[Abstract] The enzyme γ -glutamyltranspeptidase (GGT, EC 2.3.2.2) is highly conserved among eukaryotic and prokaryotic organisms (Heisterkamp *et al.*, 2008) and has a key function in glutathione metabolism. Although the enzyme is highly conserved and found throughout organisms ranging from bacteria to plants and animals several major difference between eukaryotic and prokaryotic GGT can be noticed. They mainly concern the enzyme localization and posttranslational modification. Eukaryotic GGT is cell membrane anchored and highly glycosylated whereas prokaryotic GGT does not undergo this posttranslational modification and is a soluble periplasmic protein. GGT amino acids sequences of diverse origin exhibit high amino acid similarity (Ong *et al.*, 2008). The prokaryotic GGT enzymes are produced as proenzyme, equipped with a typical prokaryotic signal sequence and transported through the inner membrane into the periplasm where the enzyme undergoes autocatalytic cleavage. This proteolysis yields a mature dimer which transfers the γ -glutamyl moieties from extracellular glutathione and related compounds to amino acids or peptides (Hanigan *et al.*, 1998). The GGT enzyme activity can be easily measured as it catalyzes the transfer of a γ -glutamyl group from a colorless substrate, L- γ -glutamyl-3-carboxy-4-nitroanilide, to the acceptor, glycylglycine with leads to the production of yellow colored product, p-nitroaniline (Figure 1) which can be measured by a spectrophotometer (Figure 2). Here we describe a protocol to measure the GGT activity in the *Gram-negative* bacterium *Campylobacter jejuni*, with some minor modifications this protocol works also for other *Gram-negative* bacterial species.

Materials and Reagents

1. 25 mm culture flasks with vent cap (Corning, catalog number: 430639)
2. 96 well plate flat bottom (Corning, Costar[®], catalog number: 3599)
3. Campylobacter culture
4. UltraPure[™] Tris Buffer (powder format) (Thermo Fisher Scientific, Invitrogen[™], catalog number: 15504-020)
5. Lysozyme from chicken egg white (Sigma-Aldrich, catalog number: L-6876)
6. L-Glutamic acid γ -(3-carboxy-4-nitroanilide) ammonium salt (Sigma-Aldrich, catalog number: 49525)
7. Glycylglycine (Sigma-Aldrich, catalog number: G3915)
8. Pierce[™] BCA Protein Assay Kit (Thermo Fisher Scientific, Thermo Scientific[™], catalog number: 23227)
9. 4-nitroaniline (Sigma-Aldrich, catalog number: 185310)
10. Hearth Infusion medium (Thomas Scientific, Oxoid, catalog number: CM1032B)
11. Tris/HCl (pH 7.6 and pH 8.2)
12. Lysis buffer (see Recipes)
13. Reaction buffer (see Recipes)
14. pNA stock solution (see Recipes)

Equipment

1. Absorbance microplate reader (such as BMG Labtech GmbH, Fluorstar Omega orequivalent)
2. Vibra-Cell™ Sonicator (Sonics & Materials, model: VC40)
3. Refrigerated table top centrifuge
4. The anoxomat system (MART Microbiology)

Procedure

1. Dilute a Campylobacter preculture in 5 ml Heart Infusion (HI) broth to an optical density 600 nm of 0.05. Growth the culture in vertically standing 25 mm culture flasks with vent cap in a microaerobic atmosphere (MART) at 42 °C, 160 rpm in HI broth for until stationary phase ~20 h.

Note: If other bacterial species are assayed use species specific growth conditions.

2. Pellet $\sim 1 \cdot 10^9$ bacteria of the bacterial culture, remove the supernatant and store the pellet at -80 °C for at least 1 h.

Note: The -80 °C freezing step will help to disrupt the cells, shorter incubation will lead to less disrupted cells.

