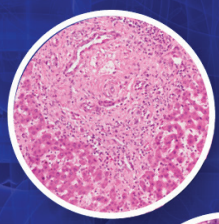
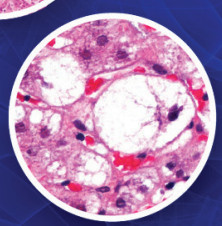
Answering Pivotal Questions in the Diagnosis and Treatment of PBC and NASH





Agenda

PBC and NASH: Serious Liver Diseases with Unmet Needs — *Michael Trauner, MD*

PBC Challenges: What is Treatment Success and What Will Emerging Therapies Offer? — *David E.J. Jones, MD, PhD*

NASH: Diagnostic Challenges, Therapeutic Targets, and New Paths to Treatment Success — *Vlad Ratziu, MD*

There is no fee for this activity.

CHAIR

Michael Trauner MD
Professor of Medicine
Chair, Division of Gastroenterology and Hepatology
Medical University of Vienna
Vienna, Austria

FACULTY

David E. J. Jones, MD, PhD
Dean of Research and Innovation
Newcastle University
Newcastle upon Tyne, UK

Vlad Ratziu, MD
Professor of Hepatology
Hospital Pitié-Salpêtrière
Université Pierre et Marie Curie
Paris, France

This Satellite Symposium is supported by an educational grant from **Intercept Pharmaceuticals, Inc.**

Application for EASL Membership can be done at http://www.easl.eu/_membership

Publication information: *Journal of Hepatology* (ISSN 0168-8278). For 2015, volumes 62 and 63 are scheduled for publication. Subscription prices are available upon request from the Publisher or from the Elsevier Customer Service Department nearest you or from this journal's website (http://www.elsevier.com/locate/jhep). Further information is available on this journal and other Elsevier products through Elsevier's website: (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

Orders, claims, and journal enquiries: please contact the Elsevier Customer Service Department nearest you:

St. Louis: Elsevier Customer Service Department, 3251 Riverport Lane, Maryland Heights, MO 63043, USA; phone: (800) 6542452 [toll free within the USA]; (+1) (314) 4478871 [outside the USA]; fax: (+1) (314) 4478029; e-mail: JournalsCustomerService-usa@elsevier.com.

Oxford: Elsevier Customer Service Department, The Boulevard, Langford Lane, Kidlington, Oxford OX5 1GB, UK; phone: (+44) (1865) 843434; fax: (+44) (1865) 843970; e-mail: JournalsCustomerServiceEMEA@elsevier.com.

Tokyo: Elsevier Customer Service Department, 4F Higashi-Azabu, 1-Chome Bldg, 1-9-15 Higashi-Azabu, Minato-ku, Tokyo 106-0044, Japan; phone: (+81) (3) 5561 5037; fax: (+81) (3) 5561 5047; e-mail: JournalsCustomerServiceJapan@elsevier.com.

Registration of Clinical Trials
The *Journal of Hepatology* endorses the policy of the WHO and the International Committee of Medical Journal Editors (ICMJE) on the registration of clinical trials. Therefore, any trial that starts recruiting on or after July 1, 2005 should be registered in a publicly owned, publicly accessible registry and should satisfy a minimal standard dataset. Trials that started recruiting before that date will be considered for publication if registered before September 13, 2005.
More detailed information regarding clinical trials and registration can be found in New Engl J Med 2004; 351:1250–1251 and New Engl J Med 2005; 352:2437–2438.

E-mail: mattyarm2010@googlemail.com

Background and Aims: Despite non-alcoholic steatohepatitis (NASH) being the commonest cause of chronic liver disease there are still no licensed therapies. Glucagon-like peptide-1 (GLP-1) analogues are licensed in type 2 diabetes, and are promising therapeutic candidates for NASH, yet no trial data exists on their efficacy in this setting. The histological efficacy and safety of the long-acting GLP-1 analogue, liraglutide, was assessed in patients with NASH.
Methods: In the Liraglutide Efficacy and Action in NASH (LEAN) trial (ClinicalTrials.gov NCT01237119) overweight patients with biopsy-confirmed NASH were randomised (1:1) to receive 48-weeks treatment with once-daily, subcutaneous injections of either 1.8 mg liraglutide or liraglutide-placebo (control). Randomisation was stratified by trial centre (n = 4) and diabetes status. The primary outcome measure as assessed centrally by two independent histopathologists (RMB, SGH) was improvement in liver histology, defined as 'resolution of definite NASH' and no worsening in fibrosis from baseline to end-of-treatment (EOT). Preliminary analyses were performed by intention-to-treat.
Results: Of the 52 patients randomised (mean age 51 years, 60% male, 33% type 2 diabetes, 52% F3/F4 Kleiner fibrosis stage), 45 patients underwent EOT liver biopsies. The primary end-point was met, and 9 (39%) of 23 patients on liraglutide had resolution of definite NASH compared to 2 (9%) of 22 patients on placebo (p = 0.019). Only 2 (9%) patients on liraglutide had worsening of fibrosis compared to 8 (36%) on placebo (p = 0.026). Moreover, liraglutide reduced weight (−5.3 vs. −0.6 kg, p = 0.001), BMI (−1.8 vs. −0.3 kg/m^2, p = 0.003), and fasting glucose (−1.0 vs −0.7 mmol, p = 0.005) compared to placebo. Reductions in ALT (−27 vs. −10, p = 0.126) and HbA1c (−0.5% vs. −0.03, p = 0.07) were also seen with liraglutide, albeit not significant versus placebo. There were no treatment differences in lipid profile or systolic BP. There were no serious adverse events in patients on liraglutide, which was well-tolerated with only 2 (8%) of 26 patients withdrawing from treatment due to drug-related gastro-intestinal (nausea, diarrhoea) side effects.
Conclusions: In a randomised controlled trial liraglutide met the primary end-point of histological clearance of NASH, and a reduction in progression of fibrosis. It was also safe and well-tolerated. Phase III registration trials are now warranted for GLP-1 therapy in patients with NASH.

G02

LEDIPASVIR/SOFOSBUVIR WITH RIBAVIRIN IS SAFE AND EFFICACIOUS IN DECOMPENSATED AND POST LIVER TRANSPLANTATION PATIENTS WITH HCV INFECTION: PRELIMINARY RESULTS OF THE PROSPECTIVE SOLAR 2 TRIAL

M. Manns[1], X. Forns[2], D. Samuel[3], J. Denning[4], S. Arterburn[4], T. Brandt-Sarif[4], H. Dvory-Sobol[4], P.S. Pang[4], J.G. McHutchison[4], E. Gane[5], D. Mutimer[6]. *[1]Hannover Medical School, Hannover, Germany; [2]Liver Unit, IDIBAPS, CIBEREHD Hospital Clinic, Barcelona, Spain; [3]Université Paris-Sud, Villejuif, France; [4]Gilead Sciences, Inc., Foster City, United States; [5]University of Auckland, Auckland, New Zealand; [6]QE Hospital and University of Birmingham, Birmingham, United Kingdom*
E-mail: jill.denning@gilead.com

Background and Aims: Treatment options for patients with chronic hepatitis C (HCV) who have decompensated liver disease or who have undergone liver transplantation are limited. We evaluated the safety and efficacy of ledipasvir/sofosbuvir (LDV/SOF) fixed dose combination with ribavirin (RBV) in such patients in Europe, Canada, Australia and New Zealand.
Methods: We enrolled HCV genotype 1 or 4 treatment-naïve or treatment-experienced patients with decompensated liver disease or post-liver transplantation with recurrent HCV. Patients were randomized to receive 12 or 24 weeks of treatment stratified into 6 groups: patients without transplant and either (1) Child–Pugh–Turcotte (CPT) B cirrhosis, or (2) CPT C cirrhosis; or patients with recurrent HCV after liver transplantation and were either (3) without cirrhosis (F0 to F3), (4) CPT A cirrhosis, (5) CPT B cirrhosis, or (6) CPT C cirrhosis.
Results: 327 patients were randomized. Most were male (76%), white (94%), and IL28B non-CC (80%). 159 (49%) had HCV genotype (GT) 1a, 131 (40%) GT 1b, and 37 (11%) GT 4. Mean baseline HCV RNA was 6.2 $\log_{10}$ IU/mL. 41 of 227 cirrhotic patients (18%) had a MELD score >15. 222 (68%) patients have completed study treatment and 171 (52%) have reached post treatment week 4, so far. Nine patients in the advanced liver disease group and 3 patients in the post-transplantation group have discontinued study treatment. 62 patients (19%) experienced serious adverse events (SAEs). Eight SAEs in 8 patients were considered related to study treatment; anemia (4), fall, diarrhea, malaise, and hyperbilirubemia. The

Table (abstract G02).

	Advanced liver disease pre-transplantation				Recurrent HCV post liver transplantation							
	CPT B		CPT C		F0–F3		CPT A		CPT B		CPT C	
	12 wks Rx (N = 29)	24 wks Rx (N = 29)	12 wks Rx (N = 24)	24 wks Rx (N = 25)	12 wks Rx (N = 51)	24 wks Rx (N = 49)	12 wks Rx (N = 34)	24 wks Rx (N = 33)	12 wks Rx (N = 22)	24 wks Rx (N = 22)	12 wks Rx (N = 3)	24 wks Rx (N = 6)
SVR4	24/28 (86)	11/11 (100)	14/16 (88)	3/6 (50)	29/31 (94)	8/8 (100)	31/32 (97)	11/12 (92)	17/17 (100)	6/6 (100)	2/2 (100)	1/2 (50)

most common adverse events were fatigue, anemia, nausea and headache. SVR4 by patient population are presented in the table.
Conclusions: Administration of LDV/SOF+RBV in patients with decompensated cirrhosis and recurrent HCV post transplantation has been well tolerated and resulted in high SVR4 rates in these very difficult to treat populations treated with either 12 or 24 weeks of this regimen. SVR 12 results will be presented.

G03
RIFAXIMIN AND PROPRANOLOL COMBINATION THERAPY IS MORE EFFECTIVE THAN PROPRANOLOL MONOTHERAPY IN THE HEPATIC VENOUS PRESSURE GRADIENT RESPONSE AND PROPRANOLOL DOSE REDUCTION – A PILOT STUDY

S.K. Baik[1], Y.L. Lim[1], Y.Z. Cho[1], M.Y. Kim[1], Y.O. Jang[2], K.T. Suk[3], G.J. Cheon[4], Y.D. Kim[4], D.H. Choi[5]. *[1]Internal Medicine, [2]Cell Therapy and Tissue Engineering, Wonju Christian Hospital, Wonju, [3]Internal Medicine, Chuncheon Sacred Heart Hospital, Chuncheon, [4]Internal Medicine, Kangneung Asan Hospital, Kangneung, [5]Internal Medicine, Kangwon University School of Medicine, Chuncheon, Korea, South*
E-mail: youn07190720@naver.com

Background and Aims: Nonselective beta blocker is the only regimen accepted to reduce the portal pressure. However its anti-portal pressure effect is insufficient in many cases and the side effects have made a limitation in clinical use. Gut bacterial translocation and production of endotoxin is known to increase portal pressure in cirrhosis. So, this study investigated the effect of addition of gut decontamination therapy using non-absorbable antibiotics, rifaximin to nonselective beta blocker, propranolol.
Methods: We included 65 patients of advanced cirrhosis from January 2011 to July 2013 and randomly assigned propranolol monotherapy (n = 48) and propranolol and rifaximin combination therapy (n = 17). For monotherapy group, propranolol dose was titrated to maximum 320 mg/day with a target of 25% heart rate (HR) reduction. In combination group, propranolol dose was also titrated according to the HR however, the maximum dose was limited to 160 mg/day and rifaximin 1200 mg/day was administered. Both baseline and treatment 3months later hepatic venous pressure gradient (HVPG) were measured in all patients. Patients with HVPG reduction by ≥20% or to less than 12 mmHg were defined as responders. Mean blood pressure (MBP) and HR, side effects and other serologic data were also collected.
Results: Portal pressure declined significantly in both groups (propranolol monotherapy group 17.0±3.9 mmHg to 13.5±4.1 mmHg, combination group 16.7±3.6 mmHg to 10.9±4.7 mmHg, each $P < 0.001$). Combination group showed better HVPG response rate than monotherapy group (82.4% vs. 50.0%, $P = 0.018$) and the mean reduction of HVPG was also larger in combination group (5.8±3.8 mmHg vs. 3.5±3.9 mmHg, $P = 0.038$). Especially, the mean dose of propranolol (152±59.3 mg vs. 127.0±32.4, $P = 0.033$) and the reduction of HR (20.5±13.0% mg vs. 7.4±15.5%, $P = 0.001$) were smaller in combination group. The reduction of MBP did not show difference between two groups (4.4±12.3 mmHg vs. 3.1±11.7 mmHg, $P = 0.695$). Dizziness related with orthostatic hypotension was observed in 8 (mono) and 2 (combination) cases of each group.
Conclusions: Propranolol and rifaximin combination therapy showed additive effect in the reduction of HVPG with smaller dose of propranolol and side effects and it suggests that addition of rifaximin can be a good solution to break the limitations of non-selective beta blocker.

G04
ENGINEERED HBV-SPECIFIC T CELLS: DISENTANGLING ANTIVIRAL FROM KILLING CAPACITY

S. Koh[1], C.Y.L. Tham[2], A.T. Tanoto[2], A. Pavesi[3], R.D. Kamm[4], A. Bertoletti[2]. *[1]Singapore Institute for Clinical Sciences A*STAR, [2]Emerging Infectious Diseases Program, Duke-NUS Graduate Medical School, [3]Singapore MIT Alliance – SMART, Singapore, Singapore; [4]Department of Biological Engineering, Massachusetts Institute of Technology, Cambridge, United States*
E-mail: sarene_koh@sics.a-star.edu.sg

Background and Aims: We have recently demonstrated that adoptive transfer of engineered HBV-specific T cells in a patient with HBsAg-productive HCC cause a profound inhbition of HBsAg production (J Hepatology 2014. doi: 10.1016/j.jhep.2014.10.001.). The difficulty to disentangle the antiviral effect of HBV T cells from their killing ability constitutes a barrier to the application of this immunotherapeutic approach in chronic HBV patients. Therefore, our aim was to produce HBV-specific T cells that can inhibit virus replication without hepatotoxicity and analyzed the antiviral mechanism mediated by these engineered T cells.
Methods: Using messenger RNA electroporation of HBV-T cell receptor in human lymphocytes, we produced HBV-specific T cells characterized by different activation and maturation stages. These distinct HBV-specific T cell populations were tested in 2 dimensional (2D) and 3D in vitro assays for their ability to inhibit HBV replication and/or lyse target cells.
Results: Among different engineered HBV-specific T cell populations, we selected a perforin/granzymelow HBV-specific T cells able to induce 50% drop in HBV viral load in HepG2.2.15 without causing detectable hepatotoxicity at an effector to target ratio of 1:3 (both in 2D and 3D models). After HBV-specific recognition, these resting naïve (CD28+CD27+) T cells produced a large range of cytokines (IFN-gamma, TNF-alpha, GM-CSF and lymphotoxin-alpha and -beta). Analysis of the specific antiviral mechanisms indicated that a specific synergy between classical antiviral cytokines (IFN-gamma, TNF-alpha, GM-CSF) and activator of lymphotoxin-β receptor (LTβR) pathway mediate the antiviral but non-cythopathic effect.
Conclusions: It is possible to produce HBV-specific T cells able to efficiently inhibit HBV replication without causing direct hepatocytes killing. This represents an attractive cell population for adoptive T cell therapy of chronic hepatitis B. The relative contribution of antiviral cytokines and/or LTβR activation to antiviral activity can lead to the development of new targeted combinatorial therapy in HBV infection.

E-mail: kschulze@uke.de

Background and Aims: Hepatocellular carcinoma (HCC) is a heterogeneous disease mainly developing in chronic liver disease and caused be a variety of etiologies. Hepatocarcinogenesis is a multi-step process in which pre-cancerous lesions can ultimately transform into liver cancer. Genomic analyses promise to unravel the mutagenic processes in order to identify molecular profiles, linked to aggressiveness of the tumor, and to optimize personalized patient care.

Methods: We performed exome sequences of 243 liver tumors from European patients (France, Italy and Spain), associated with cirrhosis (F4, n = 118), fibrosis (F2+F3, n = 46), or non-fibrotic livers (F0+F1, n = 79). Cirrhosis-associated tumors presented different stages along HCC progression: 7 dysplastic macronodules, 7 early, 17 small and progressed, 58 classic, and 29 poor-prognosis HCC. Tumors were categorized by varying risk factors: Significant alcohol intake (41%), HCV (26%), non-alcoholic steatohepatitis (18%), HBV (14%), hemochromatosis (7%), no known etiology (11%).

Results: We identified 8 mutational signatures of which 6 (Signatures 1A, 1B, 4, 5, 6, and 16) were previously validated in a pan-cancer analysis, while 2 (Signatures 23 and 24) are novel. Hierarchical clustering, based on mutational signatures, revealed 6 groups (MSig1 to 6) and 4 singletons which were significantly associated with specific risk factors, mainly combined alcohol/tobacco consumption, and aflatoxin B1. Next, we identified 161 putative driver genes associated with 11 recurrent pathways. Associations of mutations defined 3 groups of genes centered on *CTNNB1* (alcohol), *TP53* (HBV), and *AXIN1*. Analyses according to tumor stage progression revealed *TERT* promoter mutation as an early event whereas *FGF/CCND1* amplification, *TP53* and *CDKN2A* alterations, appeared at more advanced stages in aggressive tumors. Altogether, 28% of patients harbored at least one damaging alteration potentially targetable by an FDA-approved drug and 86% by a drug which has been studied in phase I to phase III clinical trials.

Conclusions: In conclusion, our study identified relationships between environmental exposures and mutational patterns in HCC as well as the landscape of driver genes and pathways altered in different clinical stages and etiological backgrounds. For patient care, genomic alterations identified in targetable genes will be useful to determine HCC patients that could potentially benefit from targeted treatment in future clinical trials.

G06

A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED PHASE III TRIAL OF TSU-68 (ORANTINIB) COMBINED WITH TRANSCATHETER ARTERIAL CHEMOEMBOLIZATION IN PATIENTS WITH UNRESECTABLE HEPATOCELLULAR CARCINOMA

J.-W. Park[1], A.-L. Cheng[2], M. Kudo[3], J.H. Park[4], P.-C. Liang[2], H. Hidaka[5], N. Izumi[6], J. Heo[7], Y.J. Lee[8], I-S. Sheen[9], C.-F. Chiu[10], H. Arioka[11], S. Morita[12], Y. Arai[13]. *[1]National Cancer Center, Korea, Goyang, Korea, South; [2]National Taiwan University Hospital, Taipei, Taiwan; [3]Kinki University School of Medicine, Osaka-sayama, Japan; [4]The Armed Forces Capital Hospital, Seoul, Korea, South; [5]Kitasato University School of Medicine, Sagamihara, [6]Musashino Red Cross Hospital, Musashino, Japan; [7]Pusan National University Hospital, [8]Inje University Busan Paik Hospital, Busan, Korea, South; [9]Chang Gung Memorial Hospital – Linkou, Kuei Shan, [10]China Medical University Hospital, Taichung, Taiwan; [11]Yokohama Rosai Hospital, Yokohama, [12]Kyoto University Graduate School of Medicine, Kyoto, [13]National Cancer Center Hospital, Tokyo, Japan*
E-mail: jwpark@ncc.re.kr

Background and Aims: Transcatheter arterial chemoembolization (TACE) is considered an effective treatment for unresectable hepatocellular carcinoma (HCC). However, TACE hardly achieves complete tumor necrosis and potentially causes tumor hypoxia inducing angiogenesis. TSU-68 is an oral tyrosine-kinase inhibitor of vascular endothelial growth factor (VEGF) and platelet-derived growth factor receptors. In a phase II study, TSU-68 treatment combined with a single TACE session tended to prolong progression-free survival compared to TACE alone (Inaba et al. 2013). Herein, we present our findings from a randomized, double-blind, placebo-controlled phase III study (ORIENTAL) to evaluate the effect of concurrent TSU-68 combined with conventional TACE (cTACE).

Methods: Patients were randomly assigned (1:1) within 28 days from receiving TACE according to their Child–Pugh score, serum alpha-foetoprotein level, and intrahepatic nodule size. TSU-68 or placebo was administered orally at 200 mg, twice per day, and continued until TACE failure or unacceptable toxicities were observed. Two levels of dose modifications (200/0 daily and 200/0 every other day) were permitted. The primary endpoint was overall survival (OS), and secondary endpoints included time to TACE failure (TTTF), safety profile, and biomarker analysis.

Results: A total of 889 patients were enrolled from Japan, Korea, and Taiwan. Patient characteristics were well balanced. The study was terminated because interim analysis showed no OS improvement by TSU-68 compared to placebo (31.1 vs. 32.3 months, p = 0.435), despite a trend towards prolonged median TTTF (23.9 vs. 19.8 months, p = 0.245). In stratified analysis, the median TTTF in the TSU-68 arm was significantly prolonged in patients with low VEGF-C (25.5 vs. 18.4 months, p = 0.0196) and Barcelona Clinic of Liver Cancer (BCLC) stage-B HCC (22.1 vs. 14.9 months, p = 0.054). The main adverse events of TSU-68 were oedema, ascites, and elevation of aspartate and alanine aminotransferases. Most of these did not affect TSU-68 treatment duration, which was 332.0 days. Only one patient died of treatment-related hepatic failure.

Conclusions: TSU-68 combined with repeated cTACE did not improve OS. However, favourable TTTF was observed in patients with low VEGF-C and those with BCLC-B HCC receiving TSU-68. Further study is needed to confirm the potential of VEGF-C as a predictive marker. TSU-68 treatment was tolerable in HCC patients receiving repeated TACE with a high safety profile and long treatment duration of 1 year.

Viral hepatitis C: Therapy

Sullivan-Bolyai[8]. *[1]IDIBAPS and CIBEREHD, Barcelona, Spain; [2]Henry Ford Health System, Detroit, United States; [3]Carmel Medical Center, Haifa, Israel; [4]The Texas Liver Institute, University of Texas Health Science Center, San Antonio, United States; [5]Hospital Universitario Valle Hebron and Ciberehd, Barcelona, [6]Hospital University Puerta de Hierro Majadahonda, Madrid, Spain; [7]Medical University of Vienna, Vienna, Austria; [8]Merck & Co., Inc., Whitehouse Station, United States*
E-mail: mark_dinubile@merck.com

Background and Aims: Treatment options are needed for patients who do not achieve SVR on regimens containing DAAs. The Phase-2 C-SALVAGE study investigated the safety and efficacy of an interferon-free combination of GZR [NS3/4A protease inhibitor (PI)] and EBR [NS5A inhibitor] with RBV for patients with chronic HCV GT1 infection who had failed licensed DAA-containing therapy.
Methods: C-SALVAGE is an international open-label study of GZR 100 mg QD, EBV 50 mg QD, and weight-based RBV BID for 12 weeks in patients with chronic HCV GT1 infection who had failed ≥4 weeks of peginterferon and RBV combined with boceprevir, telaprevir, simeprevir, or sofosbuvir. Per protocol, ~80% of the enrolled subjects were to have experienced virologic failure. Exclusion criteria included decompensated liver disease, hepatocellular carcinoma, HIV or HBV co-infection, thrombocytopenia $<50\times10^3/\mu L$, or hypoalbuminemia <3.0 g/dL. HCV RNA levels were measured by COBAS TaqMan v2.0 assay. Resistance-associated variants (RAVs) were identified at baseline by population sequencing. The primary efficacy outcome was a HCV RNA level below the limit of quantification (15 IU/mL) 12 weeks after the end of treatment (SVR_{12}).
Results: 79 patients were treated with ≥1 dose of study drug (Table): 33 (42%) were women, 2 (3%) were non-white, 34 (43%) had cirrhosis (including 8 diagnosed by biopsy), 30 (38%) had GT1a infection, and 66 (84%) had a history of virologic failure on a prior DAA-containing regimen [13 (16%) had failed for other reasons]. All had received a PI; none had received sofosbuvir. At entry, 30 (41%) of the 73 patients with available NS3 sequencing data harbored RAVs. 78 (99%) patients completed therapy with 1 early discontinuation due to an AE. At the end of therapy, RNA levels were <15 IU/mL in all 79 (100%) patients. 5 serious AEs (bacterial pharyngitis, laryngeal squamous cell carcinoma, asthma, appendicitis, and urinary tract infection) were reported, all of which were considered unrelated to study drugs.
Conclusions: In the ongoing C-SALVAGE trial, 79 HCV GT1-infected patients who had failed PI-based regimens were treated with GZR/EBR/RBV, including 43% with cirrhosis and 84% with prior virologic failure. HCV RNA levels <15 IU/mL were achieved in all patients at the end of treatment despite a high prevalence of NS3 RAVs at baseline. Study medications were well tolerated in this population. SVR_{12} rates, full safety data, and expanded resistance results will be presented.

Table: Baseline characteristics of 79 patients treated with ≥1 dose of study drug.

Age, yrs

TREATMENT OF DECOMPENSATED HCV CIRRHOSIS IN PATIENTS WITH DIVERSE GENOTYPES: 12 WEEKS SOFOSBUVIR AND NS5A INHIBITORS WITH/WITHOUT RIBAVIRIN IS EFFECTIVE IN HCV GENOTYPES 1 AND 3

G.R. Foster[1], J. McLauchlan[2], W. Irving[3], M. Cheung[4], B. Hudson[5], S. Verma[6], K. Agarwal[6], and HCV Research UK EAP Group. *[1]The Blizard Institute, Queen Marys University of London, London, [2]Centre for Virus Research, MRC University of Glasgow, Glasgow, [3]Virology, University of Nottingham, Nottingham, [4]Queen Marys University of London, London, [5]University of Nottingham, Nottingham, [6]Kings College Hospital, London, United Kingdom*
E-mail: g.r.foster@qmul.ac.uk

Introduction: All oral antiviral therapy for patients with HCV induced decompensated cirrhosis is now possible. The optimal regimen is unclear, particularly for Genotype 3, and debate continues on which patients benefit. The NHS England Early Access Program (EAP) provided 12 weeks of therapy with sofosbuvir, with or without ribavirin and an NS5A inhibitor to a cohort of ~500 patients with decompensated cirrhosis. Here we evaluate viral clearance and safety in the initial 465 patients. This is the first analysis of a large cohort of patients with decompensated cirrhosis due to genotype 3 HCV receiving sofosbuvir plus NS5A inhibitors.
Material and Methods: The EAP allowed physicians to treat patients with decompensated cirrhosis with sofosbuvir combined with either daclatasvir or ledipasvir +/− ribavirin (NS5A inhibitors kindly provided prior to license by Gilead and BMS). Choice of therapy was at the clinicians' discretion. Data and samples were collected by HCV Research UK and we present data on those patients due to have reached 4 weeks post therapy by abstract submission; all were enrolled when daclatasvir was freely available.
Results: 17 centres enrolled 465 patients between July and October 2014, 23 were co-infected with HIV. The Table shows the results and indicates response rates of >80% in patients receiving ribavirin in addition to sofosbuvir and an NS5A inhibitor. For Genotype 3 HCV with decompensated cirrhosis both daclatasvir and ledipasvir

were effective with a numerical increase in patients achieving SVR4 with daclatasvir, although this was not statistically significant. 91 patients required reduction in ribavirin dosing.
19 patients (4%) died during the study (11 on therapy), 16 (3.4%) required transplantation and 181 (39%) had an SAE, which was related to therapy in 143 patients (31%). In 19 patients (4%) liver function deteriorated (worsening ascites/encephalopathy/new variceal bleed) but in 215 patients (46%) ascites/encephalopathy improved.
Conclusions: In decompensated cirrhosis 12 weeks therapy with sofosbuvir plus an NS5A inhibitor is effective with most patients achieving SVR4. Patients infected with Genotype 1 HCV respond well with >80% achieving SVR4, response rates were slightly reduced in patients with G3. In this fragile population with end stage liver disease deaths and progression of liver disease were not uncommon but nearly half the patients had improvements in liver function.

Table: SVR4 rates in patients with decompensated cirrhosis receiving 12 weeks therapy with different treatment regimes

	SOF/LDV	SOF/LDV/Riba	SOF/DCV	SOF/DCV/Riba
Overall	21/28 (75%)	212/251 (84%)	12/15 (80%)	142/171 (83%)
Genotype 1	17/21 (81%)	144/163 (88%)	4/5 (80%)	40/45 (89%)
Genotype 3	4/7 (57%)	44/61 (72%)	5/7 (71%)	92/113 (81%)

CAN HEPATITIS C TREATMENT BE SAFELY DELAYED? EVIDENCE FROM THE VETERANS ADMINISTRATION HEALTHCARE SYSTEM

J.S. McCombs[1], I. Tonnu-MiHara[2], T. Matsuda[1], J. McGinnis[1], S. Fox[3].
[1]Schaeffer Center for Health Policy and Economics, Los Angeles, [2]Veterans Administration Healthcare System, Long Beach, [3]Keck School of Medicine, University of Southern California, Los Angeles, United States
E-mail: jmccombs@usc.edu

Background and Aims: The cost of new HCV treatments leads payers and insurance providers to question if delaying treatment for low risk patients can be accomplished without adversely impacting the patient. Retrospective patient data from the Veterans Administration [VA] were used to estimate the impact on patient risk of treatment initiation before and after the patient's FIB4 levels became elevated.
Methods: VA HCV patients with one or more reported FIB-4 values were selected. Primary outcome measures were time to death and time to the first occurrence of a composite of liver-related clinical events. The impact of time to treatment initiation and time to three different definitions of an elevated FIB4 level were estimated using a time-dependent Cox proportional hazards models.
Results: 187,860 patients met study requirements. Initiating treatment before FIB4 >1.00 reduced morbidity by 41% and death by 36%. Initiating treatment after FIB4 >1.00 remained effective but diminished in the morbidity risk reduction achieved [30%]. This is not the case if treatment initiation is delayed until after FIB4 >3.25. The risk reductions associated with treatment initiation before FIB4 >3.25 were 34% for the composite event and 45% for death but if initiated after FIB4 >3.25 were only 11% and 25%, respectively. These detrimental effects of delaying treatment until FIB4 >3.25 were due to a reduction in the likelihood that treated patients would achieve viral load suppression and a reduced impact of viral load suppression on morbidity.
Conclusions: Delaying treatment until after a patient's FIB4 level exceeds 3.25 has a clear detrimental effect on treatment effectiveness

O004
ON-TREATMENT VIROLOGIC RESPONSE AND TOLERABILITY OF SIMEPREVIR, DACLATASVIR AND RIBAVIRIN IN PATIENTS WITH RECURRENT HEPATITIS C VIRUS GENOTYPE 1b INFECTION AFTER ORTHOTOPIC LIVER TRANSPLANTATION (OLT): INTERIM DATA FROM THE PHASE II SATURN STUDY

X. Forns[1], M. Berenguer[2], K. Herzer[3], M. Sterneck[4], M.F. Donato[5], P. Andreone[6], S. Fagiuoli[7], T. Cieciura[8], M. Durlik[8], J.L. Calleja[9], Z. Mariño[1], A. Simion[10], U. E-mail: XFORNS@clinic.ub.es

Background and Aims: Simeprevir (SMV) and daclatasvir (DCV) are approved for the treatment of hepatitis C virus (HCV) infection in the non-transplant setting. SMV is a NS3/4A protease inhibitor and DCV is a NS5A replication complex inhibitor. The combination of SMV+DCV±ribavirin (RBV) has been previously evaluated in treatment-naïve and prior null responder patients (pts; LEAGUE-1). SATURN is an ongoing open-label Phase II study, investigating SMV+DCV+RBV in pts with recurrent HCV genotype 1b infection after orthotopic liver transplantation (OLT). Virologic response and tolerability results are presented from a pre-planned interim analysis.
Methods: Post-OLT treatment-naïve or -experienced (prior relapser, partial or null responder to peginterferon±RBV) adults on stable immunosuppressive therapy following OLT were included. Part 1 (P1) included pts with METAVIR score F1–F2 on cyclosporine (CsA) or tacrolimus (TAC). Part 2 (P2) included F1–F4 pts on TAC. Pts received SMV (150 mg once daily [QD]), DCV (60 mg QD) and RBV (1–1.2 g/day) for 24 weeks. At the time of analysis, all P1 pts had reached end of treatment (EOT) and in P2, Week 4 of treatment (or early discontinuation). Analyses were based on the intent-to-treat population.
Results: A total of 21 (P1) and 14 (P2) pts were included (P1/P2: female, 33%/43%; median age, 63.0 years [y]/59.5 y; mean time since transplantation, 3.98 y/5.36 y; median baseline HCV RNA 6.9 $\log_{10}$/6.9 $\log_{10}$ IU/mL; METAVIR F3/F4, 0%/57%). P1 CsA pts had ~6-fold higher SMV plasma concentrations leading to SMV dose adjustment and exclusion of CsA pts from P2. On-treatment virologic response is shown in the Table. In P1, 91% of pts had HCV RNA <25 IU/mL undetectable at EOT. In P2, 93% had HCV RNA <25 IU/mL detectable/undetectable at Week 4. The most common adverse events (AEs) were anaemia (P1/P2: 62%[CsA: 70%/TAC: 55%]/21%) and asthenia (P1: 38%). Grade 3/4 AEs were reported in 19% (P1) and 36% (P2) of pts. Serious AEs were reported in 24% and 14% of pts, while 2 P1 and 0 P2 pts discontinued at least one study drug due to an AE. RBV dose reductions occurred in 3 P1 and 2 P2 pts. Grade 3/4 haemoglobin decreases and hyperbilirubinemia were observed in 5% and 33% of P1 and 7% and 36% of P2 pts.

