CHAPTER 1

General Introduction

The human immune system functions to monitor tissue homeostasis, protect cells from foreign infection and eliminate damaged or stress-induced cells (1). In recent decades, the role of immune cells has been uncovered as one of the defense mechanisms against cancerous/neoplastic cells. Thus, cancer immunotherapy has been widely applied as one of the therapeutic options against different malignancies.

T cells play an important role in cellular immunity with antigen-specific effector function and able to develop long-term immunity from memory responses (2). The main subset of T cells carries T-cell receptor (TCR) consisting of α - and β -chain heterodimer, known as $\alpha\beta$ T cells, that recognize their cognate antigen in specific peptide-major histocompatibility complex (pMHC) dependent manner.

Ideally, target antigens for $\alpha\beta$ T cell therapies should be selectively expressed on tumor cells but not in healthy tissues (3). Also, target antigens should elicit immune responses, in this context, specifically evoke $\alpha\beta$ T cell response. Following target antigen selection, another critical factor is to obtain antigen-specific TCR with good functionality. $\alpha\beta$ T cell function is determined by its $\alpha\beta$ TCR affinity and avidity. TCR affinity affects the binding strength of the receptor to its cognate antigen, while TCR avidity governs the ability of receptor clustering between cells.

Adoptive T cell therapy (ACT)

The first known cancer immunotherapy approach is adoptive T cell therapy (ACT), in which tumor-infiltrating T lymphocytes (TILs), consisting of mainly $\alpha\beta$ T cells, found in the tumor are isolated, *ex vivo* expanded, and subsequently re-infused back to patients after lymphodepletion (Figure 1A) (4). Despite their potential, the translational effort of tumor-specific $\alpha\beta$ T cells is rather challenging as the number of TILs that could be isolated from cancer patients is limited. On the other hand, most tumor-associated antigens (TAAs) are “self-antigens” that generate low-affinity $\alpha\beta$ TCRs and render and incompetent immune response against cancer due to the elimination of self-reactive immune cells during central and peripheral tolerance mechanisms (5, 6). Furthermore, neoantigens derived from somatic mutation of cancer cells mainly found in tumor with higher tumor mutational load and limiting potential immunogenic target(s) in several tumor types, such as acute myeloid leukemia (AML) (7). As alternatives, $\alpha\beta$ TCR-engineered $\alpha\beta$ T cell and chimeric antigen receptor (CAR) therapies are developed methodologies to circumvent the limitation of TILs therapy by introducing highly-tumor reactive $\alpha\beta$ TCR that recognize antigens expressed by tumor cells (3, 5).

$\alpha\beta$ TCR-engineered $\alpha\beta$ T cell therapy

$\alpha\beta$ TCR-engineered $\alpha\beta$ T cell therapy allows the introduction of allogenic $\alpha\beta$ TCR into patient's $\alpha\beta$ T cells, follows by *ex vivo* expansion prior to re-infusion, and thereby circumvent the limited amount of autologous tumor-reactive T cells (Figure 1B). Clinical studies collectively demonstrate significantly favorable outcomes, including tumor regression (8), in the majority of patients with several malignancies, such as multiple myeloma (9), metastatic melanoma (10), and colorectal carcinoma (11).

Despite their clinical benefits, $\alpha\beta$ TCR-engineered therapies only benefit for a certain percentage of patients who express targetable tumor antigen in an MHC-restricted manner. This also holds through for ACT with allogeneic T cells, where HLA-match donor becomes a limiting factor to avoid possible graft-versus-host-disease (GvHD) (12). Moreover, tumor cells could develop resistance by downregulation of MHC molecules or antigens expression, leading to unsustainable clinical responses in patients (3).

Figure 1 Cellular T cell immunotherapy approaches for cancer patients. (A) Tumor-infiltrating T cells (TILs) found on tumor biopsy of cancer patients can be ex vivo expanded prior to reinfusion to patients to elicit better T cell response against tumor cells. **(B)** Alternatively, gene transfer of identified antigen-specific $\alpha\beta$ TCR into $\alpha\beta$ T cells could be used as therapeutic approach to circumvent the limited TILs in patients. **(C)** Chimeric antigen receptor (CAR) introduced into $\alpha\beta$ T cells redirect their tumor reactivity in antigen-specific and pMHC-independent manner. **(D)** Introduction of highly tumor-reactive $\gamma\delta$ TCR into $\alpha\beta$ T cells redirect tumor-reactivity against early metabolic changes occur in tumor cells, overcoming the proficient deficiency of unmodified $\gamma\delta$ T cells as well as their broad diversity repertoires.

Chimeric antigen receptor (CAR)

An alternative approach for cellular therapy is the introduction of chimeric antigen receptor (CAR) to T cells to redirect α B T cell anti-tumor specificity and enhance the efficacy of adoptive T cells in patients (Figure 1C) (13). CAR T cells are designed with extracellular domain of single-chain variable fragment (scFv) from immunoglobulin molecules, hinge region that important for flexibility and CAR dimerization, transmembrane domain, and intracellular signaling domain consisting of CD3 ζ (1st generation CARs) and co-stimulatory molecules (2nd and 3rd generation CARs) that are important for T cell activation and persistence (13-15).

Studies with CAR T cells directed towards CD19/CD20 antigens have shown remarkable clinical responses in patients with hematological malignancies (16-18); subsequently leads to FDA- and EMA-approved products, including Axicabtagene ciloleucel (19, 20) and Tisagenlecleucel (21-23). Nevertheless, there are still some concerns regarding the side effects of CAR T cell therapy, including tumor lysis syndrome, on-target off-tumor toxicity, cytokine release syndrome (CRS), neurotoxicity, and lymphopenia. CAR T cells induce tonic signaling leading to high risk for CRS and promoting T cell exhaustion, hence the ineffective anti-tumor efficacy and possible off-target toxicity (15).

Following the unprecedented success of CAR T cell therapy for hematological malignancies, clinical studies with CAR T cells directed towards antigens express in solid malignancies have been initiated (24-30). Unlike hematological malignancies that are dispersed, solid tumor masses developed in specific organs and resulted in the growth of immunosuppressive cells that causes lower penetration of CAR T cells into solid tumor masses (31, 32). Furthermore, the high heterogeneity of solid malignancies hampers the therapeutic effect of cancer immunotherapy, including CAR T cells.

$\gamma\delta$ T cells-based cellular therapy

Up to 1-10% of circulating CD3⁺ human T cells carry a TCR heterodimer with γ -chain and δ -chain and known as $\gamma\delta$ T cells. The unconventional $\gamma\delta$ T cells share the property of innate and adaptive immunity that allows recognition of infected, stress-induced, and malignantly-transformed cells and undergo clonal expansion and memory formation (33, 34). The role of $\gamma\delta$ T cells in cancer immunosurveillance first observed in $\gamma\delta$ T cell-deficient mice that increased the chance of cutaneous tumor development (35, 36) and spontaneous adenocarcinoma growth (37) compared to wild-type mice. The potential application of unconventional $\gamma\delta$ T cells in cancer immunotherapy increases as intratumoral $\gamma\delta$ T cells have been associated with favorable prognosis for patients across different malignancies (38, 39).

Similar to α B T cells, $\gamma\delta$ T cells able to exert cytotoxic capacity against their target antigens and elicit immune responses, either directly via perforin and granzyme or indirectly via cytokines production (40). $\gamma\delta$ T cells do not require antigen presentation in pMHC complex for their target recognition, and also do not require CD4 and CD8 co-receptor binding for proper $\gamma\delta$ TCR signaling (41), which allow antigen recognition

across a broad range of malignancies, also irrespective of their tumor mutational load. $\gamma\delta$ T cells could recognize its target in a $\gamma\delta$ TCR-independent manner via natural cytotoxicity receptors, such as NKG2D, DNAM-1, NKp30, and NKp44, contributing to their diverse repertoire (42, 43).

$\gamma\delta$ T cells are classified into two major subsets, $V\delta 2^+$ and $V\delta 2^-$ T cells. $V\delta 2^+$ cells exclusively interact with $V\gamma 9^+$ chain and subsequently known $V\gamma 9\delta 2^+$ T cells mainly reside in peripheral blood, whereas the $V\delta 2^-$ subset, i.e., $V\delta 1^+$, $V\delta 3^+$ cells, primarily reside in epithelial tissues or mucosal membranes (44, 45). $V\delta 2^+$ cells recognize metabolic changes in infected or malignantly-transformed cells by sensing accumulation of intracellular metabolite antigens, known as phosphoantigens (pAgs). pAgs are produced by bacterial pathogens with the non-mevalonate pathway for isoprenoid synthesis (46, 47). In malignantly-transformed cells, dysregulated mevalonate pathway is associated with high accumulation of intracellular isopentenyl pyrophosphate (IPP) compared to healthy cells, promoting the recognition by $V\delta 2^+$ T cells (48, 49).

$V\delta 2^-$ cells are known for their diverse stress-induced ligands, including MHC-associated antigens MICA/B protein (50-52), lipid antigens presented by CD1d molecules (53), UL16-binding protein (ULBP) family members (54-56), endothelial protein C receptor (EPCR; (57)), and Annexin A2 (58). However, the exact ligands and their mode-of-activation are yet to be elucidated. $V\delta 1^+$ cells, one of the major $V\delta 2^-$ subsets, also exert cytotoxic capacity against infected and tumor cells, yet their activation is phosphoantigen-independent. Recent studies have shown the antitumor efficacy of $V\delta 1^+$ cells against hematological and solid malignancies (59-62), suggesting their promising potential in cancer immunotherapy alongside $V\delta 2^+$ cells.

$\gamma\delta$ T cells have a diverse repertoire in function and receptor expression, complex biology, and tissue-specific tropism that may impede their application in adoptive cellular therapy (63-65). Therapeutic application of $\gamma\delta$ T cells in cancer immunotherapy mainly focuses on $V\delta 2^+$ cells, for which clinical studies are conducted against different types of cancer (39, 66-70). These studies are mainly executed with adoptive transfers of *ex vivo* expanded unmodified $\gamma\delta$ T cell, either autologous or allogeneic. Unfortunately, naturally elevated IPP levels in cancer cells does not promote sufficient antitumor response of $V\delta 2^+$ cells (71). Therefore, most clinical studies are performed together with the administration of aminobiphosphonates (i.e., Zoledronate, pamidronate), which increase the accumulation of IPP, and interleukin-2 (IL-2) to promote tumor recognition by $V\delta 2^+$ cells. These clinical studies showed a favorable safety profile of $\gamma\delta$ T cell-based therapy, including the absence of GvHDs in MHC mismatch background (72). Yet, clinical responses are still marginal.

New kid on the block: $\alpha\beta$ T cells Engineered to express defined $\gamma\delta$ TCR (TEGs)

Considering the major downsides of autologous $\gamma\delta$ T cell therapy, our group developed the concept of metabolic targeting of cancer with TEGs: $\alpha\beta$ T cell engineered to express a defined $\gamma\delta$ TCR, which utilizes the superior proliferative capacity of $\alpha\beta$ T cells while

retaining antitumor efficacy of $\gamma\delta$ TCR (Figure 1D) (73-75). Introduction of highly tumor-specific $\gamma\delta$ TCR into $\alpha\beta$ T cells bypasses the needs of MHC-restricted $\alpha\beta$ T cell recognition and could efficiently target a broad range of hematological and solid malignancies (73, 74, 76, 77). Additionally, TEGs uncouple $\gamma\delta$ TCR from its innate-like environment, such as the interplay of NK receptors, that are not present in $\alpha\beta$ T cells (78). In this way, TEGs also mitigates the underestimated diversity of $\gamma\delta$ TCR, both in function and receptor expression (63, 64).

One of the main advantages of TEG cells is the absence of TCR mispairing between $\gamma\delta$ TCR and $\alpha\beta$ TCR chains and do not produce unwanted TCRs with unknown specificities. In addition, the successful gene transfer of $\gamma\delta$ TCR into $\alpha\beta$ T cells leads to downregulation of the endogenous $\alpha\beta$ TCRs on the cell surface and thus decreases alloreactivity and facilitates the depletion of non-engineered T cells (73, 74). Our group successfully develop an untouched GMP-ready strategy using clinical-grade anti-human $\alpha\beta$ TCR antibody to purify TEG cells without cross-reactivity against $\gamma\delta$ TCR chains and therefore able to segregate between engineered- and non-engineered cells by negative selection procedures. This production process allows expansion of sufficient TEG-based cellular therapy from apheresis products from cancer patients and readily translated for clinical use (75, 79). TEG format allows efficient production of $\alpha\beta$ T cells expressing a highly tumor-specific $\gamma\delta$ TCR, either from V δ 2⁺ or V δ 2⁻ subsets. Moreover, TEGs also retain CD4⁺ and CD8⁺ effector cell functions.

OUTLINE OF THE THESIS

Before clinical implementation, efficacy and safety profiles of cellular therapy, including TEGs, have to be evaluated carefully. The efficacy profile of T cells could be determined by *in vitro* co-culture with tumor target, both cell lines and primary patient materials, and assessed for their cytotoxicity by cytokines production and direct killing capacity. The safety profile of T cells is evaluated with the same method with the co-culture of healthy cell lines or hematopoietic compartments to assess possible off-target toxicity (80). Furthermore, 3D models can be used to evaluate efficacy and toxicity profile in a closer physiologically-relevant tumor microenvironment, such as interplay with stromal and epithelial cells in the bone marrow (81). The major limitation for $\gamma\delta$ T cells translational research is the evolutionary difference between humans and mice, commonly used as preclinical model for cellular therapy. Distinct $\gamma\delta$ T cell repertoire exclusively presents in human and non-human primates, but not in their mice counterparts (82, 83). Thus, preclinical assessment of efficacy and safety profile of cellular therapy is mainly performed *in vivo* using transgenic mice or immunodeficient mice model transplanted with human tumor cells followed by adoptive transfer of human T cell therapy. Therefore, this thesis aims to evaluate efficacy and safety profiles of TEG products, particularly TEG001 and TEG011, in relevant preclinical models and thereby highlighting their therapeutic potential prior to further clinical testing.

Chapter 2, published in *J ImmunoTher Cancer* 2019;7:69 (doi:10.1186/s40425-019-0558-4), describes the efficacy-safety balance of TEG001 in more physiological relevant environments, with primary tumor tissues as well as primary healthy cells. Using a humanized mouse model, we were able to assess the activity of TEG001 against established leukemia in patient-derived xenograft (PD-X) mice and toxicity against complete hematopoietic compartment by engrafting healthy cord blood-derived CD34⁺ progenitor cells in healthy donor-derived (HD-X) mice. We provide supporting evidence for TEG001 *in vivo* therapeutic potential against primary AML without harming healthy hematopoietic compartments and bestow a rationale for the first-in-human study.

Chapter 3, published in *Blood Adv.* 2019;3(19):2870-2882 (doi: 10.1182/bloodadvances.2019032409), elucidates the antitumor reactivity of an allo-HLA-A*24:02-restricted V γ 5V δ 1TCR and CD8 α -dependent (derived from clone FE11) against both solid and hematological tumor cells, while sparing their healthy counterparts. When applied into TEG format, subsequently referred to as TEG011, this TCR retains the tumor-specific activity and the ability to differentiate between healthy and malignant cells in HLA-A*24:02-restricted manner. Importantly, we focused on the *in vivo* assessment of TEG011 efficacy in a transgenic mouse model expressing human HLA-A*24:02 and highlighting its promising therapeutic application.

Chapter 4, published in *J Leukoc Biol.* 2020;1-11 (doi: 10.1002/JLB.5MA0120-228R), extends the assessment of TEG011 safety profile *in vivo* as well as its pharmacokinetics in non-tumor bearing and tumor-bearing humanized HLA-A*24:02 transgenic NSG (NSG-A24:02) mice, where no off-target toxicity observed. Furthermore, we describe the association between TEG011 persistence and tumor control, emphasizing that the kinetics of adoptive transferred TEG011 is crucial to sustain long-term efficacy.

Chapter 5 describes the introduction of transgenic CD8 α receptor to improve TEG011 efficacy further. As shown in Chapter 3, TEG011 is critically dependent on CD8 α co-receptor and lacks support by antigen-specific CD4⁺ T cells. Thus, co-expression of both FE11 $\gamma\delta$ TCR and CD8 α receptor on T cells (referred to as TEG011_CD8 α) is deemed a good strategy to enhance TEG011 antitumor efficacy and T cell infiltration. This chapter was submitted for publication to *Frontiers in Immunology*, August 2021.

Chapter 6 summarizes the major findings in chapters mentioned earlier and puts the crucial aspects of preclinical model development within the context of $\gamma\delta$ TCR-engineered T cell immunotherapy, specifically for TEG-based therapy, and in comparison to other immunotherapeutic platforms.

CHAPTER 2

Evaluating *in vivo* efficacy - toxicity profile of TEG001 in humanized mice xenografts against primary human AML disease and healthy hematopoietic cells

ABSTRACT

$\gamma\delta 2$ T cells, which express V $\gamma 9$ and V $\delta 2$ chains of the T cell receptor (TCR), mediate cancer immune surveillance by sensing early metabolic changes in malignant leukemic blast and not their healthy hematopoietic stem counterparts via the $\gamma\delta 2$ TCR targeting joined conformational and spatial changes of CD277 at the cell membrane (CD277J). This concept led to the development of next generation CAR-T cells, so called TEGs: $\alpha\beta$ T cells Engineered to express a defined $\gamma\delta$ TCR. The high affinity $\gamma\delta 2$ TCR clone 5 has recently been selected within the TEG format as a clinical candidate (TEG001). However, exploring safety and efficacy against a target, which reflects an early metabolic change in tumor cells, remains challenging given the lack of appropriate tools. Therefore, we tested whether TEG001 is able to eliminate established leukemia in a primary disease model, without harming other parts of the healthy hematopoiesis *in vivo*.

Separate sets of NSG mice were respectively injected with primary human acute myeloid leukemia (AML) blasts and cord blood-derived human progenitor cells from healthy donors. These mice were then treated with TEG001 and mock cells. Tumor burden and human cells engraftment were measured in peripheral blood and followed up over time by quantifying for absolute cell number by flow cytometry. Statistical analysis was performed using non-parametric 2-tailed Mann-Whitney t-test. We successfully engrafted primary AML blasts and healthy hematopoietic cells after 6-8 weeks. Here we report that metabolic cancer targeting through TEG001 eradicated established primary leukemic blasts *in vivo*, while healthy hematopoietic compartments derived from human cord-blood remained unharmed in spite of TEGs persistence up to 50 days after infusion. No additional signs of off-target toxicity were observed in any other tissues. Within the limitations of humanized PD-X models, targeting CD277J by TEG001 is safe and efficient. Therefore, we have initiated clinical testing of TEG001 in a phase I first-in-human clinical trial (NTR6541; date of registration 25 July 2017).

INTRODUCTION

Adoptive cell therapy with engineered immune cells targeting hematological malignancies entered clinical practice (1). Reprogramming immune cells has been achieved so far with chimeric antigen-reactive receptors (2) and tumor-specific α BT cell receptors (TCRs) (3, 4). However, the CAR-T concept frequently targets ubiquitously expressed antigens like CD19 for B cell malignancies (5), or FLT-3 (6) for acute myeloid leukemia (AML), as well as stress antigens like NKG2D (natural-killer group 2, member D) for a broader range of cancers (7), raising the question of whether such strategies result as collateral damage in either the long-term deletion of essential hematopoietic subsets or within the context of physiological or therapeutic stress like irradiation to self-reactivity. Given the low mutational load of AML (8), the targeting of neo-antigens has not been successful, and targeting of minor antigens like HA-1 allows only the inclusion of a minority of patients (9). Thus, novel strategies are needed to attack myeloid malignancies within the context of engineered immune cells.

One very attractive and so far, not well-explored alternative to mediate tumor-specific TCR derives from unconventional $\gamma\delta$ 2T cells subsets (10). $\gamma\delta$ 2T cells sense molecular stress signatures via the accumulation of intracellular phosphoantigens level on infected and malignant cells (11). This cell subset has the ability to kill tumor cells originating from hematological and solid malignancies *in vitro*, making it a promising immunotherapeutic option (10, 12). While several clinical trials have been conducted using *ex vivo* expanded and adoptively transferred autologous $\gamma\delta$ 2T cells in patients with advanced malignancies including AML, the results showed scarce activity (13). One major obstacle has been the limited proliferative capacity of $\gamma\delta$ 2T cells in advanced cancer patients (14), as well as the underestimation of the substantial molecular and functional diversity within this subset (15, 16). Therefore, alternative strategies are needed for the clinical translation of the strong antitumor reactivity of receptors expressed on $\gamma\delta$ 2T cells (15).

To override the major weakness of $\gamma\delta$ 2T cells for its defective proliferative capacity and underestimated diversity, our group demonstrated that α BT cells engineered to express a defined $\gamma\delta$ TCR, so-called TEGs, solves the proliferation deficiency and diversity of $\gamma\delta$ 2T cells by utilizing one defined $\gamma\delta$ 2TCR with strong antitumor reactivity and the strong proliferative capacity of α BT cells. Furthermore, by utilizing α BT properties, we retain both CD4⁺ and CD8⁺ effector cell functions in our TEGs. The first clinical candidate of TEGs derived from clone 5 (TEG001) has been shown to mediate the highest antitumor reactivity against a broader panel of tumor cells *in vitro* and in cell line-derived xenograft mouse models and to outperform natural $\gamma\delta$ 2T cells (10, 12, 17, 18). However, the assessment of the true activity of TEG001 against primary leukemia as well as potential toxicity in physiologically more relevant models has not been assessed so far, but is essential prior to entering a first-in-human clinical trial. Low toxicity of natural $\gamma\delta$ 2T cells in many clinical trials (13) cannot be used as an argument for safety, given also their lack of activity in men, mainly orchestrated through many NK-like immune inhibitory receptors expressed at the cell surface of natural $\gamma\delta$ 2T cells (16). The major

driver of the activity of TEG001, but also its potential risk of toxicity, is derived from the concept of utilizing a highly active $\gamma\delta$ TCR out of the context of the natural brakes of a $\gamma\delta$ T cells, which have been also the pitfalls for their successful clinical translation to date. Thus, the key obstacle of clinical translation of TEG001 remains the assessment of its bare activity against primary leukemia as well as potential side effects against e.g. healthy hematopoietic compartments. Classical concept of efficacy and safety testing fail for this novel type of tumor-specific antigen, given that a joint conformational and spatial change of CD277 (later referred to as CD277J) mediated through early metabolic changes in cancer cells is recognized by the utilized $\gamma\delta$ TCR (12, 19, 20) and no tools are available to directly assess CD277J. To date, only cellular re-localization of RhoB can serve as a surrogate marker of CD277J (12). Antibodies used for detecting CD277 rather induce or inhibit the conformational and spatial changes of CD277J (21, 22), thus they do not have the intrinsic ability to sense these alterations. Soluble $\gamma\delta$ TCR have been suggested to sense CD277J (23), however a more comprehensive analysis of such tools could not confirm their suitability, most likely due to the low affinity of the $\gamma\delta$ TCR (J Kuball unpublished observation). To remove these obstacles before clinical testing, we developed models which allow us to assess efficacy and toxicity of TEG001 in more physiological relevant environments, with primary tumor tissues as well as primary healthy cells. One example is the recently established 3D bone marrow model which enabled us to determine the efficacy of TEG001 against primary multiple myeloma cells, and to simultaneously exclude toxicity against stroma and endothelial cells in the bone marrow niche (24). However, limited information is available when assessing activity of TEG001 against established leukemia, and toxicity against the complete hematopoietic compartment. Therefore, we utilized in this report an *in vivo* patient-derived xenograft (PD-X), and a healthy donor-derived xenograft (HD-X) model for assessing the efficacy of TEG001 against primary leukemic blasts and toxicity against the complete hematopoietic compartment, to provide a rationale for first-in-human testing of TEG001.

MATERIALS & METHODS

Functional T cell assay

IFN γ ELISPOT was performed using anti-human IFN γ mAb1-D1K(I) and mAb7-B6-1 (II) (Mabtech) in accordance with the manufacturer's protocol. Effector and target cells (E:T 1:3) were incubated for 24 hours with or without pamidronate (10 or 100 μ M; Calbiochem) as indicated. Pamidronate was added in all our *in vitro* experiment in order to enhance TEGs activation as previously reported (10).

RhoB distribution analysis using confocal microscopy

Human CD34⁺ progenitor cells from a healthy donor were subjected to different conditions as follows: 1) untreated; 2) overnight stimulation with 50 IU/ml IL-2 or 3) 1000 IU/ml IFN γ ; 4) overnight incubation in the presence of 5mM Cyclophosphamide (Cy, Sigma-Aldrich Chemie NV, South Holland), or 5) 20 μ M Fludarabine-phosphate (Flu, Sigma-Aldrich Chemie NV, South Holland), or 6) Cy/Flu combination. Primary AML, B

cells, T cells, and monocytes were exposed to 100 μ M pamidronate and all cells were subsequently loaded to poly-L-lysine-coated coverslips. Attached cells were fixed, permeabilized and stained with a rabbit polyclonal anti-RhoB antibody (AbCam) followed by a secondary Goat anti-Rabbit IgG AlexaFluor488-conjugated antibody (Jackson ImmunoResearch). Cells were also stained with DAPI for nuclear staining. Intracellular RhoB distribution was visualized by confocal microscopy. RhoB signal ratios between intra-nuclear and extra-nuclear compartments were quantified using ImageJ software as described previously (12).

Animal models

NOD.Cg-Prkdc^{scid}Il2rg^{tm1Wjl}/SzJ (NSG) and NOD.Cg-Prkdc^{scid}Il2rg^{tm1Wjl} Tg(CMVIL3,CSF2,KITLG)1Eav/ MloySzJ (NSG-SGM3) mice originally obtained from Jackson Laboratory (Bar Harbor, ME, USA) were bred and housed in the specific pathogen-free (SPF) breeding unit of the Central Animal Facility of Utrecht University. Experiments were conducted according to Institutional Guidelines under acquired permission from the local Ethical Committee and per current Dutch laws on Animal Experimentation. Mice were housed in sterile conditions using an individually ventilated cage (IVC) system and fed with sterile food and water. Irradiated mice were given sterile water with antibiotic ciproxin for the duration of the experiment. Mice were randomized with equal distribution by sex and divided into 5 mice/group (for efficacy study) or 10 mice/group (for safety study).

Adult mice (10-14 weeks old) received sublethal total body irradiation (1.75 Gy) on Day 0. On Day 1, NSG mice were injected intravenously with 5×10^6 CD3-depleted primary AML blast from donor p25 (efficacy study as PD-X model) or 0.25×10^6 healthy human CD34⁺ cells from six different donors (safety study as HD-X model). Engraftment and tumor burden were followed up in the peripheral blood as described in the subsection below. When the arbitrary threshold of 500 cells/ml was reached, treatment was initiated. Mice received 2 injections of 10^7 therapeutic TEG001 cells or TEG-LM1 mock cells (non-functional $\gamma\delta$ TCR-transduced T cells that carries length mutation of on the complementary determining region 3 (CDR3) region of the $\delta 2$ -chain (18)). For second PD-X model for efficacy study, adult NSG-SGM3 mice received 2 injections of 10^7 therapeutic TEG001 cells or TEG-LM1 mock cells at Days 8 and 16. All mice received 0.6×10^6 IU of IL-2 (Proleukin; Novartis) in IFA subcutaneously together with the first T cell injection and every 21 days until the end of the experiment. Pamidronate (10 mg/kg body weight) was injected intravenously together with the first T cell injection, and every 21 days until the end of the experiment. Pamidronate was added in all our *in vivo* experiment in order to enhance TEGs activation as previously reported (10). Mice were routinely monitored at least twice a week for weight loss and symptoms of disease (sign of paralysis, weakness, and reduced motility).

Cytology staining and analysis

Cytopathologic evaluation of mouse bone marrow cytospin was performed by May-Grünwald Giemsa staining. Each sample was qualitatively and semi-quantitatively evaluated based on the following criteria: 1) cellularity (1= high; 2= moderate; 3= low); 2) pres-

ence of megakaryocytes; 3) presence of all cell lineages; 4) presence of all stages of maturation for each cell lineage; 5) description of the cell types present for each cell lineage.

Histology staining and analysis

Histopathologic evaluation was performed by hematoxylin and eosin (H&E) staining for the following mouse tissues: liver, spleen, small (duodenum, jejunum, ileum) intestine. Each organ was semi-quantitatively evaluated based on the following criteria: 1) histologic lesions were semi-quantitatively assessed (grade: 0=absent; 1=minimal; 2=mild; 3=moderate; 4=marked); 2) the inflammation was evaluated considering the distribution (focal, multifocal, multifocal to coalescing, diffuse), severity (grade 1-4) and cell type (lymphocytes, plasma cells, macrophages, neutrophils); 3) the presence of leukemic cell infiltrate.

Statistical analysis

Data were analyzed using GraphPad Prism (GraphPad Software Inc.) and represented as mean \pm standard deviation (SD) or standard error of mean (SEM) with * $P < 0.05$; ** $P < 0.01$; and *** $P < 0.001$. Differences between groups were assessed using a two-way ANOVA, non-parametric 2-tailed Mann-Whitney t-test or Kruskal-Wallis test and Dunn's multiple comparison test where indicated. Cell lines, primary human materials, retroviral transduction and depletion of non-engineered T cells, CFU assays, flow cytometry analysis, assessment for human cell engraftment and preparation of single cell suspensions are described in Supplementary Methods.

RESULTS

In vitro and *in vivo* activity of TEG001 against primary AML

Approximately 50% of the primary AML blasts tested so far are susceptible to TEG001 ((17) and unpublished observation). We first confirmed activity of TEG001 against the primary AML blasts from multiple donors (Supplementary Table 1) by performing an IFN γ ELISPOT assay in the presence or absence of 10 μ M pamidronate (PAM) while the negative control (healthy T cells) was not recognized. Aminobiphosphonate compounds, including clinically used pamidronate, further accumulate intracellular phosphoantigens level (11). Based on our previous study (10), the application of therapeutic concentrations of PAM enhances γ 9 δ 2TCR recognition, including TEG001. Daudi served as a positive control. Most of the primary AML blasts could induce significant IFN γ production by TEG001 in the presence of PAM (Figure 1A). Furthermore, we tested the cytolytic activity of TEG001 against primary AML blasts from donor p2. Primary AML blasts were incubated with either bulk α BT cells (as mock control) or with TEG001 cells in the presence of PAM on the methylcellulose matrix for the colony formation assay. Colonies were counted 8 days later. TEG001 showed a superior reduction of AML blast as shown by less colony formation in comparison to mock T cells (Figure 1B). This result aligns with our previous data in which γ 9 δ 2TCR-transduced α BT cells inhibited colony forming unit (CFU) of primary AML blast (10).

