psi(\mathbf{h})$ induces a map from $S(\mathcal{A}; \Gamma)$ to the noncommutative cohomology set $H^1(\Gamma; N(\mathcal{A}))$, extending the map $\text{Coh}_{\mathcal{A}}$ in Proposition 5.1.

The main result of this paper is the bijectivity of this map:

Theorem 6.7. *Let \mathcal{A} denote the choice of finitely many positive weights $w_1 + 2, w_2 + 2, \dots, w_\ell + 2$ and corresponding multiplier systems v_1, \dots, v_ℓ of Γ . For each noncommutative cohomology class $c \in H^1(\Gamma; N(\mathcal{A}))$ there is a unique element $\mathbf{h} \in S(\mathcal{A}; \Gamma)$ such that $\Psi(\mathbf{h}) \in c$.*

Proof. The induction runs over $k \geq 0$. We start with a cocycle $X^0 \in Z^1(\Gamma; N(\mathcal{A}))$, and replace it in the course of an induction procedure by cocycles X^1, X^2, \dots in the same cohomology class. During the induction we form a sequence $\mathbf{h}_0, \mathbf{h}_1, \dots, \mathbf{h}_k, \dots$ of elements of $S(\mathcal{A}; \Gamma)$, and a strictly increasing sequence of integers c_0, c_1, \dots . The connection between the induction quantities X^k, \mathbf{h}_k and c_k is given by the requirement that at each stage of the induction the following conditions hold:

(H) $\mathbf{h}_k(B) = 0$ for all B with $d(B) > c_k$.

(XPs) If $X_\gamma^k - \Psi(\mathbf{h}_k)_\gamma = \sum_B a(\gamma, B)B$, where the sum B runs over all noncommutative polynomials in A_1, \dots, A_ℓ , then for each $\gamma \in \Gamma$

$$a(\gamma, B) = 0 \quad \text{for all } B \text{ with } d(B) \leq k.$$

Either at a certain stage k in the induction procedure the process stops, and we take $\mathbf{h} = \mathbf{h}_k$, or the process goes on indefinitely, in which case we construct \mathbf{h} as a limit of the \mathbf{h}_k . In both cases we show that $\Psi(\mathbf{h})$ is in the cohomology class of the X^k , and that the element \mathbf{h} is uniquely determined.

Start of the induction. For a given cocycle X^0 in the cohomology class c we put $\mathbf{h}_0 = 0$ and $c_k = 0$. Then for all $\gamma \in \Gamma$

$$X_\gamma^0 - \Psi(\mathbf{h}_0)_\gamma = X_\gamma^0 - 1$$

has no constant term, and conditions (H) and (XPs) are trivially satisfied.

Has the end of the induction process been reached? If $X^k = \Psi(\mathbf{h}_k)$, we have found a description of the class c as required in the theorem. This may happen already at the start of the induction if X^0 is the trivial cocycle $\gamma \mapsto 1$.

Induction, choice of c_{k+1} . If the process has not ended, then the difference $Y^k := X^k - \Psi(\mathbf{h}_k)$ determines a nonzero map $\gamma \mapsto Y_\gamma^k$ from Γ to $\mathcal{O}(\mathcal{A})$. It is not a cocycle.

We define c_{k+1} as the minimum degree such that $Y_\gamma^k \in \mathcal{O}(\mathcal{A})$ has nonzero terms of degree c_{k+1} in A_1, \dots, A_ℓ for some $\gamma \in \Gamma$. Since condition (XPs) holds for k we have $c_{k+1} > c_k$.

Cocycle relation. The cocycle relations for the noncommutative cocycles X^k and $\Psi(\mathbf{h}_k)$ give

$$\begin{aligned} Y_{\gamma\delta}^k &= ((Y_\gamma^k + \Psi(\mathbf{h}_k)_\gamma)|\delta)(Y_\delta^k + \Psi(\mathbf{h}_k)_\delta) - (\Psi(\mathbf{h}_k)_\gamma|\delta)\Psi(\mathbf{h}_k)_\delta \\ &= (Y_\gamma^k|\delta)\Psi(\mathbf{h}_k)_\delta + (\Psi(\mathbf{h}_k)_\gamma|\delta)Y_\delta^k + (Y_\gamma^k|\delta)Y_\delta^k. \end{aligned} \quad (6-14)$$