Table (abstract O004).

On-treatment response ITT (n/N, %)	Simeprevir (150 mg) + daclatasvir (60 mg) + ribavirin					
	Week 4 (n = 35)			End of treatment (n = 21)		
	Part 1		Part 2	Part 1		
	Cyclosporine (n = 10)	Tacrolimus (n = 11)	Tacrolimus (n = 14)	Cyclosporine (n = 10)	Tacrolimus (n = 11)*	Total (n = 21)
<25 IU/mL undetectable/detectable	10/10 (100)	10/11 (90.9)	13/14 (92.9)	10/10 (100)	9/11 (81.8)	19/21 (90.5)
<25 IU/mL undetectable**	7/10 (70.0)	8/11 (72.7)	9/14 (64.3)	10/10 (100)	9/11 (81.8)	19/21 (90.5)

ITT, intent-to-treat.
*Includes 1 HCV genotype 1a patient who was enrolled in error and who experienced viral breakthrough.
**In Part 2, this is RVR (rapid virologic response at Week 4 while on treatment).

Conclusions: SMV+DCV+RBV was generally well tolerated and led to a significant on-treatment response in post-OLT pts on immunosuppressive therapy, showing promise as a potential treatment option for the post-OLT pt population.
Study funded by Janssen.

RETREATMENT OF PATIENTS WHO FAILED 8 OR 12 WEEKS OF LEDIPASVIR/SOFOSBUVIR-BASED REGIMENS WITH LEDIPASVIR/SOFOSBUVIR FOR 24 WEEKS

E. Lawitz[1], S. Flamm[2], J.C. Yang[3], P.S. Pang[3], Y. Zhu[3], E. Svarovskaia[3], J.G. McHutchison[3], D. Wyles[4], P. Pockros[5]. *[1]Texas Liver Institute, University of Texas Health Science Center, San Antonio, TX, [2]Feinberg School of Medicine, Northwestern University, Chicago, IL, [3]Gilead Sciences, Foster City, CA, [4]University of California, San Diego, CA, [5]Scripps Clinic, La Jolla, CA, United States*
E-mail: jenny.yang@gilead.com

Background and Aims: Ledipasvir/sofosbuvir (LDV/SOF) fixed-dose combination is the first approved interferon- and ribavirin-free treatment for genotype 1 HCV-infected patients. Of the 1952 patients in LDV/SOF Phase 3 clinical trials, 35 (2%) were virologic failures following 8 or 12 weeks of treatment. This study evaluated the efficacy of LDV/SOF for 24 weeks as retreatment for these patients and other patients that have failed similar regimens in LDV/SOF Phase 2 studies.
Methods: This open-label study enrolled genotype 1 HCV-infected patients who relapsed following 8 or 12 weeks of LDV/SOF±ribavirin (RBV) in Phase 2/3 studies. NS5A and NS5B resistance associated variants were evaluated by deep sequencing. The primary endpoint was SVR12.
Results: 41 patients were enrolled and completed treatment. The mean age was 58 years, 83% male, 24% African-American, 46% had cirrhosis, 93% IL28B CT/TT genotype, 83% GT1a, and mean baseline HCV RNA was 6.2 log10 IU/mL. The overall SVR4 rate was 73% (30/41): 1 breakthrough, 9 relapse, and 1 visit pending. Table 1 presents the SVR4 rates by prior treatment. Headache was the only AE reported in ≥10% of patients. Two patients (5%) had treatment-emergent SAEs. Complete SVR12 rates and viral sequencing results will be presented.

Table 1. SVR4 according to prior treatment

Patients, n/N (%)	LDV/SOF+GS-9669	LDV/SOF±RBV	
	8 weeks (n = 8)	8 weeks (n = 22)	12 weeks (n = 11)
SVR4	7/8 (88%)	18/22 (82%)	5/11 (45%)
95% CI	47–100%	60–95%	17–77%
Breakthrough	0	0	1/11 (9%)
Relapse	1/8 (13%)	4/22 (18%)	4/10 (40%)
Visit pending	0	0	1/11 (9%)

Conclusions: Ledipasvir/sofosbuvir for 24 weeks was well tolerated and demonstrated that successful retreatment is possible in some genotype 1-infected, NS5A-failure patients.

Haber[2]. *[1]The Texas Liver Institute, University of Texas Health Science Center, San Antonio, [2]Merck & Co., Inc., Whitehouse Station, United States*
E-mail: poordad@txliver.com

Background and Aims: The safety and efficacy of several oral direct-acting antiviral (DAA) regimens for 8–24 weeks has recently been demonstrated. Shorter durations of therapy using novel combinations of DAAs may offer benefits such as increased compliance, lower cost and broader usage and acceptance by treating providers. The aim of this study was to assess the efficacy and safety of grazoprevir (GZR;NS3/4A protease inhibitor) and elbasvir (EBR; NS5A inhibitor) fixed-dose combination (FDC) + sofosbuvir (SOF; nucleotide NS5B polymerase inhibitor) in treatment-naive patients with and without cirrhosis with hepatitis C virus (HCV) genotype 1 (G1) infection for shortened durations of 4, 6 or 8 weeks and G3 infection for durations of 8 or 12 weeks.
Methods: C-SWIFT enrolled 102 G1 and 41 G3 treatment-naive patients with and without cirrhosis. G1 noncirrhotic (n = 61) patients were randomized to 4 or 6 week durations; G1 cirrhotic (n = 41) patients were randomized to 6 or 8 weeks of therapy. G3 noncirrhotic patients (n = 29) were randomized to 8 or 12 weeks and G3 cirrhotic patients (n = 12) were assigned to 12 weeks of therapy. All patients received the same regimen: GZR/EBR (100 mg/50 mg) FDC + SOF (400 mg). HCV RNA was assessed using COBAS TaqMan v2.0 (LoQ 15 IU/mL). The primary end point is the proportion of patients achieving HCV RNA <15 IU/mL 12 weeks after end of treatment (SVR12).

G1 presents SVR8 data; G3 presents SVR4 data.
[a] Excludes 3 patients with nonvirologic discontinuation: G1 cirrhotic 8-week arm (2 patients); G3 cirrhotic (1 patient).

Results: A total of 143 patients were enrolled; 66% male, 98% white, and 45% Hispanic. Of the 102 G1 patients, 82% were G1a. Mean viral load at baseline was 6.65 $\log_{10}$ IU/mL. The study is currently

ongoing; all patients have completed dosing (data are correct as of 11/21/2014). The combination was safe and well tolerated. No patient discontinued because of a drug-related adverse event and no drug-related SAE occurred.

Conclusions: This novel study uses 3 potent, once-daily DAAs, GZR/EBR FDC plus SOF, combined in a pan-genotypic regimen to assess treatment durations of 4 to 12 weeks in cirrhotic and noncirrhotic patients with G1 and G3 HCV infection. This study will expand the understanding of treatment duration and help determine how to minimize drug exposure while maximizing SVR rates.

ALL ORAL HCV THERAPY IS SAFE AND EFFECTIVE IN PATIENTS WITH DECOMPENSATED CIRRHOSIS: INTERIM REPORT FROM THE HCV-TARGET REAL WORLD EXPERIENCE

R. Reddy[1], J.K. Lim[2], A. Kuo[3], A.M. Di Bisceglie[4], H.E. Vargas[5], J.S. Galati[6], G. Morelli[7], G.T. Everson[8], P.Y. Kwo[9], R.S. Brown[10], M.S. Sulkowski[11], T.G. Stewart[12], L. Akuskevich[12], M. Vainorius[12], J.A. Peter[7], D.R. Nelson[7], M.W. Fried[12], M.P. Manns[13]. *[1]University of Pennsylvania, Philadelphia, PA, [2]Yale University School of Medicine, New Haven, CT, [3]University of California, San Diego, San Diego, CA, [4]Saint Louis University School of Medicine, St. Louis, MO, [5]Mayo Clinic, Phoenix, AZ, [6]Research Specialists of Texas, Houston, TX, [7]University of Florida, Gainesville, FL, [8]University of Colorado Denver, Aurora, CO, [9]Indiana University, Indianapolis, IN, [10]Columbia University, New York, NY, [11]Johns Hopkins, Baltimore, MD, [12]University of North Carolina, Chapel Hill, NC, United States; [13]Hannover Medical School, Hannover, Germany*
E-mail: rajender.reddy@uphs.upenn.edu

Background and Aims: Interferon-based therapy of chronic hepatitis C (HCV) is ineffective and poorly tolerated in decompensated cirrhosis. All oral, direct-acting antiviral regimens are expected to be better tolerated and achieve higher rates of sustained virologic response (SVR). We evaluated the safety and efficacy of all oral HCV therapy in patients with decompensated cirrhosis participating in an ongoing multi-center study: HCV-TARGET.

Methods: Clinical, adverse events, and virologic data were collected throughout treatment and post-treatment follow-up between December 2013 and November 2014. The analyses were restricted to patients with cirrhosis and MELD score of ≥10 who had not undergone liver transplantation. The Safety Cohort consisted of patients who reached an end-treatment (EOT) time point while the Efficacy Cohort had a known virologic outcome (treatment failure or SVR4).

Results: To date, 277 patients with a diagnosis of cirrhosis and a MELD ≥10 were started on all oral regimen for HCV treatment; 217 were part of the Safety Cohort, and 156 reached post-treatment follow-up (Efficacy Cohort). Mean age was 59 yrs, 69% male, with MELD score range from 10 to 28 (mean 13.0). 58.5% had failed prior antiviral therapy and 9.7% had failed prior telaprevir or boceprevir triple therapy. Total bilirubin ranged from 0.1–15 (mean 2.1), albumin 1.4–5.0 (mean 3.2), platelets 19K-567K (mean 83K), creatinine 0.4–6 (mean 0.9). Genotype distribution and treatment regimens are shown in table. At least one AE was reported by 88% of all patients, although most were mild. For patients with available pre/post-treatment bilirubin values, 46/58 (80%) improved, 2/58 (3%) were unchanged, while 10/58 (17%) worsened. Similarly, among patients with pre/post-treatment albumin values, 33/54 (61%) increased, 7/54 (13%) unchanged, while 14/54 (26%) decreased. 26 patients had baseline MELD and post treatment week 4 data available; 18 had improvement, 5 unchanged, and 3 worsened. SVR 4 rates in those with available data are shown in the table.

Conclusions: All oral therapy with SOF/SMV ± RBV or SOF + RBV is well tolerated and efficacious in patients with decompensated cirrhosis. Importantly, markers of hepatic and synthetic function improved during the short-term follow-up.

EFFICACY AND SAFETY OF GRAZOPREVIR AND ELBASVIR IN HEPATITIS C GENOTYPE 1-INFECTED PATIENTS WITH CHILD–PUGH CLASS B CIRRHOSIS (C-SALT PART A)

I.M. Jacobson[1], F. Poordad[2], R. Firpi-Morell[3], G.T. Everson[4], E.C. Verna[5], S. Bhanja[6], B. Zhang[6], L. Caro[6], J. Wahl[6], M. Robertson[6], E. Barr[6], E.D. Charles[6]. *[1]Weill Cornell Medical College, New York, [2]The Texas Liver Institute, University of Texas Health Science Center, San Antonio, [3]University of Florida, Gainesville, [4]University of Colorado, Aurora, [5]Columbia University, New York, [6]Merck & Co., Inc., Whitehouse Station, United States*
E-mail: edgar.charles@merck.com

Background and Aims: Improved treatments are needed for patients with hepatitis C virus (HCV) infection and advanced cirrhosis. In the C-WORTHY study, the combination of grazoprevir (MK-5172, GZR; HCV NS3/4A inhibitor) and elbasvir (MK-8742, EBR; NS5A inhibitor) showed high rates of efficacy in patients with HCV infection with and without compensated cirrhosis. The purpose of the phase 2/3 C-SALT study (PN059) is to assess the efficacy, safety and pharmacokinetics (PK) of GZR plus EBR in patients with HCV G1, G4 or G6 infection and Child–Pugh (CP) class B cirrhosis. The phase 2 portion of C-SALT (part A) is described here.

Methods: CP-B patients with HCV infection received GZR (50 mg QD) and EBR (50 mg QD) for 12 weeks without RBV. Noncirrhotic patients with HCV infection were enrolled for PK analyses and received GZR (100 mg QD) plus EBR (50 mg QD) for 12 weeks. Plasma samples for PK analyses were collected in a subset of CP-B and noncirrhotic patients over 24 hours at TW4. The primary end point is SVR12 in CP-B patients (HCV RNA <LLoQ [15 IU/mL]).

Results: 30 CP-B and 10 noncirrhotic patients were enrolled. Among the CP-B patients, 57% were male, 97% were white, 100% had G1 infection (G1a, 87%), mean MELD was 9.79 (SD, 2.46), mean albumin was 3.4 g/dL (range, 2.6–4.8) and mean platelet count was $83 \times 10^3/\mu L$ (range, 36–175). The study is ongoing; 25 CP-B patients have reached EOT (table). No patient had virologic breakthrough, had a treatment-related SAE, discontinued study drug, or had a grade 3 or 4 ALT elevation. Four patients had transient grade 3 total bilirubin elevations without increased ALT or AST. One patient developed spontaneous bacterial peritonitis and died because of hepatic failure after EOT. In CP-B (n = 9) and noncirrhotic (n = 9)

patients, steady-state preliminary plasma C2 h, C24 h and AUC0–24 concentrations were 1.12 (0.62, 2.00), 1.73 (0.87, 3.43), and 1.30 (0.76, 2.21) for GZR, and 0.95 (0.70, 1.30), 1.07 (0.75, 1.53), and 0.93 (0.69, 1.25) for EBR, respectively.

Table: Patients with HCV RNA <15 IU/mL

Population	TW4	TW8	EOT	FW4
CP-B (n = 30)	76.7% (23/30)	96.4% (27/28)	100% (25/25)	100% (13/13)

CP-B, Child–Pugh Class B; EOT, end of treatment; FW, follow-up week; TW, treatment week.

Conclusions: High rates of virologic response were observed in CP-B patients receiving a combination of GZR plus EBR. The regimen was well tolerated with no evidence of significant hepatotoxicity. Plasma GZR exposure was slightly higher in CP-B patients receiving 50 mg compared with noncirrhotic patients receiving 100 mg; EBR exposure was similar in both groups. Full efficacy (including EOT and SVR12) and safety results will be presented.

General viral hepatitis

A PROSPECTIVE STUDY OF HEPATITIS B REACTIVATION IN PATIENTS WITH PRIOR HBV EXPOSURE UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION: REACTIVATION ASSOCIATION WITH GRAFT-VERSUS-HOST DISEASE

W.-K. Seto[1], T.S.Y. Chan[1], Y.-Y. Hwang[1], D.K.-H. Wong[1], K.S.-H. Liu[1], H. Gill[1], Y.-F. Lam[1], J. Fung[1], A.K.W. Lie[1], C.-L. Lai[1], Y.-L. Kwong[1], M.-F. Yuen[1]. *[1]Medicine, The University of Hong Kong, Hong Kong, Hong Kong, China*
E-mail: wkseto@hku.hk

Background and Aims: Patterns of hepatitis B virus (HBV) reactivation in hepatitis B surface antigen (HBsAg)-negative, antibody to the hepatitis B core antigen (anti-HBc)-positive individuals undergoing hematopoietic stem cell transplantation (HSCT) have not been well described.
Methods: From September 2011 onwards, we recruited treatment-naïve HBsAg-negative, anti-HBc-positive patients with baseline undetectable serum HBV DNA (<10 IU/mL), undergoing either autologous or allogenic HSCT. For allogenic HSCT, only recipients whose donors were HBsAg-negative were recruited. Liver biochemistry, serum HBV DNA, HBsAg and antibody to HBsAg (anti-HBs) were prospectively monitoring every 4 weeks after HSCT up to 2 years. Following guidelines from the European Association for the Study of the Liver, entecavir was started when HBV reactivation, defined as detectable HBV DNA (≥10 IU/mL) was encountered.
Results: At the time of writing, among 328 patients undergoing HSCT, 89 (27.3%) were HBsAg-negative, anti-HBc-positive, of whom 67 (75.3%) fulfilled our inclusion criteria and were recruited. The median duration of follow-up was 52 (range 4–104) weeks. The 2-year cumulative HBV reactivation rate, calculated using the Kaplan–Meier method, was 36.8%. Thirteen patients developed reactivation after a median duration of 44 (range 8–100) weeks, of whom 11 patients (84.6%) remained HBsAg-negative at reactivation. Median HBV DNA level at reactivation was 24.8 (range 14.6–428) IU/mL. Patients with acute and/or chronic graft-versus-host-disease (GVHD) had a significantly higher 2-year cumulative rate of HBV reactivation than those without (acute GVHD: 78.8% *versus* 22.4%, p = 0.006; chronic GVHD: 83.8% *versus* 23.3%, p < 0.001). Other clinical parameters, including age, anti-HBs status, and donor serology had no association with HBV reactivation (all p > 0.05). Multivariate Cox regression analysis showed that chronic GVHD was the only factor independently associated with reactivation (p = 0.030, hazard ratio 3.9, 95% confidence interval 1.1–13.8). Entecavir treatment successfully controlled HBV reactivation in all cases.
Conclusions: From this interim analysis, a substantial proportion of HBsAg-negative, anti-HBc-positive patients developed HBV reactivation after HSCT, with risk of reactivation significantly higher in patients with chronic GVHD. Periodic HBV DNA monitoring was an effective strategy in preventing HBV-related complications.

T AND B CELL RESPONSES AND PREVIOUS EXPOSURE TO HEPATITIS B VIRUS IN "ANTI-HBC ALONE" PATIENTS

Q. Wang[1], N. Semmo[2]. *[1]Division of Gastroenterology and Hepatology, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai Institute of Digestive Disease, Shanghai, China; [2]Hepatology, Department of Clinical Research, Inselspital, University of Bern, Bern, Switzerland*
E-mail: wqx0221155@126.com

Background and Aims: A serologic response to hepatitis B virus (HBV), defined as "anti-HBc alone" is commonly observed, but its significance remains unclear. This study aimed to define the relationship between "anti-HBc alone" serostatus and HBV infection, including HBV-specific T and B cell memory responses.
Methods: 31 "anti-HBc alone" patients were enrolled. Total HBV DNA and cccDNA were tested by nested polymerase chain reaction (PCR) analysis in liver samples from 22 "anti-HBc alone" patients *vs* controls (chronic or resolved HBV infection), followed by HBsAg/HBcAg immunohistochemical (IHC) staining. IFN-γ secretion by HBV-specific T cells was compared in individuals who were "anti-HBc alone" (n = 27), resolved HBV (n = 21), chronic HBV (n = 24) and 12 healthy controls using enzyme-linked immunospot (ELISpot) assays. An HBsAg-IgG B-cell ELISpot assay was performed in "anti-HBc alone" patients before and after a booster dose of recombinant HBsAg vaccine.

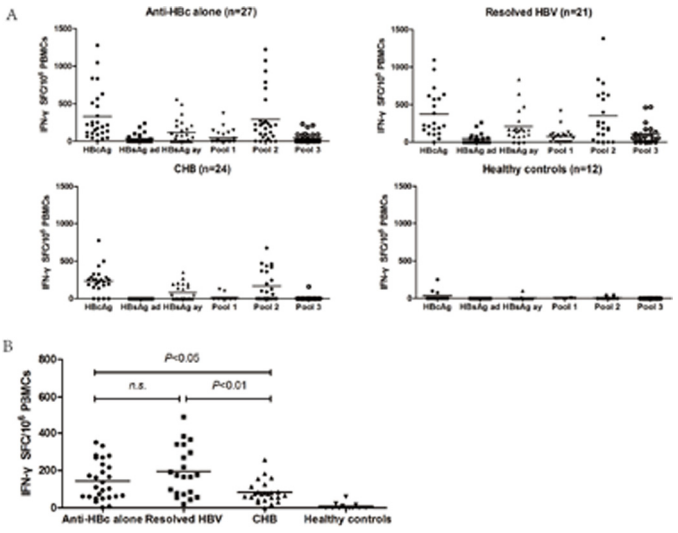

Figure 1. Analysis of HBV-specific IFN-γ producing T cells performed by ELISpot after stimulation with different HBV proteins and peptides, respectively. (A) Pooled ELISpot data for all groups. (B) Comparison of mean spots of the positive tests and frequency of positive responses (calculated on all HBV recombinant protein antigens and peptide pools) obtained in four groups are presented.

Results: Infrequent intrahepatic total HBV DNA (2/22, 9.1%) and cccDNA (1/22, 4.5%) were detected in biopsies; HBsAg and HBcAg IHC staining was negative. HBV-specific T cell responses were similar between "anti-HBc alone" individuals and HBV resolvers (Figure 1). Circulating HBV-memory B cell responses were detected in all "anti-HBc alone" individuals, consistent with an HBsAg-specific memory pool. After one HBV vaccine dose, increased anti-HBs antibody levels were observed, accompanied by an expansion of HBsAg-specific memory B cells ($P = 0.0226$) (Figure 2).
Conclusions: "Anti-HBc alone" individuals showed HBV-specific T cell and memory B cell responses typical of previous viral exposure and protective memory, suggesting a resolved infection.

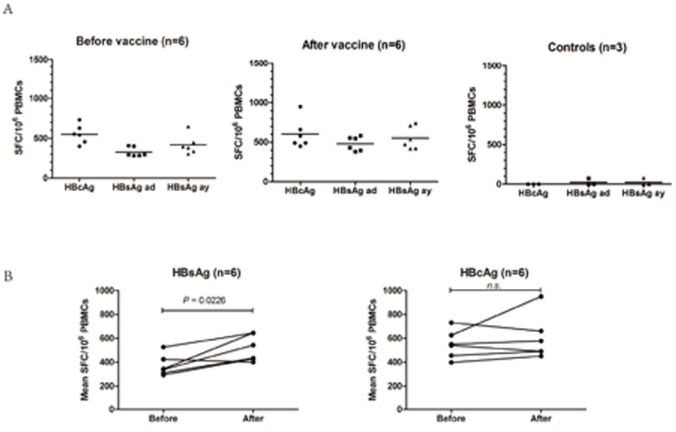

Figure 2. Analysis of HBV-specific memory B cell ELISpot responses. (A) HBV-specific B cell responses shown in SFC/106PBPMC before and after one dose of HBV vaccinated "anti-HBc alone" patients compared with three negative controls (without HBV vaccination or exposure to HBV infection). (B) Comparison of memory B cell responses against HBsAg and HBcAg protein antigen in six "anti-HBc alone" individuals before and after one dose of HBV vaccine.

O011
A NATIONWIDE SURVEY OF HEPATITIS E VIRUS INFECTION IN LIVER TRANSPLANT RECIPIENTS IN JAPAN

Y. Oshiro[1], Y. Inagaki[1], N. Ohkohchi[1], H. Okamoto[2]. *[1]Department of Surgery, University of Tsukuba, Tsukuba, [2]Department of Infection & Immunology, Jichi Med University, Shimotsuke, Japan*
E-mail: oshiro@md.tsukuba.ac.jp

Background and Aims: Hepatitis E virus (HEV) infection induces self-limiting liver disease in immunocompetent individuals. Recently, chronic hepatitis E has been reported in several immunosuppressed patients after organ transplantation. However, the prevalence of HEV infection after liver transplantation is still unknown in Japan. In the present study, we carried out a nationwide survey of the prevalence of hepatitis E virus infection in liver transplant recipients in Japan.
Methods: 1830 patients who received liver transplants and presently alive at the19 university hospitals in Japan were included in the present study. Serum samples of all patients were examined for the anti-HEV immunoglobulin G (IgG), anti-HEV immunoglobulin M (IgM), and anti-HEV immunoglobulin A (IgA) by anti-HEV enzyme-linked immunosorbent assay (ELISA). Also, HEV RNA in serum samples was analyzed with real time polymerase chain reaction (PCR).
Results: All patients were investigated for HEV infection. The prevalence of anti-HEV IgG was 2.6% (48/1830), anti-HEV IgM was 0.05% (1/1830), and anti-HEV IgA was 0% (0/1830). 1574 patients were also tested for HEV RNA in serum. Two patients were found positive for HEV RNA (0.13%; 2/1574). One of the two patients developed chronic HEV hepatitis after liver transplantation. In addition, HEV RNA was detected in one of the transfused blood units. Complete matching of HEV sequences between donor and recipient was observed in this case. The patient was infected with HEV via transfused blood from a volunteer donor. After Ribavirin therapy at a 600 mg per day for 1 month, the serum HEV RNA level decreased to an undetectable level, and the patient cleared infection under the treatment.
Conclusions: We conclude that the prevalence of HEV infection in liver transplant recipients is very low in Japan; however, liver transplant recipients have a risk for chronic HEV infection. Also, a potential risk of posttransfusion hepatitis E should be considered.

HEPATITIS DELTA VIRUS CAN SURVIVE LIVER REGENERATION AND IS AMPLIFIED THROUGH HUMAN CELL DIVISION BOTH IN VITRO AND IN VIVO

K. Giersch[1], O.D. Bhadra[1], T. Volz[1], L. Allweiss[1], A.W. Lohse[1,2], J. Petersen[3], C. Sureau[4], S. Urban[5], M. Dandri[1,2], M. Luetgehetmann[1,6]. *[1]I. Department of Internal Medicine, University Medical Center Hamburg, Hamburg, [2]German Center for Infection Research, Hamburg-Lübeck-Borstel Partner Site, [3]IFI Institute for Interdisciplinary Medicine, Asklepios Clinic St. Georg, Hamburg, Germany; [4]Laboratoire de Virologie Moleculaire, INTS, Centre National de la Recherche Scientifique, Paris, France; [5]Department of Infectious Diseases, Molecular Virology, University Hospital Heidelberg, Heidelberg, [6]Institute of Microbiology, Virology and Hygiene, University Medical Center Hamburg, Hamburg, Germany*
E-mail: kgiersch@uke.de

Background and Aims: Intrahepatic latency of the Delta antigen (HDAg) has been detected even months after liver transplantation and we previously showed that a latent HDV mono-infection can persist in vivo for at least 6 weeks in the absence of HBV before being converted into a productive HBV/HDV infection (Giersch, J. Hepatology 2014). Although these studies highlight the ability of HDV to persist in quiescent hepatocytes, little is known about the impact of cell proliferation on HDV persistence. Aim of the study was to evaluate the ability of HDV to survive cell division in vitro using NTCP-transduced hepatoma cell lines and in vivo using HBV/HDV infected human liver-chimeric uPA/SCID mice.
Methods: NTCP-transduced HepG2 cells were infected with culture-derived HDV or HBV/HDV serum (both MOI=1), treated from day 2 post infection with the entry inhibitor Myrcludex-B, passaged every 7 days (each time 1:3 dilution) for a period of 42 days. In vivo cell proliferation was triggered by transplanting primary human hepatocytes (PHHs) isolated from HBV/HDV infected humanized mice into naïve recipients. Virological parameters were determined by qRT-PCR. Presence of HDAg, HBcAg and cell proliferation (Ki67), were determined by immunofluorescence.
Results: Despite 6 in vitro cell passages (1:243 final cell dilution) and Myrcludex-B-mediated block of extracellular viral spreading, comparable amounts of HDAg-positive cells (median 4–6%) and HDV RNA expression levels (median 4×10^3 HDV-RNA/GAPDH) were detected after each cell harvesting. Notably, HDAg-positive cells in passaged cultures appeared in clusters and Ki67-HDAg co-staining indicated that infected cells proliferated as often as uninfected cells. Comparable results were seen also using a culture-derived (HBV-free) HDV inoculum. In vivo expansion of PHHs isolated from HBV/HDV-infected humanized mice was confirmed 2, 4 and 8 weeks after transplantation. While intrahepatic and serological HBV markers rapidly dropped in proliferating PHHs, HDAg-positive PHHs were observed at all-time points, preferentially forming clusters of adjacent HDAg-positive PHHs at week 4 and 8 post transplantation, indicating maintenance of HDV infection among dividing PHHs and despite the absence of detectable HDV viremia.

Conclusions: Our in vitro and in vivo findings suggest that by surviving hepatocyte proliferation, HDV may not only persist but even be able to propagate, at least to some extent, among daughter cells, despite the absence of HBV.