Figure 1 In vitro and in vivo efficacy profile of TEG001. **(A)** Antitumor reactivity of TEG001 towards patient-derived primary AML blasts in vitro. Effector cells TEG001 and primary AML blasts from multiple donors (E:T ratio is 1:3) were incubated for 24 hours with or without 10 μ M PAM as indicated. Daudi and healthy T cells were included as positive and negative target controls, respectively. IFN γ secretion was measured by ELISPOT. IFN γ spots per 15,000 T cells are shown as mean \pm SD of at least 3 independent replicates for each target. Fifty spots/15,000 cells were considered as a positive antitumor response and indicated by the black horizontal line. Statistical significances were calculated by two-way ANOVA; *, P < 0.05; **, P < 0.01; ***, P < 0.001; ****, P < 0.0001; **(B)** Bulk α BT cells (as mock T cells) or TEG001 cells were incubated with primary AML blast from donor p2 for 5 hours at E:T ratio 10:1. Then cells were plated in methylcellulose-based medium and, after 8 days, colony formation was quantified using an inverted microscope. Shown is the number of CFU formed. Data is the result of a single experiment from single primary AML donor; **(C)** Schematic overview of in vivo experiment. NSG mice were irradiated at day 0 and engrafted with primary AML cells at day 1. AML cells were followed-up in the peripheral blood by flow cytometry. When the average AML cells were >500 cells/ml, treatment was initiated. Mice received 2 injections of therapeutic TEG001 or TEG-LM1 mock in the presence of PAM (at week 7 and 9) and IL-2 (at week 7); **(D)** Tumor burden for primary AML was measured in peripheral blood by quantifying for absolute cell number by flow cytometry. Data represent mean \pm SD of all mice per group (n = 5). Statistical significances were calculated by non-parametric 2-tailed Mann-Whitney t test; *, P < 0.05; **, P < 0.01; ***, P < 0.001; ****, P < 0.0001.

From this screening, we selected AML blasts from patient 25 (p25) because of its initial susceptibility to TEG001, as well as its availability in sufficient numbers for further testing in mice. Next, we injected CD3-depleted primary AML blasts from p25 into irradiated mice intravenously (Figure 1C). Engraftment and leukemia outgrowth were detected by measuring specific AML markers huCD45⁺CD13⁺CD33⁺ in peripheral blood by flow cytometry (Figure S2). When 500 AML cells/ml were detected in peripheral blood, treatment was initiated. Mice received two injections of TEG001 or TEG-LM1 mock in the presence of PAM and IL-2 (for the first TEGs injection) to support TEGs activation and proliferation *in vivo*.

TEG-LM1 carries $\gamma\delta 2$ TCR with length mutation of on the CDR3 of the $\delta 2$ -chain, which abrogates its function (18) and therefore chosen as a suitable mock control. $\gamma\delta$ TCR expression for both TEG001 and TEG-LM1 mock is comparable, which subsequently infused into the mice (Figure S1). In the peripheral blood of the TEG001-treated mice, primary AML cells were no longer detectable five weeks after TEGs infusion, but remained measurable in mock-treated mice (Figure 1D), suggesting that in the described PD-X model TEG001 specifically eliminates primary AML blasts over time. We further addressed the influence of microenvironment to TEG001 recognition against primary AML blasts and developed a separate PD-X model using the same p25 AML in NSG-SGM3 mice that express human cytokines (i.e. IL-3, granulocyte/macrophage colony-stimulating factor (GM-CSF), and stem cell factor (SCF)) that support better engraftment of AML blast *in vivo* (25). Similarly, mice received two injections of TEG001 or TEG-LM1 mock in the presence of PAM and IL-2 (for the first TEGs injection) at Day 8 and Day 16 (Figure S3A). While we did not see elimination primary AML blasts over time, TEG001-treated mice consistently showed lower AML burden in comparison to mock-treated mice as measured in peripheral blood (Figure S3B). This result demonstrates antitumor activity of TEG001 against primary AML blasts *in vivo* as shown in two independent PD-X models.

Assessing the activity of TEG001 against healthy hematopoiesis *in vitro*

Next, we aimed to assess the toxicity of TEG001 against the hematopoietic compartment *in vitro*. Therefore, TEG001 and mock transduced T cells were incubated with the physiological hematopoietic target of $\gamma\delta$ T cells, namely CD14⁺ monocytes, activated T cells as well as non-activated and activated B cells in the absence and presence of PAM. Similar to the efficacy study, we include the presence of PAM to enhance TEG001 recognition as previously shown (10). Daudi served again as a positive control. In an IFN γ ELISpot assay cytokine secretion was only observed against the positive control and CD14⁺ monocytes in the presence of PAM, while other T and B cells did not induce IFN γ production (Figure 2A).

Figure 2 In vitro safety profile of TEG001. (A) Comparable recognition profile of Daudi tumor cells versus healthy hematopoietic cells. Effector cells TEG001 and target cells (E:T ratio 1:3) were incubated for 24 hours in the presence of 10 μ M PAM. IFN γ secretion was measured by ELISPOT. IFN γ spots per 15,000 T cells are shown as mean \pm SD of at least 3 independent replicates for each target. Fifty spots/15,000 cells were considered as a positive recognition response and indicated by the black horizontal line. (B) RhoB distribution for healthy hematopoietic cells upon irradiation as analyzed by confocal microscopy in the presence of 10 μ M PAM. Data is shown as fold-changed of RhoB distribution between irradiated cells (cellular stress condition) compared to non-irradiated cells from average ratio of at least ten different cells; (C) CD34 $^{+}$ progenitor cells from a healthy donor were treated with either 50 IU/ml IL-2, 1000 IU/ml IFN γ , 5mM Cy, 20 μ M Flu or combination of Cy/Flu. As positive control primary AML blast from donor p25 was treated with PAM. All cells were analyzed for intracellular distribution of RhoB using confocal microscopy. White bars represent healthy CD34 $^{+}$ progenitor cells, while black bar indicate primary AML blast (p25 AML). The RhoB signal ratio between nuclear and extranuclear cellular compartments was measured using ImageJ image analysis software. Graphs show average ratios of at least ten different cells \pm SEM. Statistical significance compared to untreated CD34 $^{+}$ progenitor cells was determined by using Kruskal-Wallis test and Dunn's multiple comparison test; (D) Comparable recognition profile of healthy hematopoietic cells in non-stressed (left panel) and stressed (irradiated, right panel) conditions. Effector cells TEG001 and target cells (E:T ratio 1:3) were incubated for 24 hours in the presence of 100 μ M PAM. IFN γ secretion was measured by ELISPOT. IFN γ spots per 15,000 T cells are shown as mean \pm SD of at least 3 independent replicates for each target.

Translocation of RhoB towards the cell membrane has been described as a key step for the recognition of a potential target by a $\gamma\delta$ TCR (12). This insight allowed us to test whether an additional stress of hematopoietic cells would activate this key step in the mode of action and thereby facilitate recognition of healthy compartments. As “stress” we have chosen irradiation, which is well known to activate many innate danger signals like MHC-like molecules (26), and is frequently used as preconditioning before the transfer of immune cells (27). Therefore, we assessed the translocation of RhoB towards the cell membrane in T cells, B cells and CD14 $^{+}$ monocytes in the absence and presence of irradiation. No significant increase in translocation of RhoB to the cell membrane could be observed (Figure 2B) for the tested healthy hematopoietic cells. We also assessed the RhoB localization in healthy CD34 $^{+}$ progenitor cells upon stimulation

with cytokines, such as IL-2 and IFN γ , as well as the presence of chemotherapy agents Cy/Flu and compared to primary AML blast from donor p25. While there is a significant increase in RhoB localization towards cell membrane in p25 AML blast, there are no significant increased for the healthy CD34 $^{+}$ progenitor cells in all conditions (Figure 2C). Furthermore, the recognition profile by TEG001 of the same cell subsets after irradiation was assessed by cytokine secretion. Recognition of a *priori* non-recognized cells was not induced and recognition of CD14 $^{+}$ monocytes was slightly reduced after irradiation (Figure 2D). Overall, our results suggest that TEG001 does not attack subsets of healthy hematopoiesis in the absence or presence of stress. Only CD14 $^{+}$ monocytes can be recognized in the presence of PAM as reported also for natural γ 9 δ 2T cells (10).

***In vivo* pharmacology and toxicology of TEG001**

Assessment of different hematopoietic subsets by TEGs *in vitro* is very restricted due to the limited sub-fractions available for testing. In addition, it does not allow for assessment of whether early precursors are affected. Therefore, we established a HD-X model with human cord-blood derived CD34 $^{+}$ progenitor cells from six healthy donors repopulated in irradiated mice to further assess the safety profile of TEG001 against the hematopoietic compartment (Figure 3A). Engraftment of human leukocytes (huCD45 $^{+}$) and other hematopoietic cellular subsets in peripheral blood was measured by flow cytometry (Figure S4A and S4B). When 500 huCD45 $^{+}$ cells/ml were detected in peripheral blood, treatment was initiated with either TEG001 or TEG-LM1 mock in the presence of PAM and IL-2 (for the first TEGs injection) to support TEGs activation and proliferation *in vivo*. While we observed a reduction of tumor burden by TEG001 (Figure 1D), no significant differences in engraftment of healthy hematopoietic cells between treatment groups were observed up to 50 days after infusion when assessed by huCD45 $^{+}$ (Figure 3B). TEG001 as well as TEG-LM1 cells could be detected after injection until the end of the study period in the peripheral blood of mice (Figure 3C).

Next, we investigated the reconstitution of diverse hematopoietic cellular subsets *in vivo* in more detail in the peripheral blood of mice. In particular, we were interested in the impact on monocytes given that *in vitro* natural γ 9 δ 2T cells as well as TEG001 can recognize primary monocytes. Interestingly, neither CD14 $^{+}$ monocytes, nor CD19 $^{+}$ B cells, CD3 $^{+}$ T cells, or CD34 $^{+}$ progenitor cells were impaired in outgrowth when comparing mice injected with TEG001 or TEG-LM1 (Figure 4A-D). At the end of study period, we also obtained single cell suspension from spleen and bone marrow from three mice for both the TEG001 and TEG-LM1 mock group to analyze the reconstitution of similar cell subsets in more detail in primary tissues (Figure 5A-E). In line with our observations in peripheral blood, we could observe all relevant subsets, namely CD14 $^{+}$ monocytes, CD19 $^{+}$ B cells, CD3 $^{+}$ T cells, and CD34 $^{+}$ progenitor cells.

We next collected bone marrow cytospin samples from the same mice for a more detailed cytopathology analyses. All of the bone marrow samples from both treatment groups showed a pleomorphic population of cells derived from erythroid and myeloid lineages, with all the maturation stages (Figure 6A). In almost all samples (5/6) eosin-

ophilic differentiation was also evident. Beside normal blasts, an immature population with altered morphology (dysplastic immune cells), consistent with granular blasts was detected in both TEG001 and TEG-LM1 treated mice as well as cells with blast-like phenotypes with an indented nucleus, consistent with promonocytes (4/6), but no leukemic features were observed. Importantly, we did not observe any apparent differences in their outgrowth between treatment groups indicating that TEG001 do not harm the reconstitution of healthy hematopoietic compartments *in vivo*.

Figure 3 In vivo safety profile of TEG001. **(A)** Schematic overview of the safety experiment in healthy donor-derived xenograft (H DX) model. NSG mice were irradiated at day 0 and engrafted with healthy cord blood-derived CD34⁺ progenitor cells on day 1. Engraftment was followed up in peripheral blood by flow cytometry and when >500 huCD45⁺ cells/ml were present, mice received 2 injections of therapeutic TEG001 or TEG-LM1 mock in the presence of PAM (at week 6 and 8) and IL-2 (at week 6); **(B-C)** In vivo safety profile of TEG001 towards healthy human hematopoietic cells. Healthy human cells engrafted in NSG mice **(B)** with long term persistence of TEGs in peripheral blood **(C)**. Data represent mean \pm SD of all mice per group (n = 10).

Figure 4 In vivo reconstitution of healthy human hematopoietic compartments in peripheral blood. Comparable profile between TEG001 and TEG-LM1 mock group of reconstituted healthy human hematopoietic cellular subsets, including CD14⁺ monocytes (A) B cells (B), T cells (C), and CD34⁺ progenitor cells (D) as measured by flow cytometry. Data represent mean \pm SD of all mice per group (n = 10).

To evaluate off-target toxicity of TEG001 towards healthy tissues not related to the known mode of action which is absent in mice (21), we collected further mouse spleen, liver and intestine from three mice for each TEG001 and TEG-LM1 mock group and performed histopathology analyses. Spleen tissues showed non-neoplastic, lympho/histiocytic proliferative lesions in all the examined samples, of both treatment groups (Figure 6B). Similarly, no significant histological features of toxicity or other relevant abnormalities were observed in liver or intestine in all samples (Figure 6C-D). Most of the samples showed extramedullary hematopoiesis, mainly involving the erythroid lineage (extramedullary erythropoiesis) with scattered megakaryocytes sometimes evident, as a possible consequence of the engrafted human CD34⁺ progenitor cells in this mouse model. Overall, our data indicate there are no significant differences in histology features and notably, there are no off-target toxicities observed in all healthy tissues upon TEG001 treatment.

DISCUSSION

TEG001 has been selected as the first candidate for clinical testing (NTR6541) based on its superior recognition of hematological malignancies against both cell lines and primary AML *in vitro* and its ability to limit the tumor outgrowth in cell line-derived xenograft mouse models (10, 17, 18). Within this study, we have been able, for the very first time, to assess therapeutic efficacy towards primary AML blasts in a clinically relevant model with established leukemic load *in vivo*, while excluding toxicity against other hematopoietic stem cell compartments. Our current observation that primary AML can be eliminated in an *in vivo* model by TEG001, without affecting the hematopoietic compartment, is in line with our previous observation that an alteration in the RhoB-CD277J axis, the putative ligand of $\gamma\delta$ TCR, is selectively observed in the leukemic but not healthy hematopoietic stem cell (12).

A major challenge *a priori* clinical testing of novel cell-based and gene therapy products remains to assess efficacy and toxicity in relevant pre-clinical models in order to avoid unwanted toxicities like those reported for different CAR-T (28) or α BTCT gene therapy programs (29). This reflects the quite different characteristics of cell-based gene therapy medicinal products in comparison to conventional synthetic drugs. Thus, classical clinical considerations of therapeutic efficacy and safety assessments might no longer apply for these 'living' medicinal products.

Figure 5 In vivo reconstitution of healthy human hematopoietic compartments in tissues. Comparable profile between TEG001 and TEG-LM1 mock group of reconstituted healthy human hematopoietic cellular subsets in spleen and bone marrow, including total human CD45⁺ leukocytes (A), CD14⁺ monocytes (B), B cells (C), T cells (D) and CD34⁺ progenitor cells (E) as measured by flow cytometry. Shown in the data from individual mouse (represented by different symbols) of both TEG001 (filled symbol) and TEG-LM1 mock (open symbol) group (n = 3 mice/group).

Figure 6 Cytopathology analysis of bone marrow and histopathology analysis of mouse vital organs (spleen, liver, intestine). **(A)** Representative picture of May-Grünwald Giemsa staining for bone marrow cytopsin from both treatment groups (TEG001 and TEG-LM1 mock) with pleomorphic population of cells with all maturation stages including numerous blasts (B), promyelocytes (Pr), dysplastic immature cells (DiC), megakaryocytes (Mk) and a mixed population of myeloid and erythroid (E) lineages; **(B)** Representative pictures for H&E staining of mouse spleen for both treatment group (TEG001 and TEG-LM1 mock) with non-neoplastic, lympho/histiocytic hyperplastic lesion with mitotic figure (arrows), apoptotic bodies (arrowhead) and erythroid precursors (*). Magnification: 40X; **(C)** Representative pictures for H&E staining of mouse liver for both treatment group (TEG001 and TEG-LM1 mock) with small focus of extramedullary hematopoiesis (arrows) in all samples, which could be due to the mouse model with engraftment of human CD34+ progenitor cells. Magnification: 20X; **(D)** Representative pictures for H&E staining of mouse intestine for TEG001 treated group (left) showing multifocal lymphocytic infiltration of lymphoid cells (arrows) in a small tract of the small intestine (background lesion) and TEG-LM1 mock-treated group (right) with normal jejunum. Magnification: 10X. Shown are representative pictures from an individual mouse of both TEG001 and TEG-LM1 mock group (n = 3 mice/group) with no significant differences in overall cytopathology and histology features between treatment groups.

With TEG001, a next level of complexity is introduced due to the nature of the target. In contrast to, e.g., CD19-directed CAR T gene therapy, which targets a very well-defined protein expressed on cancer cells and B cells (5), TEG001 is targeting metabolic changes in stressed and malignant cells, driven by a dysregulated mevalonate pathway (11). Although transfer of conventional $\gamma\delta$ 2T cells has not been reported to associate with substantial toxicity (13), the TEG concepts express an activating $\gamma\delta$ 2TCR outside the context of its natural brakes, through a plethora of killer immunoglobulin-like receptor (KIR) inhibitory receptors usually operational in natural $\gamma\delta$ 2T cells. Therefore, Dutch authorities have required additional safety tests for TEG001 prior to clinical testing. However, dysregulated metabolic pathways do not allow for high throughput evaluations of the ligand in all tissues through, e.g., gene expression or transcriptome analyses (30). Consequently, following the advice of the Dutch authorities, our group developed different strategies to test the efficacy and safety of TEG001 in models where healthy and malignant cells are present either simultaneously or sequentially. One such model is a 3D bone marrow model where primary multiple myeloma cells grow out along with healthy stromal cells into an artificial bone marrow niche. Upon TEG001 injection, this model confirmed the activity of TEG001 against the malignant fraction, but not healthy bystander cells present in the bone marrow niche (24). However, the 3D bone marrow niche is also limited, as it does not allow for engrafting of the complex hematopoietic system and or assessing toxicity against all cellular compartments usually generated from a hematopoietic stem cell.

To study the interaction between tumor and immune cells, we have to consider also their interaction within the same microenvironment. Xia and colleagues (31) develop humanized mice model with human hematopoietic system and autologous leukemia in the same individual mouse. This model is developed by transducing CD34⁺ fetal liver cells with retroviral vector containing mixed-lineage leukemia MLL-AF9 fusion gene, which allows recapitulation of human leukemic diseases (31, 32). Although it would be interesting to develop a similar humanized mouse model in which healthy human hematopoietic cells and primary leukemic blasts presence in the same individual mouse, the availability of healthy human CD34⁺ progenitor cells from the very same leukemia patient is a limiting factor. Hence, we develop two separate mice models and thereby avoiding limiting criteria of HLA-matching between healthy CD34⁺ progenitor cells and primary AML donors.

In order to test the efficacy of TEG001, we utilized a mouse xenograft model, which has been widely used to study therapeutic responses in heterogeneous diseases such as cancer. PD-X models, considered to closely mimic human diseases, are established by engrafting primary patient material into immunodeficient mice (33). Assessment of AML burden in mouse xenograft models is commonly performed by measuring the percentage of human leukemic cells in bone marrow at the end of study period. In this study, we developed a stringent treatment model where we infused TEG001 upon the onset of the disease (represented by an arbitrary threshold of 500 AML cells/ml detected in peripheral blood). Moreover, we developed an elegant method that allowed us to

follow the disease progression for a longer period as well as the treatment effect to reduce tumor burden over time by measuring AML cells in peripheral blood. Nonetheless, we acknowledged some limitations in our method, such as variable engraftment rates commonly observed in PD-X model (34) and a low level of AML engraftment in peripheral blood of adult NSG mice as reported previously (35). In spite of these limitations, we were able to detect a significant reduction of AML cells in peripheral blood of TEG001-treated mice in comparison to the mock-treated group. Furthermore, we developed a separate PD-X model using NSG-SGM3 mice using the same primary AML blast from donor p25 to assess the influence of microenvironment towards TEG001 efficacy profile. NSG-SGM3 mice express human cytokines, including IL-3, GM-SCF, and SCF, and thereby supporting primary AML engraftment and their survival *in vivo* (25). Here we demonstrate that TEG001-treated group showed significantly lower AML burden in comparison to mock-treated group, despite the lack of tumor clearance. This could be due to the more protective microenvironment poses by NSG-SGM3 mice, which could hamper T cell access to target cells and therefore limit the ability of TEG001 to clear primary AML burden over time. Based on the overall data and thus as proof-of-principle we have demonstrated the efficacy profile of TEG001 against primary human AML in two independent models.

In order to assess the toxicity of TEG001 against the hematopoietic compartment in the very same model we engrafted NSG mice with CD34⁺ progenitor cells derived from healthy human cord blood donors. Reconstitution of hematopoietic cellular compartments when assessed in the peripheral blood occurred at different stages, in which CD14⁺ monocytes and CD19⁺ B cells significantly increased two weeks after progenitor cell injection, whereas CD3⁺ T cells reconstituted relatively slower, however no differences could be observed between TEG001 and mock-treated mice. Furthermore, we investigated whether TEG001 does affect hematopoietic compartments in different tissues, specifically spleen and bone marrow, at which progenitor cells should reside (36, 37). While we could find all equivalent cell subsets with comparable reconstitution for both treatment groups also in spleen and bone marrow, there were differences in the prevalence for CD14⁺ monocytes and CD19⁺ B cells in different tissues, however again with no difference between TEG001 and mock treated mice. Monocytes were found in higher numbers in the peripheral blood when compared to bone marrow and spleen, whereas B cells were prevalently observed in the periphery and spleen. This observation is in line with previous studies showing that the reconstitution of human hematopoietic stem cells in host mice commences predominantly with erythroid and myeloid cells, followed by lymphoid progenitor and lastly mature lymphocytes (38). Also, neither induction of cellular stress by irradiation nor exposure to inflammatory cytokines (i.e., IL-2 and IFN γ), or the presence of chemotherapy agent Cy/Flu alter RhoB translocation towards the cell membrane for healthy CD34⁺ progenitor cells, and thus no alteration of TEG001 recognition pattern. In addition, our data confirm that different tissue compartments are comprised of different types of immune cells; and show that TEG001 treatment did not influence this pattern. Thus TEG001 most likely does not affect homing of hematological subsets nor mediate hematopoietic toxicity, as suggested by our previous work

demonstrating that the mode of action is mainly observed in tumor cells and not in the healthy hematopoietic compartment (12, 19). The only physiological target of $\gamma\delta$ 2TCRs are professional antigen presenting cells (APC) like monocytes and dendritic cells in the presence of PAM (18), as also demonstrated in this study in the *in vitro* experiments. However, as reported previously, this recognition apparently fosters the maturation of APC and potentially broadens an adaptive immune response through epitope spreading (39) rather than promoting elimination of APC. In line with this assumption, we could still detect CD14⁺ monocytes reconstitution *in vivo* after transfer of TEG001.

CONCLUSION

In conclusion, our data suggest antitumor reactivity of TEG001 against primary AML blasts *in vivo*. While we concur that the absence of evidence is not equal to the evidence of absence and within the limitation of our current models where off-target activities cannot be excluded entirely, there are no data indicating an increased safety risk specific for TEG001. A GMP-compliant production of TEG001 has now been established (17, 40), and will be used in an ongoing phase I open-label dose escalation study to explore toxicity and activity of TEG001 in patients with primary refractory or relapsed acute myeloid leukemia, as well as patients with multiple myeloma.

Competing interest

JK received funding by Gadeta. JK and ZS are inventors on different patents with $\gamma\delta$ TCR sequences, recognition mechanism and isolation strategies. JK is CSO and shareholder of Gadeta.

Funding

Funding for this study was provided by ZonMW 43400003 and VIDI-ZonMW 917.11.337, UU 2013-6426, UU 2014-6790 and UU 2015-7601 and Gadeta to JK, and UU 2018-11393 to ZS and JK.

Acknowledgement

We thank M. Plantinga (UMC Utrecht, The Netherlands) for primary human cord-blood derived CD34⁺ materials and Halvard Boenig (Institute for Transfusion Medicine and Immunohematology, Goethe University, Frankfurt a. M., Germany) for providing feeder cells.

SUPPLEMENTARY MATERIALS AND METHODS

Cells and cell lines

Daudi and Phoenix-Ampho were obtained from ATCC (authenticated by short tandem repeat profiling/karyotyping/isoenzyme analysis). Daudi cells were cultured in RPMI media supplemented with 10% fetal calf serum (FCS) and 1% Pen/Strep. Phoenix-Ampho cells were cultured in DMEM media supplemented with 10% FCS and 1% Pen/Strep. All cells were passaged for a maximum of 2 months, after which new seed stocks were thawed for experimental use. Furthermore, all cell lines were routinely verified by growth rate, morphology, and/or flow cytometry and tested negative for mycoplasma using MycoAlert Mycoplasma Kit. Peripheral blood mononuclear cells (PBMCs) were isolated using Ficoll gradient centrifugation methods from buffy coats obtained from Sanquin Blood bank (Amsterdam, The Netherlands).

Primary materials

Primary AML blasts were obtained from biobank of University Medical Center Utrecht in accordance with good clinical practice and Declaration of Helsinki regulations. All patients gave their consent prior to storage in the biobank (TCBio 16-088). For *in vivo* experiments, apheresis material from primary AML material from donor p25 was depleted for CD3⁺ cells using human CD3 Microbeads (Miltenyi Biotec) per the manufacturer's protocol. Human CD34⁺ derived from cord blood of six healthy donors were isolated using anti-CD34 magnetic beads separation (Miltenyi Biotec), and are obtained as a kind gift from Dr. Maud Platinga (University Medical Center Utrecht).

Retroviral transductions of T cells

TEGs were produced as previously described (10). Briefly, packaging cells (Phoenix-Ampho) were transfected with helper constructs gag-pol (pHIT60), env (pCOLT-GALV) and pMP71 retroviral vectors containing both $\gamma\delta$ TCR chains separated by a ribosomal skipping T2A sequence, using EugeneHD reagent (Promega). Human PBMCs from a healthy donor were pre-activated with anti-CD3 (30 ng/mL; Orthoclone OKT3; Janssen-Cilag) and IL-2 (50 IU/mL; Proleukin, Novartis) and subsequently transduced twice with viral supernatant within 48 hours in the presence of 50 IU/mL IL-2 and 6 mg/mL polybrene (Sigma-Aldrich). TCR-transduced T cells were expanded by stimulation with anti-CD3/CD28 Dynabeads (500,000 beads/ 10^6 cells; Life Technologies) and IL-2 (50 IU/mL). Thereafter, TCR-transduced T cells were depleted of the non-engineered T cells.

Depletion of non-engineered T cells

Depletion of non-engineered T cells was performed as previously described (17). Briefly, $\gamma\delta$ TCRs transduced $\alpha\beta$ T cells were incubated with a biotin-labeled anti- $\alpha\beta$ TCR antibody (clone BW242/412; Miltenyi Biotec) and subsequently incubated with an anti-biotin antibody coupled to magnetic beads (anti-biotin MicroBeads; Miltenyi Biotec). Thereafter, the cell suspension was loaded onto an LD column and $\alpha\beta$ TCR⁺ T cells were depleted by MACS cell separation per the manufacturer's protocol (Miltenyi Biotec). After depletion, TEGs were expanded using T cell REP.

CFU assay

Colony formation unit assay: $0,125 \times 10^6$ primary AML blasts from donor p2 were pre-incubated with medium only with $1,25 \times 10^6$ TEG001 or bulk α BT cells (as mock T cells) in the presence of 100 μ M pamidronate (PAM) for 5 hours at 37°C prior to plating in Methylcellulose-based medium with recombinant cytokines (MethoCult™ H4434 Classic, StemCell Technologies). Cultures were incubated in 37°C at 5% CO₂ for 8 days and colonies were counted using an inverted microscope.

Flow cytometry analysis

The following antibodies were used for flow cytometry analysis: huCD45-PB (clone HI30, Sony Biotechnology), mCD45-APC (clone 30-F11, Sony Biotechnology), CD13-PECy7 (clone WM15, Sony Biotechnology), CD33-BV711 (clone WM33, Sony Biotechnology), pan- γ TCR-PE (clone IMMU510, Beckman-Coulter), CD3-AF700 (clone UCHT1, Biolegend), CD8-PerCPCy5.5 (clone RPA-T8, Biolegend), CD8-FITC (clone TPA-T8, BD Biosciences), CD4-FITC (clone TPA-R4, Biolegend), CD34-BV650 (clone 581, BD Biosciences), CD19-PerCPCy5.5 (clone HIB19, BD Biosciences), CD14-APCeFluor780 (clone 61D3, eBioscience). To exclude non-viable cells from the analysis, Fixable Viability Dye eFluor506 was used (eBioscience). All samples were analyzed on BD LSRFortessa using FACSDiva Software (BD Biosciences).

Assessment for human cell engraftment

Peripheral blood samples were obtained via cheek vein (max. 100-200 μ l/mouse) every 1-2 weeks. Human cells in peripheral blood were quantified using Flow-count Fluorospheres (Beckman Coulter). Red blood cell lysis was performed for blood samples using 1X RBC lysis buffer (Biolegend) before cell staining. Blood samples were stained with a mixed of antibody panels as listed above. Engraftment and tumor burden was measured in peripheral blood by quantifying for absolute cell number by flow cytometry using specific markers huCD45⁺CD13⁺CD33⁺ for primary AML blasts and huCD45⁺ for healthy progenitor cells, respectively. An arbitrary threshold of 500 cells/ml was chosen to represent established human cell engraftment.

Preparation of single cell suspensions

At the end of the study, bone marrow (mixed from tibia and femur) and spleen sections were isolated and processed into single cell suspension. Femur and tibia from the hind legs were collected; bone marrow cells were collected by centrifugation of the bones at 10,000 rpm for 15 seconds and resuspension of the cells in RPMI media. Bone marrow cells were also used to make cytopsin slides (1 million cells per slide per mouse) for further cytopathology analysis. A small section of the spleen was minced and passed through a 70 μ m cell strainer (BD); cells were washed in PBS and resuspended in RPMI media. A total of 500,000 cells were stained and analyzed for human hematopoietic cellular compartments by flow cytometry analysis (BD LSRFortessa). Human cells from spleen and bone marrow were measured by quantifying absolute cell number from total 500,000 cells using Flow-count Fluorospheres (Beckman Coulter) for each hematopoietic cellular compartment.