By condition (XPs) and the choice of c_{k+1} , the element $Y_\gamma^k \in \mathcal{O}(\mathcal{A})$ has no terms with degree less than c_{k+1} . We denote by \tilde{Y}_γ^k the sum of the terms of Y_γ^k with exact degree c_{k+1} . We consider relation (6-14) modulo terms with degree strictly larger than c_{k+1} :

$$\tilde{Y}_{\gamma\delta}^k \equiv (\tilde{Y}_\gamma^k|\delta)\Psi(\mathbf{h}_k)_\delta + (\Psi(\mathbf{h}_k)_\gamma|\delta)\tilde{Y}_\delta^k + 0. \quad (6-15)$$

In the two products only the constant term 1 of $\Psi(\mathbf{h}_k)_\gamma$ and $\Psi(\mathbf{h}_k)_\delta$ is relevant, and we obtain

$$\tilde{Y}_{\gamma\delta}^k = \tilde{Y}_\gamma^k|\delta + \tilde{Y}_\delta^k. \quad (6-16)$$

So the noncommutative cocycle relations for X^k and $\Psi(\mathbf{h}_k)$ imply that $\gamma \mapsto \tilde{Y}_\gamma^k$ is a commutative cocycle with values in the additive group of $\mathcal{O}(\mathcal{A})$.

The elements \tilde{Y}_γ^k have the form

$$\tilde{Y}_\gamma^k = \sum_{n=1}^K \varphi_\gamma^n C_n, \quad C_n = A_{p_{n,1}} A_{p_{n,2}} \cdots A_{p_{n,c_{k+1}}}, \quad (6-17)$$

with $\varphi_\gamma^n \in V(\mathbf{v}(C_n), \mathbf{w}(C_n))$. The C_n have degree c_{k+1} in A_1, \dots, A_ℓ . For each n there is some $\gamma \in \Gamma$ for which $\varphi_\gamma^n \neq 0$. Relation (6-16) implies that each component of \tilde{Y}^k is a cocycle: $\varphi^n \in Z^1(\Gamma; V(\mathbf{v}(C_n), \mathbf{w}(C_n)))$. By Theorem 2.1 there exist $a_n \in V(\mathbf{v}(C_n), \mathbf{w}(C_n))$ and unique cusp forms $g_n \in \mathcal{S}_{\mathbf{w}(C_n)+2}(\Gamma, \mathbf{v}(C_n))$ such that for all $\gamma \in \Gamma$

$$\varphi_\gamma^n = -\psi_{g_n, \gamma} + a_n|_{\mathbf{v}(C_n), -\mathbf{w}(C_n)}(\gamma - 1). \quad (6-18)$$

Induction, choice of X^{k+1} . Take

$$H_k = 1 - \sum_{n=1}^K a_n C_n. \quad (6-19)$$

This is an element of $N(\mathcal{A})$. We define the cocycle X^{k+1} in the same class as X^k by

$$X_\gamma^{k+1} = (H_k|\gamma)X_\gamma^k H_k^{-1}. \quad (6-20)$$

Induction, choice of \mathbf{h}_{k+1} . It may happen that $C_n \notin \mathcal{B}(\mathcal{A})$ for some $n \in \{1, \dots, k\}$. Then $S_{\mathbf{w}(C_n)+2}(\Gamma, \mathbf{v}(C_n)) = 0$, and φ^n is a coboundary and $g_n = 0$.

By condition (H) we have $\mathbf{h}_k(C_n) = 0$ for $1 \leq n \leq K$. We construct \mathbf{h}_{k+1} from \mathbf{h}_k by taking $\mathbf{h}_{k+1}(C_n) = g_n$ for those n for which $C_n \in \mathcal{B}(\mathcal{A})$, and $\mathbf{h}_{k+1}(B) = \mathbf{h}_k(B)$ otherwise. So $\mathbf{h}_k(B) = \mathbf{h}_{k+1}(B)$ for all B with $d(B) > c_{k+1}$, and condition (H) stays valid for $k+1$. If $C_n \notin \mathcal{B}(\mathcal{A})$ for all n , then $\mathbf{h}_{k+1} = \mathbf{h}_k$.