O013

EVALUATION OF HDV QUANTIFICATION ASSAYS WORLDWIDE: RESULTS OF THE FIRST HDV INTERNATIONAL QUALITY CONTROL STUDY

F. Le Gal[1], S. Brichler[1], F. Neri Pinto[1], J. Techer[1], E. Anouhal[1], W. Mansour[1], S. Chevret[1], E. Gordien[1]. [1]*Hôpital Avicenne, Bobigny, France*
E-mail: emmanuel.gordien@avc.aphp.fr

Background and Aims: Hepatitis Delta virus (HDV), a satellite of hepatitis B virus is responsible for a more severe liver disease. Monitoring of infected-patients is based on quantification of the plasma RNA viral load (VL) using real time RT-PCR assays. Commercial kits were recently shown to significantly underestimated or failed to quantify HDV-VL. The first international quality control was organized to evaluate almost all HDV quantification assays mostly "home-made" by also commercials assays used routinely. The newly developed WHO HDV international standard (WHO-IS) allowed relevant comparison studies between the different assays.
Methods: Twenty clinical samples with various VL loads and genotypes, including 2 negative controls and a second panel of 8 samples composed of 2 dilutions (1:10 and 1:100) of the WHO-IS in triplicate together with 2 negative controls, were sent blindly for quantification to 27 laboratories worldwide: Australia (1), Belgium (1), Denmark (1), France (6), Greece (2), Germany (4), Italy (3), Luxembourg (1), Mauritania (1), Spain (1), Russia (1), Switzerland (1), Turkey (1), United Kingdom (2) and the USA (1).
Results: Twenty-four labs sent their results for the 2 panels of samples. Results obtained with the WHO-IS panel, showed a very good repeatability while 3 labs found positive 1 or the 2 negative controls of this panel. Considering the results converted into IU/mL of these 24 labs for the 20 clinical samples, the 2 negative controls were found undetectable; 12 labs (50%) failed to detect 1 or several samples with expected VL values ranging from 3.9 to 6.8 IU/mL and 7 (29.2%) underestimated (>1 to 3 log) most samples, whatever the genotype of the infected-strain. Four laboratories found comparable results whatever the nucleic acid extraction method or RT-PCR technology or devices used. Primers and probes were designed within the ribozymes regions of the genome for 3 of them and within the Delta antigen-coding region for the remaining one. Of note this latter assay underestimated 2 samples of genotype 5 and 8 by 3 and 1 log.
Conclusions: The current assays for quantification of HDV RNA seem to date very imperfect for the diagnosis and monitoring of patients. The main points toward standardization of quantification assays should consider HDV genetic variability; an internal control for all steps; automation and the use of the available WHO-IS.

A TARGETED RNAi SCREEN USING A HIGH-THROUGHPUT INFECTIOUS MODEL SYSTEM UNCOVERS GLYPICAN GPC5 AS A HOST FACTOR FOR HEPATITIS B AND D VIRUS ENTRY

E.R. Verrier[1,2], C. Bach[1,2], L. Heydmann[1,2], A. Weiss[3], M. Renaud[3], P. Fritsch[3], F. Habersetzer[4], G. Abou-Jaoudé[5], D. Durantel[6,7], C. Schuster[1,2], L. Brino[3], C. Sureau[5], M.B. Zeisel[1,2], T.F. Baumert[1,2,4]. [1]*Institut de Recherche sur les Maladies Virales et Hépatiques, Inserm U1110,* [2]*Université de Strasbourg, Strasbourg,* [3]*Plateforme de Criblage Haut-débit, IGBMC, Illkirch,* [4]*Pôle Hépato-digestif, Institut Hospitalo-universitaire, Strasbourg,* [5]*Laboratoire de Virologie Moléculaire, INTS, Paris,* [6]*Centre de Recherche en Cancérologie de Lyon, Inserm U1052,* [7]*Université de Lyon, Lyon, France*
E-mail: e.verrier@unistra.fr

Background and Aims: Chronic hepatitis B virus (HBV) infection and its co-infection with hepatitis D virus (HDV) are leading causes of liver disease and cancer world-wide. Viral entry is the first step of infection, plays a key role in spread and control of infection and has been shown to be a viable target for the development of curative therapeutic strategies. HBV and HDV viruses infect exclusively hepatocytes and share the same envelope proteins and entry pathway. Heparan sulfate proteoglycans (HSPGs) have been shown to mediate HBV and HDV attachment at the hepatocyte cell surface before interacting with sodium taurocholate cotransporting polypeptide (NTCP). However, the detailed mechanisms of entry and its host cell-dependency factors are still poorly understood. Using a targeted RNAi screen we aimed to investigate the role of HSPG core proteins in HBV/HDV entry.
Methods: We established a high-throughput HDV infection model using Huh7 cells overexpressing NTCP and susceptible to HDV infection. Unlike previous approaches, this system does not require dimethylsulfoxide or polyethylene glycol to facilitate entry, thus providing a model closely mimicking natural infection. Using a small library of siRNAs targeting the core members of the HSPG family, we performed a targeted screen to evaluate the role of individual HSPG core proteins in HDV entry.
Results: While the silencing of the expression of most HSPG core genes did not result in strong modulation of infection, silencing of Glypican GPC5 expression induced a marked and significant decrease of HDV infection as shown by immunofluorescence of HDV infected Huh7-NTCP+ cells and RT-PCR of HDV RNA. Using HepG2 cells overexpressing NTCP and individual siRNAs, we demonstrate that GPC5 silencing is a host cell-dependency factor for HBV infection. Silencing of GPC5 in HepG2-NTCP cells resulted in a marked decrease of both HBV-positive cells and HBV pregenomic RNA, confirming the functional role of this host cell surface protein for both HDV and HBV infection.
Conclusions: Collectively, this targeted RNAi screen in a high-throughput infectious model system uncovers GPC5 as an entry factor for hepatitis B and D viruses. These results advance our understanding of cell entry of HBV and HDV and open new avenues for therapies aiming at HBV cure. Since glypicans have been shown to play a role in the control of cell division and growth regulation, virus-GPC5 interactions may also play a role for pathogenesis of virus-induced liver disease.

O015

QUANTITATIVE MEASUREMENTS OF MUTATIONS IN BASAL CORE PROMOTOR REGION SUGGEST A LOSS OF IMMUNE TOLERANCE IN HBeAg POSITIVE CHRONIC HEPATITIS B INFECTIONS

G. Rosenberg[1], J. Bayliss[1], L. Yuen[1], A. Gaggar[2], K. Kitrinos[2], M. Subramanian[2], E. Gane[3], H.L. Chan[4], R. Hammond[1], S. Bowden[1], P. Revill[1], S. Locarnini[1], A. Thompson[5]. *[1]VIDRL, Melbourne, Australia; [2]Gilead Sciences, Foster City, CA, United States; [3]New Zealand Transplant Unit, Auckland, New Zealand; [4]The Chinese University of Hong Kong, Hong Kong SAR, Hong Kong, China; [5]St Vincent's Hospital, Melbourne, Australia*
E-mail: gillian.rosenberg@mh.org.au

Background and Aims: The standard clinical definition of immune tolerant (IT) CHB includes HBeAg positivity, high HBV DNA, normal ALT and minimal hepatic necroinflammation, assuming aBVHBV predominantly wildtype HBV quasispecies under no immune pressure. The GS-US-203-0101 trial evaluated TDF vs TDF+FTC therapy in IT patients, and we previously identified the presence of immune evasion mutations in a subset these patients using population sequencing, suggesting that current clinical criteria need updating. The aim of this study was to quantify immune evasion mutations by Next Generation Sequencing (NGS) and evaluate their impact at baseline and on-treatment.
Methods: Whole genome NGS was performed on baseline samples (Illumina Miseq). A bioinformatics pipeline assembled validated and mapped the sequencing data. This was analysed against baseline demographic, clinical, and virological data, as well as on-treatment outcomes after 192 weeks.
Results: Data were available for 99 patients (median age 32 yrs, 51% male, 95% Asian, genotype B/C 58%/42%; median ALT 25 IU/mL, HBV DNA 8.5 $\log_{10}$ IU/mL, HBsAg 4.8 $\log_{10}$ IU/mL, HBeAg 3.6 $\log_{10}$PEIU/mL). NGS detected and quantified mutations present >1%, including those at low frequency (<20%) that were not seen by population sequencing (see Table 1).
The levels of BCP mutations fell into three categories, <1%, 1–5% and >45%. Linear regression showed higher prevalence was associated with older age ($p = 0.001$) and lower baseline HBsAg and HBeAg titres ($p < 0.001$). A threshold of >1% BCP mutations at baseline was analysed with respect to treatment outcomes alongside previously identified parameters including treatment arm, baseline serology and genotype. >1% BCP was independently associated with improved viral suppression (89% vs 58%, OR = 12, $p = 0.005$) and increased HBeAg decline (OR = 27, $p = 0.004$). Clinically relevant thresholds for other mutations were investigated; core P130T >1% negatively impacted on HBeAg decline (OR = 0.16, $p = 0.02$) and NRE G1613A >5% negatively impacted viral suppression (OR = 0.24, $p = 0.02$).

Table 1. Key mutations

	NGS	Population sequencing
Negative Regulatory Element (NRE) G1613A	73 (74%)	19 (19%)
Basal Core Promotor (BCP) 1762/1764	23 (23%)	12 (12%)
BCP T/C1858G	0 (0%)	0 (0%)
Precore (PC) G1896A	15 (15%)	3 (3%)
Core P130T	47 (47%)	6 (6%)
PreS1 M1	33 (33%)	4 (4%)
PreS2 M1	11 (11%)	6 (6%)
HBsAg P120T/G145R	9 (9%)	4 (4%)
RT 80/169/173/180/181/184/202/204/236/250	12 (12%)	0 (0%)

Conclusions: BCP mutations are a virological response to host immune pressure. An increased prevalence was associated with lower HBeAg and HBsAg titres, improved viral suppression and HBeAg decline on-treatment. These findings demonstrate baseline heterogeneity within this immune tolerant population possibly due to variability in immune pressure. Furthermore, these results suggest that the current definition of IT may need to be updated to include detection of BCP variants.

O016

HEPATITIS B SURFACE ANTIGEN AND DNA LEVELS CAN IDENTIFY INACTIVE CARRIERS AND PREDICT LOWER RISK FOR HEPATOCELLULAR CARCINOMA AND CIRRHOSIS AMONG GENOTYPE B AND C CHRONIC HEPATITIS B CARRIERS

J. Liu[1], H.-I Yang[1], M.-H. Lee[2], R. Batrla-Utermann[3], C.-L. Jen[1], S.-N. Lu[4], L.-Y. Wang[5], S.-L. You[1], C.-J. Chen[1]. *[1]Academia Sinica Genomics Research Center, [2]Institute of Clinical Medicine, National Yang-Ming University, Taipei, Taiwan; [3]Roche Diagnostics, Basel, Switzerland; [4]Gastroenterology, Chang-Gung Memorial Hospital, Kaohsiung, [5]MacKay College of Medicine, Taipei, Taiwan*
E-mail: jessica.b.liu@gmail.com

Background and Aims: Inactive chronic hepatitis B virus (HBV) carriers have significantly decreased risk for hepatocellular carcinoma (HCC) and liver cirrhosis, and are more likely to reach HBsAg seroclearance. Differentiation between inactive and active carriers is crucial to identifying those in need of more stringent follow-up. Previous studies showed that a single point measurement of HBV DNA and HBsAg levels could identify inactive carriers in genotype D carriers. This study aims to validate these previous findings in genotype B and C carriers, and also examines rates of HCC, cirrhosis, and HBsAg seroclearance among those identified as inactive carriers using a single measurement.
Methods: 1526 HBeAg-negative individuals from the REVEAL-HBV cohort were included in this study. Participants were anti-HCV seronegative and free of cirrhosis at study entry. To identify inactive and active carriers, all participants had at least two to three measurements of HBV DNA / ALT within 1.5 years of study entry. Hazard and rate ratios of outcomes were estimated using Cox proportional hazards models.
Results: Within 1.5 years, 775 (51%) were inactive carriers (IC) with HBV DNA persistently <10,000 copies/mL, 496 (33%) were active carriers (AC) with periodic HBV DNA elevations <100,000 copies/mL, and 255 (17%) were highly replicative active carriers (HRAC) with HBV DNA fluctuating or persisting above 100,000 copies/mL. The proportion of abnormal ALT elevations (>40 U/L) was 0%, 9%, and 20% for IC, AC, and HRAC, respectively. A single point measurement of HBsAg <1000 iu/mL and HBV DNA <10,000 copies/ml could identify IC with a sensitivity, specificity, positive predictive value, and negative predictive value of 0.71, 0.85, 0.83, 0.74, respectively, and 0.71, 0.91, 0.96, 0.51, respectively, when limited to IC and HRAC only. The same single point measurement also identified individuals with significantly lower risk of HCC and cirrhosis, with adjusted hazard ratios (95% CI) of 0.20 (0.08–0.51) and 0.27 (0.14–0.50), respectively. Rates of HBsAg seroclearance were also much higher, with an adjusted rate ratio (95% CI) of 7.14 (5.62–9.09).
Conclusions: Compared with long-term determination, a single point combined measurement of HBsAg and HBV DNA is able to identify inactive carriers with moderate accuracy, while also differentiating those with reduced risk for HCC and cirrhosis, and higher probability of HBsAg seroclearance.

Non-invasive marker of liver disease management

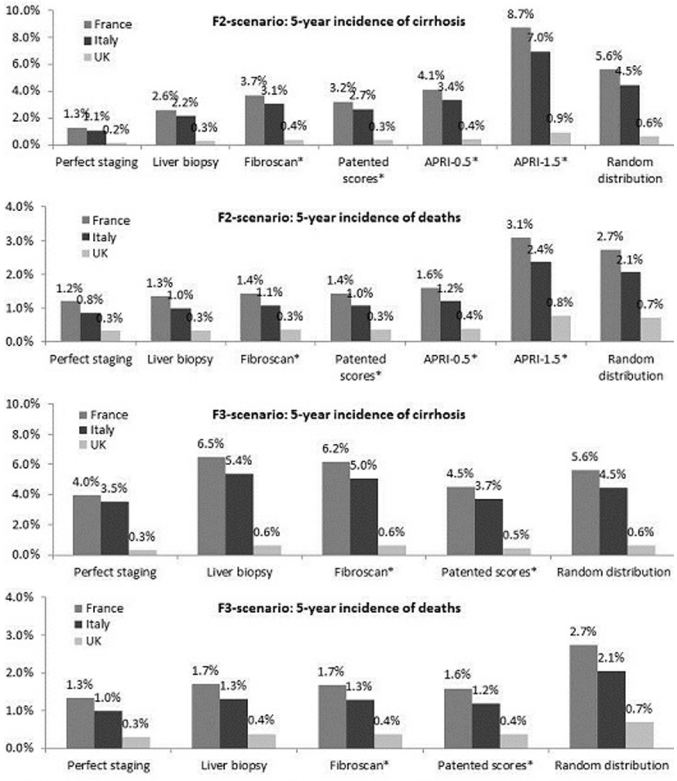
EFFECTIVENESS OF TREATMENT INITIATION BASED ON FIBROSIS STAGE ASSESSED BY METHODS OF FIBROSIS DIAGNOSIS IN TERMS OF 5-YEAR INCIDENCE OF MORBI-MORTALITY

S. Deuffic-Burban[1,2], J. Boursier[3], V. Leroy[4], L. Castera[5], P. Mathurin[1,6]. *[1]Inserm U995, Univ Lille 2, Lille, [2]Inserm IAME UMR1137, Univ Paris Diderot, Sorbonne Paris Cité, Paris, [3]Service d'Hépato-Gastroentérologie, Centre Hospitalier Universitaire d'Angers, Angers, [4]Clinique Universitaire d'Hépato-gastroentérologie, Pôle Digidune, Centre Hospitalier Universitaire Grenoble, Inserm U823, IAPC Institut Albert Bonniot, Grenoble, [5]Department of Hepatology, Beaujon Hospital, Inserm U773, University of Paris 7, Clichy, [6]Service des Maladies de l'Appareil digestif et de la Nutrition, Hôpital Huriez, CHRU Lille, Lille, France*
E-mail: sylvie.burban@inserm.fr

Background and Aims: European and American experts recommend targeting HCV antiviral therapy to patients (pts) with fibrosis ≥F2, with the highest priority assigned for F3–F4. The impact of targeted therapy has never been evaluated in light of the risk of misclassification of the methods of fibrosis diagnosis.
Methods: A country-specific decision model was used to predict 5-year (yr) incidence of cirrhosis and deaths in three countries with different profiles of natural history (France, Italy, UK). Fibrosis misclassification was integrated for different methods: liver biopsy (LB), fibroscan (FS), patented scores (fibrotest, hepascore, fibrometer), and APRI. IFN-free regimens were initiated considering two scenarios where pts are distributed in fibrosis stage ≥F2 (F2-scenario) and ≥F3 (F3-scenario), according to available thresholds of methods. Outcomes based on the use of these methods were compared to those using a perfect staging (no misclassification) and a random distribution (50% of pts were considered for therapy regardless of fibrosis stage).
Results: In F2-scenario, 5-yr incidence of cirrhosis is: 0.2–1.3% using the perfect staging, 0.3–2.6% with LB, 0.4–3.7% with FS, 0.3–3.2% with patented scores, 0.4–4.1% with APRI-0.5, 0.9–8.7% with APRI-1.5, 0.6–5.6% with random distribution; 5-yr incidence of deaths is: 0.3–1.2% using the perfect staging, 0.3–1.3% with LB, 0.3–1.4% with FS, 0.3–1.4% with patented score, 0.4–1.6% with APRI-0.5, 0.8–3.1% with APRI-1.5, 0.7–2.7% with random distribution. In F3-scenario, using the perfect staging, 5-yr incidence of cirrhosis increases dramatically, at least for France and Italy, whereas this scenario has less impact on 5-yr incidence of liver deaths; using methods of diagnosis and due to their risk of misclassification, 5-yr incidence of cirrhosis shows 28–60%> relative increase compared to F2-scenario in France and Italy, whereas the increase is lower in UK, as well as 5-yr incidence of liver deaths.
Conclusions: Based on the unrealistic scenario of perfect staging, F2- and F3-scenarios are efficient to reduce 5-yr incidence of liver-related deaths but F3-scenario is not optimal in terms of 5-yr incidence of cirrhosis. LB, FS and patented scores are efficient to select subgroups with higher risks of cirrhosis and mortality: F2- and F3-scenarios are still efficient in terms of 5-yr incidence of mortality although their impact would be lower than perfect staging; conversely, they are associated with deleterious impact on 5-yr incidence of cirrhosis, mainly F3-scenario.



*Thresholds considered were: F2-scenario: 7.0 for FibroScan, 0.49 for FibroTest, 0.5 for Hepascore, 0.411 for Fibrometer, and 0.5 (APRI-0.5) and 1.5 (APRI-1.5) for APRI; F3-scenario: 9.5 for FibroScan, 0.59 for FibroTest, 0.5 for Hepascore, 0.628 for Fibrometer (no available thresholds for Hepascore and APRI).

O017A

NON-INVASIVE TOOLS AND RISK OF VARICES AND CLINICALLY SIGNIFICANT PORTAL HYPERTENSION IN COMPENSATED CIRRHOSIS: THE "ANTICIPATE" STUDY

J.G. Abraldes[1], C. Bureau[2], H. Stefanescu[3], S. Augustin[4], M. Ney[1], B. Procopet[3], J. Bosch[5], J. Genesca[4], A. Berzigotti[5]. *[1]University of Alberta, Edmonton, Canada; [2]CHU de Toulouse, Toulouse, France; [3]Regional Institute of Gastroenterology and Hepatology, ClujNapoca, Romania; [4]VHIR, Universitat Autònoma de Barcelona, [5]University of Barcelona, Barcelona, Spain*
E-mail: juan.g.abraldes@ualberta.ca

Background and Aims: Current guidelines recommend endoscopic screening for varices in all patients with cirrhosis. Several non-invasive markers have been assessed but none have permeated clinical practice. This might be, in part, due to the use of performance measurements without direct clinical translation (sensitivity, specificity, ROC curves). Risk prediction modeling could be a better way to answer relevant clinical questions, such as what would be the risk of varices (V), varices needing treatment (VNT: medium-large varices or small with red signs) and clinically significant portal hypertension [CSPH: hepatic venous pressure gradient (HVPG) ≥10 mmHg] given a certain value of these non-invasive tests. The aim of this study was to construct risk prediction models based non-invasive tests to determine the risk of V, VNT and CSPH in patients with compensated Child A cirrhosis.
Methods: We analysed data from Child A patients with cirrhosis from 5 centers in Europe and Canada with paired endoscopic (n = 542) or HVPG (n = 315) and non-invasive data: Fibroscan (n = 542), LSPS (n = 299) and Platelet-spleen ratio (PSR, n = 299). Risk of V, VNT and CSPH was modeled with logistic regression (bootstrapped). Examples of potential decision thresholds are provided.
Results: Prevalence of V was 42% and of VNT 13%. LSPS-based model had the best accuracy in predicting V (AUC:0.79). LSPS of 0.7 was associated with a risk of V of 10% (Figure 1). However, only 6% of the patients had a LSPS <0.7. Fibroscan and PSR models still had acceptable accuracy, but could not identify a subgroup with

<10% risk of V. LSPS was also the best predictor for VNT (AUC:0.79). LSPS of 1.36 and 2.38 were associated with a 5 and 10% risk of VNT, and 24% and 51% of the sample had values below these thresholds. PSR also had good accuracy (AUC:0.74), with values of 1700 and 1050 predicting a risk of VNT of 5 and 10%. Fibroscan had a lower accuracy that LSPS and PSR (AUC:0.68). Values of 13.5 and 23 Kpa were associated with a 5 and 10% risk of VNT. Prevalence of CSPH was 63%. LSPS-based model had the best accuracy in predicting CSPH (AUC: 0.88). LSPS values of 0.71, 1.66 and 2.63 were associated with risks of CSPH of 20, 50 and 80% respectively (Figure 2). Only 6% of the patients had a predicted risk of CSPH <20%, and none of <10%. Fibroscan had also an excellent accuracy (AUC: 0.82), but could not identify a subpopulation with a very low risk of CSPH. Fibroscan values of 18 and 28 were associated with a risk of 50 and 80% of CSPH. Accuracy of PSR was lower. The best data-driven models did not outperform LSPS.

Conclusions: LSPS was the best of the 3 non-invasive markers to predict V, VNT and CSPH. In a population with a ~40% baseline risk of varices none of the tests were good enough to identify a subgroup with a <10% risk of varices. However, all three could identify a significant proportion of patients with a very low risk of VNT, suggesting that endoscopy could be avoided in 25–50% of compensated cirrhotic patients. LSPS and Fibroscan based models had an excellent performance at predicting the risk of CSPH and could reliably identify patients with a very high risk of CSPH. These tools, however, could not define a subgroup of patients with very low risk of CSPH.

E-mail: herrmann@med.uni-frankfurt.de

Background and Aims: 2D shear wave elastography (2D-SWE) based on supersonic shear imaging (SSI) has proven to be efficient for the evaluation of liver fibrosis in several small to moderate size trials. We aimed at running a larger scale analysis of individual data.

Methods: Clinical data from 1340 patients with 2D-SWE measurement and liver biopsy were collected retrospectively from 13 sites and analysed. Additionally, data on transient elastography (TE) were available in a subsample of 972 patients. The database was cleared by the French National Commission on Information Technology and Liberties and the study was registered on clinicaltrials.gov. The data were analysed using appropriate random effect models for ROC analysis as well as paired comparison of AUROC.

Results: Main etiologies were chronic hepatitis C (HCV, n = 470), hepatitis B (HBV, n = 420), non-alcoholic fatty liver disease (NAFLD, n = 172) or other liver diseases (n = 278). There was high heterogeneity between sites for liver disease etiologies and fibrosis stages. 40.8% of the patients had minimal or no fibrosis, 19.3% had significant fibrosis, 14.0% had severe fibrosis and 26.0% had cirrhosis.

Overall performance of 2D-SWE assessed by AUROC in patients with HCV, HBV and NAFLD was 86.3%, 91.6%, 85.9% for diagnosing significant fibrosis and 96.1%, 97.1% and 95.5% for diagnosing cirrhosis, respectively. Optimal cut-offs were 7.1 kPa for diagnosing significant fibrosis in all patients (75.7% correctly classified), 13.5 kPa for diagnosing cirrhosis in HCV and NAFLD patients, and 11.5 kPa for diagnosing cirrhosis in HBV patients (87% correctly classified).

Differences in AUROC were borderline significant for diagnosing significant fibrosis (95% CI for AUROC-2D-SWE minus AUROC-TE: [0.0004, 0.055], p = 0.047) and AUROC was significantly higher for 2D-SWE when diagnosing cirrhosis (95% CI for AUROC-2D-SWE minus AUROC-TE: [0.006, 0.036], p = 0.0058). 2D-SWE was superior for diagnosing cirrhosis specifically in HCV patients (AUROC difference: 0.018; p = 0.046) and HBV patients (AUROC difference: 0.062; p = 0.015). It was superior for diagnosing significant fibrosis in HBV patients (AUROC difference: 0.102; p = 0.0005) and severe fibrosis in NAFLD patients (AUROC difference: 0.152; p = 0.002).
Conclusions: 2D-SWE based on SSI showed good to excellent performance for non-invasive assessment of liver fibrosis, and was equivalent or superior to transient elastography.

O019
THE VALUE OF DIFFERENT NON-INVASIVE TESTS FOR PREDICTING THE PRESENCE OF CLINICALLY SIGNIFICANT PORTAL HYPERTENSION AND ESOPHAGEAL VARICES IN CIRRHOTIC PATIENTS

S. Bota[1], T. Purevsambuu[1], T. Reiberger[1], M. Mandorfer[1], P. Schwabl[1], W. Sieghart[1], M. Trauner[1], A. Ferlitsch[1], M. Peck-Radosavljevic[1].
[1]Vienna Hepatic Hemodynamic Lab, Div. of Gastroenterology and Hepatology, Dept. of Internal Medicine III, Medical University of Vienna, Vienna, Austria
E-mail: bota_simona1982@yahoo.com

Background and Aims: Diagnosis of clinically significant portal hypertension (CSPH) and esophageal varices (EV) in cirrhotic patients is crucial for timely initiation of prophylaxis of variceal bleeding but requires upper GI endoscopy or measurement of hepatic venous pressure gradient (HVPG). Our aim was to assess the diagnostic value of serological scores (initially developed for fibrosis evaluation) and transient elastrography (TE) for prediction of CSPH and EV.
Methods: Our study included 917 consecutive cirrhotic patients undergoing upper GI endoscopy, HVPG measurements, serological tests at the Medical University of Vienna between January/2004-January/2014. Simple serological scores were calculated: APRI, Fibrosis Index (FI), FIB-4, Forns score, King's and Lok score. In a large subset of 614 patients TE was performed at the same day of blood testing and HVPG measurement. According to the newly proposed TE quality criteria, ten valid memeasurements with a median liver stiffness value ≥7.1 kPa and IQR/median >30% were considered poorly reliable and not included for analysis. The TE cases without 10 valid measurements were also excluded.
Results: CSPH was diagnosed in 70.4% of patients and 65.6% of those showed EV at upper GI endoscopy. Etiologies of liver cirrhosis were: viral (45.4%), alcoholic (35.2%), others (19.4%). Reliable LS measurements were obtained in 65.9% of patients. All serological scores and liver stiffness were significantly correlated with the presence of CSPH and EV (table). The highest AUCs for predicting both CSPH and EV were obtained for TE, Lok and FI score (table). The performance of all non-invasive tests for predicting EV was lower compared to that obtained for prediction of CSPH.

Test	Correlation with HVPG values and prediction of CSPH					Prediction of EV presence			
	Spearman correlation coefficient	Cut-off	AUC	Se (%)	Sp (%)	Cut-off	AUC	Se (%)	Sp (%)
APRI	r = 0.165, p < 0.0001	>2.22	0.665	43.2	86	>2.32	0.556	40.6	70
FI	r = 0.394, p < 0.0001	>3.29	0.834	66.4	90.1	>3.39	0.720	76.2	61.3
FIB-4	r = 0.325, p < 0.0001	>5.09	0.795	56.1	91.7	>5.19	0.671	69.4	59
Forns	r = 0.255, p < 0.0001	>8.32	0.770	65.8	82.5	>8.53	0.672	64.5	63.3
King's	r = 0.240, p < 0.0001	>38.8	0.731	58.4	80.2	>39.4	0.596	59.6	57.5
Lok	r = 0.472, p < 0.0001	>0.64	0.834	85.2	70.2	>0.74	0.743	80.2	60.8
TE	r = 0.650, p < 0.0001	>26.3	0.897	78.8	90.1	>33.3	0.751	69.3	70.1

Conclusions: TE demonstrates an excellent performance for predicting CSPH but has only moderate accuracy for predicting EVs. While TE failed or resulted in poorly reliable results in more than 30% of patients, serological socres such as the Lok or FI score can be easily calculated for all cirrhotic patients. Upper GI-endoscopy remains the gold-standard for surveillance for EV today

MAGNETIC RESONANCE ELASTOGRAPHY IS SUPERIOR TO CLINICAL PREDICTION MODELS FOR DETERMINATION OF ADVANCED FIBROSIS IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE: A PROSPECTIVE STUDY

J.Y. Cui[1], T. Wolfson[2], B. Ang[1], W. Haufe[2], C. Hernandez[1], E.C. Verna[3], C.B. Sirlin[2], R. Loomba[1,4,5]. *[1]NAFLD Translational Research Unit, Department of Medicine, [2]Liver Imaging Group, Department of Radiology, UC San Diego School of Medicine, La Jolla, [3]Center for Liver Disease and Transplantation, Division of Digestive and Liver Diseases, Columbia University College of Physicians and Surgeons, New York, [4]Division of Gastroenterology, Department of Medicine, [5]Division of Epidemiology, Department of Family and Preventive Medicine, UC San Diego School of Medicine, La Jolla, United States*
E-mail: jycui@ucsd.edu

Background and Aims: Two-dimensional magnetic resonance elastography (2D-MRE), a novel magnetic resonance method for assessing liver stiffness, has been shown to have high diagnostic accuracy for predicting advanced fibrosis (stage 3 and 4 fibrosis) in patients with non-alcoholic fatty liver disease (NAFLD). However, head-to-head comparisons between 2D-MRE and clinical prediction rules using laboratory and demographic data have not yet been performed in a prospective cohort of patients with biopsy-proven NAFLD. The aim of this study was to compare the diagnostic accuracy of 2D-MRE with that of 8 previously defined clinical prediction rules (AST:ALT ratio, APRI, BARD, FIB-4, NAFLD Fibrosis Score, Bonacini cirrhosis discriminant score, Lok Index, and NASH CRN model) for predicting advanced fibrosis in a prospective study with paired liver biopsy as the gold standard.
Methods: This is a cross-sectional analysis of a prospective study of 102 patients (58.8% women) with biopsy-proven NAFLD. The patients underwent 2D-MRE within 1 year of biopsy and clinical and laboratory tests within 90 days of biopsy. ROC analysis was performed to assess the performance of MRE and clinical prediction rules in predicting advanced fibrosis. The radiologist was blinded to clinical data and the pathologist was blinded to pathology/imaging data. Biopsies were scored using the NASH-CRN histologic system.

	AUROC	95% CI	AUC comparison, MRE vs. clinical prediction models
2D-MRE	0.957	(0.918, 0.996)	N/A
Clinical prediction models			
AST to ALT ratio	0.825	(0.732, 0.918)	p = 0.013
APRI	0.807	(0.702, 0.911)	p = 0.006
BARD	0.816	(0.723, 0.910)	p = 0.001
FIB-4	0.861	(0.775, 0.946)	p = 0.039
NAFLD fibrosis score	0.818	(0.704, 0.932)	p = 0.013
Bonacini cirrhosis discriminant score	0.826	(0.725, 0.926)	p = 0.014
Lok index	0.838	(0.731, 0.944)	p = 0.046
NASH CRN model	0.796	(0.678, 0.915)	p = 0.009

CI, Confidence interval.