Table S1. Characterization of primary AML-patient samples

Donor	Classification ¹	% blast ²	Major phenotype	Cytogenetic	Risk classification
p1	Transformation of CML to myeloid blast crisis	80%	CD34 ⁺ , CD117 ⁺ , CD13 ⁺ , CD36 ⁺ , CD33 ⁺ , CD45 ^{low} , HLA-DR ⁺ , MPO ⁺ , CD19 ⁺ , CD22 ⁺ , cTdT ⁺ , CD79a ⁺	BCR-ABL1 fusion mRNA type Major (-t(9;22)(q34;q11))	N/A ³
p2	M5	47% blasts, 18% monocytic cells	Blasts: CD34 ⁺ , CD117 ⁺ , HDL-DR ⁺ , CD13 ⁺ , CD7 ⁺ , CD11c ⁺ , CD56 ⁺ , cCD3 ^{low} , cMPO ^{low} . Monocytic cells: CD36 ⁺ , CD14 ⁺ , CD11b ⁺ , CD13 ⁺ , CD33 ⁺ , HLA-DR ⁺ , CD3 ^{low} , CD56 ⁺	Monosomy chromosome 7	Poor
p4	M4eo	46%	CD34 ⁺ , CD117 ⁺ , CD45 ^{low} , CD33 ⁺ , CD13 ⁺ , HLA-DR ⁺ , CD38 ^{low} , CD65 ⁺ , cMPO ⁺ , cTdT ^{low}	Inversion chromosome 16 (inv(16)(p13q22))	Good
p6	AML with monocytic maturation	88%	CD45 ^{low} , CD33 ⁺ , CD11b ^{low} , CD11c ⁺ , CD15 ⁺ , CD36 ^{low} , CD65 ⁺ , CD4 ^{low} , CD117 ⁺ , HLA-DR ⁺ , CD38 ⁺ , CD56 ⁺ , CD113 ⁺ , CD79a ⁺	Complex karyotype	Very poor
p10	M4/M5 with extramedullary manifestations	50%	CD45 ^{low} , CD117 ^{low} , cMPO ^{low} , CD13 ⁺ , CD33 ⁺ , CD38 ⁺ , HLA-DR ⁺ , CD11b ^{low} , CD36 ⁺ , CD65 ⁺ , CD4 ^{low}	Normal karyotype No abnormalities detected	Poor
p13	M5	85%	CD45 ^{low} , CD33 ⁺ , CD38 ⁺ , CD4 ^{low} , CD11c ⁺ , cCD79a ⁺ , cMPO ⁺ , CD14 ⁺ , CD13 ⁺ , CD36 ⁺ , HLA-DR ⁺ , CD11b ⁺ , CD65 ⁺	MLL-MLLT3 fusion mRNA, 46XY, (t(9;11)(p21;q23))	Poor
p25	M5A	96%	CD45 ^{low} , cMPO ⁺ , CD34 ⁺ , CD117 ⁺ , CD33 ⁺ , CD13 ⁺ , CD38 ⁺ , HLA-DR ⁺ , CD36 ⁺ , CD14 ⁺ , CD15 ⁺ and CD11b ⁺	Extra chromosome 8 No other abnormalities	Poor

ABSTRACT

$\gamma\delta$ T-cells are key players in cancer immune surveillance due to their ability to recognize malignant transformed cells, which makes them promising therapeutic tools in the treatment of cancer. However, the biological mechanisms of how $\gamma\delta$ T-cell receptors (TCR) interact with their ligands are poorly understood. Within this context we describe a novel allo-HLA-restricted and CD8 α -dependent V γ 5V δ 1TCR. In contrast to the previous assumption of the general allo-HLA reactivity of a minor fraction of $\gamma\delta$ TCRs, we show that classical anti-HLA-directed $\gamma\delta$ TCR mediated reactivity can selectively act towards hematological and solid tumor cells, while not harming healthy tissues *in vitro* and *in vivo*. We identified the molecular interface with close proximity to the peptide-binding groove of HLA-A*24:02 as the essential determinant for recognition and describe the critical role of CD8 as co-receptor. We conclude that allo-reactive $\gamma\delta$ T-cell repertoires provide therapeutic opportunities either within the context of haplo-transplantation or as individual $\gamma\delta$ TCRs for genetic engineering of tumor reactive T-cells.

INTRODUCTION

Human immunity is organized by interacting innate and adaptive immune subsystems that elicit a fast or durable response respectively. $\gamma\delta$ T-cells are situated between the innate and adaptive immune systems as they share properties of both systems, illustrated by their ability to recognize malignant transformed (1), or infected (2) cells, to clonally expand, and to form memory (3). Recently, the important biological role of $\gamma\delta$ T-cells in cancer immune surveillance has been further highlighted by the fact that $\gamma\delta$ T-cells infiltrate various tumors (4, 5). However, the biological understanding of cancer immune surveillance and potential clinical applicability of $\gamma\delta$ T-cells, or their individual receptors, is substantially hampered by the lack of well-defined $\gamma\delta$ T-cell receptor (TCR) ligands as well as their precise molecular requirements for recognition (6). $\gamma\delta$ T-cell ligands that have been identified so far are mostly associated with metabolic changes in stressed cells, e.g. V γ 9V δ 2 T-cells, the major subset of $\gamma\delta$ T-cells in the periphery, are activated by cells with an increase of intracellular phosphoantigens caused by a dysregulated mevalonate pathway due to transformation or infection (7, 8). $\gamma\delta$ T-cell that do not express a V δ 2-chain, collectively called V δ 2-negative $\gamma\delta$ T-cells, are mainly found in tissues and are activated by stress-related ligands such as EPCR (9), MICA (10), and Annexin A2 (11). Furthermore, CD1c and CD1d can present self and foreign lipid antigens to V δ 2-negative $\gamma\delta$ T-cells in a classical $\alpha\beta$ T-cell HLA-like fashion (12). Since ligands of both V δ 2-positive and V δ 2-negative $\gamma\delta$ T-cells are to some extent constitutively expressed on healthy cells, it remains unclear how exactly the balance between self and tumor or infection is orchestrated. Recent data suggests that receptors, such as V γ 9V δ 2TCRs, modulate the delicate line between healthy and diseased tissue by sensing spatial and conformational changes of membrane expressed CD277, which occurs in transformed cells (8, 13). To exploit $\gamma\delta$ T-cells or their receptors as therapeutic tools, the understanding of the localization and structure of the ligands during stress or transformation needs to be understood. Furthermore, identifying new $\gamma\delta$ TCR ligands restricted to stressed or transformed cells is valuable for developing therapies for unmet medical needs. Within this context, we aimed to identify a potential ligand of a V δ 1-positive $\gamma\delta$ T-cell clone, which has been classified as reactive against different tumor cell types, as well as to understand the molecular interaction of this receptor with its ligand (2).

MATERIALS AND METHODS

Cells lines and Flow cytometry (see supplementary methods)

Generation of $\gamma\delta$ T-cell clone FE11

Clone FE11 was generated as described in a previous publication (2).

Cloning NEF134-144 and WT1126-134 -specific α BTCTRs

The HLA-A*02:01 restricted WT1₁₂₆₋₁₃₄-specific α BTCTR (14) and HLA-A*24:02 restricted NEF₁₃₄₋₁₄₄ α BTCTR (Clone C1-28 (15)) were codon-optimized, synthesized at BaseClear (Leiden, The Netherlands) and subcloned into the retroviral pBullet vector.

Retroviral transduction of TCRs

Details are provided in supplementary methods and our previous publication (16).

Retroviral transduction of HLA

Phoenix-ampho retroviral packaging cells were transduced with pLZRS-A*02:01-IRES-NGFR or pLZRS-A*24:02-IRES-NGFR and the retroviral packaging plasmids gag-pol (pHIT60) and env (pCOLT-GALV) using Fugene-HD. The HLA plasmids were kindly provided by Marieke Griffioen (Leiden University Medical Centre, the Netherlands).

CRISPR/Cas genome editing

The B2m gene-specific regions of the gRNA sequence (GAGTAGCGCGAGCACAGCTA) was designed by the CRISPR design tool from the Zhang lab (<http://crispr.mit.edu/>). As control gRNA, the eGFP gene was targeted (GGAGCGCACCATCTTCTTCA). The pSicoR-CRISPR-Cas9 vector used was a kind gift from Robert Jan Lebbink (University Medical Center Utrecht, The Netherlands). LCL-TM cells were transduced with the viral supernatants, knockdown of B2M was confirmed by flow cytometry.

Functional T cell assays

IFN γ ELISA and ELISPOT were performed as previously described (2, 16) and in supplementary methods.

Flow cytometry FRET

To study dimerization of HLA, cells were labelled with Alexa594-conjugated α -HLA-A (donor) and Alexa647-conjugated α -HLA-A (acceptor), respectively. The donor fluorescence was measured using a FACS LSRFortessa flow cytometer (BD) where donor fluorescence of the double-labeled healthy samples was compared with that of the double-labeled malignant samples. FRET efficiency was calculated from the fractional decrease of the donor fluorescence in the presence of the acceptor, using the equations as described by Sebestyen and colleagues (17). Correction factors for the spectral overlap between the different fluorescence channels were obtained from data measured on unlabeled and single-labeled cells.

Animal model

The NOD.Cg-Prkdc^{scid}Il2rg^{tm1Wjl}Tg(HLA-A24)3Dvs/Sz (NSG-A24) mice (18) were kindly provided by Leonard D. Shultz (The Jackson Laboratory, Bar Harbor, ME, USA). C57BL/6 mice were purchased from Janvier (Le Genest-Saint-Isle, France). All mice were bred and housed in the specific pathogen-free breeding unit of the Central Animal Facility of Utrecht University. Experiments were conducted according to institutional guidelines after acquiring permission from the local ethical committee and in accordance with

current Dutch laws on animal experimentation. NSG-A24 mice received sublethal total body irradiation on day -1 followed by intravenous injection of $0,1 \times 10^6$ K562-HLA-A*24:02 luciferase tumor cells on day 0, after which they were treated with 1×10^7 TEG011 or Mock TCR transduced T-cells on days 1 and 6. IL-2 (6×10^5 IU in 100 μ l incomplete Freund's adjuvant) was administered subcutaneously once every 3 weeks.

Statistical Analyses

Differences were analyzed using indicated statistical tests in GraphPad Prism 7 for Windows (GraphPad Software Inc., La Jolla, CA, USA).

RESULTS

Tumor specificity of V γ 5V δ 1T-cell clone can be transferred to $\alpha\beta$ T-cell by transfer of the $\gamma\delta$ TCR only.

To confirm the tumor reactivity of the recently identified tumor specific $\gamma\delta$ T clone FE11 (2), the clone was co-incubated with SW480 (colorectal adenocarcinoma), EBV-LCL (Epstein-Barr virus-transformed lymphoblastoid cell line), and healthy PBMCs, leading to recognition, as measured by interferon (IFN) γ ELISpot, of the 2 tumor cells lines but not the healthy PBMCs (Figure 1A). Next, both the γ and δ chain of $\gamma\delta$ T-cell clone FE11 were sequenced, identified as a V γ 5V δ 1 TCR, and cloned into pBullet retroviral vector and subsequently introduced into $\alpha\beta$ T-cells as previously described (16). Taking the $\gamma\delta$ TCR out of the innate-like environment enabled us to study the functioning of the receptor without interference of NK-receptors, which are not present on $\alpha\beta$ T-cells (19, 20). This strategy we have recently described as TEGs (T-cells engineered to express a defined $\gamma\delta$ T-cell receptor (19, 21, 22)). Introduction of FE11 $\gamma\delta$ TCR in $\alpha\beta$ T-cells (later referred to as TEG011) resulted as reported in a strong expression of the introduced FE11 $\gamma\delta$ TCR and a substantial downregulation of the endogenous $\alpha\beta$ TCR with many cells becoming single positive for the expression of the introduced $\gamma\delta$ TCR (Supplementary Figure 1). This led to a comparable recognition of target-cells when comparing TEG011 to the original clone FE11 (Figure 1B), indicating that tumor-reactivity is mediated by the $\gamma\delta$ TCR and independent of (epi)genetic factors exclusively present in the original T cell clone.

Figure 1 Introduction of FE11 $\gamma\delta$ TCR in $\alpha\beta$ T-cells can re-establish tumor cell recognition of clone FE11. **(A)** To assess tumor reactivity, FE11 cells were incubated with SW480 or EBV-LCL tumor targets. IFN γ secretion was measured by ELISPOT. Healthy PBMCs served as negative control targets. **(B)** The TCR γ and δ chains of clone FE11 were sequenced and retrovirally transduced into $\alpha\beta$ T-cells. Transfer of $\gamma\delta$ TCR-mediated tumor-reactivity was tested by co-incubating $\gamma\delta$ TCR- or mock-transduced T-cells with indicated target-cells in an IFN γ ELISpot. **(C)** The effect of blocking with FE-11 like hybridoma supernatant on the recognition of SW480 and LCL-TM by FE11 $\gamma\delta$ TCR transduced T cells. **(D)** LABScreen Single Antigen HLA class I beads were incubated with antibodies purified from hybridoma 6 (mAb 6) or antibodies purified from hybridoma 12 (mAb 12) and secondary α -mIgG-PE and measured using Luminex. Error bars represent SD ($n \geq 1$).

Hybridoma-derived antibodies indicate a role for classical HLA molecules.

The observation that the FE11 $\gamma\delta$ TCR by itself recognizes multiple tumor cell lines but not healthy PBMCs, was highly interesting. We aimed to identify the ligand of the FE11 $\gamma\delta$ TCR by generating TCR-like antibodies by the immunization of C57BL/6 mice with complete tumor cell lines SW480 and LCL-TM that were recognized *in vitro* by TEG011. From the hybridomas generated, 19 clones were isolated that produced antibodies that specifically bound FE11 $\gamma\delta$ TCR reactive tumor cells in an antibody binding screen. To further determine the ligand specificity of the antibodies, the FE11 targets SW480 and LCL-TM were pre-incubated with supernatants from these hybridomas and subsequently used in co-cultures to stimulate TEG011. 13 out of the 19 antibodies (i.e. hybridoma supernatants) blocked the activation of the TEG011 substantially, as measured by IFN γ ELISpot (Figure 1C). These data suggest that the majority of the raised antibodies were able to partially or completely prevent the binding of the FE11 $\gamma\delta$ TCR to its ligand. In contrast, none of the 19 hybridomas produced an antibody that could block the recognition of WT1₁₂₆₋₁₃₄ (HLA-A*02:01) peptide loaded SW480 by α BT-cells engineered with a WT1₁₂₆₋₁₃₄-specific α BTCTCR (Supplementary Figure 2A), suggesting that the blocking was not induced via binding to other molecules expressed on an α BT-cell than the introduced $\gamma\delta$ TCR (23). From the 19 hybridomas, one antibody that completely blocked activity (clone 6) and one that partially blocked activity (clone 12) (from here on named mAb6 and mAb12) were arbitrarily selected for the array of options for antibody production and purification. These purified antibodies were coupled to streptavidin beads and subsequently used for ligand-immunoprecipitation in cell lysates of either SW480 or LCL-TM cells. Mass spectrometry analysis resulted in the identification of a panel of mostly classical HLA molecules (Supplementary Table 1) suggesting that, in contrast to the general assumption, classical HLA molecules may be involved in recognition of tumor cells by this particular $\gamma\delta$ TCR. To confirm that raised antibodies are specific for classical HLA, we incubated LABScreen Single Antigen HLA class I beads (24) with mAb6 and mAb12 and measured the beads by Luminex to determine HLA-specificity. Figure 1D shows that mAb6 has a reactivity to a defined subgroup of HLA-A alleles, while mAb12 displayed no specificity, reacting towards all HLA class I alleles, including HLA-B and HLA-C, present on the LABScreen beads.

Target cell recognition by the FE11 $\gamma\delta$ TCR is critically dependent on HLA-A*24:02.

The raised antibodies were able to bind a broad range of different HLA types. To further narrow down the type of HLA recognized by $\gamma\delta$ TCR-FE11, we made use of the library of cell lines from the Centre d'Etude du Polymorphisme Humain (CEPH), which contains a large collection of EBV-transformed B-cell lines (EBV-LCLs) obtained from several family pedigrees with a large variety of HLA haplotypes (25). TEG011 was co-incubated with 7 different CEPH EBV-LCLs, covering multiple possible HLA molecules as suggested by the LABScreen beads (Figure 1D), Daudi and LCL-TM, and reactivity was assessed by measuring IFN γ -release. Correlating reactivity of TEG011 to the different HLA types from a large panel of LCL line covering many frequent HLA types suggested that uniquely the HLA-A*24:02 haplotype, but not HLA-A*02:01 or HLA-A*03:01 (Figure 2A and Supplementary Table 2), was involved in the recognition. To formally confirm HLA-A*24:02

mediated recognition we retrovirally introduced either HLA-A*24:02 or HLA-A*02:01 (as control) into the HLA negative cell lines COS-7 and K562. In both cell lines, introduction of HLA-A*24:02, but not HLA-A*02:01, resulted in strong activation of TEG011 (Figure 2B). Additionally, we found that the density of the ligand HLA-A*24:02 on target-cells was associated with the activity of TEG011, since reactivity of TEG011 was higher against cell lines homozygous for HLA-A*24:02 than against heterozygous cell lines (Figure 2C).

Figure 2 Activation of FE11 $\gamma\delta$ TCR transduced T-cells is dependent on expression of HLA-A*24:02. (A) Activation of T-cells, transduced with FE11 $\gamma\delta$ TCR by EBV-LCLs with different HLA genotypes. (B) Activation of T-cells, transduced with FE11 $\gamma\delta$ TCR by HLA-A*24:02 or HLA-A*02:01 target-cells. (C) Activation of T-cells, transduced with FE11 $\gamma\delta$ TCR by EBV-LCLs with different either homozygous or heterozygous HLA-A*24:02 expression. (D) Total HLA class I expression of HLA-A*24:02 positive and negative EBV-LCLs compared to TEG011 recognition (E) The effect of B2m KO of HLA-A*24:02 target-cells on the activation of FE11 $\gamma\delta$ TCR transduced T-cells. (F) Activation of T-cells, transduced with FE11 $\gamma\delta$ TCR by K562 HLA-A*24:02 cells untreated or overnight monensin incubation. (G) Activation of Jurma cells, transduced with FE11 $\gamma\delta$ TCR or $\alpha\delta$ TCR WT1126-134 (control) by LCL-TM or A2 restricted WT1126-134 pep. loaded T2 cells. CD3 crosslinking by plate-bound α -CD3 mAb clone OKT-3 served as positive control. Recognition was assessed by measuring IFN γ secretion using ELISA. Error bars represent SD ($n \geq 1$).

Major differences in HLA expression could therefore contribute to the differential recognition between healthy cells and tumor cells. Therefore, HLA class I expression was measured of multiple HLA-A*24:02 heterozygous and negative LCLs as well as HLA-A*24:02 positive PBMC. However, no correlation was observed for small variations between the total HLA class I expression and TEG011 targeting within these LCLs indicating that only the expression levels of HLA-A*24:02 are associated with TEG011 targeting (Figure 2D). Also no substantial differences in HLA expression between PBMCs and recognized LCL have been observed. A partial CRISPR/Cas9 KO of B2-microglobulin within recognized LCLs, reduced activation of TEG011 (Figure 2E and Supplementary Figure 2B) as expected. In addition, a substantial reduction of HLA expression on the cell membrane by monensin, a protein transport inhibitor, resulted in a decreased recognition of target-cells (Figure 2F). TEGs have been reported to lose allo-reactivity due the down regulation of the endogenous $\alpha\beta$ TCR due to dominance of the introduced $\gamma\delta$ TCR (21). However, in order to formally exclude any activity of endogenous $\alpha\beta$ TCR within the TEG format, we introduced either FE11 $\gamma\delta$ TCR or $\alpha\beta$ TCR- WT1₁₂₆₋₁₃₄ (as control) into the TCR β -negative Jurma cell line. The transduced Jurma cells were then co-incubated with WT1₁₂₆₋₁₃₄ peptide loaded T2 or LCL-TM tumor cells, and target-specific activation of Jurma cells was determined by measuring the activation marker CD69 by flow cytometry. As anticipated, FE11 $\gamma\delta$ TCR transduced Jurmas were only activated by the HLA-A*24:02 expressing LCL-TM, while the $\alpha\beta$ TCR-WT1₁₂₆₋₁₃₄ transduced Jurmas were only activated by WT1₁₂₆₋₁₃₄ loaded T2 cells (Figure 2G). In conclusion, target cell recognition by the FE11 $\gamma\delta$ TCR is critically dependent on and restricted to HLA-A*24:02.

The FE11 $\gamma\delta$ TCR selectively recognizes HLA-A*24:02 expressed in malignant but not healthy cells.

Allo-HLA reactivity is usually a phenomenon restricted to HLA on all cells of an individual (26). To assess if recognition is limited to HLA-A*24:02-positive transformed cells, we co-incubated TEG011 with healthy primary T-cells which were either positive or negative for HLA-A*24:02. In contrast to HLA-A*24:02-positive tumor cells, healthy primary cells were not recognized by TEG011, even when they were positive for HLA-A*24:02. B-cells isolated from multiple, healthy donors were not able to activate TEG011 even after being stressed by irradiation or by combination treatment of cyclophosphamide and fludarabine. Activation of these B-cells by administration of either LPS or CD40L and IL-4 also did not led to recognition by TEG011. This indicates that the expression of HLA-A*24:02 allele in combination with a malignant transformation is essential for the activation of TEG011 (Figure 3A and Supplementary Figure 3A). To further exclude recognition of healthy tissues in the absence or presence of stress or infection in epithelial tissues, HLA-A*24:02 positive fibroblasts were co-cultured with either TEG011 or T-cells transduced with the HLA-A*24:02 restricted NEF₁₃₄₋₁₄₄ $\alpha\beta$ TCR.¹⁵ TEG011 did not recognize the HLA-A*24:02 fibroblast being stressed by either irradiation or administration of cyclophosphamide and fludarabine. In addition, CMV infection of these fibroblasts did not induce activation of the TEG011 while the NEF₁₃₄₋₁₄₄ $\alpha\beta$ TCR transduced T-cells were able to recognize the fibroblasts in all conditions (Figure 3B and Supplementary Figure 3B). To finally confirm that malignant transformation is essential for recognition by TEG011

in an autologous system, HLA-A*24:02-positive B-cells were immortalized by using EBV transformation and did activate TEG011, while the non-transformed PBMCs of the very same donor were not recognized (Figure 3C).

Figure 3 Activation of FE11 $\gamma\delta$ TCR-transduced T cells is limited to HLA-A*24:02⁺ malignant cells. **(A)** Activation of TEG011 cells by malignant and healthy hematological cells. B cells from multiple HLA-A*24:02⁺ donors were activated or stressed before the TEG011 cell coculture. **(B)** TEG011 or NEF134-144 $\alpha\beta$ TCR-engineered $\alpha\beta$ T-cell recognition after coculture with HLA-A*24:02⁺ healthy tissues. When using NEF₁₃₄₋₁₄₄ $\alpha\beta$ TCR-engineered $\alpha\beta$ T cells, 10 mM NEF₁₃₄₋₁₄₄ was added. **(C)** Healthy donor B cells (HD1) were EBV transformed and cocultured with TEG011. Recognition was assessed by measuring IFN- γ secretion using ELISA. Error bars represent the SD ($n \geq 2$). * $P < .05$. Cyclo, cyclophosphamide; Fluda, fludarabine.

Figure 4 Activation of FE11 $\gamma\delta$ TCR-transduced T cells is dependent on the presence of a specific HLA-A*24:02-restricted peptide. (A) Activation of TEG011 by HLA-A*24:02-positive or -negative target cells. (B) The differences between HLA-A*02:01 and HLA-A*24:02 mapped on the structure of HLA-A*24:02 (Protein Data Bank: 3w19), the 2 nonhomologous amino acids between HLA-A*24:02 and HLA-A*24:03 are shown in the red circle (top). Alignment of HLA-A*24:02, 02:01, 24:03, and 25:01 with the 2 nonhomologous

Figure 4 (Continued) amino acids in red (bottom). (C) Activation of T cells, transduced with $\gamma\delta$ TCR-FE11, by HLA-A*24:02-transduced, TAP-deficient T2 cells not loaded or loaded with the A*24-restricted viral peptides NEF₁₃₄₋₁₄₄ or CMV₃₄₁₋₃₄₉ (pp65 341-349). (D) WT1₁₂₆₋₁₃₄ tetramer, NY-ESO1₁₅₇₋₁₆₅ pentamer, and CMV₃₄₁₋₃₄₉ pentamer binding to WT1₁₂₆₋₁₃₄-specific TCR, NY-ESO1₁₅₇₋₁₆₅-specific TCR, and FE11 TCR-transduced T cells. (E) The effect of bortezomib treatment of HLA-A*24:02-transduced target cells COS-7 (left) and K562 (right) on the activation of FE11 $\gamma\delta$ TCR-transduced T cells. (F) Homodimerization was assessed on HLA-A*24:02⁺ cells, recognized and not recognized by flow cytometry FRET. (G) Activation of TEGs (left) or T cells transduced with the WT1₁₂₆₋₁₃₄-specific α 8TCR (control) (right), by HLA-A*24:02-transduced COS-7 and K562 cells or HLA-A*02:01 (control). *Out of range. (H) Proximity Ligation Assay (PLA) was performed on HLA-A*24:02⁺ fibroblasts and the SW480 cell line. Cells were stained for 4',6-diamidino-2-phenylindole and PLA signal. Where indicated, target cells were fixed before coincubation; target cells were coincubated with WT1126-134. Error bars represent the SD ($n \geq 1$).

Identification of a putative binding-site of the FE11 $\gamma\delta$ TCR.

In order to further map the putative binding site of FE11, CEPH EBV-LCLs expressing HLA alleles from different supertypes were tested (i.e. HLA-A*25:01 from supertype HLA-A01 and HLA-A*02:01 from supertype HLA-A02) (27). Additionally, CEPH EBV-LCLs expressing an HLA allele within the same supertype as HLA-A*24:02 (supertype HLA-A24; HLA-A*24:03) was tested. Reactivity of TEG011 could only be observed towards the HLA-A*24:02-positive cells, not towards the strong homologous HLA-A*24:03 present on EBV-LCL-71 (Figure 4A). Sequence alignment (Figure 4B, lower part) revealed that the two amino acids on the α 2 helix at position 168 and 169 (asparagine and glycine respectively) are non-homologous between HLA-A*24:02 and the non-recognized HLA alleles, indicating that these residues are key for recognition of HLA-A*24:02 by TEG011. Structural analyses of the putative binding sites at position 168 and 169 indicated a very close proximity to the peptide binding groove (Figure 4B, upper part).

Promiscuous peptides are necessary for HLA-A*24:02 recognition by $\gamma\delta$ TCR-FE11.

Due to this close proximity of the putative binding site to the peptide binding groove, we explored the role of a peptide in the recognition of HLA-A*24:02 by the FE11 $\gamma\delta$ TCR. The cell line T2, which is deficient in TAP-dependent endogenous peptide processing and presentation in HLA molecules, was transduced with HLA-A*24:02 and HLA-A*02:01 (control) and loaded with HLA-A*24:02 restricted NEF₁₃₄₋₁₄₄ and HLA-A*02:01 restricted WT1₁₂₆₋₁₃₄ peptides respectively. In order to confirm the successful loading of HLA molecules with peptides, stabilization of HLA on the surface of T2 cells was assessed by flow cytometry (Supplementary Figure 4A). HLA-A*24:02 transduced T2 cells externally loaded with NEF₁₃₄₋₁₄₄ or CMV₃₄₁₋₃₄₉ did not lead to activation of TEG011, indicating that the presence of HLA-A*24:02 alone is not sufficient when expressed on T2 cells, but that the presentation of an endogenously processed peptide could be key to establish reactivity (Figure 4C). In order to confirm this hypothesis, we co-incubated TEG011 with a CMV₃₄₁₋₃₄₉ HLA-A*24:02 restricted pentamer. Whereas the controls, WT1₁₂₆₋₁₃₄ and NY-ESO1₁₅₇₋₁₆₅ α 8TCR-transduced T-cells with their respective tetramer or pentamer stained positive (Figure 4D), TEG011 was not stained by the HLA-A*24:02 pentamer. These data suggest that the observed recognition is not caused by classical alloreactivity and most likely involves either promiscuous peptides to stabilize the complex or a specific peptide as a critical determinant for recognition.

To further assess whether endogenously processed peptides are essential for reactivity, we interfered with the cellular peptide processing machinery by inhibiting the proteasome of recognized tumor cells by pre-treatment with Bortezomib (28). Bortezomib treatment lead to a strong decrease in recognition of both HLA-A*24:02 transduced COS-7 and K562 cells (Figure 4E) by TEG011, suggesting that peptides are at least needed for stabilization of the complex. To explore if transformation-associated peptides are involved in recognition, we selected 15 transformation-associated peptides (29-35) to load HLA-A*24:02 transduced T2 cells (Supplementary Figure 4B and Supplementary Table 2) and assessed the recognition by TEG011. None of the 15 peptides lead to activation of TEG011 (Figure 5A). Vice versa, we outcompeted the putative endogenous peptide recognized by TEG011 with NEF₁₃₄₋₁₄₄ WT peptide and NEF₁₃₄₋₁₄₄ mutants. NEF₁₃₄₋₁₄₄ mutants were designed by changing the four amino acids which are facing out of the HLA binding groove (Figure 5B). The four amino acids were substituted for the negatively charged amino acid glutamic acid (E), the positively charged amino acid arginine (R), and the smallest amino acid; glycine (G). At least part of these modified peptides could

Figure 5 Recognition of LCL-TM cells cannot be outcompeted by peptides. (A) T2 cells were transduced with HLA-A*24:02 and loaded with 10 mM of 15 different transformation-associated peptides (supplemental Table 1), after which they were coincubated with TEG011 cells. Activation of TEG011 cells was assessed by measuring IFN- γ production. (B) The 4 residues of NEF₁₃₄₋₁₄₄ that are pointed out of the peptide binding groove of HLA-A*24:02 are indicated. (C) Ten micromoles of the generated NEF₁₃₄₋₁₄₄-derived mutant peptides were loaded on LCL-TM cells, after which they were coincubated with TEG011 cells. (D) HLA-A*24:02-transduced K562 cells were loaded with 10 mM NEF₁₃₄₋₁₄₄ before loading with increasing concentrations of an HLA-A*24:02-restricted MiHA peptide (K.F., unpublished data). The peptide-loaded cells were coincubated with TEG011 cells, α BT cells engineered with an HLA-A*24:02-restricted NEF₁₃₄₋₁₄₄-specific TCR or a MiHA specific α BT cell clone. T-cell activation was assessed by measuring IFN- γ . Error bars represent the SD ($n \geq 2$).

be loaded on LCL-TM cells (Supplementary Figure 5). Next, WT NEF₁₃₄₋₁₄₄ peptide and all different NEF₁₃₄₋₁₄₄ mutants were loaded on LCL-TM after which they were co-incubated with TEG011, followed by measurement of IFN γ . None of the peptides were able to decrease the recognition, indicating that the recognition mechanism is more elaborate than a standard α BTCR peptide-HLA interaction (Figure 5C) implying that recognition is not mediated by a specific peptide, but rather promiscuous peptides are involved as stabilizer of the complex. In order to assure that peptide loading truly outcompetes HLA-A*24:02 bound peptides, HLA-A*24:02 transduced K562 cells were first loaded with WT NEF₁₃₄₋₁₄₄ peptide and subsequently loaded with different concentrations of an HLA-A*24:02-restricted minor histocompatibility antigen (MiHA) peptide (unpublished data, K. Fuchs). Peptide loaded cells were then co-incubated with TEG011, α BTCR-cells engineered with an HLA-A*24:02-restricted NEF₁₃₄₋₁₄₄-specific or a T cell clone expressing a defined HLA-A*24:02 restricted MiHA-specific α BTCR. With increasing concentrations of MiHA peptides, α BTCR-cells engineered NEF₁₃₄₋₁₄₄-specific TCR showed a reduced cytokine release while TEG011 activity was not affected against the very same target (Figure 5D).