3. Resuspend the pellet in ice cold 250 μ l lysis buffer, and incubated for 30 min on ice.
4. Sonicate 6 times (5 sec each, with 15 sec intervals on ice) at 40 mV and the output control set at 80%.
5. Centrifuge the cell lysate for 10 min at 12,000 $\times g$ at 4 °C.
6. Harvest the supernatant and keep on ice before use.
7. Measure the protein concentration of 20 μ l supernatant (BCA kit with standard) in a 96 wells plate according to the kit's protocol.
8. Make a serial dilution in a range between 0 and 200 μ M of the standard pNA [4-nitroaniline (stock solution 1 mM)] in 50 mM Tris/HCl (pH 7.6).
9. Mix 20 μ l supernatant or standard pNA in a 96 wells plate with 180 μ l of reaction buffer.
10. Measure the optical density of the samples and standard in the 96 wells plate at a wavelength of 405 nm (OD_{405}) every 60 s during an incubation period of 30 min at 37 °C (Figures 3 and 4).
11. Calculate the slope of all values in a linear range of the obtained graphs (see below).
12. GGT activity is expressed as $\text{nmol min}^{-1} \text{mg protein}^{-1}$.

Figure 3. A typical pNA standard curve

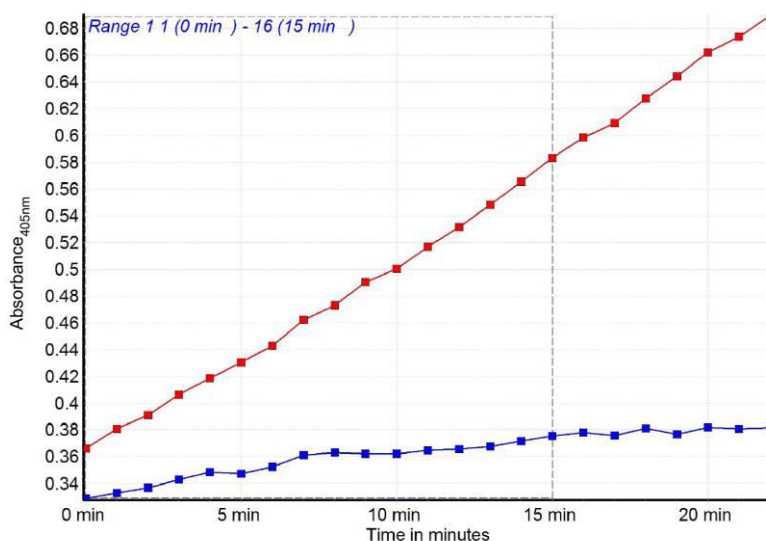

Figure 4. Graph showing in time the pNA increase in the bacterial lysates made of *C.jejuni* wt (red) and *racRS* mutant (blue)

To calculate the GGT activity first plot the pNA standard curve. Calculate the Δ absorbance (A time x - A time y) in a linear range. Next compare the calculated Δ absorbance of each sample to the standard pNA curve to determine the amount of pNA generated between time x and time y (nmol pNA).

The GGT activity is calculated by the formula: (nmol pNA)

T x M

T = the time incubated (in min)

M = mg protein determined by BCA protein kit

GGT activity is reported as $\text{nmole}/\text{min}^{-1}/\text{mg protein}^{-1}$

Example:

Δ absorbance(wt) = 0.58 (15 min) - 0.43 (5 min)=0.15

Δ absorbance 0.15 = 40 nmole pNA

Time x - time y = 10 min

M = 0.02 mg protein

GGT activity is: $40/(10 \times 0.02) = 200 \text{ nmole/min}^{-1}/ \text{mg protein}^{-1}$

Recipes

1. Lysis buffer
 - 50 mM Tris/HCl (pH 7.6)
 - 1 μ g/ml lysozyme
2. Reaction buffer
 - 2.9 mM L- γ -glutamyl-3-carboxy-4-nitroanilide
 - 100 mM glycylglycine
 - 100 mM Tris/HCl (pH 8.2)
3. pNA stock solution
 - 1 mM 4-nitroaniline
 - 50 mM Tris/HCl (pH 7.6)
 - Can be stored at -20 °C

Acknowledgments

The γ -glutamyltranspeptidase activity protocol described here and in, van der Stel *et al.* (2015), is modified from a protocol described in Chevalier *et al.* (1999). This work was supported by the NWO-ECHO grant 711.012.007 to MW.