Induction, check of condition (XPs) for $k+1$. Modulo terms of order larger than c_{k+1} , we have

$$\begin{aligned}
 \chi_\gamma^{k+1} &\equiv \left(1 - \sum_n a_n |\gamma C_n\right) (\Psi(\mathbf{h}_k)_\gamma + \bar{Y}_\gamma^k) \left(1 + \sum_n a_n C_n\right) && \text{(by (6-20), (XPs))} \\
 &\equiv \Psi(\mathbf{h}_k)_\gamma + \bar{Y}_\gamma^k - \sum_n a_n |\gamma C_n + \sum_n a_n C_n \\
 &\equiv \Psi(\mathbf{h}_k)_\gamma + \sum_n (-\psi_{g_n, \gamma} + a_n |(\gamma - 1) - a_n |\gamma + a_n) C_n && \text{(by (6-17), (6-18))} \\
 &= \Psi(\mathbf{h}_k)_\gamma + \sum_n R_1(g_n; \gamma^{-1}\infty, \infty) C_n && \text{(by (3-6)). (6-21)}
 \end{aligned}$$

By (6-13) and (6-5), we have

$$\begin{aligned}
 &\Psi(\mathbf{h}_{k+1})_\gamma \\
 &= 1 + \sum_{m \geq 1} \sum_{B_1, \dots, B_m \in \mathcal{B}(\mathcal{A})} R_m(\mathbf{h}_{k+1}(B_1), \mathbf{h}_{k+1}(B_2), \dots, \mathbf{h}_{k+1}(B_m); \gamma^{-1}\infty, \infty; t) \\
 &\hspace{25em} \times B_1 B_2 \cdots B_m,
 \end{aligned}$$

in which we can leave out the terms in which a B_i occurs with $d(B_i) > c_{k+1}$, by condition (H). If we leave out the terms with a B_i for which $d(B_i) > c_k$, we obtain $\Psi(\mathbf{h}_k)_\gamma$. If there is a B_i with $d(B_i) > c_k$ this is one of the C_n in (6-17), with $d(B_i) = d(C_n) = c_{k+1}$. Working modulo terms with degree larger than c_{k+1} we obtain

$$\begin{aligned}
 \Psi(\mathbf{h}_{k+1})_\gamma - \Psi(\mathbf{h}_k)_\gamma &\equiv \sum_{\substack{1 \leq n \leq K \\ C_n \in \mathcal{B}(\mathcal{A})}} R_1(\mathbf{h}_{k+1}(C_n); \gamma^{-1}\infty, \infty; t) C_n \\
 &= \sum_{\substack{1 \leq n \leq K \\ C_n \in \mathcal{B}(\mathcal{A})}} R_1(g_n; \gamma^{-1}\infty, \infty; t) C_n. && \text{(6-22)}
 \end{aligned}$$

A comparison of (6-21) and (6-22) gives condition (XPs) for $k+1$.

The induction may halt. It may happen that the induction stops at stage k ; namely, if $\chi^k = \Psi(\mathbf{h}_k)$. Then we have found an element $\mathbf{h} = \mathbf{h}_k \in S(\mathcal{A}; \Gamma)$ such that $\Psi(\mathbf{h})$ is in the class c .

The induction may have infinitely many steps. It may also happen that we have obtained after infinitely many steps an infinite sequence of cocycles X^k in the class c , an infinite sequence of \mathbf{h}_k , and a strictly increasing sequence of c_k satisfying conditions (H) and (XPs) for all k . For each monomial $B \in \mathcal{B}(\mathcal{A})$ there is at most one k such that $h_n(B) = 0$ for $n \leq k$, and $h_n(B) = h_{k+1}(B)$ for $n \geq k + 1$. So the componentwise limit $\mathbf{h} := \lim_{k \rightarrow \infty} \mathbf{h}_k$ exists.

The construction of the sequence $(X^k)_k$ implies that

$$X_\gamma^k = ((H_{k-1}H_{k-2} \cdots H_0)|\gamma)X_\gamma^0(H_{k-1}H_{k-2} \cdots H_0)^{-1},$$

with H_k as in (6-19). The infinite product $H = \cdots H_2H_1H_0$ converges in $N(\mathcal{A})$, since each H_k equals 1 plus a term in degree c_{k+1} . Similarly, $J(\mathbf{h}; \gamma^{-1}\infty, \infty; t)$ is the limit of the $J(\mathbf{h}_k; \gamma^{-1}\infty, \infty; t)$ as $k \rightarrow \infty$, since enlarging k we change only terms of degrees larger than c_k . Condition (XPs) is valid for all k , so the conclusion is that, in the limit,