Conformational change as additional distinguishing factor for recognition.

The hypothesis that promiscuous peptides are involved as stabilizer of the complex was supported by the observations that HLA-A*24:02 was also recognized within the context of another species (monkey, COS-7 cell line). In addition, as usually small amounts of endogenously processed and presented peptides are sensed by TCRs, doubling the amount of HLA in a homozygous as compared to heterozygous target should not substantially affect recognition. However, increased amounts of HLA in homozygous individuals nearly doubled functional activity of TEG011, suggesting that rather the HLA-complex than individual peptide-HLA combination was recognized. Therefore, we hypothesized that an additional key-spatial or structural conformational change in HLA-A*24:02 occurs as a result of transformation of a healthy cell into a tumor cell. To elaborate on this hypothesis we used Förster resonance energy transfer (FRET) based flow cytometry as described before (17), to determine if HLA-A*24:02 clusters in the membrane of tumor cells. In line with this assumption, FRET analysis suggested different behavior of HLA in tumor and healthy tissues with HLA-A*24:02 homodimers on PBMCs and monomers on tumor cells (Figure 4F). In order to formally test if membrane mobility of HLA-A*24:02 is key for recognition by γ TCR-HLA but not α BTCR-HLA, we assessed the effect of para-formaldehyde fixation on the sensing of target-cells. Whereas the recognition of α BTCR WT1₁₂₆₋₁₃₄ transduced T-cells and WT1₁₂₆₋₁₃₄ peptide loaded target-cells was not affected by fixation, the interaction by TEG011 cells and HLA-A*24:02 transduced target-cells was completely abolished, indicating that there are differences requirements for TCR activation (Figure 4G). Altered HLA clustering on tumor cells as compared to healthy cells was also supported by a proximity ligation assay of HLA class I molecules which showed reduced HLA clustering in SW480 cells compared to HLA-A*24:02 fibroblasts (Figure 4H). In summary, our data support the notion that malignant transformation of cells leads to alterations in HLA clustering on the cell surface, which might be an additional factor sensed by TEG011.

FE11 $\gamma\delta$ TCR critically depends on the CD8 co-receptor for tumor recognition.

To further support the idea that indeed the $\gamma\delta$ TCR-HLA interaction differs from classical HLA- $\alpha\beta$ TCR interactions, we investigated the potential role of co-receptors. One obvious candidate, due to HLA class I restriction, was CD8 α . First, we formally confirmed CD8 expression on the original clone in line with previous reports ((2) and Figure 6A). Next, we assessed whether TEG011 is dependent on the co-expression of CD8, like the original clone, by sorting TEG011 on CD4 and CD8 expression before co-culturing with SW480, LCL-TM or PBMCs (Figure 6B). In contrast to the $\gamma\delta$ T-cell clone FE11, most $\alpha\beta$ T-cells express CD8 as a heterodimer of CD8 α and CD8 β for providing co-stimulation. The role of the CD8 $\alpha\beta$ heterodimer on TEG011 was assessed by using blocking antibodies for either the CD8 α or CD8 β chain. Not only CD8 α , but also CD8 β blocking antibodies completely inhibited recognition of SW480 (Figure 6C), indicating that either CD8 α or CD8 β is essential for recognition. These data have also been confirmed by comparing CD8-positive and CD8-negative Jurma cells expressing FE11 $\gamma\delta$ TCR (Figure 6D) or $\alpha\beta$ TCR WT₁₂₆₋₁₃₄ (control, Figure 6E). For co-stimulation of HLA class I-restricted $\alpha\beta$ TCRs, CD8 $\alpha\beta$ can play two different roles; it serves as an adhesion molecule that stabilizes the TCR-HLA interaction and it can play an activating role by signaling via LCK (36). On the other hand, CD8 α on $\alpha\beta$ T-cells has been described as a corepressor rather than a coreceptor by competing with CD8 $\alpha\beta$ for the LCK signaling molecule (37). To investigate the role of CD8 α for TEG011, we utilized a truncated variant of CD8 α

Figure 6 The FE11 $\gamma\delta$ TCR critically depends on the CD8 coreceptor for tumor recognition. (A) CD8 α or CD8 β expression on clone FE11 cells and FE11 $\gamma\delta$ TCR-transduced $\alpha\beta$ T cells. (B) CD4 $^{+}$ and CD8 $^{+}$ $\alpha\beta$ T cells transduced with the FE11 $\gamma\delta$ TCR were sorted and cocultured with mock (left) and TEG011 (right) target cells. (C) TEG011 T-cell activation was assessed by IFN- γ ELISPOT. CD4 $^{+}$ and CD8 $^{+}$ $\alpha\beta$ T cells expressing the FE11 $\gamma\delta$ TCR were coincubated with SW480 target cells as in panel B, but in the presence of a control antibody or blocking antibodies against CD8 α or CD8 β . (D) $\alpha\beta$ T cells were transduced with WT CD8 α or α truncated, signaling-deficient CD8 α variant (CD8 α ''), alongside the $\gamma\delta$ TCR-FE11, after which the CD4 $^{+}$, CD8 $^{+}$, CD4 $^{+}$ CD8 α '', and CD4 $^{+}$ CD8 α '+' T-cell populations were sorted. Recognition of healthy PBMCs and SW480 tumor target cells was assessed by measuring IFN- γ secretion using ELISPOT. Error bars represent the standard error of the mean ($n \geq 1$). * $P < .05$; ** $P < .01$; *** $P < .001$.

which is signaling deficient due to its inability to bind LCK (38). After introducing both FE11 $\gamma\delta$ TCR and truncated CD8 α (CD8 α') in CD4 $^+$ $\alpha\beta$ T-cells we co-cultured the TEGs with SW480. A decrease in the amount of IFN γ spots of the CD8 α' variant compared to the CD8 α wild type variant was observed (Figure 6F), indicating that CD8 α indeed plays a co-stimulatory role in TEG011.

Figure 7 TEG011 treatment leads to efficient tumor control of K562-HLA*A24 tumors, whereas it shows no toxicity *in vivo* in NSG-A24 transgenic mice. NOD.Cg-Prkdc^{scid}/Il2rg^{tm1Wjl} Tg(HLA-A24)3Dvs/Sz (NSG-A24:02) mice were injected with 1×10^5 K562 HLA-A*24:02 Luciferase cells on day 0 followed by 1×10^7 TEG011 or LM1 transduced T cells on days 1 and 6 ($n = 10$ per group). In parallel, non-tumor-bearing mice also received 1×10^7 TEG011 or LM1 transduced T cells on days 1 and 6 ($n = 5$ per group). Overall survival of treated K562-HLA*A24 luciferase tumor-bearing mice for monitoring efficacy (A) and overall survival of non-tumor-bearing mice for monitoring toxicity (B) was recorded for 57 days. Data represent the mean \pm SD of all mice in each group. Statistical significance was calculated by log-rank (Mantel-Cox) test; * $P < .05$.

Improved overall survival by TEG011

To determine safety and effectivity of TEG011 *in vivo* we set up a humanized HLA-A*24:02 transgenic NSG mouse model for adoptive transfer of TEG011. The irradiated mice were injected with luciferase labelled HLA-A*24:02 transduced K562 and either TEG011 or LM1 transduced T-cells as control. Mice were taken out of the study when the human endpoint was reached. A significantly increased overall survival as observed in TEG011 treated group when compared to mice treated with LM1 transduced T cells (Figure 7A). TEG011 treated mice had also a significantly lower tumor burden when assessed by Bioluminescent imaging (Supplementary Figure 6). Importantly, surviving TEG011-treated tumor-bearing mice showed no further signs of discomfort. Performing pathology in three selected tumor bearing mice treated with TEG011 showed no histological features of toxicity of TEG011, altogether indicating that HLA-A*24:02 positive tumor cells but not healthy cells were targeted by TEG011. Lack of toxicity of TEG011 *in vivo* in a HLA-A*24:02 host was further substantiated by injecting non-tumor bearing mice with TEG011 and LM1 engineered transduced T cells in humanized HLA-A*24:02 transgenic NSG mice, which stayed alive during the whole observation time without showing any signs of discomfort (Figure 7B).

DISCUSSION

The major finding of the study is that we identified an allo-reactive $\gamma\delta$ TCR which is able to distinguish between healthy and tumor tissues. Furthermore, we elucidated the molecular interface of the investigated V γ 5V δ 1TCR clone FE11 and provide evidence that, although the binding site is close to the peptide binding groove of HLA-A*24:02, transformation-associated HLA peptides do not dictate recognition between healthy and cancer tissues. Most likely, other key-conformational changes within the membrane selectively occurring to HLA on tumor cells but not on healthy tissues *in vitro* and *in vivo*, are responsible for the differential recognition between tumor and healthy cells.

Allo-HLA type of recognition by $\gamma\delta$ TCRs has been suggested both for HLA-A*02 (39), HLA-A*24 (40), and B*27 (41). These data suggest that our observation reflects a broader phenomenon, however might be linked to unique $\gamma\delta$ TCR sequences as we could not find back the sequence used for TEG011 in many HLA-A*24:02 positive and negative donors (n= 7 HLA-A*24:02, total n=23, data not shown). The underlying molecular mechanism has not been defined so far, in contrast to allo-reactivity of $\alpha\beta$ TCRs (42-44). Considering this, a $\gamma\delta$ TCR selectively recognizing tumor cells in an allo-HLA context seems to be plausible, however, our data suggests that the mode of action differs between allo-reactive $\alpha\beta$ TCRs. We characterized the essential contact residues of FE11 $\gamma\delta$ TCR with HLA-A*24:02, which appeared to be in close proximity to the peptide binding groove. Our data suggests that the FE11 $\gamma\delta$ TCR is able to recognize amino acids 168 and 169 on the α 2-helix of HLA-A*24:02, since these are the only non-homologous amino acids between recognized HLA-A*24:02 and non-recognized HLA-A*24:03 (45). Differences in recognition of the same peptide presented by HLA-A*24:02 and HLA-A*24:03 by CD8⁺ $\alpha\beta$ T-cells has been observed before (46). Thus, not only $\alpha\beta$ TCRs, KIRs, LILRs, and CD8 molecules (47), but also $\gamma\delta$ TCRs can bind to a specific part of HLA class I. However, our data also imply that, in contrast to recognition of HLA by an allo-peptide reactive $\alpha\beta$ TCR, promiscuous peptides are involved in mediating recognition by $\gamma\delta$ TCR-FE11. This assumption would also be an explanation for the activity of TEG011 against a very broad range of tumor cells, even though being a rare TCR sequence in humans.

Our HLA membrane topology data suggests that, instead of a defined tumor-derived peptide, another key spatial or conformational change like differences in clustering of HLA-A*24:02-molecules between tumor cells and healthy cells plays a role in mediating tumor-specificity. HLA clustering has mainly been studied within the context of HLA class II on antigen presenting cells, which does not necessarily depend on the presence of a T-cell (48). Clustering of HLA has been reported to be essential for the recognition of HLA-B*27 recognition through leukocyte immunoglobulin-like receptors B2 and killer cell immunoglobulin-like receptors 3DL2 (49, 50). HLA behavior on tumor cells has mainly been studied within the context of tumor immune escape by loss or downregulation of HLA class I expression (51). The here suggested preferential monomeric form of HLA at the cell membrane of tumor cells could be part of classical tumor escape mechanisms for $\alpha\beta$ T-cells, which can however be sensed by the here described allo-reactive $\gamma\delta$ TCR.

A major concern for using the allo-reactive FE11 $\gamma\delta$ TCR in a therapeutic scenario would be that, through the nature of promiscuous peptides as part of the recognition complex, safety is difficult to assess. To partially address this concern, we performed tumor control experiments in HLA-A*24:02 transgenic mice. In histological analyses we could not observe pathological evidence for auto-immunity in the investigated organs. Our observation is also supported by the clinical observation that $\alpha\beta$ T-cell depleted haplo-transplantations associate with very good tumor control and limited toxicity (52-54). Though for therapeutic scenarios the administration of TEG is more feasible because generating high numbers of TEGs for patients is superior over using expanded allo-reactive $\gamma\delta$ T cell clones, the new wave of haplo-transplantations (55) most likely benefits from a better understanding of allo-tumor reactive $\gamma\delta$ T-cell immune repertoires as described here. This knowledge would allow e.g. the development of cellular vaccines expressing tumor-HLA to boost tumor-allo-reactive $\gamma\delta$ T cell clones *in vivo*.

In summary, we report on the very interesting nature of allo-reactivity of a $\gamma\delta$ TCR which is able to distinguish between healthy and malignant cells. This observation extends the use of $\gamma\delta$ TCR for the TEG concept as next generation of CAR T as it opens an avenue to a complete new set of tumor targets seeing conformational and spatial changes at the cell membrane (8, 56). This observation emphasizes that $\gamma\delta$ T-cells, within the context of haplo-transplantation, not only possess classical antitumor reactivity but also benefit from allo-tumor reactivity (20). In addition, such $\gamma\delta$ TCR, within the context of TCR gene therapies, can be an interesting addition to tumors expressing HLA-A*24:02.

Conflict of Interest Statement

GK, DB, ZS and JK are inventors on different patents with $\gamma\delta$ TCR sequences, recognition mechanisms and isolation strategies. GK is employed by Kiadis Pharma (www.kiadis.com). JK is scientific advisor and shareholder of Gadeta (www.gadeta.nl). No potential conflicts of interest were disclosed by the other authors.

Funding

Funding for this study was provided by ZonMW 43400003, VIDI-ZonMW 917.11.337, KWF UU 2013-6426, UU 2014-6790, UU 2015-7601, and GADETA to JK, UU2017-11393 to ZS/JK, Marie Curie 790101 to DXB, NIH R01 AI29543 to MN and CA34196 to LDS. AJRH, DVD and MA received funding through Proteins@Work, a program of the Roadmap Facilities of the Netherlands (project number 184.032.201).

SUPPLEMENTARY METHODS

Cells lines

CEPH EBV-LCL lines (CEU population panel) were a kind gift from Tuna Mutis (VU University Medical Center, Amsterdam, The Netherlands) or ordered from the Coriell Biorepository (Camden, New Jersey, USA). Daudi, K562 (WT), T2, SW480, HEK293, and Phoenix-Ampho cell lines were obtained from ATCC. HEK293FT was obtained from Thermo Fisher Scientific (Breda, The Netherlands). K562 and COS-7 (African green monkey kidney fibroblast-like) transduced with HLA-A*02:01 or HLA-A*24:02 were kindly provided by Fred Falkenburg (Leiden University Medical Centre, the Netherlands). The TCRB^{-/-} Jurma cell line (a derivate of Jurkat J.RT3-T3.5 cells cells (1), was kindly provided by Hooijberg (VU Medical Center, Amsterdam, The Netherlands), OPM2-Luciferase (OPM2-Luc) was kindly provided by Anton Martens (University Medical Center Utrecht, Utrecht, the Netherlands). LCL-TM (an EBV-LCL line separate from the CEPH panel) was kindly provided by Phil Greenberg (Fred Hutchinson Cancer Research Center, Seattle, U.S.A.). All cell lines were authenticated by short tandem repeat profiling/karyotyping/isoenzyme analysis and were passaged for a maximum of 2 months, after which new seed stocks were thawed for experimental use. All cell lines were routinely verified by growth rate, morphology, and/or flow cytometry and tested negative for mycoplasma using MycoAlert Mycoplasma Kit (Lonza, Breda, The Netherlands). HLA-A*24:02 Fibroblasts, HEK293, Phoenix-Ampho, SW480, and COS-7 cells were cultured in DMEM supplemented with 1% Pen/Strep (Invitrogen) and 10% FCS (Bodinco, Alkmaar, The Netherlands). All other cell lines were cultured in RPMI with 1% Pen/Strep and 10% FCS. Primary fresh PBMCs were isolated by Ficoll-Paque (GE Healthcare, Eindhoven, The Netherlands) from buffy coats supplied by Sanquin Blood Bank (Amsterdam, The Netherlands). Monocytes and B-cells were isolated from PBMCs by MACS-sorting using CD14 and CD19-microbeads (Miltenyi Biotec) respectively, according to the manufacturers protocol.

Functional T cell assays

IFN γ ELISA and ELISPOT were performed as previously described (2, 3). Briefly; FE11 TCR-transduced, NEF₁₃₄₋₁₀-specific α BTCT or mock-transduced T-cells and target-cells were cocultured for 18 hours in nitrocellulose-bottomed 96-well plates (Millipore) pre-coated with α -IFN γ antibody (clone 1-D1K, Mabtech). Plates were washed and incubated with a second biotinylated anti-IFN γ antibody (clone 7-B6-1, Mabtech) followed by streptavidin-HRP (Mabtech). IFN γ spots were visualized with TMB substrate (Sanquin) and the number of spots was quantified using ELISPOT Analysis Software (Aelvis). Alternatively, TEG011 and target-cells were cocultured as above in round-bottom 96-well plates, and IFN γ levels in supernatants were measured by ELISA. For testing stimulation of WT1₁₂₆₋₁₃₄-specific α BTCT-transduced T-cells, the HLA-A*02-positive target cells were pulsed with 10 μ M WT1₁₂₆₋₁₃₄ (RMFPNAPYL) peptide. For testing stimulation of TEG011, HLA-A*24:02-positive target cells were pulsed with 10 μ M CMV₃₄₁₋₃₄₉ (pp65, QYDPVAALF), NEF₁₃₄₋₁₀ (RYPLTFGWCF), NEF₁₃₄₋₁₄₄-derived peptide mutants, or transformation associated peptides as indicated in the supplements.

Flow cytometry

Antibodies used for flow cytometry included: $\gamma\delta$ TCR-PE (clone IMMU510, Beckman Coulter), CD4-PE-Cy7 (clone RPA-T4, BD), CD8 α -APC (clone RPA-T8, BD), CD8 α -PerCP-Cy5.5 (clone RPA-T8, Biolegend), CD8 α -FITC (clone G42-8, BD), CD8 $\alpha\beta$ -PE (clone 2ST8.5H7, BD), CD69-APC (Clone FN50, Sony Biotechnology) HLA-A/B/C-FITC (clone W6/32, Biolegend). NY-ESO1₁₅₇₋₁₆₅ (HLA-A*02:01 SLLMWITQV) R-PE labelled Pro5 MHC Pentamer (Prolimmune, Oxford, United Kingdom) and CMV₃₄₁₋₃₄₉ (HLA-A*24:02 QYDPVAALF) R-PE labelled Pro5 MHC Pentamer (Prolimmune) were used according to the manufacturer's instructions. Samples were measured with FACSCanto II and LSRFortessa cytometers (BD) and analyzed with FACSDiva software (BD) or FlowJo software (BD).

Retroviral transduction of TCRs

The V γ 5V δ 1TCR FE11, an HLA-A*02:01 restricted WT1₁₂₆₋₁₃₄-specific $\alpha\beta$ TCR (4) and an HLA-A*24:02 restricted NEF₁₃₄₋₁₄₀-specific $\alpha\beta$ TCR were transduced into $\alpha\beta$ T cells as described (2, 5). In brief, Phoenix-Ampho packaging cells were transfected with gag-pol (pHIT60), env (pCOLT-GALV) and pBullet retroviral constructs containing TCR γ /B-chain-IRES-neomycine or TCR δ / α -chain-IRES-puromycin, using Eugene-HD (Promega, Leiden, The Netherlands). PBMCs preactivated with α -CD3 (30 ng/ml) (clone OKT3, Miltenyi Biotec) and IL-2 (50 U/ml) were transduced twice with viral supernatant within 48 hours in the presence of 50 U/ml IL-2 and 4 μ g/ml polybrene (Sigma-Aldrich). Transduced T cells were expanded by stimulation with α -CD3/CD28 Dynabeads (0,5x10⁶ beads/10⁶ cells) (Invitrogen) and IL-2 (50 U/ml) and selected with 800 μ g/ml geneticin (Thermo Fisher Scientific) and 5 μ g/ml puromycin (Sigma-Aldrich) for one week. CD4⁺ TCR-transduced T cells were isolated by MACS-sorting using CD4-microbeads (Miltenyi Biotec). Following transduction, transduced T cells were stimulated biweekly according to the REP protocol. Where indicated, CD4⁺, CD8⁺, CD4+CD8 $\alpha\alpha$ ⁺, CD4+CD8 $\alpha\beta$ ⁺ and CD8 α ⁺ (truncated (6)) TCR-transduced T-cells were sorted using a FACSaria II (BD) flow cytometry to >99% purity. Following selection, TCR-transduced T cells were stimulated biweekly using the REP protocol. Transgenic TCR expression was routinely assessed by flow cytometry.

Target cell activation and stress induction

HLA-A*24:02 B-cells and fibroblasts were stressed by either overnight incubation with 5mM cyclophosphamide and 10 μ M fludarabine or 3500cGy irradiation one day prior to T cell administration. Activation of the HLA-A*24:02 B-cells was induced by administration of 20 μ g/ml LPS or 20ng/ml IL-4 combined with 1 μ g/ml CD40L 24 hours before T cell co-culture.

Generation of FE11-like mAbs

FE11-like mAbs were generated by immunization of C57BL/6 mice with SW480 and LCL-TM after which standard fusion of spleen cells was performed to generate hybridomas. Monoclonality was achieved by cloning by limiting dilution twice after which isotype determination was determined by flow cytometry using α -mIgG1 APC (Thermo Fisher Scientific), α -mIgG2b RPE (Jackson ImmunoResearch), α -mIgG2c dylight 405 (Jackson ImmunoResearch), and α -mIgG3 PerCP (Jackson ImmunoResearch). For mAb

production, hybridomas were cultured $5\text{--}8 \times 10^5$ cells/ml for 1 week in serum-free hybridoma medium. mAbs were purified using protein G HP SpinTrap columns (GE healthcare) following the manufacturer's instructions.

Protein separation and digestion

Samples were run on a 4-12% Bis-Tris 1D SDS-PAGE gel (BioRad) for 2.5h and stained with colloidal coomassie dye G-250 (Gel Code Blue Stain Reagent, Thermo Scientific). The lane was cut as three bands, which were treated with 6.5 mM dithiothreitol (DTT) for 1 hour at 60°C for reduction and 54 mM iodoacetamide for 30 minutes for alkylation. The proteins were digested overnight with trypsin (Promega) at 37°C . The peptides were extracted with 100% acetonitrile and dried in a vacuum concentrator.

Mass spectrometry: RP-nanoLC-MS/MS

Samples were reconstituted in 10% formic acid and analyzed by nano-LC-MS/MS on a Orbitrap Q-Exactive Plus (Thermo Fisher Scientific) coupled to an Agilent 1290 Infinity System (Agilent Technologies, Middelburg, The Netherlands) operating in reverse phase (C18) equipped with a Reprosil pur C18 (Dr. Maisch, Ammerbuch-Entringen, Germany) trap column ($100\mu\text{m} \times 2\text{ cm}$, $3\mu\text{m}$) and a Poroshell 120 EC C18 (Agilent Technologies) analytical column ($75\mu\text{m} \times 50\text{ cm}$, $2.7\mu\text{m}$). After trapping with 100% solvent A (0.1% FA in H_2O) for 10 min, peptides were eluted with a step gradient consisting of 35 min from 13% to 40% and, 3 min from 40% to 100% solvent B (0.1% FA, 80 % ACN). The Q-Exactive Plus was operated in data-dependent acquisition mode using the following settings: full-scan automatic gain control (AGC) target 3×10^6 at 35000 resolution; scan range 375-1600 m/z; Orbitrap full-scan maximum injection time 10 ms; MS2 scan AGC target 5×10^4 at 17500 resolution; maximum injection 120 ms; normalized collision energy 25; dynamic exclusion time 10s; isolation window 1.5 m/z; 10 MS2 scans per full scan.

Mass spectrometry data analysis

Raw files were processed using Proteome Discoverer 1.4 (version 1.4.1.14, Thermo Fisher Scientific). Raw files of the 3 bands per sample were combined in one search against a Uniprot database (Homo Sapiens, April 2015). The following parameters were used: carbamidomethylation of cysteines was set as a fixed modification and oxidation of methionine was set as a variable modification. Trypsin was specified as enzyme and up to two miss cleavages were allowed. A false discovery rate of 0.01 was used. Data-sets processed by Proteome Discoverer were submitted to the Contaminant Repository for Affinity Purification (CRAPome) and proteins identified were sorted by Significance Analysis of INteractome (SAINT) score, and the fold change scores FC-A or FC-B. The controls used were taken from the control immunoprecipitations performed with un-specific antibodies in each cell line. Proteins with SAINT probability greater than 0.9 were considered high-scoring interactions (7).

Proximity Ligation Assay

HLA-A*24:02⁺ fibroblasts and SW-480 cells were grown onto coverslips and fixed in 1% Paraformaldehyde for 15 minutes. Subsequently, cells were stained using the Duolink

PLA kit (Sigma Aldrich). Briefly, the PLUS and MINUS probes were both conjugated to the HLA class I antibody clone w6/32 (Cedarlane). Cells were blocked for 60min at 37°C and washed twice with PBS. The conjugated probes were incubated for 60min at 37°C. Afterwards, cells were washed three times in PBS before detection of the probes with the in situ PLA detection kit (Duolink, Sigmaaldrich). Cells were stained with DAPI and analyzed with a 20× objective on a Zeiss confocal laser scanning microscope LSM 700. Data analysis was performed using Volocity software (PerkinElmer).

Supplementary Table 1. Immunoprecipitation with FE11- like antibodies 6 & 12 indicates that classical HLA molecules are part of the ligand. Antibodies produced by hybridoma 6 and hybridoma 12 were used for immunoprecipitation and subsequent mass spectrometry. Hits with a probability score of 1.0 are displayed.

SUPPLEMENTARY FIGURES

Supplementary Figure 1. A representative FACS staining of FE11 $\gamma\delta$ TCR transduced T-cells. $\gamma\delta$ TCR, $\alpha\beta$ TCR, CD4 and CD8 expression was determined by flow cytometry.

Supplementary Figure 2. (A) The effect of blocking with FE11 like hybridoma supernatant on the recognition of SW480 loaded with WT1₁₂₆₋₁₃₄ peptide by T cells transduced with a WT1₁₂₆₋₁₃₄-specific $\alpha\beta$ TCR transduced T cells. (B) LABScreen Single Antigen HLA class I beads were incubated with antibodies purified from hybridoma 6 (mAb 6) or antibodies purified from hybridoma 12 (mAb 12) and secondary α -mIgG-PE and measured using Luminex. Error bars represent SD.

Supplementary Figure 3. (A) B-cells were isolated from HLA-A*24:02⁺ PBMCs of a healthy donor. Activation was achieved by either LPS administration or a combination of CD40L and IL-4. Activation was measured by CD69 expression via flow cytometry. (LPS administration: 42% CD69⁺, CD40L + IL-4: 92,5% CD69⁺ and untreated 0,01% CD69⁺.) (B) HLA-A*24:02⁺ fibroblasts were inoculated with the TB40 HCMV-eGFP strain. CMV infection was measured by GFP expression via flow cytometry on the day of T-cell administration (6 dpi) (CMV treatment: 47,8% GFP⁺ and untreated 0,2% GFP⁺).

Supplementary Figure 4. (A) HLA-A*24:02-transduced T2 cells were loaded with CMV₃₄₁₋₃₄₉ or NEF₁₃₄₋₁₄₄ HLA-A*24:02-restricted peptides to assess stabilization of HLA on the surface of the T2 cells, as measured by flow cytometry. (B) HLA-A*24:02 transduced T2 cells were loaded with 15 HLA-A*24:02-restricted, transformation associated peptides after which stabilization of HLA on the surface of the T2 cells was measured by flow cytometry.

Supplementary Figure 5. LCL-TM cells were loaded with 10 μ M of the WT peptide and the glutamic acid (E)-modified peptides. These loaded cells were coincubated with T-cells engineered with a NEF₁₃₄₋₁₄₄-specific $\alpha\beta$ TCR after which activation was assessed by measuring IFN γ production.

ABSTRACT

$\gamma\delta$ T cells play an important role in cancer immunosurveillance and are able to distinguish malignant cells from their healthy counterparts via their $\gamma\delta$ T cell receptor ($\gamma\delta$ TCR). This characteristic makes $\gamma\delta$ T cells an attractive candidate for therapeutic application in cancer immunotherapy. Previously, we have identified a novel CD8 α -dependent tumor-specific allo-HLA-A*24:02-restricted V γ 5V δ 1TCR with potential therapeutic value when used to engineer α BT cells from HLA-A*24:02 harboring individuals. α BT cells engineered to express this defined V γ 5V δ 1TCR (TEG011) have been suggested to recognize spatial changes in HLA-A*24:02 present selectively on tumor cells but not their healthy counterparts. However, *in vivo* efficacy and toxicity studies of TEG011 are still limited. Therefore, we extend the efficacy and toxicity studies as well as the dynamics of TEG011 *in vivo* in a humanized HLA-A*24:02 transgenic NSG (NSG-A24:02) mouse model to allow the preparation of a first-in-men clinical safety package for adoptive transfer of TEG011. Mice treated with TEG011 did not exhibit any GvHD-like symptoms and extensive analysis of pathologic changes in NSG-A24:02 mice did not show any off-target toxicity of TEG011. However, loss of persistence of TEG011 in tumor-bearing mice was associated with the outgrowth of extramedullary tumor masses as also observed for mock-treated mice. In conclusion, TEG011 is well-tolerated without harming HLA-A*24:02⁺ expressing healthy tissues, and TEG011 persistence seems to be crucial for long term tumor control *in vivo*.