Results: The mean (± standard deviation) age and BMI were 51.3 (±14.0) years and 31.7 (±5.5) kg/m^2, respectively. The median (interquartile range) time interval between biopsy and MRE was 41 (48) days, and that between biopsy and collection of clinical predictor data was 29 (28) days. 48, 26, 9, 13, and 6 patients had stage 0, 1, 2, 3, and 4 fibrosis, respectively. The area under ROC curve (AUROC) was 0.957 for 2D-MRE and between 0.796 to 0.861 for the 8 clinical prediction rules. In head-to-head comparisons using

the Delong test, 2D-MRE had significantly better AUROC ($p < 0.05$) than each of the 8 clinical prediction rules for predicting advanced fibrosis, as shown in the table.

Conclusions: Compared to clinical prediction rules, 2D-MRE provides significantly higher accuracy for the diagnosis of advanced fibrosis in NAFLD patients.

O021

NON-INVASIVE SCREENING OF LARGE ESOPHAGEAL VARICES USING ENDOSCOPIC CAPSULE AND/OR LIVER FIBROSIS TESTS

P. Cales[1], S. Sacher-Huvelin[2], A. Olivier[1], D. Valla[3], J.P. Vinel[4], J.P. Galmiche[2]. *[1]Hepatology, CHU, Angers, [2]Hepato-Gastroenterology, CHU, Nantes, [3]Hepatology, Beaujon Hospital, Clichy, [4]Hepatology, CHU, Toulouse, France*
E-mail: paul.cales@univ-angers.fr

Background and Aims: The non-invasive screening of large esophageal varices (LEV) might be useful in primary prevention of variceal bleeding in cirrhosis. The main objective was to compare strategies for the diagnosis of LEV by using predictive values and direct costs.

Methods: 330 cirrhotic patients were included in a prospective multicenter study. Diagnostic tools were upper gastro-intestinal endoscopy (UGIE, reference), esophageal capsule endoscopy (ECE), liver stiffness measurement (LSM) by Fibroscan and several blood markers and liver fibrosis tests.

Results: 287 patients had per protocol analysis defined by UGIE and ECE available. Child–Pugh class distribution was: A: 61%, B: 20%, C: 19%. Etiology was: alcohol: 45%, viral hepatitis: 27%, NASH: 5%, mixed: 11%, others: 6%. Among the 35 diagnostic predictors tested in the per protocol population, 10 had an AUROC >0.7 for LEV: Child–Pugh score (0.72), bilirubin (0.72), AST/ALT (0.74), LSM (0.74), hyaluronate (0.77), QuantiMeter (0.77), FibroMeter (0.77), CirrhoMeter (0.77), Elasto-FibroMeter (0.78), ECE (0.89). The most performant combination by binary logistic regression was either with ECE: ECE + AST/ALT (score 1, AUROC: 0.92) or without ECE: prothrombin index + AST/ALT (score 2, AUROC: 0.77), LSM having no independent role. Then, we defined 5 strategies based on non-invasive tools with high negative predictive value (NPV ≥95%) and/or positive predictive value (PPV ≥90%) for LEV in a first step; then, UGEI was used in the indeterminate zone. The 5 strategies were: S1: ECE for NPV and PPV, S2: LSM for NPV and ECE for PPV, S3: LSM for NPV and score 2 (ECE + blood markers) for PPV, S4: score 1 (blood markers) for NPV and PPV, S5: score 2 (ECE + blood markers) for NPV and PPV. The rank of strategies for decreased request to UGEI was: S5: 12.9%, S1: 28.9%, S2: 41.7%, S3:42.2%, S4: 47.5% ($p < 0.001$ between all and S5 vs others). But the rank for direct costs per patient was different: S4: 64€, S2: 393€, S3: 399€, S5: 632€, S1: 645€, reference UGEI cost being 114€.

Conclusions: This is the first study comparing capsule endoscopy and fibrosis tests in the screening of large esophageal varices. By using capsule and blood markers, one can avoid 87% of endoscopies in cirrhotic patients but this strategy has currently high direct costs (x6). By contrast, simple blood markers can avoid 48% of endoscopies and divide the direct costs by around 50%. These results should be validated in an independent population, compared to spleen stiffness and add indirect costs.

O022

THE UK-PBC RISK SCORE: DERIVATION AND VALIDATION OF A RISK SCORE TO PREDICT LIVER EVENTS IN THE UK-PBC RESEARCH COHORT

M. Carbone[1,2], S.J. Sharp[3], M.A. Heneghan[4], J.M. Neuberger[5], G.M. Hirschfield[6], A.K. Burroughs[7], D. Thorburn[7], A. Bathgate[8], M. Aldersley[9], C. Adgey[10], P. Trembling[11], K. Williamson[12], L. Jopson[13], R.T. Lim[5], N.J. Wareham[3], H.J. Cordell[14], G.J. Alexander[1], J.E. Jones[13], R.N. Sandford[2], G.F. Mells[1,2], UK-PBC Consortium.

E-mail: mc767@medschl.cam.ac.uk

Background and Aims: Outcomes in primary biliary cirrhosis (PBC) can be predicted by biochemical response to ursodeoxycholic acid (UDCA). However, stratification based on UDCA response does not take the stage of the liver disease into account. Furthermore, existing definitions dichotomise UDCA response and long-term risk, whereas both are a continuum. We analysed the UK-PBC Research Cohort to develop and validate a risk score that includes markers of disease stage, as well as the post-treatment liver biochemistries modelled as continuous variables

Methods: We constructed a PBC risk score for LT and liver-related death at 15 years in a derivation cohort (N = 2422) and evaluated it in a validation cohort (N = 1600). We used multivariable fractional polynomials (MFP) to model non-linear risk relations with continuous variables, and multiple imputation (20 imputations) to replace missing values. We fit a Cox proportional hazards model in each imputed dataset, and used Rubin's rules to combine the results. The resulting coefficients were used together with the baseline survivor function to derive an equation for absolute risk at 15 years. Net reclassification improvement (NRI) was calculated to compare the predictive performance of this risk score compared with other prognostic scores

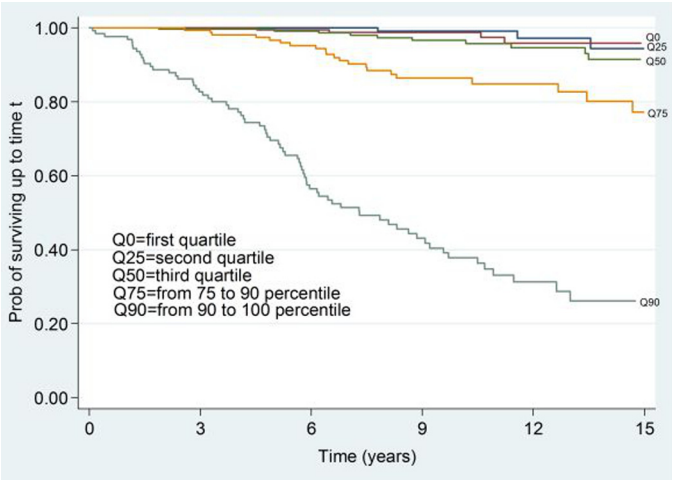

Figure 1.

Results: Median follow up time was 6.6 yrs (IQR, 3.3–11.1) and 537 patients reached the endpoint. The following variables were independently associated with a liver event: albumin and platelet

at baseline, ALP, bilirubin and transaminases after 12 months of UDCA. The score incorporated these five variables, appropriately transformed using MFP. When applied to the validation cohort, the score was highly predictive (c-statistic = 0.90). Figure 1 shows the KM survivor function according to risk groups of the score in the validation cohort. The NRI showed that the risk score had greater ability to identify individuals with and without events compared to other risk scores (NRI of PBC risk score vs. Paris1 = 90%; Paris2 = 64%; Barcelona = 38%; Toronto = 71%).
Conclusions: Prognosis of UK patients with PBC can be accurately assessed with the PBC risk score by using readily available objective clinical measures. This may be used to identify high-risk patients for closer monitoring and second-line therapies, as well as low-risk patients who require infrequent monitoring and might even be followed-up in primary care. However, validation of the score in an external independent cohort and identification of thresholds to inform clinical decision-making is required.

REPEATED MEASUREMENT OF NON-INVASIVE FIBROSIS MARKERS TO ASSESS HEPATITIS C PROGRESSION AND CLINICAL OUTCOMES

S. Lens[1], J.-E. Hernández[1], M. Bonacci[1], Z. Mariño[1], M.-C. Londoño[1], M. Gambato[1], L. Mensa[1], J.M. Sánchez-Tapias[1], X. Forns[1]. [1]*Liver Unit, Hospital Clínic, Barcelona, Spain*
E-mail: slens@clinic.ub.es

Background and Aims: Transient elastography (TE) and serologic non-invasive markers of fibrosis (NIMF) estimate disease stage in patients with chronic hepatitis C (CHC). Few data are available on the usefulness of consecutive measures to assess disease progression and particularly clinical outcomes.
Aims: To assess the prognostic value of consecutive measures of TE and NIMF (APRI, FIB4, Forns) in CHC patients without cirrhosis since the introduction of TE in 2004.
Methods: Clinical and biochemical data of consecutive non-cirrhotic CHC monoinfected patients were recorded. The time of first TE measure was considered *baseline* (BL-TE). Clinical events such as cirrhosis (LC), hepatocarcinoma (HCC), liver transplant (LT) or death were assessed during follow-up until 2014.
Results: 696 patients were included (51% male, median age 47 years, median BMI 19 kg/m^2, 4% diabetic). Genotype-1 and IL28B CT/TT were predominant (80% and 70%, respectively). Overall, median BL-TE was 6.5 kPa (P_{25}-P_{75} 5.4–8.3)] and ≥7 kPa in 41%. Median follow-up was 6.4 years (P_{25}–P_{75} 5–7) during which 60% received antiviral treatment [28% of them achieving sustained virological response (SVR)]. Sixty-eight patients (9.7%) developed LC, 7 HCC, 1 underwent LT and 2 died. After 3 years, TE and NIMF were obtained in 547 patients (78%). Patients achieving SVR or who developed LC before this time-point were censored. Delta TE (ΔTE) was calculated as (TE follow-up) − (BL-TE)/years. Mean ΔET was 0.06 kPa/year in the entire cohort, but it was significantly higher among patients who developed LC compared to those who did not (0.89 vs 0.02 kPa/year; $p < 0.001$). By Cox-Regression analysis, baseline FIB-4 (1.7 [1.3–2.2]), BL-TE≥7 kPa (6.5 [3.2–14]) and higher ΔTE (4 [2–7.7]) were associated with the development of liver events (LC/CHC). The best AUROC to predict events resulted from the combination of BL-TE and ΔTE (0.88), significantly higher than those obtained with BL-TE, Forns, FIB-4 or APRI (0.79, 0.74, 0.71 and 0.67, respectively) ($p < 0.001$). A new assessment was performed in 528 patients (76%) after 5 years, observing a mean ΔTE of 0.07 kPa/year. Again, ΔTE was significantly higher among patients who developed LC compared to those who did not (0.37 vs 0.05 kPa/year; $p < 0.001$).
Conclusions: The dynamic evaluation of liver fibrosis by TE is a useful tool to predict clinical outcomes in patients with CHC. Those patients with higher baseline TE and increase of TE value/year during follow-up, are at higher risk of liver events in the mid-term.

CYCLOPHILIN AND NS5A INHIBITORS, BUT NOT OTHER ANTI-HCV AGENTS, PRECLUDE HCV-MEDIATED FORMATION OF DOUBLE MEMBRANE VESICLE VIRAL FACTORIES

U. Chatterji[1], M. Bobardt[1], A. Tai[2], R. De Francesco[3], M. Wood[1], P. Gallay[1]. [1]*Department of Immunology & Microbial Science, The Scripps Research Institute, La Jolla,* [2]*Department of Internal Medicine, University of Michigan, Ann Arbor, United States;* [3]*Istituto Nazionale Genetica Molecolare (INGM) Romeo ed Enrica Invernizzi, Milan, Italy*
E-mail: gallay@scripps.edu

Background and Aims: Recent advances in understanding molecular aspects of the HCV life cycle lead to successful development of several classes of anti-HCV agents including NS3 (NS3i), NS5A (NS5Ai) and NS5B inhibitors (NS5Bi) as well as host-targeting antivirals such as cyclophilin inhibitors (CypI). A number of these compounds are in IFN-free clinical trials and several are now FDA-approved. The mechanisms of action (MoA) of NS3i and NS5Bi are well understood, however the MoA of CypI and NS5Ai remain elusive. In this study, we conducted a set of experiments aimed to understand how these two classes of inhibitors exert their antiviral activity during HCV replication.
Methods: We examined whether CypI and NS5Ai interfere (i) with HCV RNA synthesis of isolated replication complexes (RCs) using a quantitative replicase assay, or (ii) with earlier steps of HCV RNA replication such as the creation of ER-derived double membrane vesicles (DMVs) essential for HCV RNA replication using a DMV counting assay based on EM analysis. Image J and ITEM software were used for DMVs quantification.
Results: In contrast to NS5Bi, we found that both CypI and NS5Ai do not block the HCV RNA synthesis by isolated RCs, suggesting that they exert their antiviral activity prior to the establishment of enzymatically active RCs. HCV replication is believed to occur at an ER-derived structure called the membranous web (MW), which is thought to be composed primarily of DMVs (200–300/cell). Viral replication is not a precondition for DMVs formation since we found that expression of the NS3-NS5B polyprotein or NS5A alone suffice to create DMVs. Using a panel of anti-HCV agents, we found that only CypI and NS5Ai, but not NS5Bi, mir-122 or PI4KIIIa inhibitors, prevent NS3-NS5B- or NS5A-mediated DMVs formation. We also found that NS3-NS5B and NS5A are unable to create DMVs in cyclophilin A (CypA)-knockdown cells.
Conclusions: These results not only suggest that CypA and NS5A act in concert to build these membranous viral factories, they also suggest that CypI and NS5Ai mediate their early anti-HCV effects by preventing the formation of specific organelles where viral replication normally occurs. This is the first comprehensive investigation to examine the effect of a large panel of anti-HCV agents on DMVs formation, and the results reveal that CypI and NS5Ai act at the same MW biogenesis step of HCV RNA replication, and indicate a new therapeutic target of the HCV life cycle.

ROLE OF CX3CL1–CX3CR1 AXIS FOR LIVER DENDRITIC CELL MATURATION IN HOMEOSTASIS AND INFLAMMATION

S. Sutti[1,2], F. Heymann[2], J. Peusquens[2], C. Trautwein[2], E. Albano[1], F. Tacke[2]. [1]*Health Sciences, University of East Piedmont, Novara, Italy;* [2]*Med III, RWTH Uniklinik, Aachen, Germany*
E-mail: salvatore.sutti@med.unipmn.it

Background and Aims: Chemokines are critical regulators for liver inflammation and fibrosis. The CX3CL1/CX3CR1 chemokine pathway mediates chemotaxis, adhesion and survival of distinct

inflammatory leukocytes. CX3CR1 is expressed on multiple cell types including monocytes and dendritic cells (DCs). Recent evidence indicates that CX3CR1 deficiency exacerbates liver injury and fibrosis in CCl_4 treated mice, however, the mechanisms involved are still poorly understood. We aimed at elucidating the role of CX3CR1 for hepatic DC responses in homeostasis and acute liver injury.

Methods: $CX3CR1^{GFP/GFP}$ and $CX3CR1^{+/GFP}$ mice were injected intraperitoneally with CCl_4 (0–0.6 ml/kg) and liver mononucleated cells were analyzed by flow cytometry 36 hours later.

Results: In homeostasis, $CX3CR1^{GFP/GFP}$ mice showed a significant lower percentage of $CD11c^{high}$/MHCII$^+$/ $CX3CR1^{high}$ DCs in liver parenchyma ($p < 0.05$) than $CX3CR1^{+/GFP}$. Conversely, knockout mice displayed a higher percentage of liver plasmocytoid DCs $B220^+CD11c^+MHCII^+$ compared to $CX3CR1^{+/GFP}$. In line with the tolerogenic activity of liver DCs, CTLA4 expression by CD4+/CD25+ regulatory T-cells (Tregs) was lower in $CX3CR1^{GFP/GFP}$ mice, despite the overall number of hepatic $CD4^+$ T cells was comparable between the two strains. Recent evidence indicates that liver injury is associated with changes in hepatic DCs. CCl_4 treatment of wild-type and $CX3CR1^{GFP/GFP}$ mice lowered the pool of myeloid DCs and deeply affected the monocyte differentiation to DCs in the knockout strain. After CCl_4 treatment both $CX3CR1^{+/GFP}$ and $CX3CR1^{GFP/GFP}$ strains showed very strong liver recruitment of $CD11c^{high}$/$MHCII^+CD11b^+$ monocyte-derived DC (moDC). Interestingly, in $CX3CR1^{+/GFP}$ mice, these $CD11c^+MHCII^+CD11b^+CX3CR1^{high}$ moDCs had higher expression of the co-stimulatory proteins CD80 and CD40, indicating CX3CR1's involvement in moDCs maturation. However, CX3CR1 deficiency also affected the expression of immune regulatory PDL-1 on DCs ($p < 0.01$). Accordingly, CCl_4 treated $CX3CR1^{GFP/GFP}$ mice showed a higher expression of T-cell activation marker CD69 associated to a lowering in hepatic $CD4^+CD25^+Foxp3^+$ regulatory T cells.

Conclusions: These results suggest a novel role of CX3CL1/CX3CR1 axis in liver DC maturation/differentiation that may account for the increased severity of liver injury in CX3CR1-deficient mice.

O026

CD4+ INTRAHEPATIC LYMPHOCYTES DRIVE LIVER INFLAMMATION VIA IMPAIRED REGULATORY PATHWAYS IN A MURINE MODEL OF CROHN'S-LIKE ILEITIS

S. Omenetti[1,2], M. Brogi[1,2], W. Goodman[1], C. Straka[1], S. Eid[3], A. Huang[1,3], G. Laffi[2], F. Cominelli[1,2,4], M. Pinzani[2,4,5], T. Pizarro[1,2,4].

E-mail: sara.omenetti@gmail.com

Background and Aims: Crosstalk between the liver and intestines represents an important pathophysiological interface in inflammatory bowel disease (IBD), a disorder associated with significant hepatobiliary manifestations. We previously showed that liver inflammation precedes the onset of gut inflammation in a murine model of Crohn's disease, i.e., SAMP1/YitFc (SAMP) strain. The aim of this study was to determine the specific pathogenic mechanism(s) leading to chronic liver inflammation in ileitis-prone SAMP mice.

Methods: Liver inflammation was evaluated in reciprocal SAMP-AKR/J (AKR control strain) bone marrow chimeras (BMC), lymphocyte-depleted SAMP (SAMPXRAG-2 KO), and immunodeficient SCID mice receiving SAMP or AKR donor CD4+ cells. Isolated non-parenchymal liver cells (NPLC) were phenotypically-characterized by FACS and qPCR. Liver-resident CD4+ T effector cells (Teff) and T regulatory cells (Treg) were FACS-purified and functionally tested for in vitro proliferation and suppression activity.

Results: Construction of BMC revealed that, unlike SAMP ileitis that originates from a non-hematopoietic source, both non-hematopoietic and hematopoietic compartments are essential for liver inflammation; in fact, SAMPXRAG-2 KO mice displayed no hepatic inflammation vs SAMPXRAG-2 WT ($p < 0.001$), confirming a requirement for lymphocytes. Indeed, SAMP intrahepatic infiltrates displayed Th1-polarized, phenotypically-activated CD4+ T-cells vs AKR ($p < 0.05$). Moreover, SAMP vs AKR liver-derived CD4+ T-cells induced severe liver and ileal inflammation when adoptively transferred into SCID recipients ($p < 0.05$ and $p < 0.01$, respectively), whereas gut-associated lymphoid tissue-derived CD4+ T-cells produced ileitis ($p < 0.01$ vs AKR), but not liver inflammation. Expression of the gut homing molecules, MAdCAM-1 and CCL25, was unchanged in SAMP vs. AKR liver, suggesting that intrahepatic CD4+ T cells are not likely recruited from the gut. Interestingly, decreased frequencies of resident tolerogenic populations, i.e. liver sinusoidal endothelial cells ($p < 0.005$) and Treg ($p < 0.05$) were evident in SAMP vs AKR livers. Preliminary in vitro experiments displayed increased Teff proliferation and a marked decrease of Treg suppression activity in SAMP vs AKR liver.

Conclusions: These results challenge the current paradigm that IBD-associated liver inflammation is a consequential secondary event and suggest that intrahepatic $CD4^+$ T-cells acquire pathogenic potential in predisposed individuals through decreased liver-resident regulatory mechanisms.

O027

THE EXPRESSION OF TUMOR SUPPRESSOR PTPRD IS DOWN-REGULATED IN THE LIVER OF PATIENTS WITH HCV INFECTION AND IN TUMOR LESIONS OF PATIENTS WITH HEPATOCELLULAR CARCINOMA

N. Van Renne[1,2], F.H.T. Duong[3], C. Gondeau[4], D. Calabrese[3], N. Fontaine[1,2], A. Ababsa[1,2], S.C. Durand[1,2], P. Pessaux[1,2,5,6], M.H. Heim[3], T.F. Baumert[1,2,5,6], J. Lupberger[1,2]. *[1]Inserm U1110, Institut de Recherche sur les Maladies Virales et Hépatiques, [2]Université de Strasbourg, Strasbourg, France; [3]Depatment of Biomedicine, Hepatology Laboratory, University of Basel, Basel, Switzerland; [4]Inserm U1040, Biotherapy Research Institute, Montpellier, [5]Insitut Hospitalo-Universitaire, [6]Pole Hepato-digestif, Nouvel Hôpital Civil, Strasbourg, France*
E-mail: joachim.lupberger@unistra.fr

Background and Aims: Chronic hepatitis C virus (HCV) infection is a leading cause of chronic liver disease including hepatocellular carcinoma (HCC). It is generally assumed that HCV contributes to HCC development directly by viral proteins and indirectly by signal transduction. Cellular signaling cascades are involved in cancerogenesis and the regulation of HCV. Signaling is tightly regulated by protein phosphatases and their aberrant expression is involved in various diseases and syndromes. However, the global impact of HCV infection on the expression of phosphatases and their impact on liver disease are unknown. Therefore, we aim to identify the impact of chronic HCV on protein phosphatase expression pattern

Methods: We studied the expression of 84 pathway or disease-focused phosphatases in liver biopsies of chronic HCV-infected patients using using real-time PCR, fluorescence *in situ* hybridization (FISH) and Western blotting.

Results: We identified 29 phosphatases that are significantly ($p < 0.01$, Mann–Whitney U-test) deregulated. Among the identified hits were several phosphatases associated with cancerogenesis including the tumor suppressor gene phospho-tyrosine phosphatase, receptor type D (PTPRD). PTPRD expression did not correlate with the METAVIR score of the studied biopsies suggesting that PTPRD expression is independent from tissue inflammation and fibrosis. PTPRD expression was impaired in HCV-infected liver tissue but not by HBV. Moreover, PTPRD was

downregulated in primary human hepatocytes (PHH) infected with HCVcc (JFH1), while IFN-alpha treatment had no impact on PTPRD. Taken together, the data suggest that HCV specifically and directly impairs PTPRD expression in hepatocytes independent from the innate immune response. Furthermore, we demonstrated that PTPRD expression is impaired in transformed liver cell lines and in tumor lesions of HCC patients, which we confirmed by *in silico* analysis of a microarray database (Hoshida et al. N. Engl. J. Med. 2008). These data demonstrate an impaired PTPRD expression associated with HCC.
Conclusions: Interestingly, PTPRD dephosphorylates STAT3, which is activated in the majority of HCCs with poor prognosis. We previously demonstrated that STAT3 has an important proviral effect on HCV infection (Lupberger et al., Hepatology 2013). It is thus conceivable that HCV downregulates PTPRD for its replication and immunoevasion with potential consequences for HCC development.

E-mail: dealmeida.thiago@gmail.com

Background and Aims: Schistosomiasis mansoni is a major cause of liver fibrosis and portal hypertension. IL13 and Hedgehog (Hh) increase in schistosomiasis, regulating stellate cell activation and alternative activation of macrophages (M2). Our *aims* were to investigate if there is cross-talk between IL13 and Hh in murine and human schistosomiasis.
Methods: Male Balb/c wild-type mice (n = 9), IL13Rα1$^{-/-}$ mice lacking IL13 signaling (n = 9) and TKO [IL-10$^{-/-}$, IL12/23(p40)$^{-/-}$, IL13Rα2$^{-/-}$] mice with constitutive IL13 activity (n = 6) were infected with *Schistosoma mansoni*. Uninfected wild-type male Balb/c mice (n = 5) were controls. To investigate the effect of Hh on M2 polarization, primary murine kupffer cells (pmKC) were isolated from Smoothened$^{flox/flox}$ mice (Smo$^{flox/flox}$) by elutriation. Smo was knocked down using an adenovirus harboring Cre recombinase (or GFP control). 87 wedge liver biopsies from schistosomiasis patients (low fibrosis n = 15, severe fibrosis n = 72), 22 biopsies from noninfected transplant donors, 33 snap frozen wedge liver biopsies from patients with severe schistosomiasis and from 4 transplant donors were evaluated. IL13, Hh pathway (Ihh, Shh, Gli1, Gli2, Ptch1), fibrogenesis (Col6a1, aSMA), and M2 markers (Chi3l3, Arg1, Fizz1) were assessed by qRTPCR, Western blot and immunohistochemistry. Fibrosis was evaluated by Sirius red histochemistry and hydroxyproline content. This study was approved by the animal and human ethics committees of NIH, Duke, and UFMG.
Results: Infected TKO mice had more collagen, myofibroblasts, M2 macrophages and Hh pathway activity than infected wild-type mice, infected IL13Rα1$^{-/-}$ mice, and non-infected controls. Infected IL13Rα1$^{-/-}$ mice had lower expression of Ihh, Shh, Gli1 and Gli2 than uninfected controls, suggesting that IL13 promotes Hh signaling. Hh pathway activity correlated with collagen accumulation, M2 marker expression, and myofibroblast activation. Deletion of Smo in pmKC abrogated M2 polarization. Patients with severe schistosomiasis had increased IL13 and Hh pathway activity and Hh signaling correlated with collagen deposition and fibrosis staging by ultrasound.
Conclusions: IL13-mediated activation of Hedgehog promotes M2 polarization and liver fibrosis in schistosomiasis.

O029
HCV TRIGGERS WNT PARACRINE SIGNALLING THAT MODULATES METABOLIC LIVER ZONATION

M. Moreau[1], B. Rivière[2], J. Ramos[3], E. Assenat[1], U. Hibner[1]. *[1]Institut de Génétique Moléculaire de Montpellier, [2]Département de Biopathologie Cellulaire et Tissulaire des Tumeurs, CHU Montpellier, [3]Département de Biopathologie Cellulaire et Tissulaire des Tumeurs, CHU Montpellier, Montpellier, France*
E-mail: ula.hibner@igmm.cnrs.fr

Background and Aims: Metabolic identity of a hepatocyte is determined by its position along the centro-portal axis of a liver lobule. This functional specialisation is called metabolic liver zonation and its initiation and maintenance is under the control of wnt/β-catenin signalling. Altered metabolic zonation is associated with many hepatic pathologies, including chronic hepatitis C. Interestingly, although only a minority of hepatocytes are infected, the liver undergoes major systemic metabolic changes, implying inter-cellular cross talk between the infected and the healthy cells.
Methods: Transgenic mice with hepatocyte-targeted expression of the totality of HCV proteins and needle biopsies from hepatitis C patients at the early stages of the disease were studied in respect to patterns of lipid metabolism and accumulation in the context of metabolic zonation of the liver lobule.
Results: Low levels of viral proteins are sufficient to drive striking alterations of hepatic metabolic zonation independently of inflammation or the immune response. In mice, a major lipogenic enzyme, fatty acid synthase, was redistributed from its normal periportal expression into the midzone of the lobule, coinciding with exquisitely specific midzone accumulation of lipids. Strikingly, alteration of zonation was not limited to lipid metabolism and appeared to be driven by systemic signalling by the Wnt/β-catenin pathway. Importantly, we show that similarly perturbed metabolic zonation appears to precede steatosis in early stages of human disease associated with HCV infection.
Conclusions: Our results rationalize systemic effects on liver metabolism triggered by a minority of infected cells, thus opening new perspectives for investigation of HCV-related pathology, notably in the context of increased risk of tumorigenesis.

O030
PRO-APOPTOTIC TNF RECEPTOR SIGNALING IS THE RESULT OF A NOVEL INNATE IMMUNE SENSING PATHWAY THAT DETERMINES CELL DEATH IN VIRUS-INFECTED HEPATOCYTES

M. Janas[1], M. Heikenwälder[2], P. Knolle[3], D. Wohlleber[3]. *[1]Institute of Molecular Medicine, Universität Bonn, Bonn, [2]Institute of Virology, [3]Institute of Molecular Immunology, Technische Universität München, München, Germany*
E-mail: dirk.wohlleber@gmail.com

Background and Aims: Viral infection is detected by the innate immune system via pattern recognition receptors and by virus-specific CD8$^+$ T cells via (cross)-presentation of viral antigens. Many viruses have therefore developed mechanism to escape such immune recognition. We have previously identified a new CD8 T Cell effector function that accounts for 50% of antiviral T cell activity in viral hepatitis and overcomes immune escape by viruses that modulate MHC I presentation and conventional innate immune recognition. CD8 T effector cells (CTLs) secrete TNF upon recognition of viral antigens on cross-presenting liver sinusoidal endothelial cells which selectively kills infected hepatocytes. Here, we investigated the underlying mechanisms that render virus-infected hepatocytes susceptible to TNF-induced cell death.

Methods: We infected mice with a hepatotropic virus and challenged these mice by injecting TNF. Using knockout mice, as well as biochemical and multiparametric histological methods we analyzed the influence of different pattern recognition receptors. Additionally, we isolated mitochondria from virus-infected mice and performed metabolomic investigations to analyze the role of mitochondria in virus recognition as well as their role in apoptosis execution.
Results: We demonstrate that viral infection in hepatocytes is recognized even in the absence of classical pattern recognition receptor signaling. Rather, viral infection of hepatocytes modulates metabolic processes, leads to increased levels of the pro-apoptotic BCL-2 family members Bax and Bad that cause damage to mitochondria. This leads to a downregulation of the anti-apoptotic protein XIAP (X-chromosome linked inhibiting of apoptosis protein). Downregulation of XIAP facilitates TNF-induced activation of the initiator caspase 8 that together with increased mitochondrial sensitivity to activated caspase 8 is responsible for TNF-induced cell death in virus-infected hepatocytes.
Conclusions: We have identified a novel immune-sensing mechanisms in virus-infected hepatocytes that links effector molecules generated by virus-specific T cells to cell-autonomous induction of death selectively in virus-infected hepatocytes.