$$(H|\gamma)X^0H^{-1} = \Psi(\mathbf{h}). \tag{6-23}$$

Uniqueness. Let $X^0 = \Psi(\mathbf{h}')$ for some $\mathbf{h}' \in S(\mathcal{A}; \Gamma)$. We claim that, in the induction procedure described above applied to this cocycle X^0 , we have at each stage

$$\mathbf{h}_k(B) = \mathbf{h}'(B) \quad \text{for all } B \in \mathcal{B}(\mathcal{A}) \text{ with } d(B) \leq c_k; \tag{6-24}$$

$$X^k \equiv \Psi(\mathbf{h}') \quad \text{modulo terms of degree larger than } c_k. \tag{6-25}$$

This is true at the start of the induction (use $c_0 = 0$).

At stage k , the nonzero terms with lowest degree in

$$Y_\gamma^k = J(\mathbf{h}'; \gamma^{-1}\infty, \infty; t) - J(\mathbf{h}_k; \gamma^{-1}\infty, \infty; t)$$

are due to the $C \in \mathcal{B}(\mathcal{A})$ with degree equal to c_{k+1} . So

$$\tilde{Y}_\gamma = \sum_{\substack{C \in \mathcal{B}(\mathcal{A}) \\ d(C)=c_{k+1}}} R_1(\mathbf{h}'(B); \gamma^{-1}\infty, \infty; t)C. \tag{6-26}$$

Let us number the monomials in this sum as C_1, \dots, C_K . Then φ_γ^n in (6-18) is equal to $-\psi_{\mathbf{h}'(C_n), \gamma}$, and $a_n = 0$, $H_k = 1$. This implies that $\mathbf{h}_{k+1}(C) = \mathbf{h}'(C)$ for the monomials $C \in \mathcal{B}(\mathcal{A})$ with degree c_{k+1} , and $X^{k+1} = X^k \equiv \Psi(\mathbf{h}')$ modulo terms with degree larger than c_{k+1} .

At the end of the induction process we have $\mathcal{B} = \mathcal{B}'$, thus obtaining uniqueness. \square

Concluding remarks. (a) Manin [2005; 2006] used formal series similar to those in (4-4) to get a simple description of relations among iterated integrals. In that approach the noncommutative cohomology set $H^1(\Gamma; N(\mathcal{A}))$ is a tool. In this paper we further study the cohomology set $H^1(\Gamma; N(\mathcal{A}))$.

(b) One may apply the approach of this paper to weights in $\mathbb{Z}_{\geq 2}$ and trivial multiplier systems. Then the iterated integrals are polynomial functions. These are in a much smaller Γ -module than the functions with polynomial growth that we employ. The consequence is that the theorem analogous to the theorem of Knopp and Mawi ([Theorem 2.1](#)) does not hold. Cocycles attached to conjugates of holomorphic cusp forms have to be considered as well (see [[Knopp 1974](#)]). However, iterated integrals in which occur both holomorphic and antiholomorphic cusp forms satisfy more complicated decomposition relations. We think that Manin's formalism does not work in that situation.

(c) The same problem occurs if we use the modules in Theorems B and D of [[Bruggeman et al. 2014](#)], unless we pick the weights $w_j + 2$ in such a way that the elements $w(C)$ that occur in the sums defining $J(\mathcal{B}; y, x; t)$ are never in $\mathbb{Z}_{\geq 0}$.

(d) We work with iterated integrals of the type in (3-1). [Equation \(1-1\)](#) defines iterated integrals depending on variables t_1, \dots, t_ℓ all running independently through the lower half-plane. It would be nice to have results for the corresponding noncommutative cocycles. These cocycles can be defined, and one can show injectivity of the map from cusp forms to cohomology, like in [Proposition 5.1](#). We did not manage to adapt the proof of [Theorem 6.7](#) to cocycles of this type. The problem is to construct formal sequences of the type in (6-5) such that they have the lowest degree terms in a prescribed summand in the decomposition of the tensor products $V(v_1, w_1) \otimes \dots \otimes V(v_\ell, w_\ell)$ into submodules.

Acknowledgement

The authors would like to thank the referees for numerous helpful comments and suggestions which greatly improved the exposition of this paper, in particular the introduction.