INTRODUCTION

The presence of $\gamma\delta$ T cells in various tumor types suggests their essential role in cancer immunosurveillance (1-3). However, the biological mechanism and ligand recognitions for $\gamma\delta$ T cell activation remain to be elucidated. The most prevalent $\gamma\delta$ T cell subset found in human peripheral blood expresses a $\gamma\delta$ 2T cell receptor (TCR). $\gamma\delta$ 2T cells mediate antitumor reactivity against hematological and solid malignancies by sensing early metabolic changes through joint spatial and conformational changes in CD277 partially mediated by RhoB (CD277J) (4-7). On the other hand, very little is known about the antitumor properties of $\gamma\delta$ T cells harboring $\gamma\delta$ TCRs from other subfamilies (non- $\gamma\delta$ 2 $\gamma\delta$ T cells). One of the non- $\gamma\delta$ 2 $\gamma\delta$ T cell subset, $V\delta 1^+$ T cells, which mainly reside in tissues, are known to recognize stress-induced ligands, including MHC associated proteins MICA and MICB, CMV associated glycoprotein UL16, and foreign lipid antigens presented on CD1c and CD1d in classical HLA-like manner, which are often upregulated on stressed or malignant cells (8-12). Several studies have also shown the cytotoxic activity of $V\delta 1^+$ T cells against leukemia and solid tumors (13-15), thereby revealing their therapeutic potential.

Despite the therapeutic potential of $\gamma\delta$ T cells, their successful clinical implementation remains challenging. For examples, adoptive transfer of *in vitro* expanded $\gamma\delta$ 2T cell failed to show clinical responses to date (3, 16) while adoptive transfer of *ex vivo* expanded non- $\gamma\delta$ 2T cells (17) remain to be tested in the clinic. Major remaining hurdles encompass diversity in function and receptor expression as well as differences in products when generated from different donors (for review (3)). To partially overcome these obstacles, we introduced the concept of TEGs, $\alpha\beta$ T cells engineered to express a defined $\gamma\delta$ TCR. TEGs allow the production of $\alpha\beta$ T cells-transduced with highly tumor-reactive $\gamma\delta$ TCR from both $V\delta 2^+$ (18-20) and $V\delta 2^-$ (21-23) subsets and thereby engineering strong tumor reactivity against a broad panel of malignancies. Within this context, we previously identified an allo-HLA-restricted and CD8 α -dependent Vy5V δ 1TCR. When this particular receptor was utilized for the TEG concept (later referred as TEG011), selective reactivity towards HLA-A*24:02 expressing tumor cells, but not healthy tissues was observed (24). However, safety studies have been so far very limited and also *in vivo* persistence and expansion profiles have not been assessed but are crucial before first-in-men studies. To further enrich the preclinical safety and efficacy studies needed for regulatory approval, we describe now a more detailed safety profile as well as pharmacokinetics of TEG011 after infusion in non-tumor bearing and tumor-bearing humanized HLA-A*24:02 transgenic NSG (NSG-A24:02) mice and their association with tumor control.

MATERIALS AND METHODS

Retroviral transductions of T cells

TEGs were produced as previously described (5). Briefly, Phoenix-Ampho cells were transfected with *gag-pol* (pHIT60), *env* (pCOLT-GALV), and pMP71 retroviral constructs

containing both $\gamma\delta$ TCR chains separated by a ribosomal skipping T2A sequence, using EugeneHD reagent (Promega, Leiden, The Netherlands). Human PBMCs from a healthy donor were pre-activated with 30 ng/mL anti-CD3 (Orthoclone OKT3; Janssen-Cilag, Breda, The Netherlands) and 50 IU/mL IL-2 (Proleukin, Novartis, Arnhem, The Netherlands) and subsequently transduced twice with viral supernatant within 48 hours in the presence of 50 IU/mL IL-2 and 6 μ g/mL polybrene (Sigma-Aldrich, Zwijndrecht, The Netherlands). TCR-transduced T cells were expanded by stimulation with anti-CD3/CD28 Dynabeads (500,000 beads/ 10^6 cells; Thermo Fisher Scientific, Breda, The Netherlands) and 50 IU/mL IL-2. Thereafter, TCR-transduced T cells were depleted of the non-engineered T cells.

Depletion of non-engineered T cells

Depletion of non-engineered T cells was performed as previously described (19). Briefly, TCR-transduced T cells were incubated with a biotin-labeled anti- $\alpha\delta$ TCR antibody (clone BW242/412; Miltenyi Biotec, Leiden, The Netherlands) and incubated with an anti-biotin antibody coupled to magnetic beads (anti-biotin MicroBeads; Miltenyi Biotec). Thereafter, the cell suspension was loaded onto an LD column and $\alpha\delta$ TCR⁺ T cells were depleted by MACS cell separation per the manufacturer's protocol (Miltenyi Biotec). After depletion, TEGs were expanded biweekly with 1 μ g/mL PHA-L (Sigma-Aldrich), 50 IU/mL IL-2, 5 ng/mL IL-15 (R&D Systems), and irradiated allogeneic PBMCs, Daudi and LCL-TM cells. IL-2 and IL-15 was added twice a week as reported also for the T cell rapid expansion protocol (REP) (5).

Animal model

The NOD.Cg-*Prkdc^{scid} Il2rg^{tm1Wjl}* Tg(HLA-A24)3Dvs/Sz (NSG-A24:02) mice (25) were bred and housed in the breeding unit of the Central Animal Facility of Utrecht University as previously reported (24). Experiments were conducted under institutional guidelines after permission from the local Ethical Committee and in accordance with the current Dutch laws on Animal Experimentation. Mice were housed in sterile conditions using an individually ventilated cage (IVC) system and fed with sterile food and water. Irradiated mice were given sterile water with antibiotic ciproxin for the duration of the experiment. Mice were randomized with equal distribution by sex and divided into 5 mice/group (for non-tumor bearing model) or 9-10 mice/group (for tumor-bearing model). For the non-tumor bearing mouse model, adult NSG-A24:02 mice (8-11 weeks old) received sublethal total body irradiation (1,75 Gy) on day -1 followed by two injections of 1×10^7 TEG011 or TEG expressing a non-functional $\gamma\delta$ TCR (TEG-LM1) (6) on day 1 and day 6. Mice were monitored at least twice a week for weight loss and graft-versus-host disease (GvHD) symptoms (scoring parameter included hunched appearance, activity, fur texture, skin integrity, and diarrhea). The GvHD scoring system is listed in Supplementary Table S1. Humane endpoint (HEP) was reached when mice experienced a 20% weight loss from the initial weight (measured on day -1) and in the case of GvHD score 2 was reached for an individual GvHD parameter or a total GvHD score of 4. For the tumor-bearing mouse model, adult NSG-A24:02 mice (8-11 weeks old) received sublethal total body irradiation (1,75 Gy) on day -1 followed by intravenous injection

of 1×10^5 K562 HLA-A*24:02 luciferase tumor cells on day 0, and received 2 injections of TEG011 and TEG-LM1 mock on day 1 and 6 as previously reported (24). All mice received $0,6 \times 10^6$ IU of IL-2 (Proleukin; Novartis) in 100 μ l incomplete Freund's adjuvant (IFA) subcutaneously together with the first TEGs injection and every 3 weeks until the end of the experiment. Mice were monitored at least twice a week for weight loss and clinical appearance scoring (scoring parameter included hunched appearance, activity, fur texture, and piloerection). The clinical appearance scoring system is listed in Supplementary Table S2. HEP was reached when mice experienced a 20% weight loss from the initial weight (measured on day -1), showed symptoms of disease (sign of paralysis, weakness, and reduced motility), extramedullary tumor masses (if any) reached 2 cm^3 in volume and in the case of clinical appearance score 2 was reached for an individual parameter or a total score of 4.

Flow cytometry analysis

The following antibodies were used for flow cytometry analysis: huCD45-PB (clone HI30; Sony Biotechnology, Surrey, UK), mCD45-APC (clone 30-F11, Sony Biotechnology), $\alpha\beta$ TCR-FITC (clone IP26; Biolegend, London, United Kingdom), pan- $\gamma\delta$ TCR-PE (clone IMMU510; Beckman-Coulter, Woerden, The Netherlands), CD8-PerCPCy5.5 (clone RPA-T8, Biolegend), CD4-PeCy7 (clone TPA-R4, Biolegend), and V δ 1-FITC (clone TS8.2, Thermo Fisher Scientific, Landsmeer, The Netherlands). To exclude non-viable cells from the analysis, Fixable Viability Dye eFluor506 was used (eBioscience, Thermo Fisher Scientific). All samples were analyzed on a BD LSRFortessa using FACSDiva Software (BD Biosciences).

Assessment for TEGs persistence

Mouse peripheral blood samples were obtained via cheek vein (max. 50-80 μ l/mouse) once a week. Human cells in peripheral blood were quantified using Flow-count Fluorospheres (Beckman Coulter). Red blood cell lysis was performed for blood samples using 1X RBC lysis buffer (Biolegend) before cell staining. Blood samples were stained with a mixture of antibody panels as listed above. The persistence of TEG cells was measured in peripheral blood by quantifying for absolute cell number by flow cytometry using specific markers huCD45 $^+$ $\gamma\delta$ TCR $^+$ CD8 $^+$.

Preparation of single cell suspensions

At the end of the study, extramedullary tumor (if any) sections were isolated and processed into single cell suspensions as previously described (26). A small section of the extramedullary tumor masses was minced and passed through a 70 μ m cell strainer (BD); cells were washed in PBS and resuspended in RPMI media. A total of 10^6 cells were stained and analyzed for tumor burden (determined by GFP $^+$ cells) by flow cytometry analysis (BD LSRFortessa). Human cells were measured by quantifying absolute cell numbers from a total of 10^6 cells using Flow-count Fluorospheres (Beckman Coulter).

Histology staining and analysis

Histopathologic evaluation was performed by hematoxylin and eosin (H&E) staining for the following mouse tissues: liver, spleen, small (duodenum, jejunum, ileum) intestine, bone marrow, and extramedullary tumor masses. When present, histological lesions in major organs were semi-quantitatively evaluated based on the following criteria: 1) white pulp atrophy; 2) extramedullary hematopoiesis and cell type (including blasts, erythroid precursors, band cells, and megakaryocytes); 3) the presence of pigment and apoptotic cells. Bone marrows were evaluated based on the following criteria: 1) cellularity (percentage of hematopoietic cells relative to marrow fat); 2) ratio of the myeloid and erythroid precursors (M/E ratio); and 3) the presence of megakaryocytes. The grading system was used as follows: 0 = absent; 1 =minimal; 2 = mild; 3 =moderate; 4 = marked.

Extramedullary tumor masses were evaluated based on the following histological features: number of mitotic figures and apoptotic cells (express as a range per high-power fields (HPFs), calculated in the same, randomly selected 5 HPFs, 40X); extension of the necrotic tumor tissue and associated inflammation were graded from 0 to 4 (0: no lesions; 1: minimal; 2: mild; 3: moderate; 4: severe).

Images were taken using an Olympus BX45 microscope with the Olympus DP25 camera and analyzed using DP2-BSW (version.2.2) software.

Double immunofluorescence staining

Formalin-fixed extramedullary tumor masses were embedded in paraffin and cut into 4µm sections. After deparaffinization and dehydration, slides were pretreated with 10mM citrate buffer pH 6.0 for 15min, followed by cooling at room temperature for 30min. Immunofluorescent staining was done using anti-human Anti-Nuclei Antibody (dilution 1:100; clone 3E1.3, Merck Millipore BV, North-Holland, The Netherlands) and anti-human CD3 polyclonal antibody (dilution 1:250; Agilent Technologies, Amstelveen, The Netherlands). Slides were mounted in VECTASHIELD® Antifade Mounting Medium with DAPI (Vector Laboratories, Peterborough, United Kingdom). Images were taken using a Leica LMD7 fluorescence microscope and analyzed using LAS X (Leica Application Suite X) imaging software.

Statistical Analyses

Data were analyzed using GraphPad Prism (GraphPad Software Inc., La Jolla, CA, USA) and represented as mean ± standard deviation (SD) or standard error of mean (SEM) with * $P < 0,05$ and ** $P < 0,01$. Differences between groups were assessed using a 2-way ANOVA with repeated measures, a mixed-effects model with repeated measures, a non-parametric Mann-Whitney t-test, or Kruskal-Wallis test where indicated.

RESULTS

TEG011 do not exhibit off-target toxicity in major organs of non-tumor bearing NSG-A24:02 mice

The introduction of a novel allo-HLA-restricted and CD8 α -dependent V γ 5V δ 1TCR in the concept of TEGs (α β T cells Engineered to express a defined $\gamma\delta$ TCR) (6, 19), hereby known as TEG011, has shown its efficacy against HLA-A*24:02 expressing malignant cells *in vitro* as well as *in vivo* (24). However, to date, *in vivo* efficacy and toxicity studies are limited but essential for a first-in-men study with TEG011. Therefore, we extended our *in vivo* analysis to assess in more detail the safety profile of TEG011 in a separate set of non-tumor bearing NSG mice, which express human HLA-A*24:02 (NSG-A24:02). Non-tumor bearing NSG-A24:02 mice received either two infusions of TEG011 or mock control TEG-LM1 cells. $\gamma\delta$ TCR expression for both TEG011 and TEG-LM1 mock was comparable (Supplementary Figure S1A) and most of the transduced $\alpha\beta$ T cells expressed V δ 1⁺ TCR for TEG011 (Supplementary Figure S1B). Mice were subsequently monitored for T cell persistence and any possible manifestation of graft-versus-host disease (GvHD) and any other signs of toxicity (experimental outline Figure 1A).

Figure 1 Humanized NSG-A24:02 transgenic mice models. Schematic overview of the *in vivo* experiment for non-tumor bearing (A) and K562 HLA-A*24:02 tumor-bearing mice (B). Non-tumor bearing NSG-A24:02 mice were irradiated at day -1 and received 2 injections of TEG011 or TEG-LM1 mock on day 1 and 6. Irradiated tumor-bearing NSG-A24:02 mice were injected with K562 HLA-A*24:02 luciferase tumor cells on day 0 followed by received 2 injections of TEG011 or TEG-LM1 mock on day 1 and 6. Mice were monitored weekly and sacrificed at Day 72 or earlier when humane endpoint (HEP) is reached.

Figure 2 Weight loss, overall GvHD scoring and histopathology analysis of bone marrow and mouse vital organs (spleen, liver, intestine) of non-tumor bearing mice. **(A)** Percentages of weight change measured weekly during study period for non-tumor bearing mice treated with TEG011 (filled black circle) and TEG LM1 mock (open grey circle) tabulated on left Y axis. A total of 20% weight loss from initial weight measured on day -1 were considered humane endpoint (HEP) and indicated by black tick line. Overall GvHD scoring was tabulated on right Y axis for non-tumor bearing mice treated with TEG011 (filled black rectangle) and TEG-LM1 mock (open grey rectangle). Scoring was calculated based on following parameters: hunching, activity, fur texture, skin integrity, and diarrhea. Score range from 0 to 10 (see [Supplementary Table S1](#) for detail scoring system), where total overall score of 4 were considered HEP and indicated by black tick line. Score 0 depicts normal appearance for all GvHD parameters. Data represent mean \pm SEM of all mice per group (n = 5 mice/group). **(B)** Representative photomicrographs H&E stained of mouse bone marrow from both TEG-LM1 mock (left panel) and TEG011-treated group (right panel). Magnification: 20X; **(C)** Representative photomicrographs for H&E stained of mouse liver for both TEG-LM1 mock (left) and TEG011-treated group (right) with apparent no histological lesion. Magnification: 20X; **(D)** Representative pictures for H&E staining of mouse intestine for both TEG-LM1 mock (left) and TEG011-treated group (right) with apparent no histological lesion. Magnification: 20X; **(E)** Representative photomicrographs for H&E stained of female mouse spleen for both TEG-LM1 mock (left) and TEG011-treated group (right) with a higher number of erythrocyte precursors and megakaryocytes. Magnification: 20X; Shown are representative photomicrographs from individual mice of both TEG011 and TEG-LM1 mock group (n = 5 mice/group) with no observable differences in overall histology features between treatment groups.

GvHD-like symptoms were monitored twice weekly for all mice using a scoring system based on hunching posture, activity, fur texture, skin integrity, and diarrhea (See [Supplementary Table S1](#) for GvHD scoring system) ranging from 0 (normal behavior and posture), 1 (slight decreased in fitness), and 2 (moderate decreased in fitness). Score 2 of an individual parameter or an overall score of 4 was defined as humane endpoint (HEP) and mice were sacrificed. All mice did neither experience weight loss, nor any abnormality observed in relation to GvHD symptoms during the entire study duration of 72 days ([Figure 2A](#)). In addition, all mice did not exhibit any observable discomfort and survived throughout the entire study duration (24). Persistence of TEGs was assessed by measuring viable $\text{huCD45}^+\gamma\delta\text{TCR}^+\text{CD8}^+$ in mouse peripheral blood by flow cytometry ([Supplementary Figure S2A](#)). In non-tumor bearing mice, T cells persisted in peripheral blood up to 48 days after infusion and had although not significant a second peak of expansion after administration of IL-2 which was more pronounced in TEG011-treated mice ([Figure 3A](#)). To evaluate in more detail possible off-target toxicity of TEG011 against human HLA-A*24:02 expressing healthy tissues, we collected bone marrow, liver, intestine, and spleen from both treatment groups of non-tumor bearing mice at the end of the study period (Day 72) for further histopathology analysis ([Figure 2B](#)). No differences were observed in terms of bone marrow cellularity (percentage of hematopoietic cells relative to marrow fat) nor in the ratio of the myeloid and erythroid precursors (M/E ratio) for both treatment group ([Supplementary Table S3](#)). Furthermore, no abnormal histological lesions were observed in liver ([Figure 2C](#)) and intestine ([Figure 2D](#)) of all mice in the study. We observed slightly increased extramedullary hematopoiesis (EMH) in the spleen of TEG011-treated female mice when compared to TEG-LM1 mock-treated mice ([Figure 2E](#)), which was determined by a higher number of erythrocyte precursors and megakaryocytes.

On the other hand, a minimal decrease of EMH was observed in the spleen of the TEG011-treated male group compared to mock-treated mice (Supplementary Table S3). Importantly, all spleen samples from both TEG011 and TEG-LM1 mock groups showed a comparable population of cells, including normal blasts, band cells, erythrocyte precursors, and megakaryocytes. Hence, these observations on spleen were deemed minimal and not associated with an evident increase of histological toxicity of TEG011. In conclusion, our data show no relevant GvHD manifestation in all mice and no histological signs of toxicity in the major organs of all healthy tissues upon TEG011 treatment. Thus, we conclude that TEG011 does not associate with off-target toxicity in an HLA-A*24:02 environment.

***In vivo* dynamic of TEG011 in tumor-bearing mice**

Clinical data for anti-CD19 CART therapy highlight the correlation of antitumor effects with their *in vivo* persistence (27-29). To assess whether persistence of TEG011, which carries a CD8 α -dependent V γ 5V δ 1TCR (24), is also key in long-term tumor control, we studied in more detail CD8⁺ TEG persistence in tumor-bearing NSG-A24:02 mice injected with K562 HLA-A*24:02 luciferase tumor cells and subsequently treated with either TEG011 or TEG-LM1 mock cells (experimental outline Figure 1B). Thereafter, we measured viable huCD45⁺ $\gamma\delta$ TCR⁺CD8⁺ in mouse peripheral blood by flow cytometry (Supplementary Figure S2B). While non-functional TEG-LM1 cells diminished in all tumor-bearing control mice 29 days after infusion (Figure 3B), TEG011 cells expanded and remained detectable in peripheral blood up to 64 days. However, only 44% of TEG011-treated mice (4/9) showed significant long-term persistence of T cells until the end of the study period, while the remaining 56% of the mice (5/9) did not show long-term persistence. Therefore, we subsequently defined TEG011-treated mice into two subgroup: “persisters” and “non-persisters”, respectively (Figure 3C). TEG011 “persisters” showed significantly higher TEG cell counts on Day 22 until Day 37 upon expansion compared to “non-persisters”, where TEG cells were no longer detectable after Day 48 and did not recover even after IL-2 injection on Day 50. Given the fluctuating persistence profile of TEG011, we analyzed further the difference between TEG011 “persisters” and “non-persisters” by calculating area under curve (AUC) of absolute cell counts TEG011 for both “persisters” and “non-persisters” subgroup and also confirmed significant difference in T cell persistence (Figure 3C, D).

Figure 3 Long-term persistence of TEG011 cells in peripheral blood of tumor-bearing mice and its association with tumor burden. **(A)** TEG persistence was measured in peripheral blood by quantifying for absolute cell numbers by flow cytometry for TEG LM1 mock (open light-grey rectangle) and TEG011 (filled black circle) in non-tumor bearing mice. Data represent mean \pm SEM of all mice per group ($n = 5$ mice). Statistical significances were calculated by mixed-effects model with repeated measures; *, $P < 0.05$. **(B)** TEG persistence was measured in peripheral blood by quantifying for absolute cell numbers by flow cytometry for TEG LM1 mock (open light-grey rectangle; $n = 10$ mice) and TEG011 (filled black circle; $n = 9$ mice) in tumor-bearing mice. Data represent mean \pm SEM of all mice per group. Statistical significances were calculated by mixed-effects model with repeated measures; *, $P < 0.05$. **(C)** Area under the curve (AUC) of CD8⁺ TEG011 persistence were calculated for both TEG011 "persisters" (black line, dark grey area; 4/9 mice) and TEG011 "non-persisters" (grey line, light grey area; 5/9 mice) up to 64 days after infusion. Data represent mean \pm SEM of all mice per group. 95% Confidence Interval (95%

Figure 3 (Continued) CI) were tabulated for AUC of both subgroup. (D) Mean AUC of CD8⁺ TEG011 persistence from individual mouse of both TEG011 “persisters” (filled dark grey bar; 4/9 mice) and TEG011 “non-persisters” (filled light grey bar; 5/9 mice) groups were tabulated and shown as mean \pm SEM of all mice per group. Statistical significances were calculated by non-parametric Mann-Whitney t-test; *, $P < 0.05$. (E) Tumor burden for K562-HLA*A24-luciferase was assessed in vivo by bioluminescence imaging (BLI) measuring integrated density of the entire area of mice with abdomen facing up. Data shown as mean \pm SD of all mice per group (TEG011 “persisters” (filled black circle; 4/9 mice), TEG011 “non-persisters” (open dark-grey circle 5/9 mice), and TEG-LM1 mock (open light-grey rectangle; $n = 10$ mice)). Statistical significances were calculated by non-parametric Mann-Whitney t-test in comparison to TEG-LM1 mock control; *, $P < 0.05$; **, $P < 0.01$. (F) Tumor burden for K562-HLA*A24-luciferase and infiltrating CD8⁺ TEGs were assessed from isolated extramedullary tumor masses by quantifying for absolute cell number GFP⁺ cells by flow cytometry. Each symbol represents an individual mouse per treatment group that developed extramedullary tumor masses. Readouts on infiltrating T cells are set to 5 cells/ml for individual mouse in the Y axis for data visualization purpose. Data represent mean \pm SD of all mice per group (TEG011 “non-persisters” (open dark-grey circle; 2/5 mice) and TEG-LM1 mock (open light-grey rectangle; 3/10 mice)). FACS analyses of extramedullary tumor mass from TEG-LM1 group were only obtained from 3 out of 4 mice.

TEG011 persistence and its association with tumor control

Next, we assessed whether TEG011 persistence was associated with overall tumor control and analyzed tumor burden over time measured by bioluminescence imaging in the tumor-bearing mice injected with K562 HLA-A*24:02 luciferase tumor cells. In line with our hypothesis that the immune effector persistence is key to achieve long-term tumor control, the TEG011 “persisters” associated with a better tumor control as compared to TEG-LM1 mock group, as well as a trend of lower tumor burden in comparison to TEG011 “non-persisters” subgroup (Figure 3E). Approximately 40% of mock-treated mice (4/10) and 40% TEG011 “non-persisters” mice (2/5) developed extramedullary tumor masses, while interestingly, none of the TEG011 “persisters” mice developed any extramedullary tumor masses. Tumor burden was comparable between extramedullary tumor masses isolated from TEG011 “non-persisters” and TEG-LM1 mock-treated mice and no tumor infiltrating CD8⁺ TEGs could be observed in all isolated tumor masses (Figure 3F).

To measure possible discomfort due to tumor growth, all mice were monitored for weight loss and a scoring system based hunching posture, activity, fur texture, and piloerection (See Supplementary Table S2 for clinical appearance scoring system) ranging from 0 (normal behavior and posture), 1 (slight decreased in fitness), and 2 (moderate decreased in fitness). Similar to GvHD scoring system for non-tumor bearing mice, score 2 of an individual parameter or an overall score of 4 was defined as HEP and mice were sacrificed. While TEG011 treatment significantly decreased tumor progression, TEG-LM1 treated mice experienced diminished fitness and significant weight loss over time (Figure 4A). Extramedullary tumor masses were analyzed in further detail and histologically characterized by undifferentiated tumor cells of human origin, with a solid and invasive growth pattern (Figure 4B, C), consistent with a myeloid sarcoma development in line with previous reports (30, 31). We also performed immunofluorescence (IF) staining to detect any presence of human T cells within the inflammatory infiltrate associated with the multiple tumor masses observed in the xenograft mouse models. However, while we confirmed that tumor cells are of human origin, no human T cells were observed in

Figure 4 Weight loss, overall clinical appearance scoring, histopathology and immunofluorescence (IF) staining analysis of extramedullary tumor masses. **(A)** Percentages of weight loss measured weekly during study period for tumor-bearing mice treated with TEG011 (filled black circle; $n = 9$ mice) and TEG-LM1 mock (open grey circle; $n = 10$ mice) tabulated on left Y axis. A total of 20% weight loss from initial weight measured on day -1 were considered HEP and indicated by black tick line. Overall clinical appearance scoring was tabulated on right Y axis for tumor-bearing mice treated with TEG011 (filled black rectangle; $n = 9$ mice) and TEG-LM1 mock (open grey rectangle; $n = 10$ mice). Scoring was calculated based on following parameters: hunching, activity, fur texture, and piloerection. Score range from

Figure 4 (Continued) 0 to 8 (see Supplementary Table S2 for detail scoring system), where total overall score of 4 were considered HEP and indicated by black tick line. Score 0 depicts normal appearance for all clinical appearance parameters. Data represent mean \pm SEM of all mice per group. Statistical significances were calculated by non-parametric Mann-Whitney t-test; *, $P < 0.05$. **(B)** Representative photomicrographs H&E stained of multiple areas of hemorrhages and necrosis from both TEG-LM1 mock (left panel - stated as control) and TEG011-treated group (right panel). Aberrant mitotic figures were frequently observed in all samples. Magnification: 2X; **(C)** Representative photomicrographs H&E stained tissues of high mitotic rate tumor cells from both TEG-LM1 mock (left panel) and TEG011-treated group (right panel). No evident differences were observed comparing the extension of necrotic areas in the tumor tissue, associated inflammation, number of apoptotic cells and mitotic figures. Magnification: 20X. **(D)** Representative double IF staining of extramedullary tumor masses from both TEG-LM1 mock (left panel) and TEG011-treated group (right panel). Tumor mass of human origin (human nuclear antigen positive cells, green) with scattered CD3 positive cells (red; pointed by arrows) with DAPI (blue) staining for the nuclei. Magnification 63X. Shown are representative pictures from an individual mouse of both TEG-LM1 mock ($n = 4$ mice) and TEG011 ($n = 2$ mice).

all evaluated samples, as scattered positive CD3⁺ T cells observed within the multiple tumor masses were all negative for the human nuclear antigen (Figure 4D). Thus, no TEGs could be observed by immunohistochemistry in extramedullary tumor masses as also confirmed by flow cytometry analysis (Figure 3F). Overall, our data indicate that TEG011 persistence associates with a reduced chance for developing extramedullary tumor masses *in vivo* without harming healthy compartments.

DISCUSSION

TEG011 has been reported to target HLA-A*24:02 expressing hematological tumors without harming healthy tissues (24). Within this study, we now extend previous *in vivo* analyses followed by pathological studies to further assess the efficacy-toxicity balance of TEG011 prior to clinical testing. Major findings of our study are that TEG011 treatment does not associate with any discomfort nor histopathological evidence of toxicity in an HLA-A*24:02 background. In addition, we report on an association between TEG011 persistence and lack of extramedullary tumor growth.

Toxicity studies of compounds targeting metabolic changes remain a major challenge as such changes cannot be readily studied in detail in all organs (3). Therefore, we proposed efficacy-toxicity models for TEGs targeting joint spatial and conformational changes in CD277 (later referred as CD277J) (3) through a $\gamma\delta$ 2TCR (TEG001) by co-incubating TEG001 with healthy and diseased tissues in an artificial 3D bone marrow niche (32) or in a mouse model where either healthy cord blood-derived CD34⁺ progenitor or primary leukemia cells were engrafted (26). These models partially overcome the absence of the natural ligand CD277J in mice (3, 7, 33) and allowed the initiation of a first-in-men study (NTR6541) (18, 19, 34). With TEG011, we could utilize transgenic mice expressing human HLA-A*24:02 (25), allowing thereby more extensive toxicity studies of TEG011 in different tissues as compared to TEG001 (26, 32). Although we did not investigate all organs, and despite the fact that TEG011 did not persist until day 72 in the peripheral blood of all mice, we provide strong evidence that TEG011 does not

induce toxicity against human HLA-A*24:02 expressing non-tumor healthy tissues. This is also supported by our observation that tumor control in mice did not associate with any signs of toxicity against healthy tissues.

Considering the natural properties of T cells to proliferate and migrate in tissues, T cell expansion and persistence are commonly used to determine the pharmacokinetics properties of cell-based therapy (35). Our models also allowed us to investigate TEG011 kinetics in tumor-bearing mice in more detail. TEG persistence until the end of the study period was only observed in tumor-bearing mice treated with TEG011 but not TEG-LM1 cells, suggesting that antigen presence and cognate recognition through the TCR are key for long-term persistence of TEG011 in this model. Higher T cell exposure observed between day 22 to day 36 after TEG infusion correlated with superior tumor control of TEG011 (“persisters”). These data align with a recent study that showed complete response in leukemia patients that receive CART therapy when high T cell exposure has been observed in the first 48 days of infusion (36).

However, TEG011 long-term persistence was only observed in 44% of tumor-bearing mice. Within the limitation of our model, we could not identify the exact factor(s) that determine the difference between TEG011 “persisters” and “non-persisters”. Most likely this is the consequence of a stochastically driven intrinsic T cell fitness and composition of the infused product. The presence of memory (stem) T cells have been reported to correlate with long-term persistence (37, 38) and complete response in patients receiving adoptive transfers of CART or antigen-specific T cells (37, 38).