TG1050, A NOVEL IMMUNOTHERAPEUTIC TO TREAT CHRONIC HEPATITIS B, CAN CONTROL HBsAg AND PROVOKE HBsAg SEROCONVERSION IN HBV-PERSISTENT MOUSE MODELS

K. Lélu[1], A. Evlachev[1], R. Kratzer[1], S. Dion[2], M. Mancini-Bourgine[2], O. Godon[1,2], D. Schmitt[3], C. Dubois[1], J.-F. Méritet[4], Y. Schlesinger[3], J.-B. Marchand[5], M. Geist[3], R. Brandely[3], A. Findeli[3], T. Menguy[3], N. Silvestre[3], M.-L. Michel[2], G. Inchauspe[1], P. Martin[1]. *[1]Infectious Diseases, TRANSGENE, Lyon, [2]Laboratoire de pathogénèse des virus de l'hépatite B Paris and INSERM U994, Institut Pasteur, Paris, [3]Vector Engineering, TRANSGENE, Illkirch-Graffenstaden, [4]Virology, Hôpital Cochin, Paris, [5]Protein Science, TRANSGENE, Illkirch-Graffenstaden, France*
E-mail: perrine.martin@transgene.fr

Background and Aims: Current therapies [nucleos(t)ide analogs (NUC) or pegylated-IFN-alpha] for chronic hepatitis B (CHB) virus infection rarely achieve virus clearance. Cohort studies have shown the critical role of cellular immune responses to control HBV infection. We developed a HBV-targeted immunotherapeutic called TG1050 and have shown that this Adenovirus based product encoding multiple HBV antigens in the frame of a large fusion protein is able to induce robust, multispecific, long-lasting and polyfunctional CD8+ T cells in different naive mouse models. We have now further characterized capacity of TG1050 to induce functional T cells and exert antiviral control in an HBV-persistent mouse model based on an adeno-associated virus recombinant for an over length HBV genome (AAV-HBV) causing the expression of infectious HBV particles in mouse livers.
Methods: Two mouse strains, HLA-A2/DR1 and C57BL/6J mice, were infected by the AAV-HBV. Following establishment of persistent HBV expression, TG1050 was injected once or multiple times and induced HBV-specific T cells were monitored along time (from 2 to 18 weeks post-vaccination) by IFN-gamma ELISPOT or intracellular cytokine staining. Viral parameters were followed in blood by qualitative or quantitative HBsAg, HBeAg, anti-HBs and anti-HBc ELISA assays and by RT-qPCR for HBV DNA quantification.
Results: In HBV persistent HLA-A2/HLA-DR1 mice, single and multiple TG1050 injections induce multispecific CD8 T cells producing multiple cytokines (IFNg, TNFa and/or IL2) detected in the liver at day 14 and 128 post-TG1050 injection. TG1050 exerts an early antiviral effect by controlling viral load and/or circulating HBsAg compared with control mice. In HBV-persistent C57BL/6J mice, multiple TG1050 injections induce multispecific CD8 T cells producing cytokines (IFNg and/or TNFa) detected 14 days after the first injection. A significant impact was observed on viral parameters with a sustained decrease in viral load, circulating HBsAg level (from 2 weeks and up to 3 months post-TG1050 injection). In this model, HBsAg/anti-HBsAg seroconversion was achieved in 30% of TG1050-injected mice.
Conclusions: Elimination of HBsAg and HBsAg seroconversion are the hallmarks of chronic HBV cure. We have shown here that TG1050, used in a stand-alone approach, can reach this key clinical goal, opening the road to clinical development. First-in-man study is currently being organized.

STEROID THERAPY DIFFERENTIALLY ALTERS GUT MICROBIOTA COMPOSITION IN SEVERE ALCOHOLIC HEPATITIS

S. Sharma[1], J. Singh[1], S. Das[1], S. Hussain[1], S. Sm[2], V. Khillan[3], S.K. Sarin[2]. *[1]Research, [2]Hepatology, [3]Microbiology, Institute of Liver and Biliary Sciences, New Delhi, India*
E-mail: shvetanks@gmail.com

Background and Aims: Chronic alcohol consumption leads to severe alcoholic hepatitis (SAH) with high 28 day mortality. It has been recently demonstrated that gut microbiota changes in individuals consuming alcohol. The standard of care in such patients is steroid therapy with response rates ~50%. Gut microbiota are known to play an important role in steroid metabolism. We hypothesized that at baseline and on therpy modulation of gut microbiota may influence the response to steroid therapy.
Methods: Consecutive patients with SAH [chronic alcohol use >5 years, DF >32, transjugular liver biopsy suggestive of SAH, absence of any known liver disease or h/o immunosuppressive drugs] were included and treated with prednisolone (40 mg/day) for 28 days. The response to streoids was assessed at day-7 by Lille score [<0.45 as responder (R), >0.45 as non-responder (NR)]. Stool samples were collected in sterile vials at baseline and day-7 of therapy and snap frozen until processed. 250 mg of frozen samples were processed for DNA isolation and with Primers for 16S rRNA gene V4 region. Samples were analyzed on MiSeq (Illumina).
Results: Stool samples were processed for 6-R and 6-NR for microbiome analysis. Total of 305 species belonging to 135 genera were identified. At baseline dominant species in NR were *Klebsiella* (32%) and *Enterococcus* (24%) in contrast to *Bacteroides* (26%) and *Lactobacillus* (21%) in R. After therapy, R showed a shift to *E. coli* (45%) and *Bifidobacterium* (21%); NR had *E. coli (40%)* and *Lactobacillus* (26%). Steroid therapy resulted in 6-fold increase ($p < 0.05$) in Proteobacteria in R and marginal reduction in NR. Members of Bacteroidetes reduced significantly ($p < 0.05$) after steroid treatment in R and NR. Similar observations were made in R for firmicutes, while the group demonstrated ~20% increase in NR. Actinobacteria (gram-positive) on the other hand were significantly ($p < 0.05$) increased (7-fold) in R and reduced (50%) in NR. Enterotype classification revealed responders to be type-1 and non-responders to type-2 at baseline. Post-therapy both groups shifted to type-3. It has been suggested that enterotypes are defined by diet. In our group while the diet of the patients was similar, the species composition of type-3 varied, suggesting an effect of steroid on species composition.
Conclusions: Gut microbial community is significantly different in the SAH patients. Gut microbiota also demonstrate differential compositional alterations in response to steroid.

O033

CCR2+ INFILTRATING MONOCYTES PROMOTE ACETAMINOPHEN-INDUCED ACUTE LIVER INJURY – THERAPEUTIC IMPLICATIONS OF INHIBITING CCR2 AND CCL2

O. Krenkel[1], J.C. Mossanen[1], C. Ergen[1], F. Heymann[1], E. Lefebvre[2], D. Eulberg[3], C. Trautwein[1], F. Tacke[1]. *[1]Department of Medicine III, RWTH-University Hospital, Aachen, Germany; [2]Tobira Therapeutics, Inc., South San Francisco, CA, United States; [3]Noxxon, Inc., Berlin, Germany*
E-mail: okrenkel@ukaachen.de

Background and Aims: Liver injury following acetaminophen (APAP) intoxication is one of the leading courses of acute liver failure (ALF). APAP causes necrosis of hepatocytes followed by an activation of resident immune cells like Kupffer cells (KC), release of various chemokines (e.g., CCL2) and immune cell infiltration (e.g., monocytes). We hypothesized that CCR2+ monocytes promote APAP-induced injury and investigated the therapeutic potential of pharmacologically blocking either CCR2 or CCL2.
Methods: C57BL/6J (WT) and *Ccr2*$^{-/-}$ mice were subjected to ALF by iv. injection of APAP (250 mg/kg body weight). Liver injury and immune cell phenotypes were analyzed in *Ccr2*$^{-/-}$ and WT mice, as well as in WT mice treated with mNOX-E36 s.c., a potent CCL2 inhibitor, or with the oral CCR2/CCR5 antagonist cenicriviroc (CVC). The human counterparts of both agents are currently tested in phase II trials for different indications (diabetic nephropathy or NASH, respectively).
Results: *Ccr2*$^{-/-}$ mice showed significantly reduced liver injury compared to WT mice 12 h after APAP injection as determined by histology and reduced ALT values ($p < 0.05$, Figure 1). Flow cytometry analyses revealed significantly reduced numbers of pro-inflammatory Ly6C+ monocyte-derived macrophages in livers of *Ccr2*$^{-/-}$ mice, whereas the numbers of neutrophils or other immune cell subsets remained similar to WT mice. While hepatic IL1β, TNF-α and CCL2 were similarly increased in both WT and *Ccr2*$^{-/-}$ mice, IL10 was higher in livers from *Ccr2*$^{-/-}$ mice ($p < 0.05$), alongside differential marker expression (CD1d, CD68) on hepatic macrophages. Both pharmacological inhibitors, mNOX-E36 or CVC, were capable of significantly reducing monocyte accumulation in APAP-injured livers, resulting in significant protection from liver damage (ALT levels, $p < 0.05$ for mNOX and $p < 0.01$ for CVC).
Conclusions: Targeting detrimental actions of pro-inflammatory monocytes by inhibiting either the chemokine receptor CCR2 or its ligand CCL2 (MCP-1) is a promising therapeutic option to restrict liver injury following an acetaminophen overdose.

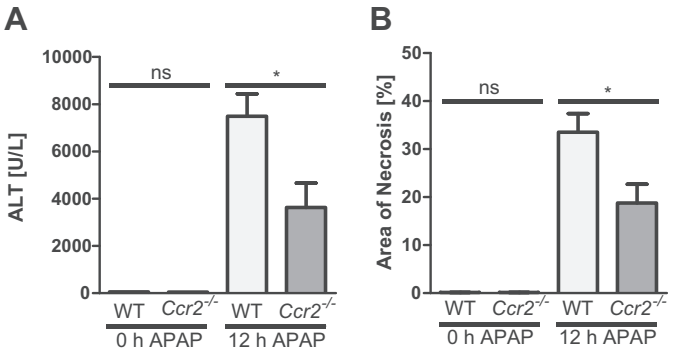

Figure 1. Acetaminophen-induced liver injury as determined by ALT (A) and histology (B) is significantly reduced in *Ccr2*$^{-/-}$ compared to WT mice.

O034

FREQUENCY AND FUNCTION OF ANTI-BACTERIAL MAIT CELLS ARE SIGNIFICANTLY IMPAIRED IN ADVANCED ALCOHOLIC LIVER DISEASE

A. Riva[1], J.M. Ryan[2], R. Williams[1], D.L. Shawcross[2], S. Tarff[3], A. Evans[4], G. Wright[3], S. Chokshi[1]. *[1]Institute of Hepatology, Foundation for Liver Research, [2]Institute of Liver Studies, King's College Hospital, London, [3]Basildon and Thurrock University Hospital, Nethermayne, Basildon, [4]Department of Gastroenterology, Royal Berkshire Hospital, Reading, United Kingdom*
E-mail: a.riva@researchinliver.org.uk

Background and Aims: Intestinal bacterial translocation and systemic gut-derived bacterial products are increasingly being shown to play a central role in the immunopathogenesis of alcoholic liver disease (ALD), yet the mechanisms of susceptibility to infection and the link with intestinal immunity remain elusive. Mucosal associated invariant T-cells (MAIT) are unconventional T-cells which only respond to bacteria-derived metabolites and are found in large numbers in the blood, intestinal mucosae and liver. They represent a key sentinel system for the homeostatic control of the gut flora and exert essential roles for control of bacterial infections. The aim of this study was to assess the role of MAIT cells in ALD.
Methods: Peripheral blood mononuclear cells from subjects with acute alcoholic hepatitis (AAH, Maddrey's discriminant function >32; n = 9), compensated alcohol-related cirrhosis (ARC, n = 9) and healthy controls (HC, n = 9) were examined by FACS. MAIT cells were identified as CD161+/Vα7.2+ CD8+ T-cells and MAIT-presenting cells (MPC) as MR1+ monocytes or B-cells. We quantified (1) frequency, activation status (CD69/HLA-DR) and immunoinhibitory signatures (PD1/TIM3/LAG3) of MAIT cells; (2) frequency and immunoinhibitory status (PD1/PDL1/TIM3/mGal9) of MPC; (3) cytokine/cytotoxicity profiles [IFNγ/TNFα/IL17; GranzymeB (GrB)/Perforin/CD107a] of MAIT cells after in-vitro stimulation with fixed *E. coli*. Plasma cytokines and endotoxin levels were assessed by ELISA.
Results: MAIT frequencies were reduced in ARC ($p = 0.005$) and dramatically lower in AAH ($p < 0.001$) compared to HC. MAIT cells from AAH and ARC were activated and hyperexpressed immunoinhibitory receptors compared to HC ($p < 0.03$). Frequencies of MR1+ MPC were comparable in all groups but expression of immunoinhibitory molecules was higher in AAH and ARC ($p < 0.03$). Membrane-bound MPC Gal9 was lower in AAH and ARC ($p < 0.01$) than HC whereas soluble Gal9 was higher ($p = 0.004$). Levels of *E. coli*-stimulated IFNγ from MAIT cells were comparable in all groups, but in ARC they produced less TNFα ($p = 0.024$) than HC. IL17 responses were observed only in HC. The cytotoxic potential of MAIT cells (GrB) was higher in AAH than HC.
Conclusions: This is the first report addressing the role of MAIT cells in liver disease. We show that MAIT cells have quantitative and functional impairments in ALD, with defective TNFα and IL17 responses, increased killing potential and hyperexpression of immunoinhibitory receptors. MAIT cells may represent a novel immunotherapeutic target for ALD.

O035

CCR9 AND CCL25 ARE EARLY PRO-INFLAMMATORY MEDIATORS IN ACUTE LIVER INJURY

R. Parker[1], C. Weston[1], L.A. Possamai[2], G.S. Petts[2], E. Triantafyllou[1,3], C. Bersmeier[3], W. Khamri[2], J. Wendon[3], C.G. Antoniades[1,2,3], D.H. Adams[1]. *[1]Centre for Liver Research, University of Birmingham, Birmingham, [2]Imperial College London, [3]Institute of Liver Sciences, Kings College London, London, United Kingdom*
E-mail: richardparker@nhs.net

Background and Aims: Paracetamol is the most common of drug-induced acute liver failure (ALF). Paracetamol-induced ALF has a

significant associated mortality and few treatment options: liver transplantation remains the only treatment option for those not responding to medical treatment. $CCR9^+$ macrophages have recently been reported as playing a key role in a mouse model of acute liver injury. We investigated the CCR9/CCL25 receptor/ligand axis in acute liver injury.

Methods: Serum concentration of CCL25, the ligand for CCR9, was measured by ELISA in patients with ALF admitted to Kings College Hospital, London. Blood and liver-infiltrating immune cells were analysed by FACS. In murine models of ALF, mice were administered carbon tetrachloride (CCl_4) (1 ml/kg) or paracetamol (400 mg/kg) and sacrificed at specified time points. Liver injury was assessed by serum transaminase concentration.

Results: In patients with ALF, serum CCL25 concentration was markedly higher than healthy controls (mean 3.96 ng/ml vs. 0.878, $p < 0.001$). This was an early phenomenon with levels highest on the first day after admission and then decreasing ($p < 0.01$). $CCR9^+$ macrophages were identified in peripheral blood and explanted liver tissue of patients with ALF. In mice, liver-infiltrating macrophage numbers peaked within 24 hours of liver injury, which coincided with peak hepatic inflammation, measured by serum ALT levels. Expression of CCR9 on macrophages peaked between 6–12 hours and was greater in paracetamol than CCl_4 induced liver injury (mean percentage CCR9 expression 25.8% vs 11.0%).

Conclusions: The CCR9/CCL25 axis is upregulated early in both human and mouse acute liver failure. In mice, infiltration of liver tissue by $CCR9^+$ macrophages coinceides with the peak of necroinflammation as assessed by ALT. These data suggest a pro-inflammatory role for $CCR9^+$ macrophages in ALF.

OVEREXPRESSION OF C-MYC IN HEPATOCYTES PROMOTES INITIATION AND PROGRESSION OF ALCOHOLIC LIVER DISEASE

Y.A. Nevzorova[1], W. Hu[1], F.J. Cubero[1], U. Haas[1], N. Gassler[2], P. Strnad[1], H.W. Zimmermann[1], C. Trautwein[1], C. Liedtke[1].
[1]Department of Internal Medicine III, [2]Institute of Pathology, RWTH Aachen University, Aachen, Germany
E-mail: ynevzorova@ukaachen.de

Background and Aims: Alcohol exposure may result in the overexpression of certain oncogenes in human cells thereby increasing the intracellular concentration of reactive oxygen species (ROS) and, thus, triggering initiation and progression of alcoholic liver disease (ALD). We previously showed that prolonged c-myc expression in hepatocytes leads to spontaneous fibrogenesis and end-stage high-latency tumor development. In the present study, we hypothesized that c-myc overexpression might exert a crucial role in the development of ALD.

Methods: Expression of c-myc was measured in biopsies of patients with ALD by quantitative real-time PCR (qPCR) and by immunohistochemistry (IHC). ALD in mice carrying transgenic over-expression of c-myc in hepatocytes (alb-myctg) and wildtype (WT) controls was induced by administration of control or ethanol (EtOH) Lieber DeCarli diet for 4 weeks. Primary hepatocytes were isolated from WT and alb-myctg mice, subjected to EtOH treatment and investigated for markers of cell cycle progression and oxidative stress by Western blotting, immunofluorescence and electron microscopy.

Results: Hepatic c-myc was strongly up-regulated in human patients with advanced ALD and in WT mice fed with EtOH-diet. Conversely, the over-expression of c-myc in hepatocytes led to early ballooning degeneration, increase of liver collagen deposition and ethanol-induced hepatic lipotoxicity, in conjunction with excessive CYP2E1-derived ROS after EtOH-diet. Unexpectedly, alb-myc^{tg}-livers displayed impaired cell proliferation resulting in remarkable hepatic hypertrophy and hepatocyte enlargement in response to EtOH challenge. Moreover, EtOH-fed alb-myc^{tg} mice exhibited profound dramatic changes in the mitochondrial morphology associated with mitochondrial dysfunction. Consistently, alb-myc^{tg}-derived primary hepatocytes showed blockade of proliferation and dramatic increase of cellular ROS, in response to EtOH challenge. Therefore, we explored the underlying molecular mechanisms, which demonstrated that in our experimental model of ALD, *c-myc* overexpression leads to strong activation of AKT, and, consequently phosphorylation of Mdm2 and degradation of p53 function.

Conclusions: Our findings show that the proto-oncogen *c-myc* accelerated the progression of ALD thereby increasing collagen deposition and intracellular concentrations of oxidants through a p53 pathway-depending mechanism. These results render *c-myc* as a plausible novel diagnostic and prognostic tool for early detection of ALD.

O037

MACROPHAGE AUTOPHAGY MEDIATED THE BENEFICIAL EFFECTS OF CANNABINOID RECEPTOR 2 IN ALCOHOLIC LIVER DISEASE

T. Denaes[1,2], J. Lodder[1,2,3,4], M.-N. Chobert[1,2], J.-M. Pawlotsky[1,2], S. Lotersztajn[1,2,3,4], F. Teixeira-Clerc[1,2]. *[1]INSERM, U955, [2]Université Paris-Est, Faculté de Médecine, UMR-S955, Créteil, [3]INSERM, U1149, [4]Université Paris 7 Denis Diderot, Faculté de Médecine, Bichat, Paris, France*
E-mail: fatima.clerc@inserm.fr

Background and Aims: Kupffer cells play a major role in the pathogenesis of alcoholic liver disease. We have previously reported that during experimental ALD, the cannabinoid receptor 2 (CB2) limits Kupffer cells polarization towards a pro-inflammatory phenotype, thereby leading to decreased hepatic inflammation and steatosis. The aim of this study was to investigate the contribution of macrophagic CB2 receptor to these effects and the mechanisms involved.

Methods: Female mice were fed a Lieber-DeCarli liquid diet containing 5% ethanol for 10 days then gavaged with a single dose of ethanol (5 g/kg body weight) and sacrificed 9 hours later (NIAAA model). Experiments were performed in mice invalidated for CB2 receptor in the myeloid lineage ($CB2^{Mye-/-}$ mice) or in mice invalidated for the autophagy gene ATG5 in the myeloid lineage ($ATG5^{Mye-/-}$ mice) and treated with the CB2 agonist JWH-133. *In vitro* studies were performed on peritoneal macrophages isolated from WT or $ATG5^{Mye-/-}$ mice.

Results: As compared to WT littermates, $CB2^{Mye-/-}$ mice showed ennhanced alcohol-induced pro-inflammatory phenotype of Kupffer cells and hepatic steatosis. CB2 receptor activation by JWH-133 stimulated macrophage autophagy in the liver of alcohol-fed mice, whereas macrophage autophagy was inhibited in the liver of alcohol-fed $CB2^{Mye-/-}$ mice. These findings were confirmed in studies with cultured peritoneal macrophages, showing that autophagy is induced in macrophages exposed to JWH-133 and inhibited in CB2-deficient macrophages. Finally, JWH-133 reduced the induction of inflammatory genes by LPS in WT peritoneal macrophages, but not in ATG5-deficient cells. The CB2 agonist also protected from alcohol-induced liver inflammation and steatosis in WT, but not in $ATG5^{Mye-/-}$ mice demonstrating that macrophage autophagy mediated the anti-inflammatory and anti-steatogenic effects of CB2 receptor.

Conclusions: These results demonstrated that CB2 receptor activation in macrophages protects from alcohol-induced steatosis by inhibiting hepatic inflammation through an autophagy-dependent pathway in Kupffer cell.

O038

INVESTIGATING PARACETAMOL TOXICITY IN HepaRG-BASED 3D HUMAN HEPATIC ORGANOTYPIC MODELS WITH NON-INVASIVE OPTICAL COHERENCE PHASE MICROSCOPY (OCPM)

L.J. Nelson[1], P. Treskes[1], K. Morgan[1], W. Gamal[2], C. Chesne[3], J.N. Plevris[1], P.O. Bagnaninchi[4]. *[1]Hepatology, [2]Institute for Biomedical Engineering, University of Edinburgh, Edinburgh, United Kingdom; [3]BioPredic International, Rennes, France; [4]MRC Centre for Regenerative Medicine; Institute for Biomedical Engineering, University of Edinburgh, Edinburgh, United Kingdom*
E-mail: lnelson1@staffmail.ed.ac.uk

Background and Aims: Conventional 2D primary human hepatocyte (PHHs) or HepG2/C3A cultures for drug testing rapidly lose polarity and differentiated function and poorly represents normal liver tissue. Human HepaRGs are the closest surrogate to PHHs – maintaining intact phase I–III drug metabolism. Our aim was to develop and test a more physiologically-relevant 3D hepatic organotypic co-culture platform for drug metabolism/ toxicology applications. Given established endpoint toxicity assays are often incompatible with assessing 3D tissues, we investigated the use of optical coherence phase microscopy (3D-OCPM) as a novel approach to assess cell viability in response to paracetamol hepatotoxicity.
Methods: HepaRG or HepG2/C3A (as comparators) cells, as 2D monolayers (controls), overlay ('2.5D') or hydrogel-encapsulated (3D), were prepared in either Matrigel (MG) or Hyaluronic acid hydrogels (HAH) in 96-well plates; and viability tested (LIVE/DEAD fluorescent staining). Paracetamol hepatotoxicity [0–40mM; 24 h] was assessed in optimal 3D cultures, with 3D-OCPM in-depth microstructural and functional imaging of 3D-encapsulated cells. This new approach was compared with established hepatotoxicity assays: Prestoblue (PB; Life Technologies), lactate release, and ATP content (Promega CellTiter-Glo-3D Real-Time Cell Viability) assays.

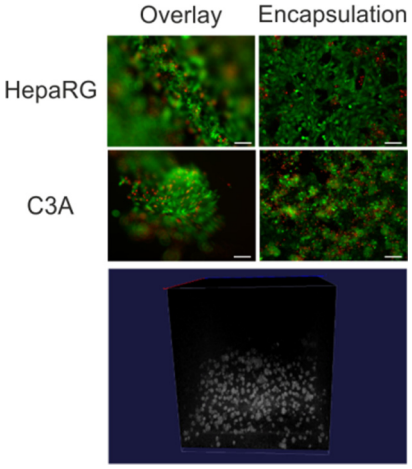

Figure 1. Upper panels: LIVE/DEAD (green/red) staining of 3D-encapsulated or 2.5D overlay HepaRG or C3A cells cultured in hyaluronan-based hydrogels with 'liver-like' compliance; Top right panel: viability = 95%. Lower panel: In-depth 3D microstructural imaging of hydrogel-encapsulated hepatocytes with optical coherence phase microscopy. Field of view 2×2×1 mm.

Results: Highest cell viability (Fig-1, LIVE/DEAD staining; PB assays) for optimal 3D culture was achieved using 3D HepaRGs encapsulated in HAH – and used for paracetamol hepatotoxicity. 3D-HepaRGs showed significantly less oxidative stress (lactate production; ATP-depletion) compared with all HepG2/C3A culture formats, and more resistant to paracetamol hepatotoxicity, in all 2D-3D culture configurations tested. 3D-OCPM (Fig. 1) was able to image at a microstructural level all encapsulated cells in 3D (in a 2x2x1 mm field of view), and the dose-dependent effect of paracetamol upon spheroid integrity. In addition, cell viability was retrieved from functional OCPM measurements and integrated over the volume investigated to yield a dose-dependency of paracetamol cytotoxicity on 3D liver cultures – that correlated with standard hepatotoxicity assays.
Conclusions: In this study we demonstrated 3D-HAH-encapsulated HepaRG organoids as a potential model for hepatotoxicity studies; and validated Optical coherence phase microscopy as a non-invasive enabling technology to assess hepatotoxicity in 3D liver models at the microstructural level.

O039

CIRCULATING EXTRACELLULAR VESICLES WITH SPECIFIC PROTEOME ARE NOVEL BIOMARKERS AND THERAPEUTIC TARGETS FOR ALCOHOLIC LIVER DISEASE

A. Eguchi[1], R.G. Lazaro[2], J. Wang[2], H. Tsukamoto[2,3], A.E. Feldstein[1]. *[1]Department of Pediatrics, University of California San Diego, La Jolla, [2]Southern California Research Center for ALPD and Cirrhosis and Departments of Pathology, Keck School of Medicine of the University of Southern California, [3]Department of Veterans Affairs, Greater Los Angeles Healthcare System, Los Angeles, United States*
E-mail: aeguchi@ucsd.edu

Background and Aims: *Background:* Alcoholic liver disease (ALD) is one of the most common forms of chronic liver disease and includes a wide spectrum of disease from benign steatosis to steatohepatitis (ASH) to severe alcoholic hepatitis (AH). Noninvasive reliable tools that allow to determine the severity of liver damage and risk stratification as well as novel therapies for the severe forms are greatly needed. Our *aims* were to identify and characterize circulating extracellular vesicles, membrane bound vesicles released during cellular stress and key cell-to-cell communicators as potential novel non-invasive biomarkers and therapeutic targets for ALD.
Methods: C57/B6 mice were placed on the intragastric feeding model of continuous ethanol infusion for 4 weeks, or continuous ethanol infusion plus weekly binge for 8 week to reproduce a physiologically relevant model of mild ASH and AH, respectively. The extent of liver steatosis, inflammation, and fibrosis was assessed by histological and molecular analyses on liver specimens. Circulating extracellular vesicles (EVs) were isolated by ultracentrifugation from plasma and a complete characterization of EVs was performed by FACS, electron microscopy, dynamic light scattering and LC-MS/MS. Circulating EV biological function was investigated in bone marrow derived macrophage (BMDM) by FACS.
Results: We observed highly significant differences in the levels of circulating EVs in the plasma between control group and mild ASH ($p < 0.05$) or AH ($p < 0.01$). Extensive characterization of circulating EVs identified both microparticles (MPs) and exosomes (EXO) present in blood of mild ASH or AH mice. Proteomics analysis of circulating EVs from mild ASH detected various differentially expressed proteins compared to control mice. Finally, Incubation of BMDM with circulating EVs from mild ASH mice resulted in a significant up-regulation of various macrophage activation markers including, CD40 ($p < 0.05$), CD80 ($p < 0.05$), CD86 ($p < 0.01$), and MHCII, compared to control circulating EVs.
Conclusions: These findings uncover EVs as potential novel noninvasive biomarkers and therapeutic targets for ALD.

HERITABILITY OF HEPATIC FIBROSIS AND HEPATIC STEATOSIS, AND THEIR SHARED GENE EFFECTS WITH METABOLIC TRAITS IN NAFLD: A PROSPECTIVE TWIN STUDY

R. Loomba[1,2], N. Schork[3], C.-H. Chen[4], A. Bhatt[2], B. Ang[2], P. Nguyen[2], C. Hernandez[2], L. Richards[2], J. Salotti[2], S. Lin[2], K. Nelson[3], C.B. Sirlin[4,5], D. Brenner[1], on behalf of The Genetics of NAFLD in Twins Consortium. *[1]Gastroenterology, [2]NAFLD Translational Research Unit, University of California at San Diego, [3]J. Craig Venter Institute, [4]Radiology, [5]Liver Imaging Group, University of California at San Diego, La Jolla, United States*
E-mail: roloomba@ucsd.edu

Background and Aims: Heritability of hepatic fibrosis is unknown and heritability of hepatic steatosis has not been systematically assessed in adults. *Aims:* To determine the heritability of hepatic fibrosis and steatosis, and their shared gene effects with metabolic traits in a prospective community-dwelling human twin cohort specifically designed to study genetics of NAFLD.
Methods: This is a *cross-sectional* analysis of a prospective cohort study of uniquely well-characterized community-dwelling twins in Southern California. All participants underwent a standardized research visit including history, physical examination, fasting laboratory tests, exclusion of other causes of liver disease and hepatic steatosis. The hepatic steatosis was quantified non-invasively by MRI determined proton-density-fat-fraction (MRI-PDFF) and hepatic fibrosis was quantified non-invasively by MR elastography (MRE) determined stiffness. NAFLD was diagnosed after exclusion of secondary causes of hepatic steatosis in those who had a MRI ≥5% consistent with NAFLD practice guidelines.
Results: 106 twins were screened and 96 were included in the present study. The average (±SD) age and BMI was 48.6 (± 20.6) yrs and 24.9 (± 5.8) kg/m^2, respectively. The mono-zygotic (MZ) twin-pairs showed a robust correlation in hepatic steatosis as quantifed by MRI-PDFF (r^2 of 0.77, p-value <0.0001) but not the di-zygotic (DZ) twin-pairs (r^2 of 0.19, p-value 0.5). Similarly, the MZ twin-pairs showed a robust correlation in hepatic fibrosis as quantified by MRE (r^2 of 0.43, p-value <0.015) but not the DZ twin-pairs (r^2 of 0.08, p-value 0.8). The heritability of hepatic steatosis (assessed by MRI-PDFF) was 0.67 (CI: 0.57–0.77, p-value $<1.1\times10^{-15}$) and the heritability of hepatic fibrosis (assessed by MRE) was 0.66 (CI: 0.47–0.85, p-value $<9.7\times10^{-14}$), respectively. Genetic co-variance assessment revealed a significant association between hepatic steatosis and BMI (p-value <0.01) and hyperinsulinemia (p-value $<10^{-8}$), and between hepatic fibrosis and HbA1c (p-value <0.001). There was no significant shared gene effect between hepatic steatosis and hepatic fibrosis.
Conclusions: Utilizing a uniquley, well-characterized cohort of community-dwelling twins, this study demonstrates that both hepatic steatosis and hepatic fibrosis are heritable traits. Although both are heritable, they appear to have distinct basis for their genetic susceptibility.