Furthermore, in non-tumor bearing mice some advantage of the TEG011 product has been observed when compared to T cell bearing the non-functional receptor, though no long-term persistence has been observed. This might be the consequence of some residual TCR signal via HLA-A*24:02 which is sufficient to maintain some homeostatic proliferation but does not induce toxicity in healthy tissues. In particular, after administration of IL-2 T cell survival of cognate T cells in tumor-bearing mice has been prolonged suggesting that additional help through e.g. CD4⁺ engineered T cells could further improve potency of TEG011. Indeed, the presence of antigen-specific TCR-engineered CD4⁺ T cells synergistically enhances persistence and long-term tumor control when infused together with antigen-specific TCR-engineered CD8⁺ T cells (39). Similarly, *in vivo* persistence of CD4⁺ CART cells provides helper signal, which then increases CD8⁺ CART cell persistence (40).

As TEG011 is CD8 α -dependent and consequently in the current design lacking support by antigen-specific CD4⁺ T cells (22, 24), equipping engineered TEG011 with CD8 α could be a strategy to further enhance T cell persistence and long-term tumor control. The precise molecular interaction between CD8 α with its specific ligand in our context remains however elusive. Possible ligands are the classical MHC-I molecule HLA-A*24:02 itself or alternative candidates such as the non-classical MHC molecule HLA-G (41, 42) and CEACAM5 (43).

Overall, we demonstrate that TEG011 does not show signs of off-target toxicity in more detailed toxicity studies. In addition, long-term persistence of TEG011 associated with lower tumor burden without harming healthy tissues, thereby highlight the potential of TEG011 for clinical application.

Conflict of Interest Disclosure

DB, ZS and JK are inventors on different patents with $\gamma\delta$ TCR sequences, recognition mechanisms and isolation strategies. JK is scientific advisor and shareholder of Gadeta (www.gadeta.nl). No potential conflicts of interest were disclosed by the other authors.

ABSTRACT

$\gamma\delta$ T cell receptors ($\gamma\delta$ TCRs) recognize a broad range of malignantly-transformed cells in mainly a major histocompatibility complex (MHC)-independent manner, making them valuable additions to the engineered immune effector cell therapy that currently focuses primarily on $\alpha\beta$ TCRs and chimeric antigen receptors (CARs). As an exception to the rule, we have previously identified a $\gamma\delta$ TCR, which exerts antitumor reactivity against HLA-A*24:02-expressing malignant cells, however without the need for defined HLA-restricted peptides, and without exhibiting any sign of off-target toxicity in humanized HLA-A*24:02 transgenic NSG (NSG-A24:02) mouse models. This particular tumor-HLA-A*24:02-specific $\gamma\gamma$ 5V δ 1TCR required CD8 $\alpha\alpha$ co-receptor for its tumor reactive capacity when introduced into $\alpha\beta$ T cells engineered to express a defined $\gamma\delta$ TCR (TEG), referred to as TEG011, thus it was only active in CD8 $^{+}$ TEG011. We subsequently explored the concept of additional redirection of CD4 $^{+}$ T cells through co-expression of the human CD8 α gene into CD4 $^{+}$ and CD8 $^{+}$ TEG011 cells, later referred as TEG011_CD8 α . Adoptive transfer of TEG011_CD8 α cells in humanized HLA-A*24:02 transgenic NSG (NSG-A24:02) mice injected with tumor HLA-A*24:02 $^{+}$ cells showed superior tumor control in comparison to TEG011, and to mock control groups. The total number of functional TEG011_CD8 α cells persisted significantly longer in mice peripheral blood up to 4 weeks after TEG infusion, mainly due to a dominance of CD4 $^{+}$ CD8 $^{+}$ double positive TEG011_CD8 α which resulted in higher total counts of functional T cells in spleen and bone marrow. We observed that tumor clearance in the bone marrow of TEG011_CD8 α -treated mice associated with better human T cell infiltration, which was not observed in the TEG011-treated group. Overall, introduction of transgenic human CD8 α receptor on TEG011 improves antitumor reactivity against HLA-A*24:02 $^{+}$ tumor cells, and further enhances *in vivo* tumor control.

Keywords: cancer immunotherapy, TEGs, mouse model, preclinical, TCR engineering, human leukocyte antigens, persistence, efficacy

INTRODUCTION

$\gamma\delta$ T cells share the properties of both innate and adaptive immunity and play an essential role in cancer immunosurveillance (1, 2). Unlike conventional $\alpha\beta$ T cells, $\gamma\delta$ T cells recognize their cognate antigens in an MHC-unrestricted manner, targeting stress-induced and malignantly-transformed self-antigens (3, 4). As such, $\gamma\delta$ T cells represent an attractive cell subset to substantiate T cell-based immunotherapeutic strategies that still mainly focus on $\alpha\beta$ T cells.

Based on their TCR δ chain repertoire, $\gamma\delta$ T cells can be distinguished into two major subsets: $V\delta 2^+$ and $V\delta 2^-$ cells. $V\delta 2^+$ cells mainly reside in human peripheral blood, representing up to 5% of total circulating T cells, and sense metabolic changes in tumor cells with intracellular accumulation of phosphoantigens (pAgs) level. $V\delta 2^+$ T cell recognition is facilitated by butyrophilin (BTN) family molecules, including BTN2A1 and BTN3A1 (5-10). On the other hand, $V\delta 2^-$ cells mainly localize in mucosal and epithelial tissues, but their antitumor properties are scarcely known (4). $V\delta 2^-$ cells recognize broad range of stress-induced ligands, such as the MHC-associated proteins MICA and MICB, foreign lipid antigens presented on CD1c/d molecules in classical HLA-like manner, and CMV-associated UL16-binding protein (ULBP) family members, that are upregulated in stressed or malignant cells (11-15).

$V\delta 1^+$ T cells, one of the major $V\delta 2^-$ subsets, have been shown to exert antitumor reactivity against leukemia and solid tumors (16-21), indicating their potential in cancer immunotherapy. Adoptive transfer of in vitro expanded $V\delta 2^+$ cells only showed marginal clinical responses to date (4, 22), while adoptive transfer of $V\delta 2^-$ cells is yet to be tested in the clinic (23). Translational efforts using $\gamma\delta$ T cells and their receptors outside the context of allogeneic stem cell transplantation (24, 25) face substantial hurdles, due to their limited proliferative capacity, underestimated diversity in co-receptors expression and function, as well as scarce information on how $\gamma\delta$ TCRs interact with their targets.

To bypass these major drawbacks of translating $\gamma\delta$ T cells-based immune therapies into clinical practice, we developed the concept of TEGs: $\alpha\beta$ T cells engineered to express a defined $\gamma\delta$ TCR, allowing the introduction of highly tumor-reactive $\gamma\delta$ TCR, both $V\delta 2^+$ (26, 27) or $V\delta 2^-$ (28, 29) subsets, into proliferatively-proficient $\alpha\beta$ T cells (27, 30, 31). We previously identified an allo-HLA-restricted and tumor-specific $V\gamma 5V\delta 1$ TCR, introduced in TEG concept as TEG011, which was, although not dependent on a defined peptide, selectively targeting HLA-A*24:02⁺ tumor cells without impairing the healthy tissues (32). Within this scope, we also highlighted the function of CD8 α as costimulatory receptor required for antitumor reactivity of FE11 $\gamma\delta$ TCR and showed that both CD8 $\alpha\alpha$ on the original clone FE11 and CD8 $\alpha\beta$ on transduced $\alpha\beta$ T cells are capable of providing co-stimulation to the FE11 $\gamma\delta$ TCR (32).

Human CD8 is a membrane glycoprotein classified in an immunoglobulin-like super family consisting of hetero- or homodimer of α and β chains, making up for the CD8 $\alpha\beta$

or CD8 $\alpha\alpha$ co-receptor on the cell surface. CD8 $\alpha\beta$ predominantly expressed on $\alpha\beta$ T cells, while CD8 $\alpha\alpha$ mainly expressed on the cell membrane of innate immune cells, including macrophages, dendritic cells, natural killer (NK) cells, and $\gamma\delta$ T cells (33). Within this context, we addressed the implication of CD8 $\alpha\alpha$ -dependency of FE11 $\gamma\delta$ TCR in relation to its tumor immunity. Importantly, we demonstrate that introduction of transgenic human CD8 α co-receptor into CD4 $^{+}$ TEG011 cells successfully enhanced its antitumor efficacy *in vitro* and *in vivo*, and thus did not require CD8 β . Furthermore, we show that the co-expression of CD8 α in CD4 $^{+}$ TEG011 provides additional survival signal and facilitates better T cell persistence and infiltration *in vivo*, both of which are essential to sustain long-term tumor control of adoptively transferred TCR-based immunotherapy.

MATERIALS AND METHODS

Cell lines

Daudi, SW480, and Phoenix-Ampho cell lines were obtained from ATCC. K562 with HLA-A*24:02-transduced cell line was kindly provided by Fred Falkenburg (Leiden University Medical Centre, the Netherlands) and subsequently transduced with luciferase for *in vivo* imaging purposes. EBV-LCL was kindly provided by Phil Greenberg (Seattle, WA). Phoenix-Ampho and SW480 cells were cultured in DMEM supplemented with 1% Pen/Strep (Invitrogen) and 10% FCS (Bodinco), whereas all other cell lines in RPMI with 1% Pen/Strep and 10% FCS. All cell lines were authenticated by short tandem repeat profiling/karyotyping/iso-enzyme analysis and were passaged for a maximum of 2 months, after which new cell line stocks were thawed for experimental use. Furthermore, all cell lines were routinely verified by growth rate, morphology, and/or flow cytometry and tested negative for mycoplasma using MycoAlert Mycoplasma Kit (Lonza, Breda, The Netherlands). Peripheral blood mononuclear cells (PBMCs) from healthy donors were isolated by Ficoll-Paque (GE Healthcare, Eindhoven, The Netherlands) from buffy coats supplied by Sanquin Blood Bank (Amsterdam, The Netherlands).

Cloning of TEG011_CD8 α and TEGLM1_CD8 α

Clone FE11 was generated as previously described (28). FE11 and LM1 (non-functional $\gamma\delta$ 2TCR with length mutation on the complementary determining region 3 (CDR3) of the δ 2-chain (31)) $\gamma\delta$ TCRs were subcloned to pMP71 retroviral vectors containing both γ TCR and δ TCR chains, separated by a ribosomal skipping T2A sequence. pU57 constructs containing a ribosomal skipping P2A sequence, followed by full-length human CD8 α were purchased from Baseclear (Leiden, The Netherlands). Thereafter, CD8 α was subcloned into pMP71 vector using *Xho*I and *Hind*III restriction sites downstream of γ 115TCR-T2A- δ 115_LM1 sequence to generate a TEGLM1_CD8 α construct that contained *Nco*I and *Xho*I restriction sites up- and downstream of LM1 $\gamma\delta$ TCR chains. *Nco*I and *Xho*I restriction sites were then inserted up- and downstream of FE11 $\gamma\delta$ TCR sequences by site-directed mutagenesis PCR, after which this sequence was ligated to P2A-CD8 α sequence in pMP71 vector using the introduced *Nco*I and *Xho*I sites, generating a TEG011_CD8 α construct (Supplementary Table 1). Where indicated, CD4 $^{+}$, CD8 $^{+}$, CD4 $^{+}$ CD8 $\alpha\alpha^{+}$ and

CD4⁺CD8 $\alpha\beta$ ⁺ TCR-transduced T-cells were sorted using a FACSaria II (BD) flow cytometry to >99% purity. Expression levels of CD8 α mutants were measured by flow cytometry using anti-CD8 α antibody (clones RPA-T8).

Functional T cell assays

IFN γ ELISPOT was performed using anti-human IFN γ mAb1-D1K (I) and mAb7-B6-1 (II) (Mabtech) per the manufacturer's protocol. 15,000 TEG cells (TEG011, TEGLM1, TEG011_CD8 α , or TEGLM1_CD8 α) were co-incubated with 50,000 target cells (E:T ratio 1:3) for 18-24 hours in nitrocellulose-bottomed 96-well plates (Millipore). IFN γ spots were visualized with TMB substrate (Sanquin) and subsequently the number of spots was quantified using ELISPOT Analysis Software (Aelvis). Where indicated, blocking of CD8 α was performed using 10 μ g/ml anti-CD8 α antibody clone OKT8 (eBioscience) and blocking of CD8 β with 10 μ g/ml anti-CD8 β clone 2ST8.5H7 (Abcam).

Retroviral transductions of T cells

TEGs were generated as previously described (30). Briefly, Phoenix-Ampho packaging cells were transfected with gag-pol (pHIT60), env (pCOLT-GALV), and pMP71 retroviral constructs containing both γ TCR and δ TCR chains separated by a ribosomal skipping T2A sequence and followed by CD8 α sequence separated by P2A sequence where applicable, using EugeneHD reagent (Promega, Leiden, The Netherlands). PBMCs from a healthy donor pre-activated with 30 ng/mL anti-CD3 (clone OKT3, Miltenyi Biotec) and 50 IU/mL IL-2 (Proleukin, Novartis, Arnhem, The Netherlands) were transduced twice with viral supernatant within 48 hours, in the presence of 50 IU/mL IL-2 and 6 μ g/mL polybrene (Sigma-Aldrich, Zwijndrecht, The Netherlands). TCR-transduced T cells were expanded by stimulation with anti-CD3/CD28 Dynabeads (500,000 beads/10⁶ cells; Thermo Fisher Scientific, Breda, The Netherlands) and 50 IU/mL IL-2. Thereafter, transduced T cells were depleted of the non-engineered T cells.

Depletion of non-engineered T cells

Non-engineered T cells was depleted as previously described (27). In brief, transduced T cells were incubated with a biotin-labeled anti- $\alpha\beta$ TCR antibody (clone BW242/412; Miltenyi Biotec, Leiden, The Netherlands) and then incubated with an anti-biotin antibody coupled to magnetic beads (anti-biotin MicroBeads; Miltenyi Biotec). Thereafter, the cell suspension was loaded onto an LD column, and $\alpha\beta$ TCR⁺ T cells were depleted by MACS cell separation per the manufacturer's protocol (Miltenyi Biotec). After depletion, TEGs were expanded using a T cell rapid expansion protocol (REP) (30).

Separation of CD4⁺ subsets of TEGs

The separation of CD4⁺ TEGs was performed using CD4 Microbeads (Miltenyi Biotec) as per manufacturer's instructions. Briefly, TEGs were incubated with magnetic microbeads cells and loaded into LS column for MACS cell separation. Thereafter, CD4⁺ selected or bulk (with CD4:CD8 ratio 50:50) TEGs were expanded separately using REP. TEG expression was monitored prior to functional assays or *in vivo* infusion by flow cytometry using anti- $\alpha\beta$ TCR-APC (clone IP26, eBioscience), anti-pan- $\gamma\delta$ TCR-PE (clone IMM510, Beckman

Coulter), anti-CD8-PerCP-Cy5.5 (clone RPA-T8, Biolegend), anti-CD4-PeCy7 (clone TPA-R4, Biolegend), anti-CD4-FITC (clone TPA-R4, Biolegend), and V δ 1-FITC (clone TS8.2, Thermo Fisher Scientific) antibodies.

Animal model

The NOD.Cg-*Prkdc^{scid}Il2rg^{tm1Wjl}*Tg(HLA-A24)3Dvs/Sz (NSG-A24:02) mice (34) were bred and housed in the breeding unit of the Central Animal Facility of Utrecht University. Experiments were conducted per institutional guidelines after obtaining permission from the local Ethical Committee, and performed in accordance with the current Dutch laws on Animal Experimentation. Mice were housed in individually ventilated cage (IVC) system to maintain sterile conditions and fed with sterile food and water. After irradiation, mice were given the antibiotic ciproxin in the sterile water for the duration of the experiment. Both male and female mice were randomized with equal distribution among the different groups, based on age and initial weight (measure on Day -1) into 10 mice/group. Adult NSG-A24:02 mice (11-20 weeks old) received sub-lethal total body irradiation (1,75 Gy) on day -1 followed by intravenous injection of 1×10^5 K562-HLA-A*24:02 luciferase tumor cells on day 0, and received 2 intravenous injections of TEG011, TEG011_CD8 α or TEGLM1_CD8 α cells on day 1 and 6 as previously reported (32). Together with the first TEGs injection, all mice received $0,6 \times 10^6$ IU of IL-2 (Proleukin; Novartis) in 100 μ l incomplete Freund's adjuvant (IFA) subcutaneously and subsequently administered every 3 weeks until the end of the experiment. Mice were monitored at least twice a week for any symptoms of disease (sign of paralysis, weakness, and reduced motility), weight loss, and clinical appearance scoring (scoring parameter included hunched appearance, activity, fur texture, and piloerection). The humane endpoint was reached when mice showed aforementioned symptoms of disease, experienced a 20% weight loss from the initial weight (measured on day -1), developed extramedullary solid tumor masses (if any) reached 2 cm³ in volume and when clinical appearance score 2 was reached for an individual parameter or a total score of 4.

Flow cytometry analysis

The following antibodies were used for flow cytometry analysis: huCD45-PB (clone HI30; Sony Biotechnology), pan- $\gamma\delta$ TCR-PE (clone IMMU510; Beckman-Coulter), mCD45-APC (clone 30-F11, Sony Biotechnology), $\alpha\delta$ TCR-FITC (clone IP26; Biolegend), CD4-PeCy7 (clone RPA-T4, Biolegend), CD8-PerCPCy5.5 (clone RPA-T8, Biolegend), PD-1-BV711 (clone EH12.2H7, Biolegend), and TIM3-BV650 (clone F38-2E2, Biolegend). To exclude non-viable cells from the analysis, Fixable Viability Dye eFluor506 was used (eBioscience). All samples were analyzed on a BD LSRFortessa using FACSDiva Software (BD Biosciences).

Assessment for TEGs persistence

Mouse peripheral blood samples were obtained via cheek vein (max. 50-70 μ l/mouse) once a week. Red blood cell was lysed using 1X RBC lysis buffer (Biolegend) and were then stained with a mixture of antibody panels as listed above. The persistence of TEG cells were counted as absolute cell number of huCD45 $^+$ $\gamma\delta$ TCR $^+$ CD8 $^+$ population in mouse

peripheral blood using Flow-count Fluorospheres (Beckman Coulter) measured by flow cytometry.

Preparation of single cell suspensions

At the end of the study period, bone marrow (mixed from tibia and femur) and spleen sections were isolated and processed into single cell suspension. Femur and tibia from the hind legs were collected; bone marrow cells were collected by centrifugation of the bones at 10,000 rpm for 15 seconds and resuspension of the cells in phosphate buffer saline (PBS).

A small section of the spleen was minced and filtered through a 70 μ m cell strainer (BD); incubated with 1X RBC lysis buffer cells for maximum 4 minutes, and subsequently cells were washed and resuspended in PBS.

Absolute cell number of TEG cells were quantified using Flow-count Fluorospheres and measured from a total of 10^6 cells stained for the presence of TEG cells in spleen and bone marrow by flow cytometry analysis (BD LSRFortessa).

Histology staining and analysis

Formalin-fixed femur for bone marrow sections were embedded in paraffin and cut into 4 μ m sections. Hematoxylin and eosin (H&E) staining was performed for the femur, for bone marrow section. Tissue sections were evaluated to assess for any differences in the presence, distribution and extension of neoplastic foci indicating tumor tissue. Tissue sections of the femur were evaluated for quantification of tumor tissue by dividing the area covered by the tumor cells by the total area of bone marrow tissue visible in the section using the ImageJ analysis system software (NHI, Bethesda, Maryland, USA) and expressed as a percentage. Images were taken using an Olympus BX45 microscope with the Olympus DP25 camera and analyzed using DP2-BSW (version 2.2) or ImageJ softwares.

Statistical Analyses

Experimental data were analyzed using GraphPad Prism (GraphPad Software Inc., La Jolla, CA, USA) and shown as mean \pm standard deviation (SD) or standard error of mean (SEM) with * $P < 0.05$; ** $P < 0.01$; *** $P < 0.001$; and **** $P < 0.0001$. Statistical significances between groups were assessed using a non-parametric Kruskal-Wallis test, a two-way ANOVA, and a mixed-effects model with repeated measures where indicated.

RESULTS

Co-transfer of transgenic CD8 α receptor is sufficient to re-establish tumor reactivity of CD4 $^+$ TEG011 cells

We previously identified an allo-restricted CD8 α -dependent V γ 5V δ 1TCR clone FE11 (28), which showed *in vitro* antitumor reactivity against HLA-A*24:02-expressing tumor cells

(32). We therefore investigated whether introduction of CD8 α or CD8 $\alpha\beta$ along with V γ 5V δ 1TCR derived from clone FE11 could re-establish antitumor reactivity of not only CD8 $^+$, but also CD4 $^+$ TEG011 cells. Hence, we co-transduced T cells with the FE11 $\gamma\delta$ TCR, and with either CD8 α alone or CD8 α together with CD8 β (Figure S1). Subsequently, we sorted separate sets of CD4 $^+$ TEG011 cells that co-expressed either exogenous CD8 α (CD4 $^+$ CD8 α^+) or CD8 $\alpha\beta$ (CD4 $^+$ CD8 $\alpha\beta^+$) as well as TEG011 cells expressing only endogenous CD4 and CD8 as negative and positive controls for tumor recognition, respectively (Figure 1A). Thereafter, TEG cells were co-cultured with SW480 and EBV-LCL target cells or healthy PBMCs as mock control. Both CD4 $^+$ CD8 α^+ and CD4 $^+$ CD8 $\alpha\beta^+$ TEG011 cells secreted significantly higher levels of IFN γ upon exposure to tumor targets than CD4 $^+$ TEG011 cells. The acquired antitumor reactivity of CD4 $^+$ CD8 α^+ and CD4 $^+$ CD8 $\alpha\beta^+$ TEG011 cells could be blocked by CD8 α and CD8 β blocking antibodies (Figure 1B), confirming the strict dependence of FE11 $\gamma\delta$ TCR on introduced CD8 molecules. Taken together, we showed that introduction of CD8 α alone is sufficient to re-establish antitumor reactivity of CD4 $^+$ T cells expressing FE11 $\gamma\delta$ TCR. Introduction of CD8 β did not further enhance tumor recognition, but was functionally involved in the molecular interaction with its target when present.

For clinical administration, co-expression of both CD8 α and the $\gamma\delta$ TCR in one vector is preferred to allow reproducible and cost-effective production processes (26, 27, 35). Moreover, co-expressing both CD8 α and the $\gamma\delta$ TCR in one vector can also overcome the difference in transduction efficiency when they were transduced separately. Therefore, we generated new retroviral constructs carrying either FE11 $\gamma\delta$ TCR or a non-functional length mutant clone LM1 $\gamma\delta$ TCR ((31); served as mock control) followed by full-length human CD8 α receptor sequences (TEG011_CD8 α and TEGLM1_CD8 α , Figure 1C). To elucidate whether introduction of transgenic CD8 α receptor adequately rescues TEG011 reactivity in CD4-transduced cells once delivered by the very same vector, we co-cultured tumor target HLA-A*24:02-transduced K562, SW480, and EBV-LCL cells with either CD4 $^+$ TEG011_CD8 α , CD4 $^+$ TEGLM1_CD8 α , or CD4 $^+$ TEG011 (without introduction of the CD8 α receptor). Healthy T cells and TEG011 bulk cells (with CD4:CD8 1:1 ratio) were used as the untransformed mock target and positive effector control, respectively (Figure 1D). CD4 $^+$ TEG011_CD8 α cells produced a significantly higher IFN γ level compared to CD4 $^+$ TEG011, which was equivalent to those of TEG011 bulk cells against all tumor targets, without affecting healthy cells. Importantly, enhanced tumor recognition was strictly restricted to TEG011_CD8 α cells and not TEGLM1_CD8 α mock cells, highlighting the specific role of CD8 α as co-stimulation for the introduced FE11 $\gamma\delta$ TCR. We concluded that introduction of transgenic CD8 α receptor in combination with V γ 5V δ 1TCR derived from clone FE11 allowed reprogramming of CD4 $^+$ T cells towards HLA-A*24:02-expressing tumor cells *in vitro*.

Figure 1 Introduction of transgenic CD8 α receptor on TEG011 improves T cell activation. (A) TEG011 were retrovirally transduced with either CD8 α alone or CD8 α in combination with CD8 β . CD4⁺, CD8⁺, CD4⁺CD8 α ⁺ and CD4⁺CD8 α β ⁺ subsets of T cells were subsequently sorted (left panel is a representative sorting plot for CD4⁺, CD8⁺ and CD4⁺CD8 α ⁺ cells; CD4⁺CD8 α β ⁺ cells were sorted in a similar manner) and tested for recognition of SW480 and EBV-LCL target cells by IFN γ ELISPOT (right panel). Healthy PBMCs were included as untransformed mock control target cells. Data are of representative of four independent experiments and error bars represent mean \pm SEM (**P < 0.01; ***P < 0.001) calculated by two-way ANOVA. (B) CD8 α and CD8 β blocking on CD4⁺ T cells were transduced with the FE11 $\gamma\delta$ TCR and CD8 α alone, or CD8 α with CD8 β . TEG011 was co-incubated with SW480 target cells in the presence of a control antibody, or CD8 α or CD8 β blocking antibodies. IFN γ production was measured by ELISPOT. Data represent mean \pm SD of replicates for each effector (**P < 0.01; ***P < 0.001; ****P < 0.0001) calculated by two-way ANOVA. (C) Schematic diagram of pMP71 retroviral vector constructs containing codon-optimized human $\gamma\delta$ TCR sequences from either clone FE11 (referred as TEG011_CD8 α) or non-functional LM1 chains (referred as TEGLM1_CD8 α) in combination with full length of human CD8 α receptor (top panel). Within the transgene cassettes, individual γ TCR and δ TCR chains have been linked with a self-cleaving thioesterase 2A (T2A; black box) ribosomal skipping sequence, while the CD8 α sequence was connected with a porcine teschovirus-1-derived 2A (P2A; grey box) ribosomal skipping sequence. (D) CD4⁺ $\alpha\beta$ T cells were transduced with either TEGLM1_CD8 α , TEG011, or TEG011_CD8 α $\gamma\delta$ TCR (as effector cells) and subsequently co-cultured with HLA-A*24:02-expressing target cell lines or healthy T cells (E:T ratio is 1:3) for 18–24 h. TEG011 bulk population with 50:50 ratio of both CD4⁺ and CD8⁺ TEGs and T cells from healthy donor were used as

Figure 1 (Continued) positive and untransformed mock controls, respectively. Antitumor reactivity was measured by IFN γ ELISPOT, where 50 spots/15,000 cells were considered as a positive antitumor response and indicated by the dashed horizontal line. Data are representative of three independent experiment with replicates for each target and error bars represent mean \pm SD (*P < 0.05; **P < 0.01; ****P < 0.0001) calculated by two-way ANOVA.

TEG011_CD8 α improves *in vivo* tumor control and associates with higher persistence of functional T cells

In previous studies, we have shown TEG011 efficacy against HLA-A*24:02-expressing tumor cells *in vitro* and an extended *in vivo* safety profile as well as peripheral persistence of TEG011, where long-term persistence of TEG associated with reduced probability for developing extramedullary solid tumor masses *in vivo* (32, 36). To assess the consequence of the additional expression of TEG011_CD8 α , NSG transgenic mice expressing human HLA-A*24:02 (NSG-A24:02) were irradiated, received luciferase-labeled HLA-A*24:02-transduced CML tumor cells (K562) and subsequently obtained two infusions of either mock control TEGLM1_CD8 α , TEG011_CD8 α , or TEG011 cells. All infused TEG variants showed comparable $\gamma\delta$ TCR expression, where the transduced $\alpha\beta$ T cells expressed V δ 1⁺ TCR for TEG011 and TEG011_CD8 α (Figure S2). Mice were monitored for tumor burden assessed by bioluminescent imaging, T cell persistence and infiltration, as well as any other signs of discomfort. Mice were sacrificed when the humane endpoints were reached (experimental outline Figure 2A). TEG011_CD8 α -treated mice had a significantly lower tumor burden over time compared to the mock control TEGLM1_CD8 α and TEG011-treated groups (Figure 2B), indicating superior tumor control *in vivo* by TEG011_CD8 α .

Next, we assessed CD8-expressing TEG cell product properties and persistence by measuring viable huCD45⁺ $\gamma\delta$ TCR⁺CD8⁺ single positive and huCD45⁺ $\gamma\delta$ TCR⁺CD4⁺CD8⁺ double positive cells (present in mock TEGLM1_CD8 α and TEG011_CD8 α only) in mouse peripheral blood using flow cytometry. TEG cells persisted up to 4 weeks after infusion in the mouse peripheral blood (Figure 2C). Despite some repeated measure; (*P < 0.05; **P < 0.01). (C) TEG cells were measured in peripheral blood using flow cytometry by quantifying the absolute cell numbers of TEGLM1_CD8 α mock (open light gray rectangle), TEG011 (open black circle), and TEG011_CD8 α (open black triangle) in tumor-bearing mice. TEG cells are distinguished into different cellular compartments: CD8⁺ single positive (SP; white stacked bar), CD4⁺ single positive (SP; grey stacked bar), and CD4⁺CD8⁺ double positive (DP; grey dotted stacked bar). Black arrows indicate higher or lower T cell counts observed. Data are shown as mean \pm SEM of all mice per group (n = 10 mice). Statistical significances were calculated by a mixed-effects model with repeated measures (*P < 0.05; ****P < 0.0001). (D) Functional CD8-expressing TEG cells was assessed in spleen and bone marrow by quantifying the total viable cells of huCD45⁺ $\gamma\delta$ TCR⁺CD8⁺ and huCD45⁺ $\gamma\delta$ TCR⁺CD4⁺CD8⁺ per one million single cell suspension by flow cytometry. Cell counts of individual mouse per treatment group are represented by each symbol. Functional TEG011 cells consist of two different cellular compartments: CD8⁺ single positive (SP; white stacked bar) and CD4⁺CD8⁺ double positive (DP; grey dotted stacked bar). Data are shown as mean \pm SEM (*P < 0.05; **P < 0.01) calculated by a mixed-effects model with repeated measures.

Figure 2 TEG011_CD8 α improves *in vivo* tumor control against HLA-A*24:02⁺ tumor cells and enhances TEG persistence and infiltration. (A) Schematic overview of the *in vivo* experiment for NSG-A24:02 tumor-bearing mice. Irradiated mice were intravenously injected with K562-HLA*A24:02-luciferase tumor cells on day 0 followed by two infusions of TEG011, TEG011_CD8 α or TEGLM1_CD8 α mock cells on days 1 and 6. Mice were monitored regularly and sacrificed when the humane endpoint (HEP) was reached. (B) Tumor burden for K562-HLA*A24:02-luciferase was assessed *in vivo* by measuring integrated signal density per total surface area (count/mm²) using bioluminescence imaging (BLI) with the mouse abdomen facing up. Data are shown only up to week 3 for the TEGLM1_CD8 α mock-treated group (open light gray rectangle) due to subsequent mouse dropout >50%, while data for TEG011 (open black circle) and TEG011_CD8 α (open black triangle) are shown up to week 4. Data are shown as mean \pm SEM of all mice per group (n = 10). Statistical significances were calculated by a mixed-effects model with imbalance in the CD4:CD8 ratio with lower numbers for CD8⁺ TEG011 infused (Figure S2), more CD8⁺ TEG011 persisted over time when compared to CD8⁺ single positive TEG011_CD8 α . Vice versa, endogenous CD4 T cells for TEG011_CD8 α were lower before infusion when compared to TEG011 prior to infusion, while CD4⁺CD8⁺ double positive TEG011_CD8 α were higher in numbers over time when compared to both non-functional CD4⁺CD8⁺ TEGLM1_CD8 α and non-functional CD4⁺ TEG011 cells (Figure 2C). As a net effect, we observed more functional CD8-expressing T cells for TEG011_CD8 α cells when compared to TEG011 (Figure 2C and S3). Next, we investigated the expression of PD1 and TIM3 on CD8⁺ single positive cells and CD4⁺ single

Figure 2 (Continued) positive or CD4⁺CD8⁺ double positive cells. Higher numbers of T cells expressing PD1 or TIM3 were observed on TEG011_CD8 α cells, as compared to mock TEGLM1_CD8 α and TEG011 cells (Figure S4A and B). CD8⁺ single positive TEG011 and TEG011_CD8 α showed an increased PD1 expression when compared to CD8⁺ single positive TEG_LM1 (Figure S4A). A partial decline of TIM3 expression was most pronounced over time in CD8⁺ single positive TEG011_CD8 α (Figure S4B).

Thereafter, we investigated infiltration of TEG cells into spleen and bone marrow on weeks 1 and 2 after infusion. Specifically, we compared the TEG011 and TEG011_CD8 α groups to elucidate the contribution of transgenic CD8 α co-expression in TEG011 infiltration *in vivo*, and focused on the total sum of functional CD8-expressing TEG011 cells. We detected a significantly higher number of functional TEG cells infiltrating in the spleen and bone marrow of TEG011_CD8 α -treated mice at both time points (Figure 2D). Importantly, we did not observe rapid clearance of functional TEG011_CD8 α cells in these tissues within these time points, whereas TEG011 cells were barely detected. Thus, we conclude that CD8 α co-stimulation with TEG011 improves overall *in vivo* tumor control, T cell persistence and infiltration.

Figure 3 TEG011_CD8 α effectively cleared tumor cells in bone marrow, without a significant difference in tumor infiltration observed in other major organs. (A) Representative pictures H&E stained of mouse bone marrow from where no neoplastic cells (black arrow) observed only in TEG011_CD8 α treated group for each individual mouse. Magnification:10 \times ; Shown are representative pictures from individual mice of each treatment group (n = 5mice/group); (B) Percentage cases of tumor infiltration in mouse bone marrow for each treatment group (n = 5mice/group). Calculation was performed by dividing the area covered by the tumor cells per the total area of bone marrow tissue visible in the section using ImageJ. Data are shown as mean \pm SEM (*P < 0.05) calculated by non-parametric Kruskal-Wallis test.

TEG011_CD8 α enhanced T cell infiltration and effectively cleared tumor cells in bone marrow

We previously reported an extensive *in vivo* safety profile of TEG011 against healthy tissues that express HLA-A*24:02 molecules, in which no significant histological lesions were observed in major organs, including liver, spleen, and intestine (36). For histopathology analysis, we collected a femur bone marrow section from each treatment group at the end of the study period to further evaluate antitumor efficacy of the new TEG011_CD8 α cells (Figure 3A). Tissue sections were assessed for the presence and extension of the neoplastic foci. The mock control TEGLM1_CD8 α -treated group showed evident 19,2% neoplastic infiltration, whereas the TEG011-treated group showed up to 3,4% neoplastic infiltration of a homogeneous population of neoplastic cells in the bone marrow. Interestingly, we did not observe any neoplastic infiltration in the bone marrow of mice in the TEG011_CD8 α group and the appearance of bone marrow cell composition and cellularity were normal (Figure 3B). In conclusion, here we report that TEG011_CD8 α effectively cleared tumor cells in bone marrow, emphasizing the role of CD8 α co-stimulation for better *in vivo* tumor control of TEG011 cells. Overall, our data indicate that introduction of transgenic CD8 α on TEG011 cells effectively improves *in vivo* tumor control and better T cell infiltration into bone marrow.

5

DISCUSSION

TEG011 has been reported to specifically recognize HLA-A*24:02⁺ malignant cells while sparing the HLA-A*24:02-expressing healthy tissues with the requirement of CD8 α co-stimulation (32, 36). While TEG011 has shown a favorable efficacy profile *in vivo*, we only observed in 44% of the mice long-term persistence of functional TEG011 cells, which could be due to the lack of support by antigen-specific CD4⁺ T cells (29, 36). To further improve the antitumor efficacy of TEG011, we introduced transgenic CD8 α co-receptor together with TEG011 cells. In this study, we reported on the capacity of the introduced CD8 α co-receptor to successfully redirect non-reactive CD4⁺ TEG011 cells *in vivo* and *in vitro* against tumor targets that express HLA-A*24:02 molecules. Furthermore, TEG011_CD8 α cells showed higher T cell counts and stable peripheral persistence *in vivo*, which was, however, mainly a consequence of the persistence of CD4⁺CD8⁺ double positive TEG011_CD8 α and not an improved persistence of CD8⁺ single positive TEG011_CD8 α . Regardless of the precise underlying molecular mechanism, for the first time we observed tumor clearance in the bone marrow by TEG011_CD8 α , but not by TEG011 alone.

Reprogramming CD4⁺ T cells by genetic engineering has been reported to clinically impact efficacy and toxicity by high affinity receptors, like CARs (37). V γ 9V δ 2TCR (30) and CD8 $\alpha\beta$ independent $\alpha\delta$ TCRs (38) have been also reported to reprogram CD4⁺ T cells which have the not only the ability to exert tumor cell killing but also induce maturation of professional antigen presenting cells. Transfer of CD8 $\alpha\beta$ in combination with intermediate affinity tumor reactive $\alpha\delta$ TCR has been reported to support tumor control *in*

vitro and *in vivo* (39, 40) and for high affinity α BTCR with artificial signaling domains adding CD8 α alone has been shown to reprogram CD4 $^{+}$ T cells (41). Within this context, our data show that CD8 α in combination with a natural $\gamma\delta$ TCR functions serves as co-stimulatory receptor, as opposed to the well-described inhibitory function of CD8 α on α BTCR cells within the context of a natural α BTCR. Expression of that CD8 α on activated CD4 $^{+}$ and CD8 $\alpha\beta^{+}$ α BTCR cells has been reported to act as corepressor by competing with CD8 $\alpha\beta^{+}$ cells for p56^{lck} signaling molecule (42). Though we investigated the role of CD8 α in the TEG concept, our data support the notion that CD8 α in combination with a $\gamma\delta$ TCR are synergistic on natural $\gamma\delta$ T cells, as activated CD8 $\alpha\alpha^{+}$ $\gamma\delta$ T cells were reported in supporting control of HIV infection (43). We have also previously reported significant increases in circulating CD8 $\alpha\alpha^{+}$ $\gamma\delta$ T cells in CMV-positive population (28). Thus, CD8 α appears to have opposing functions on innate and adaptive immune cells, where it acts as co-stimulatory receptor in the context of a $\gamma\delta$ TCR.

Using humanized transgenic mice expressing human HLA-A*24:02, we could study the implication of CD8 α introduction to TEG011, referred to as TEG011_CD8 α , elucidating their improved efficacy *in vivo*. We provide evidence that TEG011_CD8 α effectively cleared tumor cells in bone marrow and elicited better tumor control against human HLA-A*24:02-expressing tumor cells. We cannot entirely exclude that superior tumor control in TEG011_CD8 α may have been caused initially by more CD8 single positive cells in the TEG011_CD8 α product compared to TEG011 product, as CD4 $^{+}$ /CD8 $^{+}$ ratios could not be entirely controlled in the experimental set up prior to infusion. However, our mouse model also allowed us to investigate TEG011_CD8 α kinetics in the presence of tumor cells; and we observed sustained long-term TEG persistence mainly for $\gamma\delta$ TCR $^{+}$ CD4 $^{+}$ CD8 $^{+}$ double positive and a decline in $\gamma\delta$ TCR $^{+}$ CD8 $^{+}$ single positive TEG011_CD8 α cells. Importantly, the sustained peripheral TEG persistence was only observed for TEG011_CD8 α but not TEGLM1_CD8 α , highlighting the key role of a functional tumor-reactive $\gamma\delta$ TCR. This observation rather argues against the classical helper function of $\gamma\delta$ TCR $^{+}$ CD4 $^{+}$ CD8 $^{+}$ double positive TEG011_CD8 α cells within the context of TEG011_CD8 α . Hence, the concurrent expression of CD4 $^{+}$ and CD8 $^{+}$ co-receptor most likely provided additional survival signal for tumor-specific CD4 $^{+}$ T cells, which did not, however, translate into classical helper functions towards CD8 $^{+}$ T cells (36, 44, 45). CD4 $^{+}$ T cells have been reported to avoid expression of inhibitory receptors on CD8 $^{+}$ T cells (46) and as an important cell subset to induce memory T cell formation (47). Along this line we observed over time reduced expression of TIM3 in CD8 $^{+}$ single positive TEG011_CD8 α cells compared to mock and TEG011 group. CD4 $^{+}$ CD8 $^{+}$ double positive TEG011_CD8 α cells had lower levels of TIM3 when compared to CD8 $^{+}$ single positive TEG011_CD8 α cells. These data remain difficult to interpret, and most likely simply reflect different regulation and activation of functional and non-functional CD4 $^{+}$ and CD8 $^{+}$ TEG cells. We also acknowledge that xenograft mouse models do not allow to completely mimic all potential helper roles of human CD4 $^{+}$ T cells, due to the lack of human professional antigen presenting cells.

The precise molecular interaction between CD8 α and its specific ligand in our context remains yet to be unraveled. The CD8 α receptor has been shown to bind to MHC

Class I molecules, including HLA-A*02:01, HLA-A*11:01, HLA-B*35:01, HLA-C*07:02, via protruding $\alpha 3$ domain loop of MHC molecules with lower affinity than the binding of a TCR-pMHC complex (48-51). Polymorphisms in the MHC $\alpha 3$ domain contributes to a binding variation of CD8 α to different HLA molecules, such as HLA-A*24:02. In this context, HLA-A*24:02 is one of the possible ligands for CD8 α on TEG011, in line with an earlier study that reported CD8 α interaction with HLA-A*24:02 in a similar way with HLA-A*02:01, involving binding to the $\alpha 2$ and $\alpha 3$ domains, as well as to the $\beta 2m$ domain of pMHC complex, but with different conformation that suggests CD8 α plasticity (52). The non-classical MHC molecules are also reported to interact with CD8 α , such as HLA-G and HLA-E (53). HLA-G is a known ligand for CD8 α , which is expressed on some colorectal cancer (54-56), while HLA-E is mainly expressed in human endothelial cells and is highly expressed in tumor cells (53). Other studies also demonstrated the interaction between CD8 and CEACAM5, which support the possibility of CEACAM5 as CD8 α ligands (57). Overall, we demonstrate that TEG011 equipped with human CD8 α co-receptor elicits superior tumor control and long-term persistence, which mainly impacted numbers of functional $\gamma\delta$ TCR⁺CD4⁺CD8⁺ double positive TEG011_CD8 α cells, and associated with better T cell infiltration. In addition, TEG011_CD8 α cells successfully cleared tumor cells in the bone marrow, which highlights its potential for further clinical application.

Conflict of Interest Disclosure

DB, ZS and JK are inventors on different patents with $\gamma\delta$ TCR sequences, recognition mechanisms and isolation strategies. JK is cofounder and shareholder of Gadeta (www.gadeta.nl). No potential conflicts of interest were disclosed by the other authors.

Author Contributions

IJ, TS, ZS and JK conceptualized, designed and developed the *in vivo* models. IJ, PH, WS and SH performed the *in vitro* and *in vivo* experiments. LB and AB performed the histopathology examination of the mouse tissues. DB and RO contributed vital components. IJ analyzed all *in vitro* and *in vivo* data and was a major contributor in writing the manuscript. IJ, ZS, and JK interpret all *in vitro* and *in vivo* data. IJ and JK wrote the manuscript; all authors read, review and approved the final manuscript.

Funding

Funding for this study was provided by ZonMW 43400003 and VIDI-ZonMW 917.11.337, KWF 6426, 6790 and 7601, to JK; 12586 to TS and JK; 11393 and 13043 to ZS and JK; 11979 to JK and DB.

Acknowledgments

We thank Halvard Boenig (Institute for Transfusion Medicine and Immunohematology, Goethe University, Frankfurt a. M., Germany) for providing PBMCs for feeder cells.

SUPPLEMENTARY FIGURES

Figure S1 Transgene expression levels on T cells transduced with the FE11 $\gamma\delta$ TCR in combination with CD8 α alone or CD8 α and CD8 β . $\alpha\beta$ T cells were transduced with the FE11 $\gamma\delta$ TCR, and with either CD8 α alone or CD8 α combined with CD8 β . Thereafter, CD4⁺, CD8⁺, CD4⁺CD8 α ⁺ and CD4⁺CD8 $\alpha\beta$ ⁺ TEG011 cells were sorted, and the expression of $\gamma\delta$ TCR and CD8 α was measured by flow cytometry.

Figure S2 $\gamma\delta$ TCR expression of TEG011, TEG011_CD8 α , and TEGLM1_CD8 α mock. Representative flow cytometry plots for $\gamma\delta$ TCR expression of TEGLM1_CD8 α (top panel), TEG011_CD8 α (middle panel), and TEG011 (bottom panel) prior to infusion into mice after 2 weeks expansion. Representative plots for V δ 1 TCR expression of TEG011 and TEG011_CD8 α were included as quality control for flow cytometry panel using pan- $\gamma\delta$ TCR monoclonal antibody.

Figure S3 Overall functional TEG011 cells in periphery. Absolute number of CD8-expressing TEG011 cells were measured in peripheral blood by flow cytometry for TEG011 (open black circle) and TEG011_CD8α (open black triangle) in tumor-bearing mice. TEG cells are distinguished into two different cellular compartments: CD8⁺ single positive (SP; white stacked bar) and CD4⁺CD8⁺ double positive (DP; grey dotted stacked bar). Black arrows indicate higher or lower T cell counts observed. Data represent mean \pm SEM of all mice per group (n = 10 mice). Statistical significances were calculated by a mixed-effects model with repeated measures (*P < 0.05).

Figure S4 PD1 and TIM3 expression on CD4⁺ and CD8⁺ TEGs. Absolute cell counts of PD1-expressing (A) and TIM3-expressing (B) huCD45- $\gamma\delta$ TCR-CD8⁺ single positive cells (left panel) and huCD45- $\gamma\delta$ TCR-CD4⁺ single positive or CD4⁺CD8⁺ double positive cells (right panel) were measured by flow cytometry for TEGLM1_CD8α mock (open light gray rectangle), TEG011 (open black circle), and TEG011_CD8α (grey triangle). Black arrows indicate higher or lower T cell counts observed. Data represent mean \pm SEM of all mice per group (n = 10 mice). Statistical significances were calculated by a mixed-effects model with repeated measures (*P < 0.05; ****P < 0.0001).

CHAPTER 6

General discussion

Despite the surmounting clinical responses from immunotherapy against cancer, only some cancer patient populations benefit from the treatment (1). This is the consequence of our rather limited understanding of how to better engineer a balance between the targeted killing of malignant cells while protecting their healthy counterparts. Within this context, T cells are a major player which facilitates cellular immunity against different foreign proteins, including malignantly-transformed cells. If this delicate balance of cancer immunosurveillance failed, multiple reasons are accountable for tumor development. Reasons for immune escape are as follows, e.g., loss of antigens, because tumor-reactive T cells became anergic or deleted, or immune cells are kept outside the established immunosuppressive tumor microenvironment (1). To overcome these hurdles, better understanding of the interplay between the immune system, cancer cells, and healthy tissues is crucial for developing effective cancer immunotherapy options to offer better outcome for patients. With this perspective, multiple cancer immunotherapies have been developed in laboratories, as described in **Chapter 1** (2, 3). However, a critical step in clinical translation is to substantially reduce the gap between laboratory findings and clinical exploration of novel therapeutic candidates. This thesis focuses on bridging the path from the laboratory findings to first-in-men studies by studying the efficacy and safety balance of two novel therapeutic candidates of cancer immunotherapy, namely α BT cells Engineered to express a defined $\gamma\delta$ TCR (TEG), expressing two distinct $\gamma\delta$ TCRs: a tumor-reactive $\gamma\delta$ 2TCR (TEG001) and a tumor-reactive $\gamma\delta$ 1TCR (TEG011). In this chapter, I will summarize my findings related to TEG-based therapies in the broader perspective of cellular therapy with respect to current literature.

Strength and weakness of TIL, α BTCR-engineering, CART-, and TEG-based therapies

The field of adoptive immunotherapies started by exploring the potential benefit of autologous *ex vivo* expanded tumor-infiltrating lymphocytes (TILs). Despite their initial clinical success, TILs are hindered by their scarce numbers of infiltrating T cells that can be isolated from cancer patients for a broader clinical administration. Moreover, clinical outcomes of adoptive T cell therapy (ACT) using TILs has shown only occasional efficacy in a small percentage of the patients (3, 4), which could be due to low tumor mutational load (5) or the effect of immunosuppressive tumor microenvironment impeding immune infiltration (1).

To partially override the aforementioned drawbacks, α BTCR-engineered α BT cell and chimeric antigen receptor (CAR) therapies were introduced. α BT cells recognize specific tumor antigens presented in major histocompatibility complex (MHC) molecules. α BTCR-engineered α BT cell therapy is performed by isolating tumor-specific α BTCR and genetically transfer them into polyclonal α BT cells, and thus redirecting their tumor specificity and broadening the applicability for larger patient populations (6). Using this approach, tumor-specific α BT cells expressing α BTCR with high avidity α BTCR could be generated bypassing the central tolerance mechanism. However, this approach is still impeded by the requirement of human leukocytes antigens (HLA)-matching donors that are vital to avoid possible graft-versus-host-disease (GvHD) manifestation (7). Moreover, it is challenging to identify tumor antigens that are exclusively restricted to

tumor cells, contributing to significant off-target or on-target off-tumor toxicities (8). Therefore, targeting neoantigens with tumor-specific α BTCR is heavily explored, but clinical logistics to identify a defined α BTCR and engineer α BT cells under GMP-grade conditions with individual receptors for each patient are major logistical and regulatory hurdles yet to overcome (9).

CAR T cells have been explored side by side with the aforementioned strategies and are to date the “winner” immunotherapeutic strategy, resulting in a clinically approved and reimbursed drug (10). CAR T cells carry a synthetic receptor with antibody-like specificity and CD3 signaling domain that allow tumor recognition in an MHC-independent manner and, therefore, not only applicable for a particular patient population with specific HLA alleles (11, 12). Based on the promising clinical results, CAR T cells directed towards CD19 antigen have been approved by FDA and EMA (13) to target B cells malignancies, including acute lymphoblastic leukemia (14) and diffuse large B cell lymphoma (15). Inspired by this groundbreaking success that resulted in the introduction of living drugs as one of the standard-of-care arsenal to cancer patients across the globe, many additional clinical studies have been initiated for CAR T cells with different target antigens across different type of malignancies (16, 17). However, CAR T cells only recognize surface antigens, unlike TCR-engineered T cells that could recognize both surface and intracellular antigens presented on MHC molecules (18). As CAR T cells recognition is determined on tumor antigen expression, it also contributes to their on-target off-tumor toxicity where target antigens may be expressed on healthy cells in low density (19). Moreover, tumor cells downregulate or shed their targeted tumor antigens as a tumor escape mechanism and promote therapy resistance (20).

A recent novel cancer immunotherapy strategy arose by observing that enrichment of $\gamma\delta$ T cells in tumors was associated with improved clinical outcomes (21). This observation inspired the usage of unmodified $\gamma\delta$ T cells and engineering strategy, including TEGs, as further explored in detail in this thesis.

Strength and weakness of $\gamma\delta$ T cell-based versus TEG-based therapies

$\gamma\delta$ T cells recognize their targets mainly independent of MHC-restriction and thus target a broad range of malignancies, including cancer cells with a low mutational burden (22, 23). $\gamma\delta$ TCR can differentiate between healthy and malignant cells mainly by recognizing stress-induced ligands or metabolic alterations, which are not restricted by one specific tumor antigen. Whether the antitumor property of $\gamma\delta$ T cell-based immunotherapy arises from the $\gamma\delta$ TCR (24, 25), other natural killer (NK)-types of receptors (26), or both, remains debatable. Clinical studies which aimed to harvest the antitumor reactivity of both $\gamma\delta$ TCR and NK receptors by harnessing autologous unmodified $\gamma\delta$ T cells showed rather disappointing clinical responses (27).

The lack of success of autologous unmodified $\gamma\delta$ T cell-based therapy could be contributed by the limited proliferative capacity and rapid clearance of circulating $\gamma\delta$ T cells in cancer patients, even in the presence of aminobisphosphonate and IL-2 (28-34) or

their underestimated diversity (35). Furthermore, some studies also observed scarce infiltration of $\gamma\delta$ T cells in target tissues (36). Nevertheless, these clinical studies showed a favorable safety profile of $\gamma\delta$ T cell-based therapy, including the absence of GvHDs in MHC mismatch background (37). However, without a well-defined antitumor efficacy, this lack of toxicity property is clinically not very meaningful. Therefore, careful selection of optimal tumor-reactive $\gamma\delta$ T cells, e.g., expanded $\gamma\delta$ T cells with defined cytokine cocktails (38) or extraction and expression of individual receptors, might be a critical parameter in designing $\gamma\delta$ TCR-based cancer immunotherapy (27).

Strong evidence that the $\gamma\delta$ TCR itself is a key for antitumor reactivity and thus can be used for clinical therapeutic concepts is shown in my thesis. Antitumor reactivity of TEG cells expressing a $\gamma 9\delta 2$ TCR sense joint conformational and spatial changes of target ligands on the surface of tumor cells, which does not occur on healthy cells (35, 39, 40). Introduction of $\gamma\delta$ TCR into $\alpha\beta$ T cells do not cause TCR mispairing or promote alloreactivity, which might occur in antigen-specific $\alpha\beta$ TCR transfer or CAR T cells (24, 41). Hence, this approach allowed studying tumor control efficacy in different models within the TEG concept as described in **Chapters 2 to 5** (39, 42, 43).

However, the major limitation of $\gamma\delta$ TCR-based therapeutic is the frequently inadequate characterization of specific ligands involved in $\gamma\delta$ TCR tumor recognition, which obscures the assessment of their efficacy and safety profiles prior to first-in-men studies (27). With the TEG concept, we redirect $\alpha\beta$ TCR antitumor response using highly tumor-reactive $\gamma\delta$ TCR and override the requirement of HLA-restriction while retaining the proliferative capacity (24, 41, 44). We also uncoupled innate-like receptors from the tolerance mechanism and mitigated the highly diverse $\gamma\delta$ TCR repertoire and their functions (27, 45). Using the TEG concept, we could retain both CD4⁺ and CD8⁺ effector cell functions while exerting the antitumor reactivity from $\gamma\delta$ TCR, either from V δ 2⁺ or V δ 2⁻ subsets.

Bridging the gap towards first-in-men studies: efficacy-safety balance of TEG001

The main focus of my research was the assessment of therapeutic efficacy and safety of novel cell-based therapy, which is classified as advanced therapy medicinal products (ATMP) consisting of ‘living’ medicinal products that are heterogeneous and far more complex than other biological products. Due to this characteristic, therapeutic assessment of cell-based therapeutic can frequently not follow the established procedure for conventional drugs. Hence, ATMP products require distinct assessments involving advanced technology transfer from laboratory-grade processes into the implementation of Good Manufacturing Practices (GMP) for production processes (46, 47). Moreover, separate pharmacological and toxicological data are needed considering the desired interaction of the cellular product with surrounding normal tissues and cancer cells (48, 49), as well as pharmacokinetics properties measured by biodistribution of the medicinal product itself, i.e., cell viability, growth, persistence, and migration (50, 51).

Due to these prerequisites, selecting suitable preclinical models to assess the nonclinical efficacy and safety studies is rather challenging, taking into account the dissimilar

microenvironment and relevant receptors involved in the reactivity of the cell-based therapeutics (51). Moreover, the activity of cell-based therapy products in animal models may be limited or even absent due to the unrelated immunogenicity due to artificial immune reactivity against human cells, and therefore it has to be carefully considered (52-54).

In this manner, assessment of efficacy-safety balance for TEG001 adds further complexity as a result of its underestimated diversity in functions, receptors, and the nature of its targets, as outlined above. However, despite this complexity, the development of relevant preclinical models remains critical to enhance efficacy and minimize the risk of off- and on-target off-tumor toxicity (55, 56). To assess the efficacy and safety of TEG-based therapies, we developed different models where healthy and tumor cells are sequentially or simultaneously present *in vitro* and *in vivo*. Within this context, we first explored in **Chapter 2** *in vitro* activity of TEG001 against several primary leukemic cell blasts and healthy tissues. Our data showed that induction of cellular stress, either by irradiation or exposure to inflammatory cytokines, and the presence of chemotherapy agents do not induce TEG001 off-target toxicity, even in the presence of monocytes as a physiological target of $\gamma\delta$ TCRs. However, the number of healthy tissues to be tested has been limited due to the scarce healthy tissues that can be isolated and tested in the laboratory. Also, the physiological environment does not entirely mimic the bone marrow niche. To overcome this shortcoming, we also simultaneously tested the efficacy and toxicity of TEG001 in a 3D model, which allowed additional stroma of the bone marrow niche. This model also enabled us to assess the effect of TEG001 antitumor activity against autologous stroma and tumor targets as described that seem otherwise impossible to test because of their low numbers, as only limited numbers of immune cells and tumor cells are needed in this autologous system (57). Yet, also 3D models do not mimic the complete hematopoietic niche and all counter-attacks of a tumor.

To partially overcome the limitations of *in vitro* 2D and 3D efficacy and toxicity models, we next moved to an *in vivo* model and explored TEG001 efficacy and toxicity in mice. However, as immunocompetent mice have different $\gamma\delta$ T cell subsets (58, 59), they are also devoid of the natural ligands CD277 in the context of $\gamma\delta$ TCR and TEG001 (27, 40, 60). This created the need to work with immunodeficient NSG mice transplanted with human tumor cells or healthy tissues followed by infusion of TEG cells. I report in **Chapter 2** on the therapeutic efficacy profile of TEG001 towards primary AML blast. We established a patient-derived xenograft (PDX) model by inoculating primary patient materials to better mimic human tumor characteristics and complexity, as well as maintain biological and histological features of the original tumor, including their intra-tumoral and inter-tumoral heterogeneity (61, 62). The major limitations of this model are the limited availability of primary patient materials and poor engraftment rates (63). In addition, donor variation influences the treatment outcome of the PDX tumor due to allogeneic response. Autologous PDX models would have been a more favorable tool to assess the efficacy and safety of immunotherapeutic agents; however, harvesting a sufficient amount of tumor cells and immune cells from one patient remains challeng-

ing, particularly when requiring repetitions for statistics. Despite these restrictions, our PDX model allowed us to confirm a reduction of the leukemic burden by TEG001 in these rather more complex models and served as a positive control for toxicity tests, which were performed in a different set of mice. The toxicity of TEG001 against healthy hematopoietic compartments was explored after engrafting NSG mice with healthy cord-blood derived CD34⁺ hematopoietic stem cells (HD-X). Our data showed that TEG001 treatment does not impair the reconstitution of healthy hematopoietic compartments in the periphery, spleen, and bone marrow, even in the presence of physiological target of $\gamma\delta$ TCRs, such as monocytes, which were still detectable *in vivo* after TEG001 treatment. Using humanized mouse models, we are able to perform a detailed evaluation of the therapeutic efficacy of immunotherapy. Nevertheless, careful evaluation for further translation into the clinics remains critical as these models may not fully represent human immune responses as seen in patients.

Bridging the gap towards first-in-men studies: efficacy-safety balance of TEG011

In the next set of chapters, I worked on the further drug development of TEG011. As described in **Chapter 3**, in contrast to classical $\gamma\delta$ TCR and peptide-MHC recognition for alloreactive $\alpha\beta$ TCRs, TEG011 recognizes spatial changes and alteration of HLA-A*24:02 clustering on tumor cells irrespective of the specific peptide presented and thus contributing to their broad range reactivity against tumor cells. TEG011 follows an unconventional recognition pattern compared to the previously known tumor antigen recognition via classical HLA molecules (64), whereby it recognizes target cells in an alloreactive-MHC class I-restricted fashion to discriminate healthy and tumor cells. Moreover, the contribution of HLA molecules expressed on tumor cells is mainly studied in relation to tumor escape mechanism from antigen-specific $\alpha\beta$ TCRs by downregulation or loss of Class I MHC expression (65). The differential HLA clustering on tumor cells in monomeric form suggests the possibility of a tumor escape mechanism from $\alpha\beta$ TCRs, yet still targetable by an alloreactive $\gamma\delta$ TCR, including the identified FE11 $\gamma\delta$ TCR. Previous studies have suggested allo-HLA reactivity of $\gamma\delta$ T cells as a general occurrence and not limited to malignantly-transformed cells (66, 67). However, it is noteworthy to acknowledge that these studies did not investigate the $\gamma\delta$ TCR reactivity against healthy and tumor cells in detail.