O041
INCREASING ASSOCIATION OF NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD) WITH HEPATOCELLULAR CARCINOMA IN THE UNITED STATES: DATA FROM SURVEILLANCE, EPIDEMIOLOGY AND END RESULTS (SEER)-MEDICARE REGISTRIES (2004–2009)

Z. Younossi[1,2,3], M. Otgonsuren[3], L. Henry[3], C. Venkatesan[2], A. Mishra[2], M. Erario[2], S. Hunt[3]. *[1]Center for Liver Disease, Department of Medicine, [2]Department of Medicine, Inova Fairfax Hospital, [3]Betty and Guy Beatty Center for Integrated Research, Inova Health Systems, Falls Church, United States*
E-mail: zobair.younossi@inova.org

Background and Aims: HCC is increasingly reported in patients with NAFLD. Our aim was to assess the incidence and mortality of patients with HCC and NAFLD.
Methods: We examined SEER registries (2004–2009) with Medicare linkage claims files for patients with HCC. HCC cases were identified by the ICD-O-3 codes using topography and morphology codes 8170–8175. The linked Medicare data was used to identify NAFLD, hepatitis C (HCV), hepatitis B (HBV), alcoholic liver disease (ALD), and other liver disease by ICD-9-CM codes. NAFLD was defined by ICD-9 codes and by clinical diagnosis (cryptogenic cirrhosis, obese diabetics). Logistic regression model was used to calculate odds ratios (ORs) and 95% confidence intervals (CIs) for risk of HCC. In addition, adjusted hazard ratios (HRs) for within one-year mortality were estimated by Cox proportional hazard regression model in the HCC.
Results: After exclusion criteria, 7,255 HCC cases and 21,765 controls without HCC remained. Of the HCC cases, 43% (n = 3,128) were related to HCV, 16% (1,133) to NAFLD, 13% (975) to ALD and 7% (542) to HBV. Of HCC cases, 16% (1,194) did not have a liver disease diagnostic code. Across the six-year period, there was an increasing trend in the number of HCC cases, from 928 (287 per 1000 cases) in 2004 to 1,464 (346 per 1000) in 2009, a 4% annual increase. The prevalence HCC in HCV increased by 8% (from 110 per 1000 in 2004 to 156 per 1000 in 2009) with a 5% increase in NAFLD (from 44 per 1000 in 2004 to 55 per 1000 in 2009), all p < 0.001. Compared to HBV/HCV patients with HCC, NAFLD with HCC patients were older (74±8 vs. 68±11 yrs), more likely to be White, had shorter survival time, higher tumor stage and more heart disease (all p < 0.0001). Also, 1-year mortality of HCV/HBV with HCC was about 50%, while it was 70% NAFLD with HCC (p < 0.0001). Of those who received a transplant after HCC diagnosis (n = 508); only 4% was related to NAFLD/HCC. In multivariate analysis, NAFLD increased the risk of HCC (OR: 95% CI = 6.32: 5.55–7.19) as compared to the controls without liver disease. Additionally, older age, lower income, un-staged HCC were associated with higher risk of 1-year mortality while receiving liver transplant and having localized tumor stage were protective against the risk of 1-year mortality (all p < 0.05).
Conclusions: NAFLD is becoming a major cause of HCC in the U.S. NAFLD HCC is associated with shorter survival time, more advanced tumor stage and lower possibility of liver transplant.

O042
WEIGHT LOSS INTENSITY IS STRONGLY ASSOCIATED TO IMPROVEMENT OF HISTOLOGICAL PARAMETERS IN PATIENTS WITH NONALCOHOLIC STEATOHEPATITIS AFTER 52 WEEKS OF LIFESTYLE MODIFICATION

E. Vilar-Gomez[1,2], L. Calzadilla[1], A. Yasells Garcia[1], Y. Martinez Perez[1], M. Romero-Gomez[2], M. Diago[3]. *[1]Hepatology, National Institute of Gastrioenterology, Havana, Cuba; [2]Unit for the Clinical Management of Digestive Diseases, Valme University Hospital, Seville, [3]Liver Unit, Valencia University Hospital, Valencia, Spain*
E-mail: eduardovilar2000@yahoo.com

Background and Aims: The effect of weight loss (WL) intensity on different histological features of nonalcoholic steatohepatitis

(NASH) remains unclear. Thus, we evaluated the effect of different cutoffs of WL percentage on individual histological parameters in patients with NASH treated with lifestyle changes during 52 weeks.

Methods: This was a prospective study performed in 293 subjects with histologically proven NASH treated in clinical practice with low-fat hypocaloric diet and increased physical activity for 52 weeks. At baseline, patients were classified as having definite NASH and excluded those with borderline NASH and cirrhosis. NAFLD activity score (NAS) and their components, and fibrosis score were computed. A paired liver biopsy at 52 weeks was performed to determine a minimum two-point improvement in NAS or NASH resolution without fibrosis impairment. Furthermore, changes on individual components of NAS and fibrosis were recorded. A blinded central review of biopsies was performed by two experienced pathologist. At the end of 52 weeks, patients were stratified in subgroups according to different weight loss percentage cutoffs (<1%, 1–3%, 3–5%, 5–7%, 7–10% and >10%).

Results: A total of 261 patients underwent paired biopsies. A significant WL > 7% was achieved in 54 of 293 patients. Although NAS improvement and resolution were observed in all subgroups with WL, these were more remarkable in those with WL > 7%, however, no significant differences were detected between those with WL 7–10% (72% and 83%, respectively) and >10% (88% and 83%, respectively). While subjects with WL > 7% experienced higher rates of ballooning and lobular inflammation improvement, these were similar for those achieving 7–10% (88% and 86%, respectively) or >10% (96% and 90%, respectively). Mild reductions in the weight were associated with notable steatosis improvement, thus, patients with 3–5% of WL showed 65% of steatosis improvement. Of the 29 individuals with WL > 10%, 13 (45%) and 12 (42%) reduced the portal inflammation and fibrosis scores. No significant difference in these parameters were seen across the subgroups with WL < 10%.

Conclusions: The intensity of weight loss induced by lifestyle changes is strongly associated to the grade of improvement of histological features of NASH. A weight loss >7% has a positive impact in most of the histological parameters; however, >10% is necessary to induce fibrosis and portal inflammation improvements.

THE FNDC5 RS3480 IS PROTECTIVE ON THE STEATOSIS AND FIBROSIS IN PATIENTS WITH NAFLD

R. Anty[1], Y.L. Liu[2], A. Iannelli[1], S. Patouraux[3], C. Canivet[1], I. Ben-Amor[1], A.-S. Schneck[1], M.-C. Saint-Paul[3], J. Gugenheim[1], C. Day[2], A. Daly[2], A. Tran[1], P. Gual[1], Q. Anstee[2]. [1]*Hepatology unit, Digestive department, University Hospital of Nice; INSERM U1065, Nice, France;* [2]*Institute of Cellular Medicine, The Medical School, Newcastle University, Newcastle upon Tyne, United Kingdom;* [3]*Pathological unit, Digestive department, University Hospital of Nice; INSERM U1065, Nice, France*
E-mail: rodolphe.anty@laposte.net

Background and Aims: Irisin, the cleaved extra-cellular part of the protein Fibronectin type III domain-containing protein 5 (*FNDC5*), is released by muscles during exercise through PGC1alpha activation and could have a favourable metabolic action. The aim of this study was to investigate the potential association of *FNDC5* Single Nucleotide Polymorphisms (SNPs) with histological severity of Non Alcoholic Fatty Liver Disease (NAFLD) in European Caucasian patients.

Methods: Two large cohorts of patients ["discovery" (n = 304) and "validation" (n = 309)] with histologically characterized NAFLD (SAF score) were studied. Four *FNDC5* SNPs (rs3480, rs1683198, rs1746661, rs1298190) and the patatin-like phospholipase domain containing 3 (*PNPLA3*) rs738409 variant were genotyped by allelic discrimination using TaqMan reagents (Applied Biosystems Inc., USA). Multivariate logistic regression analysis (additive model) was conducted incorporating biologically relevant covariates that were associated with risk of NAFLD progression [age, gender, Body mass index, presence of type 2 diabetes mellitus (T2DM) and *PNPLA3* rs738409 genotype] to test the genetic association.

Results: The discovery and validation cohorts differed in some characteristics including gender mix (Female gender 82% vs 40%, $p < 0.0001$), BMI (42.9 vs 34.3, $p < 0.0001$), age (40.9 vs 50.4, $p < 0.0001$), prevalence of T2DM (20.1 vs 41.1%, $p < 0.0001$) and the histological grade of activity score (≥A1 36.2 vs 71.2%, $p < 0.0001$). However, degrees of steatosis (≥S2 59.5 vs 70.6%, p = NS) and stage of fibrosis (≥F2 28.6 vs 40.1%, p = NS) were not significantly different between cohorts. Of the four *FNDC5* SNPs tested, only rs3480 was significantly associated with steatosis and fibrosis in the discovery cohort. In multivariate analysis, carriage of *FNDC5* rs3480 minor allele was protective against advanced steatosis in both the discovery and validation cohorts as well as the combined cohorts ($\beta = 0.69 \pm 0.13$, 95% CI 0.54–0.89; P = 0.0036). Although no association with histological activity was seen, carriage of *FNDC5* rs3480 was also protective regarding the degree of fibrosis in the combined cohort ($\beta = 0.73 \pm 0.13$, 95% CI 0.57–0.95; P = 0.0172).

Conclusions: Carriage of the *FNDC5* rs3480 minor G allele is associated with less severe steatosis and milder fibrosis in a population of European Caucasian patients. Further work is ongoing to determine the mechanisms through which this variant mediates its effect.

DISTINCT FECAL AND PLASMA BILE ACID METABOLOME OF MICROBIAL ORIGIN CHARACTERIZES HUMAN NONALCOHOLIC FATTY LIVER DISEASE (NAFLD)

P. Puri[1], S.M. Siddiqui[1], S. Boyette[1], C. Sargeant[1], L.D. White[1], S. Walker[1], K. Daita[1], C. Ammons[1], S. Cazanave[1], A. Asgharpour[1], F. Mirshahi[1], A. Joyce[2], A.J. Sanyal[1]. [1]*Virginia Commonwealth University,* [2]*Venebio, Richomnd, United States*
E-mail: ppuri@mcvh-vcu.edu

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is the fastest growing global liver disease with two well described phenotypes: nonalcoholic fatty liver (NAFL) and nonalcoholic steatohepatitis (NASH). Bile acid (BA) metabolism is emerging to be an important pathophysiologic determinant and a potential therapeutic target in the more aggressive phenotype NASH. We hypothesized that NASH is associated with dysregulated BA metabolism.

Aims: (1) To characterize plasma and fecal BA metabolome in NAFL and NASH compared to healthy controls, and (2) to test and validate BA metabolite as a potential biomarker to distinguish NASH.

Methods: Healthy controls and subjects with histologically proven NAFL and NASH were recruited after informed consent. Clinical, demographic and pertinent medical information was collected. Plasma and stool samples were also collected per protocol. High throughput mass spectrometry was used for metabolomics. Welch t-test, and multiple group comparisons by ANOVA were applied. Random forest classification and mean decrease accuracy was measured for biomarker detection in initial training set followed by testing in validation cohort.

Results: Training (n = 51, control 7, NAFL 13, NASH 31) and validation (n = 32, control 17, NAFL 9, NASH 6) cohorts were age and gender matched for the three study groups.

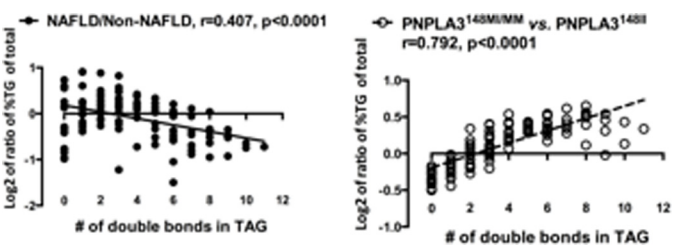
Plasma BA metabolome changes: Despite no significant changes in the training cohort, compared to the controls primary BA taurocholate was significantly decreased in NASH by 3.28 fold ($p < 0.05$) in the validation cohort. NAFL had significantly higher glycocholate ($p = 0.009$) and taurocholate ($p = 0.01$) compared to the controls. Plasma glycoursodeoxycholate was significantly increased in both NAFL ($p = 0.026$) and NASH ($p = 0.03$). Secondary conjugated

bile acid tauroursodeoxycholate was 4 and 17 folds increased in NASH (p = 0.08) and NAFL (p = 0.05) respectively vs. control.
Fecal BA metabolome: Several secondary BA were significantly altered in the training and validation cohorts. Glycodeoxycholate (GDCA) emeerged as the sole concordant marker that was significantly increased in NASH compared to NAFL and control groups. Interestingly, GDCA is a secondary BA produced by the action of enzymes existing in the microbial flora of the colon and promotes apoptosis.
Conclusions: NASH is characterized by distinct fecal and plasma BA metabolome with microbial metabolite GDCA as a potential fecal biomarker and future therapeutic target.

O045
BIOACTIVE LIPIDS IN THE HUMAN LIVER IN 'COMMON NAFLD' AND 'PNPLA3 NAFLD'

P. Luukkonen[1,2], Y. Zhou[2], S. Sädevirta[1], M. Oresic[3], T. Hyötyläinen[3], M. Orho-Melander[4], J. Arola[5], M. Leivonen[6], H. Yki-Järvinen[1,2].
[1]Department of Medicine, University of Helsinki, [2]Minerva Foundation Institute for Medical Research, Helsinki, Finland; [3]Steno Diabetes Center, Gentofte, Denmark; [4]Department of Clinical Sciences, Diabetes and Endocrinology, University Hospital Malmö, Lund University, Malmö, Sweden; [5]Department of Pathology, The Laboratory of Helsinki University Central Hospital, [6]Department of Surgery, Helsinki University Central Hospital, Helsinki, Finland
E-mail: panu.luukkonen@fimnet.fi

Background and Aims: 'Common NAFLD' is associated with hepatic insulin resistance and features of the metabolic syndrome while NAFLD due to the PNPLA3 I148M gene variant ('PNPLA3 NAFLD') is associated with increased liver fat but not insulin resistance. We hypothesized that this could be due to a difference in insulin resistance-inducing bioactive lipids, especially ceramides and diacylglycerols (DAGs) between the two types of NAFLD.
Methods: Liver biopsies from 126 subjects undergoing bariatric surgery were taken for profiling of molecular lipids using UPLC-MS. Liver histology, metabolic features and PNPLA3 genotype at rs738409 were also assessed. Subjects were divided into groups based on the presence of NAFLD ('Common NAFLD', n = 69, vs. 'Non-NAFLD', n = 57) and the PNPLA3 genotype (PNPLA3148MI/MM, n = 61 vs. PNPLA3148II, n = 65).
Results: Liver triacylglycerol (TAG) content was significantly increased in both types of NAFLD. The 'Common NAFLD' group was insulin-resistant compared with the 'Non-NAFLD' group (HOMA-IR 3.8 [2.3–5.4] vs. 2.6 [1.3–3.9], p < 0.0005), while HOMA-IR was similar in PNPLA3148MI/MM and PNPLA3148II groups (3.2 [1.7–5.1] vs. 3.2 [1.9–4.6], NS). Cluster analyses showed that the liver in the 'Common NAFLD' group was enriched in saturated and monounsaturated TAGs, ceramides and DAGs. Hepatic TAGs in the PNPLA3148MI/MM group were characterized by increases in polyunsaturated TAGs and no changes in ceramides and DAGs. Consequently, the number of double bonds in TAGs was negatively correlated with the fold-change of relative TAG ratios between the 'Common NAFLD' and the 'Non-NAFLD' groups (r = −0.407, p < 0.0001) but not between PNPLA3148MI/MM and PNPLA3148II groups (r = 0.792, p < 0.0001) (Figure).



Conclusions: The human liver lipidome differs markedly between 'Common NAFLD' and 'PNPLA3 NAFLD'. Lack of insulin resistance in 'PNPLA3 NAFLD' could be attributed to lack of an increase in saturated TAGs and accompanying increases in ceramides and DAGs.

O046
SHORT-TERM VITAMIN D SUPPLEMENTATION IMPROVES HEPATIC STEATOSIS AS QUANTIFIED BY CONTROLLED ATTENUATION PARAMETER (CAP)

I. Papapostoli[1], F. Lammert[1], C.S. Stokes[1]. *[1]Department of Medicine II, Saarland University Medical Center, Homburg, Germany*
E-mail: caroline.stokes@uks.eu

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is the most common cause of chronic liver disease in Western countries. A recent meta-analysis has confirmed decreased serum 25-hydroxyvitamin D levels in patients with NAFLD. This intervention study investigates whether vitamin D therapy ameliorates hepatic steatosis in patients referred to the outpatient liver clinic of a tertiary centre.
Methods: We prospectively recruited patients with NAFLD and vitamin D deficiency, as defined by serum concentrations <20 ng/ml. Hepatic steatosis was assessed using the controlled attenuation parameter (CAP), which quantifies the degree of ultrasound attenuation by liver fat during vibration-controlled transient elastography (FibroScan). Patients were included if they had significant liver fat accumulation, which we defined by a CAP score ≥280 dB/m. Serum 25-hydroxyvitamin D were measured by chemiluminescent immunoassays. Body composition was determined with bioelectrical impedance analysis (TANITA BC-418 MA). Currently, 32 patients entered the intervention arm of the study and received 20,000 IU vitamin D daily for 7 days, thereon weekly for 6 months, while vitamin D, liver function tests, BMI and CAP levels were monitored.
Results: Overall, the cohort comprised 48.7% women (mean age 54±12 years; mean BMI 29.5±3.1 kg/m^2). Moderate vitamin D deficiency was present in 59.5% and severe vitamin D deficiency (<10 ng/ml) in 40.5% of patients. Fatty liver quantification showed a mean CAP of 328.5±30.9 dB/m. The CAP score was significantly lower in patients with severe vitamin D deficiency (342.8±31.8 *vs.* 317.3±27.0 dB/m, P = 0.013). A rapid increase in vitamin D levels was noted after 4 weeks of vitamin D supplementation (33.2 *vs.* 10.9 ng/ml, P < 0.0001), with 73% of patients displaying normal levels (>30 ng/ml). CAP scores significantly decreased by 5% at the 4-week interval (312.8 *vs.* 328.5 dB/m, P = 0.047). During this time-frame LFTs, BMI and body fat levels remained unchanged. Patients will be monitored again at 3 and 6 months.
Conclusions: Vitamin D levels correlate with the degree of hepatic steatosis, which significantly improves after only 4 weeks of vitamin D replacement therapy. We conclude that hepatic steatosis as assessed by CAP is a dynamic process, which appears to be modulated by short-term therapeutic interventions such as vitamin D substitution. The molecular mechanisms underlying hepatocellular lipid remodelling by vitamin D remain to be identified.

O047
REMOGLIFLOZIN ETABONATE REDUCES INSULIN RESISTANCE AND LIVER FUNCTION ENZYMES: ROLE FOR TREATMENT OF NASH

W. Wilkison[1], B. Cheatham[2], S. Walker[2]. *[1]Islet Sciences, Inc., [2]BHV Pharma, Raleigh, United States*
E-mail: bill@bhvpharma.com

Background and Aims: The etiology of non-alcoholic steatohepatitis (NASH) is due, in part, to insulin resistance and oxidative stress resulting from steatosis. To date, studies with anti-diabetics and anti-oxidants have resulted in small effects on reversal of these factors in NASH patients. Remogliflozin etabonate (Remo) is an SGLT2 inhibitor shown to reduce HbA1c in type 2 diabetics. We show here that Remo significantly reduces insulin resistance and,

Table 1 (abstract O047).

unlike other SGLT2 inhibitors, has intrinsic anti-oxidant activity, which may reverse the steatohepatitis and oxidative stress required to progress and maintain NASH.

Methods: A 12-week, double-blind, randomized, active and placebo-controlled trial was conducted with 336 treatment naïve subjects with type 2 diabetes and an HbA1c of >7.0% to <9.5% where the primary endpoint was change from baseline in HbA1c. Subjects were equally randomized to each of the Remo treatments (50, 100, 250, 500, or 1000 mg bid), matching placebo or 30 mg qd pioglitazone. Chemistry laboratories including LFTs, HOMA

Results: At Week 12, Remo improved both insulin sensitivity and beta cell function by 6–39% and 23–43%, respectively (Table 1). A significant decrease from baseline in AUC (0–2 hour) weighted mean plasma glucose following the OGTT was observed for all Remo treatment groups (Table 1). Post-hoc analysis of changes in alanine aminotransferase (ALT) indicated that subjects with elevated ALT at the Baseline (Week 0) showed 42–32% reductions at Week 12. Additionally, unlike other SGLT2 inhibitors, Remo has significant anti-oxidant activity as measured by the oxygen radical antioxidant capacity (ORAC) assay and reduces serum markers of oxidative stress in animal models of steatohepatitis.

Conclusions: Remo is a safe and potent anti-diabetic compound in late stage clinical development. Given its ability to reverse insulin resistance, lower ALT, and provide anti-oxidant activity, remogliflozin etabonate may be a useful treatment for NAFLD and NASH.

THE PHASE 3 C-EDGE TREATMENT-NAÏVE (TN) STUDY OF A 12-WEEK ORAL REGIMEN OF GRAZOPREVIR (GZR, MK-5172)/ ELBASVIR (EBR, MK-8742) IN PATIENTS WITH CHRONIC HCV GENOTYPE (GT) 1, 4, OR 6 INFECTION

S. Zeuzem[1], R. Ghalib[2], K.R. Reddy[3], P.J. Pockros[4], Z.B. Ari[5], Y. Zhao[6], D. Brown[7], M. DiNubile[6], M. Robertson[6], J. Wahl[7], E. Barr[6], J. Butterton[6]. *[1]Goethe University Hospital, Frankfurt, Germany; [2]Texas Clinical Research Institute, Dallas, [3]University of Pennsylvania, Philadelphia, [4]Scripps Translational Science Institute, La Jolla, United States; [5]Sheba Medical Center, Ramat Gan, Israel; [6]Merck, [7]Meck, Whitehouse Station, United States*
E-mail: zeuzem@em.uni-frankfurt.de

Background and Aims: Safe, efficacious, and convenient antiviral regimens without interferon or ribavirin are being developed for chronic HCV infection. The C-EDGE TN study (P060) investigated the safety and efficacy of a once daily regimen of GZR (NS3/4A protease inhibitor) and EBR (NS5A inhibitor) for 12 weeks (wks) in TN patients (pts) with GT 1, 4, or 6 infection.
Methods: C-EDGE TN is an international, randomized, blinded, placebo-controlled, parallel-group trial of an oral fixed-dosed combination of GZR 100 mg/EBR 50 mg once daily in TN, HCV GT 1-, 4-, or 6-infected pts. Cirrhotic patients were eligible. Exclusion criteria included decompensated liver disease, HCC, HIV or HBV co-infection, platelets $<50\times10^3/\mu L$, or albumin <3.0 g/dL. Pts were assigned in a 3:1 ratio to receive either immediate or deferred therapy after stratification by GT and fibrosis stage assessed by biopsy or noninvasive means. HCV RNA levels were measured by the COBAS TaqMan v2.0 assay. The primary efficacy endpoint was prespecified as the proportion of treated pts in the immediate GZR/EBR arm with unquantifiable RNA levels (<15 IU/mL) 12 wks after the end of study treatment (SVR12).
Results: Overall, 421 (90%) of 469 screened pts were enrolled, randomized, and treated with ≥1 dose of study drug: 194 (46%) women; 157 (37%) non-white; 385 (91%) GT1 and 36 (9%) GT4/6 infections. Among the 92 (22%) pts with cirrhosis, the diagnosis was biopsy-proven in 26 (28%); the median platelet count [IQR] and albumin level [IQR] in cirrhotics were 123.5 [91.5–157.5] $\times10^3/\mu L$ and 4.1 [3.8–4.4] g/dL, respectively. All pts have reached follow-up (F/U) Wk4. Based on preliminary results from 315 GZR/EBR recipients in the immediate treatment arm, 306 (97%) achieved SVR4. Virologic failure occurred in 5/315 (1.6%) pts: 1 GT1a breakthrough at treatment Wk8 and 4 relapses (2 GT1a, 2 GT6) by F/U Wk4. There were 4 (1.3%) additional pts not achieving SVR4: 2 drug-unrelated deaths (incarcerated hiatal hernia and cardiac arrhythmia), 1 drug-related AE (palpitations/anxiety with drug discontinuation on treatment Day 4), and 1 loss to F/U. Serious AEs occurred in 10 (3.2%) and 3 (2.9%) pts in the active (immediate treatment) and placebo (deferred treatment) arms, respectively.
Conclusions: Early results suggest GZR/EBR for 12 wks is efficacious and well tolerated in TN pts with GT 1, 4, or 6 infection, including pts with compensated cirrhosis. SVR12 rates and full safety data will be presented.

E-mail: nathalie.ganne@jvr.aphp.fr

Background and Aims: To assess the incidence of complications, mainly HCC, in alcoholic compensated cirrhosis.
Methods: Patients with histologically proven alcohol-related cirrhosis, Child–Pugh A, no HBV or HCV infection and no previous HCC were included then prospectively screened for HCC. At inclusion then yearly, biobanks and breath ethanol concentrations were colected.
Results: From october 2010 to september 2014, 538 eligible patients were consecutively enrolled in 20 active centres of whom 46 were excluded from the analysis (mainly because of absence of liver biopsy n = 7, Child–Pugh ≥B7 n = 21, or HCC n = 6). Of the 492 patients [median age 59 yrs, males 67%, seniority of the cirrhosis: 28.5 months, previous decompensation 65%], 304 (65%) were completely abstinent (median duration for alcohol withdrawn: 28.8 months) and 73 (15%) had still a mild consumption <7 glasses/week (absence of ethanol in breath for 309/378 patients at enrolment, 82%). Most patients were smokers (past-history of tabacco 35%, active smokers 39%) and regular consumption of coffee [78%; median: 2 cups/day; ≥3 cups/day in 123/317 (39%)]. Metabolic syndrome defined according to International Diabetes Federation (2005) was present in 84 patients (21%). At enrolment, 21 patients (4%) had a liver nodule (hemangioma n = 3, biliary kyste n = 7, regenerative nodule n = 1, miscellaneous n = 10) that was not

ELSEVIER

anymore described during follow-up in 13 of them. Based on a median follow-up of 12.4 months: (i) liver nodule(s) occurred in 50 patients (1-yr cumulative incidence: 11%) diagnosed as HCC in 14 cases (1-yr cumulative incidence: 1.3%) without any statistically difference according to alcohol consumption or the presence of metabolic syndrome; description of the baseline characteristics of HCC ongoing; (ii) 160 events besides HCC were censored in 90 patients (1-yr cumulative incidence: 18%) related to a complication of cirrhose in half of cases; (iii) 28 deaths occurred directly attributable to the liver disease in 54% cases.

Conclusions: Early results of this prospective cohort are: (a) only 28% of detected liver nodules were confirmed as primary liver cancer; (b) after a follow-up of 1 yr, liver-related mortality already had concerned more than one half of deaths. Additional enrollments are ongoing. This cohort constitutes the backbone permitting precise study of HCC and other complications of cirrhosis, particularly through subsequent follow-up and nested studies exploiting high quality clinical data and biobank.

TARGETING A HOST-CELL ENTRY FACTOR BARRICADES ANTIVIRAL RESISTANT HCV VARIANTS FROM ON-THERAPY BREAKTHROUGH IN HUMAN-LIVER MICE

K. Vercauteren[1], R. Brown[2], A.A. Mesalam[1], J. Doerrbecker[2], S. Bhuju[3], R. Geffers[3], N. Van Den Eede[1], F. Troise[4], L. Verhoye[1], T. Baumert[5], A. Farhoudi[1], R. Cortese[6], G. Leroux-Roels[1], T. Pietschmann[2], A. Nicosia[4], P. Meuleman[1]. *[1]Department of Clinical Chemistry, Microbiology and Immunology, Ghent University, Ghent, Belgium; [2]Institute of Experimental Virology, TWINCORE, Centre for Experimental and Clinical Infection Research, Hannover, [3]Genome Analytics, Helmholtz Centre for Infection Research, Braunschweig, Germany; [4]Department of Molecular Medicine and Medical Biotechnology, University of Naples Frederico II, Naples, Italy; [5]Institut National de la Santé et de la Recherche Médicale, U1110, Université de Strasbourg, Strasbourg, Germany; [6]Keires AG, Basel, Switzerland*
E-mail: philip.meuleman@ugent.be

Background and Aims: Both viral and host proteins are involved during the hepatitis C virus (HCV) life cycle. Direct Acting Antivirals (DAAs) inhibit HCV infection by targeting viral proteins and are successfully used to treat HCV infections. However, therapy failure caused by the emergence of DAA-resistance associated variants (RAVs) remains a reasonable concern. Presumably, future anti-HCV therapies will consist of drug combinations that target distinct steps of the viral life cycle. The conserved host factors used by the virus for its propagation seem interesting alternative targets for antiviral intervention, complimentary to the action of DAAs.

Methods: We have previously shown that monoclonal antibodies (mAbs) against the HCV co-receptor scavenger receptor class B type I (SR-BI) inhibit HCV infection of different genotypes in human-liver chimeric mice, even when therapy was initiated several days after exposure. In addition we have recently shown that viral variants with *in vitro* reduced dependency on SR-BI can still be successfully blocked *in vivo* by our mAb. These observations suggested that anti-SR-BI mAb1671 efficiently prevents intrahepatic viral spread. Therefore we hypothesized that mAb1671 could prevent on-therapy breakthrough of DAA-RAVs, by restricting DAA-RAVs to the hepatocytes in which they are selected, thereby improving virologic response. Thirteen gt1b-infected mice were randomized over two study groups. Seven mice received BILN-2061 (Ciluprevir) monotherapy, while the six remaining ones received a combination consisting of BILN-2061 and mAb1671. During a six-week period BILN-2061 was administered (10 mg/kg, BID, oral gavage) with or without additional injections of mAb1671 (400 μg per injection) at day 0, 2, 4, 7, 10, 13, 16, 20, 23, 27, 30, 34, 37, 41.

Results: In this study, we observed that human-liver chimeric mice receiving monotherapy of the protease inhibitor BILN-2061 rapidly experience on-therapy virologic breakthrough. Deep sequencing analysis of the HCV protease domain confirmed the dominant manifestation of PI-RAVs upon viral rebound. In contrast, such on-treatment breakthrough was completely absent in mice treated with a combination of the PI with mAb1671. Our data suggest that mAb1671 precludes the emergence and dissemination of PI-RAVs during combination therapy.

Conclusions: We provide preclinical *in vivo* evidence that the addition of an entry inhibitor to a DAA regimen is an excellent strategy to prevent therapeutic failure due to the selection and rebound of DAA-RAVs.