The ability of TEG011 to differentiate healthy and malignant cells by sensing distinct spatial and conformational changes of HLA-A*24:02 molecules pose a very intriguing nature of alloreactive- $\gamma\delta$ TCR. Nevertheless, due to their mode-of-action, it is rather difficult to assess the safety profile of TEG011 properly. To mitigate this limitation, I evaluated the efficacy-safety balance of TEG011 in tumor-bearing and non-tumor bearing transgenic NSG mice expressing human HLA-A*24:02 (NSG-A24:02) as shown in **Chapter 3**. Despite the advantages of the primary leukemic PDX mouse model as shown for the abovementioned efficacy-safety studies for TEG001, it is rather difficult to obtain primary patient materials with HLA-A*24:02-expressing tumors sufficient for *in vivo* studies due to their infrequent allele occurrence. Hence, I utilized HLA-A*24:02-transduced chronic myeloid leukemia (K562) cell line and developed a cell line-derived xenograft

(CDX) model. This model has been well-established, easy to control, and frequently used for efficacy study of therapeutic agents (68). Using cancer cell lines, we can generate tumor models that partially recapitulate the molecular and genetic diversity of cancer cells *in vivo* (69). However, we acknowledge the limitation of this model, in which they do not fully represent the stromal complexity and heterogeneity of human tumors (70). Despite these shortcomings, we observed a significant reduction of tumor progression and prolonged overall survival of tumor-bearing mice treated with TEG011 cells. Separately, we could also evaluate TEG011 toxicity in different tissues more extensively compared to TEG001. As shown in **Chapter 4**, we did not observe any histopathological evidence of toxicity against the investigated healthy tissues. All non-tumor bearing mice did not show decreased in physical fitness throughout the study period, suggesting the absence of autoimmunity or GvHDs development against healthy tissues.

Alongside the aforementioned efficacy and safety evaluations, our mouse models allowed the extensive pharmacokinetics assessment of TEG011 expansion and persistence *in vivo*. As previously described, T cell persistence can be used to measure the pharmacokinetics of cell-based therapy. Furthermore, short-term T cell persistence in patients receiving TCR-engineered therapies has been shown to limit their antitumor activity (71). In **Chapter 2**, I showed that TEG001 persisted in mouse peripheral blood up to 4 weeks after infusion, while in **Chapter 4**, I unexpectedly observed 44% of mice that showed the presence of TEG011 “persister” up to 9 weeks after infusion, which was then associated with the absence of extramedullary solid tumor growth in these mice. The difference between TEG001 and TEG011 persistence is most likely a consequence of the HLA-A*24:02 background when using TEG011, which could have provided tonic signaling, while no binding at all was possible to TEG001 as both BTN2A1 and BTN3A1 are absent in mice (58, 60, 72).

Based on the observation of different TEG persistence *in vivo*, I was interested in investigating which factor(s) influenced the long-term TEG persistence *in vivo*. The presence of both tumor-specific CD4⁺ and CD8⁺ αBT cells has been reported to significantly improved clinical responses compared to tumor-specific CD8⁺ αBT cells alone (73). Therefore, I further investigated the contribution of each αBT cell subset for *in vivo* persistence and antitumor reactivity of TEG011, which selectively redirected CD8⁺ αBT cells. The introduction of transgenic CD8α co-receptor in TEG011, referred to as TEG011_CD8α, successfully redirected non-reactive CD4⁺ TEG011 cell *in vitro* and *in vivo* against tumor targets. Interestingly, for the first time, we observed tumor clearance in mouse bone marrow after treatment of TEG011_CD8α, but not TEG011 alone. Also, TEG011_CD8α stably persisted with higher T cell counts consisting of mainly CD4⁺CD8⁺ double-positive T cells. This observation supports the notion that simultaneous expression of CD4⁺ and CD8⁺ co-receptor provides additional survival for tumor-specific CD4⁺ T cells. This finding is in line with clinical studies for CAR T cells directed against CD19 have shown that a mixture of both CD4⁺ and CD8⁺ T cells with 1:1 ratio facilitated better tumor remission in B-ALL patients that could be due to increasing T cell survival by CD4⁺ T cells that not only enhanced their own persistence but simultaneously improved CD8⁺ T cells persistence

(74, 75). Moreover, it has been indicated that CD4⁺ T cells are less prone to exhaustion and AICDs (76-79), leading to robust antitumor capacity than CD8⁺ T cells. While T cell persistence may indicate the biodistribution and longevity of cell-based therapeutics, it is important to acknowledge that the circulating compartment of T cells detected in the periphery neither accurately reflects the presence of T cells at the primary tumor or metastasis sites, nor does it indicate T cell dynamic and tumor trafficking.

CONCLUSION

In conclusion, a careful choice of relevant preclinical models and appropriate study designs are pivotal to assess the efficacy-safety balance to support the successful translation of cell-based immunotherapy into the clinic. Within this context, I bridged the gap from preclinical development of different TEG formats to first-in-men studies. While 2D and 3D models provided some hints for efficacy and lack of toxicity, *in vivo* models are very valuable in studying the impact on the complete human hematopoietic compartment and studying important parameters that impact persistence, even in the absence of the appropriate target molecule. Within the limitation of our preclinical mouse models, we could proficiently assess the efficacy-safety profile of both TEG001 and TEG011 against hematological malignancies and hereby provide sufficient nonclinical evidence prior to first-in-men studies, in which TEG-based therapy may have beneficial effects for cancer patients. As a result, TEG001 is currently tested in a first-in-men study (clinical trial registration NTR6541).

APPENDICES

SUMMARY

Conventional treatment options for cancer, including surgery, chemotherapy, radiotherapy, and targeted therapy, can successfully eliminate cancer cells. To date, there are still significant relapses in cancer patients after these treatments. In addition, there are still substantial unwanted side effects that cause damage to the healthy tissues and reduce the quality of life over many years, even after the treatment has been completed. Thus, other treatment alternatives are needed. To overcome these limitations, cancer immunotherapy has been explored as one of the therapeutic options against different malignancies and implemented, due to its efficacy in safety profile into many daily treatment concepts. This strategy was based on the observation that the human immune system protects not only from infection but also has been shown to recognize and target malignantly transformed cells and prevent further developments of cancer cells.

Chapter 1 provides an overview on how cancer immunotherapy aims to stimulate antitumor response without harming healthy tissues by using the patients' own immune system to eliminate cancer cells. Furthermore, we elaborate on different immunotherapy options and focus on differences between conventional α BT cells and unconventional $\gamma\delta$ T cells. We emphasize that α BT cells recognize specific tumor peptides represented on Human Leukocytes Antigens (HLA) molecules and eventually eliminate the tumor cells. On the other hand, $\gamma\delta$ T cells express $\gamma\delta$ T cell receptor (TCR) on the cell surface and recognize infected and tumor cells by sensing metabolic changes in these cells without the need of specific peptide representation on HLA molecules, making them applicable for a broader patient population compared to α BT cells. Our research group specifically interested in $\gamma\delta$ T cells for their ability to target cancer cells and without harming healthy cells, and thus focusing on the development of a new cancer immunotherapy approach based on potent antitumor reactivity of $\gamma\delta$ T cells. Furthermore, in this chapter we introduce alternative treatment concepts based on the observation that despite their promising potential, clinical responses of adoptive transfer of *ex vivo* expanded unmodified $\gamma\delta$ T cells are relatively marginal. We propose to focus on new insights into $\gamma\delta$ T cell biology which uncovered the underestimated diversity in T cell functions and molecular activation modes. Considering these obstacles, we introduce the concept of TEGs: α BT cells engineered to express a defined $\gamma\delta$ TCR, where highly-tumor reactive $\gamma\delta$ TCR is introduced into α BT cell with superior proliferative capacity in cancer patients. Careful considerations of the efficacy-safety balance of cell-based therapeutic modalities against cancer are critical prior to clinical implementation. Hence, this thesis mainly focuses on evaluating the efficacy-safety balance of our TEG-based cellular therapy in preclinical mouse models.

In **Chapter 2**, the efficacy-safety balance of TEG001 were evaluated against primary tumor tissues and primary healthy cells, respectively. TEG001 has been selected as the first clinical candidate of TEG-based therapy based on its ability to target a broad range of hematological malignancies *in vitro* and has previously shown *in vivo* to control tumor growth in mouse model injected with tumor cell lines. Here, I assessed for the first

time the efficacy of TEG001 treatment in clinically relevant model of leukemic mouse model that injected with primary AML blast derived from a patient. In parallel, I also assessed the safety of TEG001 treatment by injecting mice with cord blood-derived stem cells that reconstituted into complete healthy hematological cell subsets. In this way, I studied the effect of TEG001 treatment for any potential toxicity against these healthy cells. Overall, we showed that TEG001 effectively suppress the growth of primary AML blast without any indicative side effects against healthy cells *in vivo*. Thus, within the limitation of the current models, there are no data indicating increased safety risk for TEG001.

Chapter 3 focuses on the identification of the ligand for tumor-specific $\gamma\delta$ TCR that have been identified previously. Unlike $\alpha\beta$ T cells, $\gamma\delta$ T cells do not require antigen presentation via Human Leukocytes Antigen (HLA) molecules on the infected or malignantly-transformed cells. Here, we attempt to identify specific ligand for this FE11 $\gamma\delta$ TCR and its recognition mechanism against tumor cells. We identified HLA-A*24:02 molecule as ligand of tumor-specific FE11 $\gamma\delta$ TCR. We also uncovered the mode-of-action of this particular $\gamma\delta$ TCR that recognizes alteration in HLA-A*24:02 clustering on the cell surface of tumor cells, independent of a specific tumor peptide. When introduced into TEG format, subsequently named as TEG011, the antitumor reactivity of FE11 $\gamma\delta$ TCR was retained and thus able to differentiate healthy and malignant cells expressing HLA-A*24:02 molecules. I specifically focused on the assessment of therapeutic efficacy of TEG011 in humanized transgenic NSG mouse model expressing human HLA-A*24:02 molecules. I reported an improved overall survival of tumor-bearing mice treated with TEG011. Since TEG011 is able to target many different HLA-A*24:02-expressing tumor cells, it is attractive to eventually use this $\gamma\delta$ TCR as immunotherapy. The sequence of FE11 and its potential applications have been patented by our group.

Chapter 4 describes further the efficacy-safety balance of TEG011 assessed in tumor-bearing and non-tumor bearing NSG-A24:02 mice. I showed that TEG011 treatment does not associate with any discomfort nor any clear evidence of toxicity in HLA-A*24:02-expressing non-tumor healthy tissues. I reported that no relevant graft-versus-host disease (GvHD) manifestation in all mice and no signs of toxicity in the major organs of all healthy tissues upon TEG011 treatment. The pharmacokinetics properties of cell-based therapy can be determined by *in vivo* T cell expansion and persistence in the cancer patients. I also reported long-term persistence of TEG011 in approximately 44% of the TEG011-treated mice, which were associated with the absence of solid tumor growth outside of the bone marrow, emphasizing the crucial aspect of T cell persistence to sustain long-term efficacy.

In **Chapter 5**, I extended the biological mechanism of TEG011 that is CD8 α -dependent and investigated further their functions as coreceptor for FE11 $\gamma\delta$ TCR. Introduction of transgenic CD8 α receptor on TEG011 cells is considered an additional strategy to further enhance T cell persistence and long-term tumor control. The new construct design is subsequently referred to as TEG011_CD8 α . I showed that non-reactive CD4 $^{+}$

TEG011 cells can be redirected to target HLA-A*24:02-expressing tumor targets after genetic introduction of human CD8 α gene. In transgenic NSG-A24:02 mice engrafted with HLA-A*24:02-expressing tumor cells, TEG011_CD8 α treatment showed stable peripheral persistence with higher T cell counts in comparison with TEG011 cells alone. Moreover, I showed that TEG011 equipped with human CD8 α co-receptor elicits better tumor control, promotes long-term T cell persistence and associated with better T cell infiltration. In addition, I observed for the first time that TEG011_CD8 α treatment successfully cleared tumor cells in bone marrow and thus further highlight its potential clinical application.

In the last chapter, **Chapter 6**, earlier findings in the afore-mentioned chapters were put in broader perspective of preclinical model development within the context of TEG-based therapy and in relation to current literatures.

NEDERLANDSE SAMENVATTING

Conventionele behandelingen voor kanker zoals operatie, chemotherapie, radiotherapie en doelgerichte therapie kunnen kankercellen succesvol opruimen. Helaas keert de ziekte na deze behandelingen tot op heden nog steeds bij een aanzienlijk deel van de kankerpatiënten terug. Daarnaast treden er vaak ook ongewenste bijwerkingen op die schade toebrengen aan gezonde weefsels en de kwaliteit van leven gedurende vele jaren verminderen, zelfs nadat de behandeling is beëindigd. Er zijn dus nog andere behandelopties nodig.

Immunotherapie is onderzocht als een van de verbeterde therapeutische opties tegen verschillende soorten kanker. Tegenwoordig is het al geïmplementeerd in vele dagelijkse behandelplannen vanwege zijn werkzaamheid en veiligheid. Immunotherapie is gebaseerd op het vermogen van het immuunsysteem van de mens om niet alleen te beschermen tegen infecties maar ook om kwaadaardige cellen in een vroeg stadium te herkennen en op te ruimen en zo de verdere ontwikkeling van kanker te voorkomen.

Hoofdstuk 1 geeft een overzicht over hoe immunotherapie het eigen immuunsysteem van een patiënt tracht te stimuleren om kanker te bestrijden, zonder gezonde weefsels te beschadigen. Verder gaan we dieper in op verschillende vormen van immunotherapie en we richten ons op de verschillen tussen conventionele α BT cellen en de onconventionele γ DT cellen. We benadrukken dat α BT cellen specifieke tumor eiwitten herkennen die gepresenteerd worden door zogenaamde Humane Leukocyten Antigenen (HLA) moleculen, waarna de α BT cel de tumorcellen zal opruimen. Anders dan α BT cellen, brengen γ DT cellen een γ DT cel receptor (TCR) tot expressie, waarmee ze subtiele veranderingen herkennen in het metabolisme van tumorcellen, die vaak vroeg in de transformatie van een gezonde- naar een tumorcel ontstaan. Deze herkenning is onafhankelijk van de expressie van specifieke HLA moleculen, waardoor γ DT cellen geschikt zijn voor een bredere patiëntenpopulatie dan α BT cellen. Onze onderzoeksgroep is voornamelijk geïnteresseerd in γ DT cellen om hun unieke vermogen om tumorcellen te kunnen onderscheiden van gezonde cellen, en concentreert zich daarom op de ontwikkeling van immunotherapie tegen kanker gebaseerd op de antitumor activiteit van γ DT cellen. Helaas is de klinische effectiviteit van kankertherapieën waarbij ex vivo geëxpandeerde en ongemodificeerde γ DT cellen worden gebruikt tot nu toe gering gebleken. Om dit te verbeteren, introduceren we in dit hoofdstuk andere mogelijke behandelconcepten gebaseerd op γ DT cellen. We richten ons op nieuwe inzichten in de biologie van γ DT cellen die de onderschatte diversiteit in T cel functies, en moleculaire activeringsmodi onthullen. Onze groep heeft het concept van genetisch gemodificeerde cellen ontwikkeld, ook wel TEGs genoemd. Deze afkorting staat voor het Engelse “ α BT cells engineered to express a defined γ DTCR”, waarbij een geselecteerde hoge affiniteit tumor reactieve γ DTCR geïntroduceerd wordt in een α BT cel die een hoge groeisnelheid heeft in kankerpatiënten. Een zorgvuldige overweging van de balans tussen werkzaamheid en veiligheid van cellulaire therapieën tegen kanker is van cruciaal belang voorafgaand aan de klinische implementatie. Daarom richt dit proefschrift zich met name op de

evaluatie van de balans tussen werkzaamheid en veiligheid van onze TEG-therapie in preklinische muismodellen.

In **hoofdstuk 2** bespreken we de balans tussen werkzaamheid en veiligheid van TEG001 tegen primaire tumorweefsels en primaire gezonde hematologische cellen. TEG001 is geselecteerd als eerste klinische kandidaat van TEG-therapie vanwege zijn hoge reactiviteit tegen verschillende hematologische tumoren in vitro en verminderde tumorgroei in muizen geïnjecteerd met tumor cellijnen. In dit hoofdstuk laat ik voor de eerste keer de therapeutische werkzaamheid van TEG001 zien, getest in een klinisch relevant leukemisch muismodel, waarbij de uitgroei van leukemische cellen van een patiënt in de muizen wordt gevolgd na behandeling met TEG001- of mock cellen. Tegelijkertijd heb ik ook de veiligheid van TEG001 behandeling beoordeeld door muizen te injecteren met stamcellen uit navelstrengbloed waaruit vervolgens de volledige gezonde hematologische cel subsets uitgroeiden. Op deze manier heb ik de mogelijke toxiciteit van TEG001 tegen deze gezonde cellen onderzocht. Kortom, we hebben laten zien dat TEG001 de groei van primaire AML blasten effectief inhibeert, zonder enige aanwijzing van bijwerkingen tegen gezonde cellen in vivo. Dus, ondanks de beperking van de huidige muismodellen, zijn er geen data die wijzen op een verhoogd veiligheidsrisico door TEG001.

Hoofdstuk 3 beschrijft de zoektocht naar het ligand van een van de tumor-specifieke $\gamma\delta$ TCRs die we eerder hebben geïdentificeerd. In tegenstelling tot $\alpha\beta$ T cellen, zijn $\gamma\delta$ T cellen niet afhankelijk van de expressie van specifieke HLA moleculen voor herkenning en activatie. In dit hoofdstuk hebben we echter wel een HLA-A*24:02 molecuul geïdentificeerd als ligand van de tumor-specifieke FE11 $\gamma\delta$ TCR. We laten zien dat deze FE11 $\gamma\delta$ TCR een verandering in de clustering van het HLA-A*24:02 molecuul op kwaadaardige cellen herkent, onafhankelijk van de presentatie van specifiek peptide. Als TEG, in het vervolg TEG011 genoemd, bleef de antitumor reactiviteit van FE11 $\gamma\delta$ TCR behouden. TEG011 is dus in staat gezonde en kwaadaardige cellen van elkaar te onderscheiden op basis van de clustering van HLA-A*24:02. Ik heb mij specifiek gericht op de beoordeling van de therapeutische werkzaamheid van TEG011 in een gehumaniseerd transgeen NSG muismodel dat HLA-A*24:02 (NSG-A24:02) tot expressie brengt, waarbij we een verlenging van de levensduur hebben aangetoond voor muizen met tumor die behandeld werden met TEG011. Aangezien TEG011 in staat is om veel verschillende tumoren die HLA-A*24:02 tot expressie brengen te herkennen, is het een veelbelovende kandidaat om uiteindelijk als immunotherapie te gebruiken. De sequentie van FE11 en de mogelijke toepassingen zijn door onze groep gepatenteerd.

Hoofdstuk 4 beschrijft de balans tussen werkzaamheid en veiligheid van TEG011, onderzocht in NSG-A24:02 muizen die al dan niet geïnjecteerd werden met HLA-A*24:02⁺ tumorcellen. Ik heb laten zien dat TEG011 behandeling niet gepaard gaat met enig ongerief voor de muizen, en ik vond geen bewijs van toxiciteit in gezonde weefsels die HLA-A*24:02 tot expressie brengen. Na TEG011 behandeling zag ik in geen enkele muis tekenen van graft-vs-host ziekte (GvHD), en ook geen toxiciteit in weefsels van de belangrijke organen. Verder rapporteer ik langdurige persistentie van TEG011 in 44% van

de met TEG011 behandelde muizen, wat geassocieerd is met de afwezigheid van groei van solide tumoren buiten het beenmerg. Dit benadrukt dat T cel persistentie belangrijk is voor langdurige werkzaamheid van de therapie.

In **Hoofdstuk 5** heb ik mij verder verdiept in het biologische activerings mechanisme van TEG011, specifiek in de rol die CD8 α speelt als co-receptor voor de FE11 $\gamma\delta$ TCR. De introductie van de CD8 α receptor op TEG011 cellen kan leiden tot verbeterde T cel persistentie en tumorcontrole. Het nieuwe construct wordt in het vervolg TEG011_CD8 α genoemd. Ik laat zien dat niet-reactieve CD4⁺ TEG011 cellen na genetische introductie van het humane CD8 α -gen, tumorcellen die HLA-A*24:02 tot expressie brengen kunnen herkennen. In transgene NSG-A24:02 muizen met een HLA-A*24:02⁺ tumor zag ik na behandeling met TEG011_CD8 α , een stabiele perifere persistentie van T cellen, met hogere cel aantallen in vergelijking tot TEG011. Verder heb ik aangetoond dat TEG011_CD8 α zorgt voor een betere tumorcontrole, de T cel persistentie voor lange tijd bevordert, en zorgt voor een betere T cel infiltratie. Daarnaast heb ik voor de eerste keer gezien dat behandeling met TEG011_CD8 α succesvol tumorcellen opruimt in het beenmerg. Dit benadrukt de potentiële klinische toepassing van deze behandeling.

In het laatste hoofdstuk, **Hoofdstuk 6**, worden de hierboven beschreven resultaten in een breder perspectief geplaatst en vergeleken met de resultaten die momenteel in de literatuur bekend zijn.

ACKNOWLEDGMENTS

This thesis would not be possible without the input and support of various people who cheering and accompany my PhD journey in the last years. I would like to thank every single one of you immensely for this!

My promoter Prof. dr. Jürgen Kuball, dear **Jürgen**, I always amaze how do you divide your time to still invest on research of the group, seeing patients, and family time. You are super busy and yet super approachable whenever I need to discuss something. Thank you for all your input in my projects and for being my debate partners during meetings. And I was proud for a moment I can be 20% exception of student to be right against your approach! Most of all, thank you for all your support during my difficult time and understanding with my situations. If I ever decide to pursue my career in academia, you are definitely my role model as a great mentor. I hope we will have the opportunity to work together again in the future and I wish all the best with everything you do.

My co-promoter Dr. Zsolt Sebestyén, dear **Zsolt**, there are so many things I could say about you, a paragraph may not be enough! From the first meeting, I already feel that you're very nice and helpful. Over time, I got to learn that you're very easy-going and social. I enjoyed so much all our discussion, both scientific and all about random stuffs. Thank you for your patience to entertain all my hard-headedness and listened to all my rambling and frustrations in the past 5 years. I will always give you food recommendations, anytime. And please stop with the rumor about me as model! I hope we could keep in contact and probably work together again in future. Till then, I wish you all the best including to make a reservation at Sea Palace, Amsterdam! ;)

Dear **Trudy**, thanks for all your input for all the experiments and also to train me with mice work at the beginning. Although sometimes we didn't really see eye-to-eye, I enjoyed working together with you and all the discussions we had. I wish you all the best for the upcoming projects!

Dear **Sabine**, I am happy to say that we work together very well from the beginning. We started the mice team with only two of us, until finally Patricia joined us. I could not ask for a more solid team to work together! I love all our chitchat and coffee time. We went through all kinds of difficulty together and yet we still worked it out! Also I love all our rambling time together, knowing I am not crazy alone :P Thanks for all your help during my PhD, translating all my documents to Dutch when needed and always give a good input. And of course, to be my paranymp and helping me with all the defense stuffs. I really enjoyed working together and hope to keep in contact!

Dear **Patricia**, who made our mice team complete! I had such great time working and being stress together with you ;P We went through working only the 2 of us when COVID lockdown first happened and still got out of it without killing each other! It's a good sign! ;) Thanks for all your help with the experiments, especially when you came over

the weekend to take care of my mice. I also enjoy all our hangouts outside of work and glad I have a friend in not liking beer too much. And of course, thanks a lot to help me as paranymph. I hope the rest of your PhD time will go smooth!

All other (past and present) Kuball group members: **Sanne** thanks for your help with Illustrator for my paper. **Guido**, meeting with Jurgen and you is never a dull one! **Marleen**, thanks for all the help at the beginning at my PhD and to keep the friendship outside of work, I enjoy all our hangout times! **Febi** and **Alberto**, thank you for all your help with all my statistical questions. **Koen** and **Ruud**, who never fails to greet me any time and thanks for all the fun coffee times. **Lovro**, though we didn't really work together for a project, I enjoyed the time you were in the group and always nice to hang out with. Hopefully one day I can come to Slovenia and we can have a short catchup! **Anna**, although you are quite busy but I enjoyed all our corridor conversation to just update each other about work and life in general. All the best for the training to be hematologist, I am sure you will be a great one!

Anke, thank you for the help with my first paper and I enjoyed our time in Keystone together. All the best with your time in the clinic and also finishing the thesis and of course enjoy the motherhood!

Esther, really nice to have you in a group for a short period, and I enjoyed our short meetup again in Madrid and Utrecht. My student **Willemijn**, thank you for your contribution to my project. I had a great time being your supervisor, from all the discussion about the project and all other fun borrel we had. Wish you all the best for the future! **Domenico**, I enjoyed the time when you're part of the group. All your snappy, funny stories and comments when we were both busy in ML-2. I wish all the best with the current job and hopefully our path cross again in the future. **Luuk**, too bad I only found out you are also wine person during your farewell picnic! I will give you a nudge when I'm in Nijmegen for a wine time ;) Thanks for all the help with FACS phenotype panel and hope you enjoy the new job! **Annet**, nice to have you in the group and all the best for you! **Moniek**, although we don't really interact much, I appreciate your input to my projects and also enjoyed our conversations during Kuball outjes. **Monique**, thank you for your help arranging meeting with Jurgen and also other administrative work you done during my PhD. **Froso** my twin in pulling Dr. Zsolt's leg, you are always helpful whenever I have questions no matter how busy your day was. Hope we can keep in touch outside of work for some drinks and chitchat. Congrats again for your recent wedding and keep loving each other every day. I hope you enjoy the new job also! **Tineke** thanks for always helping every time I have (stupid) questions, what would the Kuball group do without you! **Astrid**, it's nice working together with you for and also our ranting sessions together and all the best for the remaining of your PhD! **Eline**, my buddy since Day 1, I will always remember all the frustration we had to make GABs model works and we still need celebration now it's working! All the best for the thesis and the next chapter of your career. Do keep in touch! **Angelo**, the shadow personnel of our mice team, I enjoyed the time we have to do some in vivo experiments together and also the morning

meetings that we both struggle with. Good luck with your PhD and looking forward to more borrels and trips together with the others. Do report yourself to Dr. Zsolt, else he will always look for you! **Mara, Lucrezia, and Konstantinos**, happy to have you join the group and also get close during the short period I have left. Enjoy your PhD period and I look forward to our mischiefs together ;)

Jeroen and Pien, thank you for all the help with FACS setup. I appreciate all the brainstorm session to make our in vivo panel works fine. Hopefully we will cross path again in future.

My office roommates: **Kim**, I enjoyed all our chitchat together that keep me sane during busy period. **Ingrid**, another PhD buddy, thanks for all the gezelligheid as my next desk partner and to figure stuff together about the PhD program. I look forward for your defense! **Anna**, I enjoyed our dinner out together during the PhD and I wish you all the best for the postdoc position! **All other CTI colleagues**, I may not mention one by one, but thank you for making me feel welcomed and enjoyed my PhD time in the department.

Dear **Elsbeth, Saskia, Laura**, thank you for all the help and collaboration with all the pathology samples and analysis. I appreciate all the communication, arrangement, and training to accommodate our studies. Dear **Jarno, Kai, SangHo, Florijn and Heggert**, thank you for the collaboration with some of the projects that we managed to do together and also to facilitate the cells for in vivo experiments.

Dear besties, I could never make it without you all. **Anna**, I always looking forward to all our coffee break/getaway and to listen to all my rambling. Hopefully your thesis will be done soon and you get a position that you enjoy this time. My super smart girl **Lorenita**, thank for all our group therapy sessions ;) even though we are apart but you always checking up on me. My best man **Andrea**, you are way too far sometimes, but always close at heart. Thank you for all the video calls at strange times and hopefully we can see each other again soon! Try to reply our texts promptly! My lovely **Sarita**, I love all the voice notes we sent each other, all the random conversations. I couldn't wait to enjoy some holiday with you again soon and all the best for your PhD! My thanksgiving buddies **Adri, Aniko, Nik, Emilie, Marti and Ziva**, I always look forward for our fun tradition every year. Although the last couple of years we can't manage to get together, I hope we can get back on track soon! So many places we still need to explore in a short friendsgiving weekend. **Rianne and Melissa**, I always love all our dinner and weekend sleepover with all the heart-to-heart conversations we have. Although your calendar usually fully booked, we still have our catchup moments and feels like we talk to each other every day, which were always fun! Hopefully we can hangout more often! I love you, all!

Oom Bing, Oom Thijs, Elske who supports my journey from the first time I stepped foot in The Netherlands. Thank you for all your input and advise in my career as well as in everyday life. I am happy to have a family here that I know I can count on. **Mama, Mia,**

and **all my family members in Jakarta** who always be my motivator to keep going and pursue what I want to do in life and supports me in everything. I love you all.

Dearest **Michael**, no words are enough to show how grateful I am to have you. My personal walking encyclopedia, who helped me win Kuball Pubquiz. You always have my back, always support me when I feel stress about work, always listen to all my frustrations in a calm way, always push me forward and who keep me sane during all the crazy times and never forget to hold my hand in every step of the way. You never failed to bring smile on my face, always. I look forward to our future days together, till we're old, smelly, and senile. I love you, through good fa*** and (unfortunately) also bad ones.

CURRICULUM VITAE

Inez Johanna Gan was born on October 10th 1988 in Jakarta, Indonesia. In 2006 she started with a bachelor's degree in Biology at Atma Jaya Catholic University of Indonesia and graduated at 2010 as top 5% honor student of her class. During her bachelor's program, she obtained work experience as laboratory assistant for practical subjects of basic biochemistry and animal cell culture. Thereafter, she started internship program abroad as research officer at System Biology lab, Genome Institute of Singapore. After this internship, she started working at contract manufacturing facility at Lonza Biologics Tuas Pte Ltd, Singapore where she worked as Validation Specialist for several costumer projects in production active pharmaceutical ingredients (API). She mainly responsible for development, execution and documentation of Cleaning and Autoclaves Qualifications, including supporting site discrepancies and deviations investigation/closure. In this position, she also actively involved in FDA/EMA audits as subject matter expert (SME) for Cleaning and Autoclaves Qualification. In 2014 Inez decided to pursue a master's degree in Infection and Immunity at Universiteit van Amsterdam. Her master's literature thesis titled "The Degree of Off-Target Effects Associated with CRISPR/Cas9 as Gene Editing Tool and the Implications for Future Applications" was written at Netherlands Cancer Institute (NKI) under supervision of Dr. Roderick Beijersbergen. After completing her master's degree, Inez pursued her cancer immunotherapy interest and started her PhD at the Center for Translational Immunology (CTI), Utrecht University Medical Center, under supervision of Prof. Jürgen Kuball and Dr. Zsolt Sebestyén. Here, she focused on development of preclinical mouse model to test efficacy-safety balance of engineered $\gamma\delta$ TCR-based cellular therapy against cancer. The results of Inez' work are described in this thesis.