MITOCHONDRIAL-TARGETED ANTIOXIDANT MITOQUINONE REDUCES PORTAL HYPERTENSION IN CCl_4-CIRRHOTIC RATS BY DECREASING INTRAHEPATIC RESISTANCE

M. Vilaseca Barceló[1], C. López-Sanjurjo[1], M.P. Murphy[2], J. Bosch[1], V. Hernández-Gea[1], J. Gracia-Sancho[1], J.C. García-Pagán[1]. *[1]Barcelona Hepatic Hemodynamic Laboratory, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS) – Hospital Clínic de Barcelona – CIBEREHD – University of Barcelona Medical School, Barcelona, Spain; [2]MRC Mitochondrial Biology Unit, Medical Research Council, Cambridge, United Kingdom*
E-mail: mvilaseca7@gmail.com

Background and Aims: Increased intrahepatic resistance (IHR) due to both architectural alterations of the liver parenchyma as well as to dynamic increase in the hepatic vascular tone, is the primary factor in the development of portal hypertension. Hepatic Stellate Cells (HSC) are the main cells contributing to disrupt liver parenchyma by promoting fibrogenesis when activated. We have shown that cirrhotic livers have an increased production of reactive oxidative species (ROS), and that antioxidant therapy decreases portal pressure. It is also known that part of these ROS is produced within mitochondria. The aim of this study was to asses if the mitochondrial-directed antioxidant Mitoquinone was able to reduce oxidative stress, decrease intrahepatic fibrosis and attenuate portal hypertension.

Methods: *In vitro*: The expression of *col1*, *α-SMA* and *pdgfrb* (qPCR) was determined in human activated HSC (LX-2) in response to Mitoquinone (1 nM for 24 h; n = 3). Proliferation and viability were also assessed.

In vivo: CCl_4-cirrhotic Wistar rats were treated with Mitoquinone (MIT: 25 mg/kg/day p.o.; n = 9) or its vehicle, DecylTPP (Veh: 25 mg/kg/day; n = 9) for 2 weeks. Cellular and mitochondrial oxidative stress was assessed by DHE and MitoSox staining. Systemic and hepatic hemodynamics were determined *in vivo*. Liver fibrosis was determined by Sirius Red staining and HSC phenotype by gene expression of *col1*, *col1α2, pdgfrb, timp1, timp2* (qPCR) and α-SMA and desmin expression (IHC).

Results: *In vitro*: Mitoquinone induced a significant deactivation of HSC (*col1* [-67%], *α-SMA* [-65%] and *pdgfrb* [-48%]), and decreased proliferation (−43%). No effects on viability were observed.

In vivo: Mitoquinone markedly decreased mitochondrial (−34%) and cellular (−34%) oxidative stress. These effects were associated with a significant reduction in PP (Veh: 13.6±0.9 *vs* MIT: 10.9±0.6 mmHg; −20%) without affecting PBF resulting in a decrease in IHR (−34%). MAP was not significantly modified. Livers from Mitoquinone-treated rats showed significantly lower fibrosis (−36%) and expression of *col1*, *pdgfrb* and *timp2* (−68%, −54% and −31%, respectively) without significant changes in α-SMA and desmin. These data suggest Mitoquinone evokes a change in HSC to a more inactive form.

Conclusions: Mitoquinone significantly reduces mitochondrial ROS, PP and IHR, mostly by decreasing collagen deposition due to inactivation of HSC. We herein propose directed mitochondrial antioxidants as a novel treatment against portal hypertension and cirrhosis.

G11
MICROBIAL TRANSLOCATION IN LIVER FIBROSIS INDUCES CHRONIC IFNAR SIGNALING THAT IMPAIRS INNATE IMMUNITY AGAINST BACTERIAL INFECTION

Z. Abdullah[1], P. Hackstein[1], M. Beyer[2], J. Trebicka[3], T. Sauerbruch[3], U. Spengler[4], J.L. Schultze[2], C. Kurts[1], W. Kastenmüller[1], P.A. Knolle[1,5]. [1]*Institute of Experimental Immunology,* [2]*Genomics and Immunoregulation, Life and Medical Sciences Institute (LIMES),* [3]*Department of Internal Medicine I,* [4]*Department of General Internal Medicine, University Hospital, Bonn,* [5]*Institute of Molecular Immunology (IMI), Technische Universität München, Munich, Germany*
E-mail: zeinab.abdullah@ukb.uni-bonn.de

Background and Aims: A common clinical complication in patients with liver fibrosis or cirrhosis is enhanced susceptibility and failure to control bacterial infections.
Methods: To identify the underlying cellular and molecular mechanisms, we used the bile-duct ligation model for the induction of liver fibrosis in mice and characterized the immune responses to *Listeria monocytogenes* infections in the context of liver fibrosis and cirrhosis.
Results: Our data revealed an enhanced susceptibility to *Listeria* infections in mice with liver fibrosis/cirrhosis leading to persistence of infection, which recapitulates the clinical situations in humans with chronic liver disease. While the innate immunity and clearance of *Listeria* in the spleen of those mice was unaltered, the bactericidal activity of intrahepatic macrophages and bacterial clearance in the liver were strongly impaired. This reduced local clearance of *Listeria* correlates with impaired IFNγ, IL-12 and ROS production by myeloid cells in the liver.
Mechanistically, we identified IFNAR signaling in myeloid cells as initiating event for the impaired anti-bacterial immunity in mice with liver fibrosis. Using germ free mice we show that IFNAR signaling is induced by translocated gut microbiota during liver fibrosis. Chronic Type I IFN signaling in myeloid cells in turn causes IL-10 release, which directly inhibited IFNg, IL-12 and ROS production. Strikingly, we could rescue mice from chronic bacterial infection by either blocking IFN signaling specifically in myeloid cells or by systemic blockade of IL-10 signaling.
Conclusions: This murine model allowed to identify important IFNAR-mediated supressive mechanisms in chronic liver diseases, opening new therapeutics avenue to control bacterial infections in patients with liver fibrosis or cirrhosis.

G12
THE BURDEN OF CARDIOVASCULAR DISEASE AND MORTALITY ACROSS A SPECTRUM OF NON-ALCOHOLIC FATTY LIVER DISEASE: A 14-YEAR FOLLOW-UP POPULATION STUDY OF 929,465 INDIVIDUALS

J.P. Mann[1], M.J. Armstrong[2], H. Uppal[3], S. Chandran[4], P.N. Newsome[2], R. Potluri[3]. [1]*Paediatrics, University of Cambridge, Cambridge,* [2]*NIHR Centre for Liver Research, University of Birmingham,* [3]*ACALM Study Unit in collaboration with Aston Medical School, Aston University, Birmingham,* [4]*Deptartment of acute medicine, North Western Deanery, Manchester, United Kingdom*
E-mail: jakemann@doctors.org.uk

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is recognised as a risk factor for cardiovascular disease (CVD) with some evidence, albeit from small studies, that non-alcoholic steatohepatitis (NASH) conveys greater risk than NAFLD. In this large UK study we studied the overall burden of CVD and all-cause mortality across the spectrum of NAFLD.
Methods: Anonymous data was obtained from a local computerised hospital activity analysis register regarding a total population of 929,465 patients in England area during 2000–2013. Data was processed using the ACALM (Algorithm for Co-morbidity, Associations, Length of stay and Mortality) study protocol, using ICD-10 codes to identify patients with NAFLD (K76.0), NASH (75.8), and NAFLD cirrhosis [cryptogenic cirrhosis (K74.6)] throughout the study period. Cardiovascular comorbidities were coded according to the ICD-10 criteria and their prevalence were analysed over 14-years.
Results: During the 14-year study period, 2701 patients were diagnosed with NAFLD-spectrum conditions: 1294 with NAFLD, 122 with NASH, and 1285 with cirrhosis. Mean ages at diagnosis were 51±0.4, 52±2 and 59±0.4 years, respectively. All groups had a male predominance (56–58%) and were 78–80% Caucasian. All-cause mortality was higher in NASH than NAFLD (22.1% vs. 14.5%, $p = 0.025$), and in cirrhosis than NAFLD (53.1% vs. 14.5%, $p < 0.001$). Congestive cardiac failure (CCF) was less prevalent in NAFLD than NASH ($p = 0.001$) and cirrhosis ($p < 0.001$). The prevalence of type 2 diabetes mellitus, atrial fibrillation, hyperlipidaemia, chronic kidney disease were higher in the advanced stages of NAFLD (Table 1). There was no difference in the prevalence of hypertension between the groups.

Table 1. Prevalence of mortality, metabolic and cardiovascular outcomes for patients within the spectrum of NAFLD during a 14-year study period

Clinical outcome	Number (%)		
	NAFLD (n = 1294)	NASH (n = =122)	Cirrhosis (n = 1285)
Congestive cardiac failure	49 (3.8)	11 (9.0)‡	85 (6.6)*
Atrial fibrillation	64 (4.9)	10 (8.2)	107 (8.3)**
Type 2 diabetes	271 (20.9)	30 (24.6)	401 (31.2)**
Chronic kidney disease	40 (3.1)	6 (4.9)	89 (6.9)**
Hyperlipidaemia	156 (12.1)	21 (17.2)	64 (5.0)**
Hypertension	381 (29.4)	42 (34.4)	351 (27.3)
Mortality	188 (14.5)	27 (22.1)†	682 (53.1)**

For NAFLD vs. NASH: †$p < 0.05$, ‡$p < 0.01$. For NAFLD vs. cirrhosis: *$p < 0.001$, **$p < 0.0001$.

Conclusions: By utilising a large population based cohort this study provides important new insights into mortality and cardiovascular disease in patients with NAFLD. Notably, during a 14-year study period, death occurs in over 20% of patients diagnosed with NASH and 50% with related-cirrhosis.

Liver tumours: Clinical

O048
FIRST SELECTIVE SMALL MOLECULE INHIBITOR OF FGFR4 FOR THE TREATMENT OF HEPATOCELLULAR CARCINOMAS WITH AN ACTIVATED FGFR4 SIGNALING PATHWAY

K. Hoeflich[1], M. Hagel[1], C. Miduturu[1], M. Sheets[1], N. Rubin[1], W. Weng[1], N. Stransky[1], N. Bifulco[1], J. Kim[1], B. Hodous[1], N. Brooijmans[1], A. Shutes[1], C. Winter[2], C. Lengauer[1], N. Kohl[1], T. Guzi[1]. [1]*Blueprint Medicines,* [2]*Sanofi, Cambridge, United States*
E-mail: khoeflich@blueprintmedicines.com

Introduction: Limited treatment options are available to patients with hepatocellular carcinoma (HCC) and the multi-kinase inhibitor sorafenib remains the only approved drug for this devastating disease. However, molecularly-stratified treatment schemes are beginning to be developed for HCC.
Material and Methods: Fibroblast growth factor 19 (FGF19), the ligand for fibroblast growth factor receptor 4 (FGFR4), is not expressed in normal liver, but is made in the ileum and delivered to the liver via portal circulation. However, a subset of human HCCs (7%) harbor amplification of *FGF19* and an additional one-fourth of tumors (21–34%) overexpress *FGF19* in the absence of gene amplification. In the presence of FGFR4 and its co-receptor *klotho β*

(*KLB*), *FGF19* overexpression can promote liver tumor formation in mice, a process which can be blocked by inhibiting FGFR4 signaling. This suggests that FGFR4 inhibition might be an effective treatment strategy in HCC patients whose tumors have an active FGF19/FGFR4 signaling axis.

Results: Here, we report the discovery of BLU9931, a potent and irreversible small molecule inhibitor of FGFR4. BLU9931 is exquisitely selective for FGFR4 versus other kinases, including FGFR family members. HCC cell lines with an activated FGFR4 signaling pathway were sensitive to FGFR4 inhibition and BLU9931 treatment decreased proliferation and induced apoptosis. BLU9931 also showed remarkable antitumor activity towards HCC tumor xenografts expressing *FGFR4*/*KLB* and harboring amplified *FGF19*. Furthermore, similar antitumor activity was observed in liver tumor xenografts which express detectable levels of *FGF19* mRNA and whose FGFR4 pathway remains intact, but lack *FGF19* amplification.

Conclusions: Taken together, these findings demonstrate a novel therapeutic strategy that targets a defined subset of HCC patients with a selective FGFR4 inhibitor and clinical trials to test this hypothesis are underway.

SERUM LIPIDOMIC PROFILING FOR SCREENING POTENTIAL BIOMARKERS OF HEPATOCELLULAR CARCINOMA BY ULTRAPERFORMANCE LIQUID CHROMATOGRAPHY–MASS SPECTROMETRY

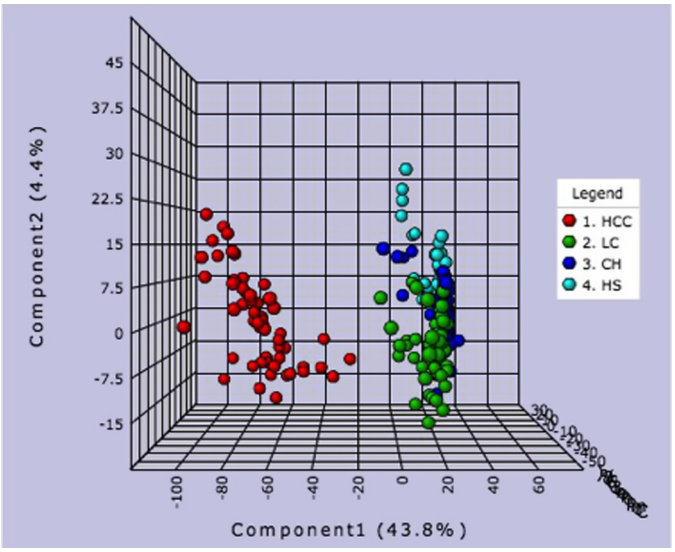
A.M. Passos-Castilho[1], V.M. Carvalho[2], K.H.M. Cardozo[2], L. Kikuchi[3], A. Chagas[3], J.R. Pinho[3], M.S. Gomes-Gouvêa[3], F. Malta[3], F.J. Carrilho[3], C.F.H. Granato[1,2]. *[1]Division of Infectious Diseases, Department of Medicine, Federal University of Sao Paulo, [2]Fleury SA Group, [3]Department of Gastroenterology, School of Medicine, University of Sao Paulo, Sao Paulo, Brazil*
E-mail: anampassos@gmail.com

Background and Aims: Hepatocellular carcinoma (HCC) is the fifth most common cancer worldwide and usually develops in patients with liver cirrhosis (LC). Biomarkers for HCC are limited. We explored the serum lipidome profiles of HCC to identify potential diagnostic biomarkers.

Methods: A total of 234 subjects were enrolled from 2011 to 2014. An ultraperformance liquid chromatography–mass spectrometry (UPLC-MS) lipidomic method was used to characterize serum profiles from HCC (n = 56), LC (n = 59), chronic hepatitis (CH) (n = 62), and healthy subjects (n = 57). Patients were diagnosed by laboratory and imaging evidence and all presented with hepatitis C virus-induced CH while healthy controls had normal liver function and no infectious diseases. Reversed-phased analysis was performed on a Waters ACQUITY IClass UPLC system coupled to a Waters Synapt-MS hidrid quadrupole-time of flight mass spectrometer in the positive ion electrospray mode with a mass scan range 200–1200 m/z for data acquisition in continuous mode. Data were processed with Progenesis software (Waters). The resulting multivariate data set was analyzed with MetaboAnalyst (TMIC) using supervised partial least-squares discriminate analysis (PLS-DA). Potential biomarkers were selected according to variable importance in the projection (VIP) and statistical significance was evaluated using Mann–Whitney test. The receiver operating characteristic (ROC) curve was performed to compare the accuracy of selected biomarkers and alpha-fetoprotein (AFP) levels in HCC diagnosis. To identify the potential biomarkers, the HMDB and LipidMaps databases were queried with the exact mass.

Results: The UPLC–MS-based serum lipidomic profile distinguished all HCC patients and provided more accurate diagnosis for LC patients than conventional AFP detection. HCC patients were discriminated from LC, CH and controls with 100% sensitivity and specificity. In comparison, AFP showed sensitivity and specificity of 18% and 98% for HCC diagnosis when the reference value was 200 ng/mL and 50% and 72%, respectively, in the range of 20 ng/mL. The 10 potential biomarkers comprised cardiolipins, glycerophospholipids and sphingolipids. Ganglioside GD3, an acidic glycosphingolipid involved in cell proliferation, differentiation and apoptosis, exhibited a significant increase in HCC and a decrease in LC and was proposed as an important indicator of HCC.

Conclusions: UPLC-MS lipid profiling proved to be an efficient and convenient tool for diagnosis and screening of HCC in a high-risk population.



O050

A NEW ALGORITHM FOR PREDICTING THE HEPATOCELLULAR CARCINOMA OCCURRENCE IN CIRRHOTIC PATIENTS

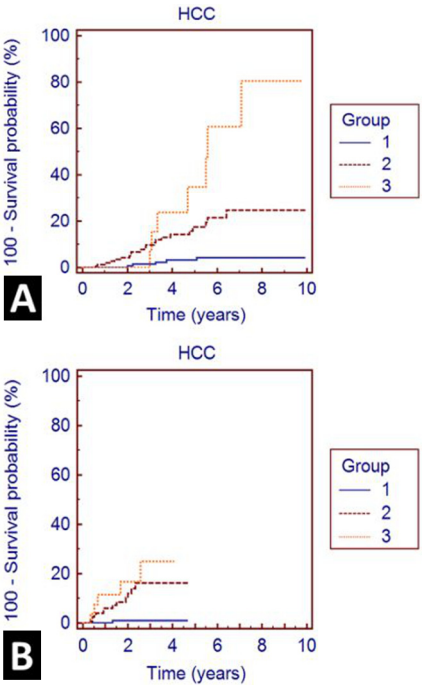
S. Bota[1], T. Purevsambuu[1], F. Hucke[1], T. Reiberger[1], A. Ferlitsch[1], H. Hofer[1], W. Sieghart[1], M. Peck-Radosavljevic[1]. *[1]Vienna HCC Study Group, Vienna Hepatic Hemodynamic Lab Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria*
E-mail: bota_simona1982@yahoo.com

Background and Aims: Guidelines recommend ultrasound every 6 months for HCC screening in cirrhotic patients. However, due to the large number of patients/limited resources some biomarkers for prioritizing patients for screening would be helpful. We aimed to develop an algorithm for predicting HCC incidence in a cohort of mixed etiologies of cirrhosis.

Methods: We retrospectively collected data of cirrhotic patients evaluated between January 2004 and January 2014. In the same session hepatovenous pressure gradient (HVPG) measurements, laboratory parameters and tumor markers (AFP) were determined. Patients with HCC at first presentation and those with a follow-up shorter than 90 days were excluded. HCC diagnosis was established by imaging/biopsy during follow-up.

Results: We identified 940 cirrhotic patients who were evaluated with HVPG and laboratory blood tests. We excluded 167 patients with HCC at first presentation and 93 with follow-up <90 days. The remaining patients were divided in 2 groups: training cohort (379 patients: 2004–2009) and validation cohort (301 patients: 2010-January 2014). The HCC incidence in the training and validation cohort was: 8.7% [median follow-up 3.75 years (0.25–9.9 years)] and 6.3% [median follow-up: 1.75 years (0.25–4.7 years)].
Univariate analysis in the training cohort showed that presence of clinically significant portal hypertension (p = 0.007), platelet count <100,000/mm^3 (p < 0.0001), AFP >10 ng/ml (p = 0.002), esophageal varices (p = 0.03), and age >50 years (p = 0.04) were associated

with HCC occurrence. The following factors were not associated with HCC occurrence: gender, liver cirrhosis etiology, presence of diabetes mellitus, HIV coinfection, BMI, Child–Pugh class, MELD score, presence/history of ascites, presence/history of hepatic encephalopathy, aminotransferases values, GGT, alkaline phosphatase, bilirubin, albumin.
In multivariate analysis, platelet count <100,000/mm^3 (OR = 4.36), age >50 years (OR = 2.46) and AFP >10 ng/ml (OR = 2.36) reached statistical significance.
Based on the odds ratio, the following points were assigned: platelet count <100,000/mm^3 – 2 points, age >50 years – 1 point, and AFP >10 ng/ml – 1 point.
The patients were classified in three groups: group 1 0–1 points, group 2 2–3 points and group 3 4 points.
The HCC incidence/year in the three groups in the training and validation cohorts was 0.6%, 3.2% and 9.2% ($p < 0.0001$) (Fig. 1A) and respectively 0.3%, 5.5% and 9.2% ($p < 0.0001$) (Fig. 1B).



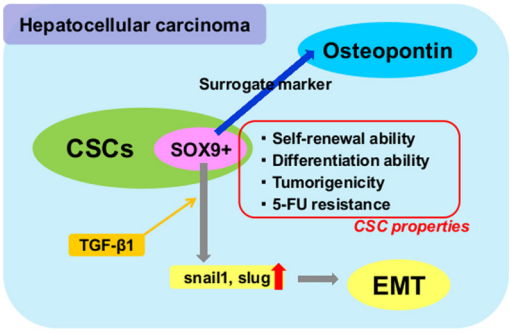
Conclusions: The proposed algorithm can identify the patients with very low, moderate and high risk of HCC, which could be used for more targeted screening approaches.

O051
SOX9 IS A NOVEL CANCER STEM CELL MARKER SURROGATED BY OSTEOPONTIN IN HUMAN HEPATOCELLULAR CARCINOMA

T. Kawai[1], K. Yasuchika[1], T. Ishii[2], H. Katayama[1], E.Y. Yoshitoshi[1], S. Ogiso[1], S. Kita[1], K. Yasuda[1], K. Fukumitsu[1], M. Mizumoto[1], E. Hatano[1], Y. Kawaguchi[3], S. Uemoto[1]. *[1]Department of Surgery, Kyoto University, Kyoto city, [2]Department of Surgery, Nishikobe Medical Center, Kobe city, [3]Department of Clinical Application, Center for iPS cell Research and Application (CiRA), Kyoto University, Kyoto city, Japan*
E-mail: u12323@kuhp.kyoto-u.ac.jp

Background and Aims: Cancer stem cells (CSCs) are receiving considerable attention as targets for cancer therapy. Although sex determining region Y-box 9 (SOX9) is known to be an important marker in normal liver development, the relationship between SOX9 and CSCs of hepatocellular carcinoma (HCC) is unclear. Here, we aimed to determine if SOX9 can use as a new CSC marker in HCC.

Methods: We examined SOX9 expression of consecutive 166 human primary HCC specimens and 11 extrahepatic HCC metastatic tissues using immunohistochemistry, and analyzed the serum osteopontin level of SOX9$^+$/SOX9$^-$ patients. We transfected the SOX9 promoter-driven enhanced green fluorescence protein gene into HCC cell lines, and investigated fluorescence-activated cell sorting (FACS)-isolated SOX9$^+$/SOX9$^-$ cells.
Results: SOX9$^+$ HCC patients had significantly poorer recurrence-free survival, stronger venous invasion, and higher serum osteopontin level than SOX9$^-$ patients. SOX9 expression was strongly correlated with osteopontin expression in both primary HCC and metastatic HCC regions. Additionally, co-expression of SOX9 and osteopontin were detected more frequently in metastatic HCC regions than in primary HCC regions. FACS-isolated single SOX9$^+$ cells showed the ability to self-renew and differentiate into SOX9$^-$ cells, while single SOX9$^-$ cells never produced SOX9$^+$ cells. SOX9$^+$ cells displayed significantly greater proliferation capacity, higher sphere forming ability, and stronger 5-fluorouracil resistance based on higher expression of multidrug-resistant protein 5 in vitro. Xenotransplantation into immunodeficiency mice revealed that SOX9$^+$ cells could reproduce themselves, differentiate into SOX9$^-$ cells, and generate larger tumors at a higher frequency in vivo. SOX9$^+$ cells also showed greater motility and higher expression of EMT-related genes than SOX9$^-$ cells. Moreover, SOX9$^+$ cells showed higher osteopontin expression than SOX9$^-$ cells, and this property was suppressed by SOX9 knockdown via RNA interference.



Conclusions: SOX9$^+$ cells possess cancer stem cell properties correlated with EMT in human HCC. Osteopontin should be expected the clinical application as a useful surrogate marker of SOX9.

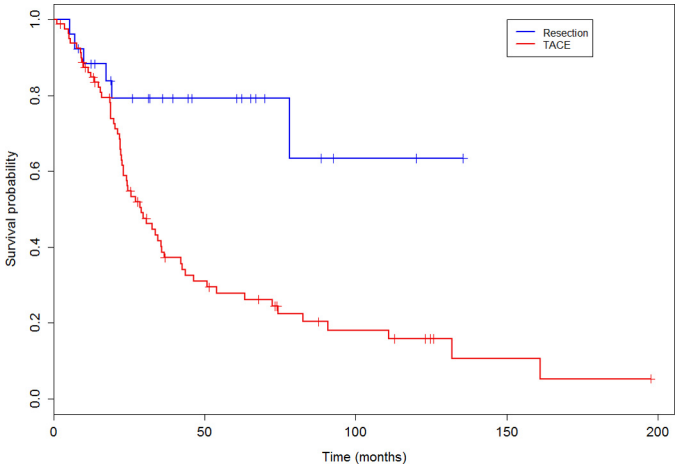
ASSESSMENT OF THE HONG KONG LIVER CANCER STAGING SYSTEM IN EUROPE

P. Kolly[1,2], H.L. Reeves[3,4], B. Sangro[5], M. Knöpfli[2], D. Candinas[2], J.-F. Dufour[1,2]. *[1]Hepatology, Department of Clinical Research, University of Bern, [2]University Clinic for Visceral Surgery and Medicine, Inselspital Bern, Bern, Switzerland; [3]The Northern Institute for Cancer Research, Newcastle University, Newcastle-upon-Tyne, [4]The Liver Unit, Freeman Hospital, Newcastle-upon-Tyne Hospitals NHS Foundation Trust, United Kingdom; [5]Liver Unit, Clínica Universidad de Navarra, Pamplona, Spain*
E-mail: philippe.kolly@students.unibe.ch

Background and Aims: European guidelines have endorsed the Barcelona Clinic Liver Cancer (BCLC) staging system. The aim of this study was to assess the performance of the recently developed Hong Kong Liver Cancer (HKLC) classification as a staging system for hepatocellular carcinoma (HCC) in Europe.
Methods: We used a pooled set of 1671 HCC patients combining three prospective European cohorts. Discrimination ability between the nine substages and five stages of the HKLC classification system was assessed. Cox regressions were used to evaluate the predictive

power of the HKLC and BCLC staging systems on overall survival (OS). The treatment algorithms were compared for patients with intermediate HCC, assessing the OS between surgical resection and trans-arterial chemoembolisation (TACE).
Results: The HKLC classification in nine substages shows suboptimal discrimination between the staging groups. The classification in five stages shows better discrimination between groups, with all stages being statistically significantly different. However, the BCLC classification performs better than the HKLC classification in the ability to predict OS. Comparing treatment options for patients with intermediate HCC (Figure), the survival of patients treated with surgical resection was better than the survival of patients treated with TACE (5-year survival probability: 79% vs 28%, p = 0.001).
Conclusions: The BCLC staging system performs better for European patients than the HKLC staging system. The superior survival of patients with intermediate HCC undergoing surgical resection is remarkable. This work highlights the need to identify criteria for selecting patients with intermediate HCC who benefit from surgical resection.



O053
GALNT14 GENOTYPE INDEPENDENTLY PREDICTS COMPLETE THERAPEUTIC RESPONSES OF TRANSCATHETER ARTERIAL CHEMOEMBOLIZATION IN PATIENTS WITH UNRESECTABLE HEPATOCELLULAR CARCINOMA

C.-T. Yeh[1], k.-H. Liang[1], C.-L. Lin[2], C.-C. Lin[1]. [1]*Liver Research Center, Chang Gung Memorial Hospital, Taoyuan,* [2]*Liver Research Center, Kee-Lung Chang Gung Mem Hosp, Kee-Lung, Taiwan*
E-mail: chautingy@gmail.com

Background and Aims: Recent prospective study indicated that genotype of polypeptide N-acetylgalactosaminyltransferase 14 (GALNT14) predicted chemotherapy responses as well as overall survivals in patients with advanced hepatocellular carcinoma (HCC). In the present study, we examined the predictive value of this marker in HCC patients receiving transcatheter arterial chemoembolization (TACE). The molecular mechanisms responsible for such correlations were also explored.
Methods: 327 HCC patients receiving TACE were included. Complete response was defined as absence of viable HCC tissues after TACE under computed tomography examination for at least 3 months. The GALNT14 genotype was determined by PCR – sequencing method. The predictive value was assessed by Cox proportional hazard model through calculation of time-to-complete response. 44 paired of cancerous and non-cancerous tissues derived from TACE-treated patients (previously receiving surgical resection) were submitted for phenotypic examination of GALNT14 expression levels.
Results: Of 327 TACE-treated HCC patients, 95 (29.0%) were rs9679162 "TT" and 232 (70.9%) were "non-TT" ("GG" + "GT") genotype. Univariate and multivariate Cox proportional hazard analysis including all clinical and biochemical factors showed that only previous ablation therapy (P = 0.017) and GALN14 "TT" genotype (P = 0.004) independently predicted favorable (shorter) time-to-complete therapeutic responses. Examination of the HCC tissues derived from TACE-treated patients showed that "TT" genotype was associated with a lower GALNT14 expression level, a higher cancerous/non-cancerous ratio of GALNT14 levels and a lower cancerous/non-cancerous ratio of cFLIP-S levels. Mass spectrum analysis showed that O-glycosylation of DR4/5 drastically increased in the cancerous tissue of "TT" genotype, compatible with a pro-apoptotic phenotype.
Conclusions: GALNT14 genotype independently predicted complete responses of TACE in HCC patients. Molecular analysis of the HCC tissues revealed that the GALNT14 "TT" genotype was associated with a pro-apoptotic phenotype.

O054
TM6SF2-T AND PNPLA3-G GENETIC VARIANTS CO-MODULATE THE RISK OF HEPATOCELLULAR CARCINOMA IN CAUCASIAN PATIENTS WITH ALCOHOLIC CIRRHOSIS. INTER-COHORT VALIDATION IN 1068 PATIENTS

P. Nahon[1], Q. Cao[2], E. Guyot[3], P. Rufat[4], A. Sutton[3], N. Ganne-Carrié[1], M. Ziol[5], T. Gustot[6], E. Quertinmont[6], J. Devière[6], D. Degré[6], J. Schreiber[6], A. Labkriman[6], N. Charnaux[3], C. Moreno[6], J.-C. Trinchet[1], D. Franchimont[6], J. Zucman-Rossi[2], E. Trepo[6].

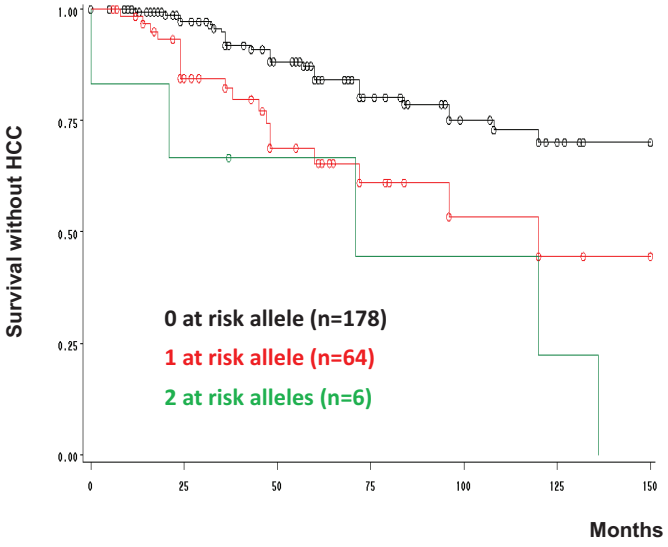
E-mail: pierre.nahon@jvr.aphp.fr

Background and Aims: A genetic variant, TM6SF2 (rs58542926) C>T, involved in lipid metabolism, has been recently linked to liver damage in patients with NAFLD. The aims of this study were (1) to assess the potential impact of TM6SF2 (rs58542926) C>T on alcoholic carcinogenesis, and (2) to evaluate its contribution to HCC risk stratification in combination with PNPLA3 (rs738409) C>G.
Methods: Three distinct cohorts were genotyped for both SNPs. The first one (Belgium, cohort 1/ALD) was a case-control cohort including alcoholic cirrhotics without (n = 484) and with HCC (n = 71). The second cohort (France, cohort 2/ALD) was a prospective cohort of alcoholic cirrhotics (n = 249), enrolled between 1997 and 2007, currently followed-up and screened for HCC (incident cases during 68 months follow-up, n = 51, 21%). The third cohort (France, cohort 3/HCV) was similar to the previous one and included 267 patients with HCV-related cirrhosis in whom 84 (31%) HCC were detected during 102 months of follow-up.
Results: In the case-control cohort 1/ALD, patients with HCC were highly enriched in TM6SF2-T risk allele [20 (28.2%) vs. 70 (14.5%), $P = 0.0006$]. Using a multivariable model (including age, gender, BMI and diabetes), this variant was independently associated with the presence of HCC [OR = 2.5 (1.4–4.3), $P = 0.002$]. In multivariable analysis, the risk for HCC increased in carriers of more than one PNPLA3-G and/or TM6SF2-T risk allele compare to those without (OR = 2.8 [1.3–5.7], P = 0.007). In the prospective cohort 2/ALD, patients with the TM6SF2-T allele had a higher risk of HCC occurrence (HR = 2.49 [1.5–4.5], P = 0.003). When the population was stratified into three groups according to the presence of none (n = 179), at least one (n = 64) or two (n = 6) PNPLA3-G and/or TM6SF2-T risk alleles, the number of HCC cases gradually increased [27 (15.1%) vs. 19 (29.7%) vs. 5 (83.3%) respectively, $P < 0.0001$]. This genotypic combination was an independent risk factor associated with HCC onset (HR = 2.31 [1.5–3.4], $P < 0.0001$). Conversely, in the

prospective cohort 3/HCV, TM6SF2-T allele was not significantly associated with HCC.

Conclusions: TM6SF2 (rs58542926) C>T is associated with HCC occurrence in patients with alcoholic cirrhosis but not with HCV infection. The risk of HCC increases in parallel with the number of PNPLA3-G and/or TM6SF2-T mutant alleles.



HR=2.31 [1.53-3.47], *P*<0.0001

PUSHING THE LIMITS FOR TACE: SELECTION FOR TRANSARTERIAL CHEMOEMBOLISATION TREATMENT (STATE) SCORE IDENTIFIES HCC PATIENTS AT BCLC STAGE C SUITABLE FOR TACE

F. Hucke[1], M. Pinter[1], I. Graziadei[2], S. Bota[1], W. Vogel[2], C.J. Müller[1], F. Wanek[3], M. Trauner[1], M. Peck-Radosavljevic[1], W. Sieghart[1].
[1]Department of Gastroenterology/Hepatology, Medical University of Vienna, Vienna, [2]Department of Gastroenterology/Hepatology, Medical University of Innsbruck, Innsbruck, [3]Department of Interventional Radiology, Medical University of Vienna, Vienna, Austria
E-mail: florian.hucke@meduniwien.ac.at

Background and Aims: Recently, we developed the STATE score, which guides the decision for the first treatment with transarterial chemoembolization (TACE) in patients with intermediate stage hepatocellular carcinoma (HCC).

Here, we investigated the prognostic impact of the STATE-score in patients with advanced HCC (BCLC stage C).

Methods: 80 patients diagnosed with HCC at BCLC-stage C and treated with transarterial treatments between 1/2002 and 12/2011 at the Medical Universities of Vienna (training cohort, n = 61) and Innsbruck (validation cohort, n = 19) were included. Patients with major branch portal vein thrombosis were excluded.

The STATE-score is calculated by using the serum-albumin level (mg/dl), which is reduced by 12 points each, if the tumor load exceeds the up-to-7 criteria and/or CRP-levels are ≥1 mg/dl (maximum reduction: 24 points).

The up-to-7 criteria (in vs. out) were used to assess intrahepatic tumor load only, while macrovascular invasion, lymph-node and distant metastases were separately included into statistical analysis.

Results: The STATE score discriminated two groups [<18 (n = 36) vs. ≥18 points (n = 44)] with different prognosis (median OS: 5.2 vs. 14.3 months, p = 0.001): and remained a valid predictor of OS independent of Child–Pugh score, ECOG-PS, macrovascular invasion, lymph-node, distant metastasis and subsequent sorafenib treatment.

These results were confirmed upon separate analysis of patients treated in the training and the validation cohort.

Conclusions: The STATE-score identifies patients with advanced HCC who may be suitable for TACE.

Viral hepatitis C: Clinical

LEDIPASVIR/SOFOSBUVIR TREATMENT RESULTS IN HIGH SVR RATES IN PATIENTS WITH CHRONIC GENOTYPE 4 AND 5 HCV INFECTION

A. Abergel[1], V. Loustaud-Ratti[2], S. Metivier[3], D. Jiang[4], K. Kersey[4], S.J. Knox[4], P.S. Pang[4], D. Samuel[5], T. Asselah[6]. *[1]Médecine digestive, CHU ESTAING, Université d'Auvergne, Clermont Ferrand, [2]Service d'Hépatogastroentérologie, CHU Limoges, Inserm UMR 1092, Limoges, [3]Service d'Hépatogastroentérologie, CHU Purpan, Toulouse, France; [4]Gilead Sciences, Inc., Foster City, United States; [5]Centre Hepatobiliaire, Hôpital Paul Brousse, Université Paris Sud, Villejuif, [6]Hepatology Department, University Paris Diderot and INSERM U773, Beaujon Hospital, Clichy, France*
E-mail: kathryn.kersey@gilead.com

Background and Aims: Hepatitis C virus (HCV) genotype (GT) 4 is estimated to account for 8% to 13% and GT5 for ~1% of all chronic HCV infections globally (Gower et al. 2014 J Hepatol;61:S45-S57; Messina et al. 2014 Hepatology doi: 10.1002/hep.27259). GT4 HCV is found primarily in the Middle East and Sub-Saharan Africa and GT5 HCV primarily in Southern Africa. Clinical studies evaluating the treatment outcome with new direct acting antiviral agents in GT4 and especially GT5 HCV infection have been limited. The aim of the current ongoing study is to assess the safety, tolerability and efficacy of ledipasvir/sofosbuvir (LDV/SOF) in patients with chronic GT4 or GT5 HCV infection.

Methods: Treatment-naïve and treatment-experienced patients with chronic GT4 or GT5 HCV infection were enrolled at 5 sites in France to receive 12 weeks of LDV/SOF (90 mg/400 mg daily). Up to 50% of patients could have compensated cirrhosis at screening. The primary endpoint is the SVR12 rate with SVR4 as a secondary endpoint.

Results: 85 patients were enrolled: 44 patients had GT4 and 41 patients had GT5 chronic HCV infection. Overall, GT4 patients were 64% male, mean age 51 years, 50% were treatment-experienced, 18% had IL28B-CC genotype, 23% had compensated cirrhosis, and 70% had HCV RNA ≥800,000 IU/mL at baseline. Overall, GT5 patients were 51% male, mean age 63 years, 49% were treatment-experienced, 46% had IL28B CC genotype, 22% had compensated cirrhosis, and 85% had HCV RNA ≥800,000 IU/mL at baseline.

SVR4 rates are shown in the Table. Complete SVR12 data will be presented.

Table: SVR4 rates following LDV/SOF in GT4 and GT5 HCV infection

	SVR4 rate, % (n/N)	
	GT4	GT5
Overall	93 (41/44)	93 (38/41)[a]
Treatment naive	95 (21/22)	90 (19/21)[a]
Treatment experienced	91 (20/22)	95 (19/20)
Cirrhosis	100 (10/10)	89 (8/9)
No cirrhosis	91 (31/34)	94 (30/32)

[a] 1 patient lost to follow-up.

The most common adverse events (>10% of patients) were asthenia, headache, and fatigue. Most AEs were mild or moderate in severity and none resulted in treatment discontinuation. One patient

experienced an SAE of worsening of pre-existing depression which was considered unrelated to study drug. There were no grade 3 or 4 clinical laboratory abnormalities.
Conclusions: A ribavirin- and interferon-free regimen of ledipasvir/sofosbuvir administered in a fixed-dose combination tablet once daily for 12 weeks resulted in high SVR4 rates of 93% in GT4 and in GT5 HCV-infected treatment-naïve and treatment-experienced patients with or without cirrhosis. This regimen was well tolerated and represents a simple, highly effective all-oral treatment option which could facilitate more widespread treatment of patients.

O057

LONG-TERM FOLLOW-UP OF TREATMENT-EMERGENT RESISTANCE-ASSOCIATED VARIANTS IN NS3, NS5A AND NS5B WITH PARITAPREVIR/R-, OMBITASVIR- AND DASABUVIR-BASED REGIMENS

P. Krishnan[1], R. Tripathi[1], G. Schnell[1], T. Reisch[1], J. Beyer[1], T. Dekhtyar[1], M. Irvin[1], W. Xie[1], L. Larsen[1], T. Podsadecki[1], T. Pilot-Matias[1], C. Collins[1]. [1]*AbbVie Inc., North Chicago, United States*
E-mail: preethi.krishnan@abbvie.com

Background and Aims: Approximately 3000 HCV genotype (GT) 1-infected patients have been treated with paritaprevir (formerly ABT-450, identified by AbbVie and Enanta)/ritonavir (designated paritaprevir/r), ombitasvir (formerly ABT-267), and/or dasabuvir (formerly ABT-333) +/− ribavirin (RBV) in three Phase 2 (M12–746, M12–998 and AVIATOR) and six Phase 3 (Sapphire-I, Sapphire-II, Pearl-II, Pearl-III, Pearl-IV, and Turquoise-II) clinical trials. Patients with treatment-emergent resistance-associated variants (RAVs) in these studies are being followed to post-treatment week (PTW) 48 for evaluation of the persistence of RAVs.
Methods: The persistence of treatment-emergent RAVs in HCV NS3, NS5A and NS5B was assessed in patients who did not achieve SVR in Phase 2 and 3 clinical trials, with available data through at least PTW24, by population and clonal sequencing.
Results: In patients who experienced virologic failure in the Phase 2 and 3 clinical trials, the predominant RAVs in GT1a were R155K and D168V in NS3, M28T and Q30R in NS5A, and S556G in NS5B. For paritaprevir, RAVs (any position) in NS3 persisted at detectable levels through at least PTW24 in 45% (31/69) of the patients, and through PTW48 in 7% (4/55) of patients. NS3 R155K remained detectable in 66% (8/12) and 25% (2/8) of the patients through PTW24 and 48, respectively; and D168 variants remained detectable in 37% (21/56) and 2% (1/53) of the patients through PTW24 and 48, respectively. For ombitasvir, RAVs in NS5A including M28T and Q30R persisted at detectable levels through PTW24 in 98% (67/68) of the patients, and through PTW48 in 96% (50/52) of the patients. For dasabuvir, RAVs in NS5B persisted at detectable levels through at least PTW24 in 75% (30/40) of the patients, and through PTW48 in 61% (22/36) of the patients. NS5B S556G persisted in 89% (24/27) and 79% (19/24) of patients through PTW24 and 48, respectively. Minor variants G558R and D559G/N in NS5B were not detectable at PTW24 and 48. Due to very high SVR rates in GT1b, trends in persistence of treatment-emergent RAVs could not be evaluated.
Conclusions: Studies to evaluate persistence of treatment-emergent RAVs in paritaprevir/r, ombitasvir and dasabuvir-based regimens are ongoing. In GT1a, the proportion of subjects with RAVs in NS3 declined over time, while most subjects with RAVs in NS5A and NS5B had these variants detectable through Post-Treatment Week 48.

O058

INCREASED CANCER RATES IN PATIENTS WITH CHRONIC HEPATITIS C: AN ANALYSIS OF THE CANCER REGISTRY IN A LARGE U.S. HEALTH MAINTENANCE ORGANIZATION

A.H. Nyberg[1], J.W. Chung[2], J.M. Shi[3], T.C. Cheetham[3], K.M. Chiang[4], R. Haque[5], Z.M. Younossi[6], L.M. Nyberg[1]. [1]*Gastroenterology/Hepatology, Kaiser Permanente, San Diego,* [2]*Kaiser Permanete, Research and Evaluation,* [3]*Research and Evaluation, Kaiser Permanente, Pasadena,* [4]*Pharmacy Analytical Services, Kaiser Permanente, Downey,* [5]*Research and Evaluatuion, Kaiser Permanente, Pasadena,* [6]*Center for Liver Diseases, Inova Fairfax Hospital, Falls Church, United States*
E-mail: Anders.H.Nyberg@kp.org

Background and Aims: Hepatitis C virus (HCV) is an oncogenic virus, and an increased risk of malignancy in HCV has previously been reported. Cancer types associated with HCV include non-Hodgkin's lymphoma, renal and prostate cancers; as well as liver cancer. The aim of this study was to describe cancer rates in our cohort of HCV patients compared to cancer rates in the non-HCV population.
Methods: This is a retrospective study at Kaiser Permanente Southern California (KPSC), a large health maintenance organization with 3.5–4 million members. The KPSC cancer registry is an accredited program maintaining a complete profile of all cancer diagnoses for all KP members. In this study, we recorded all cancer diagnoses in patients ≥18 years of age with or without HCV during 2008–2012.
Results: From 2008 to 2012, 145,210 patient years were included in the HCV cohort, and 13,948,826 patient years were included in the non HCV cohort. Mean age at cancer diagnosis in the HCV cohort was 61.8 years, in the non-HCV cohort, 63.5 years. In the HCV cohort there were 2,213 cancer diagnoses (1524/100000) during the 5 year period and 1,654 cancer diagnoses when liver cancer was excluded (1139/100000). In the non HCV cohort there were 84,419 cancer diagnoses (605/100000) during the same 5 year period and 83,795 (601/100000) when liver cancer was excluded. The rate ratios between the HCV and non HCV cohorts for the total number of cancer cases including and excluding liver cancer are shown in Table 1.
Conclusions: In our cohort of Hepatitis C infected patients, cancer rates were significantly increased compared to the non-HCV cohort. This suggests that another extrahepatic manifestation of HCV may be an increased risk of cancer.

Table 1.

Cancer diagnosis 2008–2012	Rate			
Site	HCV members N = 145,210	Non HCV members N = 13,948,826	Rate ratio, HCV vs Non HCV	p-value
Head & neck	47.5	16.7	2.85 (2.24, 3.62)	<0.0001
Esophagus	10.3	4.4	2.34 (1.40, 3.91)	0.0011
Stomach	28.2	9.1	3.10 (2.27, 4.23)	<0.0001
Colon/rectum	106.7	55.2	1.93 (1.65, 2.27)	<0.0001
Liver	385.0	4.5	86.05 (76.77, 96.46)	<0.0001
Pancreas	34.4	12.6	2.74 (2.07, 3.63)	<0.0001
Lung/bronchus	111.6	46.8	2.38 (2.04, 2.79)	<0.0001
Prostate	174.9	88.4	1.98 (1.75, 2.24)	<0.0001
Renal	66.8	20.4	3.27 (2.67, 4.00)	<0.0001
Non-Hodgkin's lymphoma	80.6	22.2	3.63 (3.02, 4.37)	<0.0001
Myeloma	22.7	7.8	2.93 (2.07, 4.14)	<0.0001
All sites, incl liver cancer	1524	605	2.52 (2.41, 2.63)	<0.0001
All sites, excl liver cancer	1139	601	1.90 (1.81, 1.99)	<0.0001

O059

LONG-TERM PERSISTENCE OF HCV NS5A VARIANTS AFTER TREATMENT WITH NS5A INHIBITOR LEDIPASVIR

H. Dvory-Sobol[1], D. Wyles[2], W. Ouyang[1], K. Chodavarapu[1], J. McNally[1], W. Cheng[3], S. Shafran[4], A. Mangia[5], C. Schwabe[6], M.D. Miller[1], H. Mo[1]. [1]*Gilead Sciences, Foster City, CA,* [2]*University of California San Diego, CA, USA, United States;* [3]*Royal Perth Hospital, Western Australia, Australia;* [4]*University of Alberta, Edmonton, Canada;* [5]*Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Italy;* [6]*Auckland Clinical Studies Ltd, Auckland, Australia*
E-mail: Hadas.Dvory-Sobol@Gilead.com

Background and Aims: Ledipasvir (LDV) is a hepatitis C virus (HCV) NS5A inhibitor with potent antiviral activity against HCV genotype 1a and 1b. The aim of this study is to evaluate the persistence of resistance-associated variants (RAVs) in subjects who did not achieve SVR in previous Gilead-sponsored HCV clinical studies after receiving LDV without SOF who were then enrolled in a 3-year follow-up registry study.
Methods: Specimens from subjects treated with LDV in Gilead studies GS-US-248-0120, GS-US-248-0121, GS-US-248-0131, GS-US-248-0132, GS-US-256-0124 and GS-US-256-0148, were analyzed to determine their NS5A RAVs at baseline (BL) in the parent study (n = 84), post-BL in the parent study (n = 78), BL in the registry study (n = 80), and follow-up (FU) visits weeks 12 (n = 66), 24 (n = 66), 36 (n = 19), 48 (n = 80) and 96 (n = 65) in the registry study. Population sequencing was used for majority of samples at BL and Post-BL of the parent study, and deep sequencing for all samples in the registry study. If RAVs were observed, samples from subsequent timepoints were deep sequenced until RAVs were no longer detected (1% detection threshold).
Results: Of the 84 subjects with sequencing at BL in the parent study, 12 had NS5A RAVs at BL that persisted through FU96 except A92T that wasn't observed at Post-BL. NS5A RAVs were detected in 95% of subjects at virologic failure in the parent study and in 97%, 96.5%, 100%, 100%, 96%, and 94.0% of the subjects at BL, FU12, FU24, FU36, FU48 and FU96 visits in the registry study, respectively. At BL in the registry study subjects had up to 9 NS5A RAVs compared to FU96 when most subjects had <5 RAVs except 2 subjects with 7 RAVs. Except L31M, all variants: K24N/R, M28T/A, Q30E/H/K/R, L31V, H58D and Y93H/N/C were detected in fewer subjects at FU96 than BL. While the frequencies of some variants declined slowly over time in some subjects, at FU96, 51 of 54 (94.4%, 48 GT 1a and 3 GT 1b) subjects had NS5A RAVs detected by deep sequencing. For the 3 GT 1b subjects, the observed variants were L31I/M/V and Y93H/T and had frequencies up to 99.7% of the viral population. In GT1a subjects, most subjects had Q30R, L31M and H58D. Highest frequencies of variants were seen for K24N (73.2%), K24G (63.0%), H58D (57.2%), Y93C (56.9%), L31M (48.3%), Q30R (45.1%), Q30H (33.8%) and Y92N (27.6%).
Conclusions: NS5A variants can persist for >96 weeks post-treatment in subjects who relapse to regimens containing NS5A inhibitor suggesting high fitness of the NS5A RAVs.

O060

MIR-17/92 EXPRESSION PATTERN: A MOLECULAR SIGNATURE OF HCV-RELATED MIXED CRYOGLOBULINEMIA

A. Piluso[1], L. Gragnani[1], A. Genovesi[1], M. Monti[1], T. Urraro[1], A.L. Zignego[1]. [1]*Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy*
E-mail: alepilu80@libero.it

Background and Aims: HCV chronic infection is closely related to the development of lymphoproliferative disorders (LPDs), mainly mixed cryoglobulinemia (MC) and some subtypes of B-cell lymphoma. The pathogenesis of HCV-LPDs is still largely unknown. Modification of the expression levels of specific microRNAs (miRNAs) has been associated with different autoimmune and/or LPDs. In particular, the endogenous miR-17/92 cluster is very often amplified in cancer and in autoimmunity. Scarce data exist about the modifications of miRNA expression levels in HCV-related LPDs.
The aim of this study was to evaluate the modifications of the expression levels of the miR-17/92 cluster in a large population of HCV patients with and without MC and the effects of viral eradication.
Methods: The expression levels of miR-17/92 cluster were evaluated by Real Time PCR in PBMC samples from 79 HCV patients: 34 without LPD [HCV] and 45 with MC [HCV-MC]; among the 45 MC patients were included 20 patients who experienced a sustained virological and clinical response after antiviral treatment and of which pre and post therapy sampling was available. Relative expression levels of all the members of the miR-17/92 cluster (namely, miR-17, miR-18a, miR-19a, miR-19b, miR-20a and miR-92a) were evaluated with the 2-ΔΔCt method, using miR-let-7d as housekeeping.
Results: All the members of the miR-17/92 cluster were highly upregulated in PBMCs from HCV-MC patients ($p < 0.001$) when compared to HCV group. A restoration of miRNAs levels was observed in the samples taken after viral eradication (miR-17, miR-18a, miR-19a, miR-19b, miR-20a, $p < 0.001$ and miR-92a, $p < 0.05$, when compared with pre-treatment levels). Regarding miR-20a, the levels in samples taken after HCV eradication continued to be significantly higher than in controls (HCV patients) ($p < 0.05$), in spite of the sudden fall observed after therapy.
Conclusions: This study, for the first time, shows that the expression pattern of miRNA-17/92 cluster is modified in PBMC from HCV patients with MC. The sudden restoration of these values of expression in patients achieving a sustained virological and clinical response after antiviral treatment, strongly suggests that miR-17/92 cluster plays a key role in the pathogenesis of MC.

O061

INCIDENCE OF HEPATITIS C REINFECTION FOLLOWING SUSTAINED VIROLOGICAL RESPONSE – A SEVEN YEAR FOLLOW-UP OF SCANDINAVIAN PATIENTS INFECTED THROUGH INJECTING DRUG USE

H. Midgard[1], B. Bjøro[2], O. Dalgard[3]. [1]*Akershus University Hospital, University of Oslo,* [2]*Section for Gastroenterology, Department of Transplantation Medicine, Oslo University Hospital,* [3]*Department of Infectious Diseases, Akershus University Hospital, Oslo, Norway*
E-mail: havardmi@medisin.uio.no

Background and Aims: Access to hepatitis C (HCV) treatment among people who inject drugs (PWID) remains limited and is often withheld based on the perceived risk of reinfection following treatment. No prospective study has yet given any robust estimate of this risk, an issue that will become increasingly important in the interferon-free era. The aim of this study was therefore to assess the long-term incidence of HCV reinfection in PWID following sustained virological response (SVR).
Methods: In 2004–2005 we performed a multicentre treatment study comprising 428 monoinfected HCV genotype 2 or 3 patients in the Scandinavian countries Norway, Sweden and Denmark (the North-C trial). The overall SVR rate was 76% and two thirds were PWID who had all been abstinent from drug use at least six months prior to treatment. This follow-up study was performed in 2012–14 and all Norwegian patients (22 study sites) who had obtained SVR (n = 161) were eligible for participation. Clinical, laboratory and behavioural data were collected and the incidence of HCV reinfection was calculated using person-time techniques.
Results: Follow-up data were available in 137/161 (85%) individuals (60% male, median age 44 years) with a median follow-up time of 7.1 years (IQR 1.5). Of 92 (67%) individuals who had acquired HCV infection through injecting drug use [follow-up time 610 person-years (PY)], 36 (40%) had relapsed to injecting behaviour after treatment (follow-up time 232 PY). Recurrence of HCV RNA

was identified in 12 patients and 11 of those cases occurred in individuals who had relapsed to injecting drug use. The incidence of reinfection was 1.8/100 PY (95% CI 1.0–3.2) among individuals with injecting drug use prior to treatment, 4.7/100 PY (95% CI 2.7–8.4) among those who had relapsed to injecting behaviour during follow-up and 0.32/100 PY (95% CI 0.04–2.2) among those with no history of injecting drug use. In multivariate regression analysis, low education level (OR 7.3, 95% CI 1.8–29.7; p = 0.006) was the only independent baseline predictor for HCV reinfection.

Conclusions: In this seven year follow-up study mainly comprising PWID who had been abstinent from drug use at least six months prior to HCV treatment, we demonstrate frequent relapse to injecting drug use but still low to moderate long-term incidence of HCV reinfection (1.8/100 PY). Our findings are in line with estimates from previous smaller studies and should be addressed when providing HCV care for PWID.

O062

FACTORS ASSOCIATED WITH SPONTANEOUS CLEARANCE OF CHRONIC HEPATITIS C VIRUS INFECTION: A RETROSPECTIVE CASE CONTROL STUDY

N. Bulteel[1], P. Partha Sarathy[2], E. Forrest[3], H. Innes[4], P. Mills[5], H. Valerio[4,6], A. Stanley[3], R.N. Gunson[7], C. Aitken[7], J. Morris[8], S.T. Barclay[3]. *[1]Centre for Virus Research, MRC – University of Glasgow, [2]Medical School, University of Glasgow, [3]The Walton Liver Clinic, Glasgow Royal Infirmary, [4]School of Health and Life Sciences, Glasgow Caledonian University, [5]Department of Hepatology, Gartnavel General Hospital, [6]Blood-borne Viruses and Sexually Transmitted Infections Section, Health Protection Scotland, [7]West of Scotland Specialist Virology Centre, Glasgow Royal Infirmary, [8]Department of Gastroenterology, Southern General Hospital, Glasgow, United Kingdom*

E-mail: Naomi.Bulteel@glasgow.ac.uk

Background and Aims: Chronic HCV infection (CHC) develops in ~75% of people who acquire HCV, and is defined as infection persisting beyond six months. Spontaneous clearance of CHC is rare and poorly characterised. We conducted a retrospective case control study of patients attending centres in Glasgow to identify factors associated with spontaneous clearance of CHC.

Methods: Data were obtained from the West of Scotland specialist virus laboratories on HCV testing between 1994 and 2013. Patients with ≥2 sequential RNA positive samples at least 6 months apart, followed by at least one negative HCV RNA (potential spontaneous clearance cohort), were identified in addition to patients with ≥2 positive samples at least 6 months apart with no subsequent negative samples (chronic infection cohort). Both cohorts were linked to the Scottish Hepatitis C database to exclude treated patients and obtain relevant patient data. A control group was randomly selected from the chronic infection cohort with a frequency of 4 per spontaneous clearer. Case notes were reviewed to verify the clinical course. Categorical variables were compared using χ^2. Continuous variables were analysed using the exact Wilcoxon Mann–Whitney test. P values are 2-sided, and values of <0.05 were considered significant.

Results: 25113 HCV RNA positive samples, relating to 10318 patients were identified. 116 patients, not linked as treated, had 2 sequential positive results followed by a negative. 66 patients were excluded following case note review leaving 50 patients of interest, contributing 241 person years follow up. 2518 untreated, chronically infected patients were identified, contributing 13766 person years follow up. 200 control patients were randomly selected from this cohort. Table 1 summarises demographic and clinical characteristics of the study populations. Spontaneous clearance of CHC was associated with female gender, HBsAg positivity, younger age at infection and lower HCV RNA. Spontaneous clearance was negatively associated with current IDU. The overall incidence rate of spontaneous clearance of CHC was 0.36 per 100 person years follow up, occurring after a median 49.5 months of infection.

Table 1. Main demographic and clinical patient characteristics

	Late spontaneous clearance (n = 50)	Chronically infected (n = 200)	P value
Male sex [n (%)]	19 (38)	129 (64.5)	**0.001**
Median age [years (IQR)]	41 (37–48)	43 (38–49)	0.36

Unknown	12 (24)	62 (31)	
Median duration of infection [months (IQR)]	49.5 (30.5–81.25)	50 (19–101.5)	0.94
HCV VL (IU/ml)			**<0.001**
Median	1000 †	341,142	
Interquartile range	1000–375,792	59,496–1,517,864	

† Data on HCV VL only available for 20 patients.

Conclusions: This is the largest cohort of patients with spontaneous clearance of CHC studied to date. Our data suggest that clearance occurs rarely in CHC but can occur after a prolonged duration, and is associated with female sex, HBV co-infection, younger age at infection and low HCV RNA titres.

O063

HCV REINFECTION CASES IN PHASE 3 STUDIES OF SOFOSBUVIR

E. Svarovskaia[1], R. Martin[1], K. Chodavarapu Chodavarapu[1], C. Hedskog Hedskog[1], D. Brainard[1], M.D. Miller[1], H. Mo[1]. *[1]Gilead Sciences, Foster City, United States*

E-mail: jenny.svarovskaia@gilead.com

Background and Aims: Relapse accounted for all virologic failures among treatment-adherent patients in the ledipasvir/sofosbuvir (LDV/SOF) and SOF Phase 3 clinical development program with most of relapse cases occurring 4–12 weeks post-treatment. It has been shown that SVR12 is an appropriate time point for the reliable assessment of a durable treatment response to SOF-containing regimens. However, in very rare cases, patients became positive again for HCV RNA after week 12 post-treatment. In this study, relapse cases that occurred after week 12 post-treatment in the phase 3 SOF studies were investigated for possible HCV reinfection.

Methods: Sequencing analysis of the NS5B gene was performed from patients who had relapse HCV after week 12 post-treatment in NEUTRINO, FISSION, POSITRON, FUSION, VALENCE, PHOTON-1, PHOTON-2 and GS-US-334-0118 SOF studies. Maximum likelihood

phylogenetic trees were constructed for baseline and relapse time points to investigate the genetic distance of these HCV samples. Longitudinal samples from patients with viral relapse prior to week 12 and then subsequent follow-up samples were used as a control for viral genetic drift over the same time period.
Results: In the 8 SOF studies, of 1154 patients who achieved SVR12, 1142 also had SVR24. However, there were 12 patients who achieved SVR12, but did not achieve SVR24 and had available samples for testing. Of 12 patients, samples from 10 patients were successfully sequenced at baseline and relapse and samples from 2 patients failed amplification at relapse. Phylogenetic analyses that included baseline and relapse samples from these 10 patients as well 30 patients that who relapsed prior to week 12 post-treatment and had longitudinal samples beyond week 12 post-treatment were performed. The genetic distance in NS5B between the baseline and relapse time points in 4 of 10 late virologic failures suggested a re-infection event and not relapse growth of the baseline HCV. In 1 of 4 reinfected patients, there was also a switch in genotype of virus between baseline and reinfection. Longitudinal samples from control patients showed minimal genetic drift over the same time period.
Conclusions: About half of the relapse cases in the SOF Phase 3 clinical development program who relapsed after achieving SVR12 were found to have HCV reinfection and not a relapse of the baseline virus. This result further supports SVR12 as an appropriate time point for the reliable assessment of a durable treatment response to SOF regimens.

Fatty liver disease: Experimental

GUT–LIVER AXIS DERANGEMENT DUE TO LACK OF INFLAMMASOME ACTIVITY LEADS TO VISCERAL OBESITY AND NASH DEVELOPMENT

L. Agostinelli[1], C. Riclicki[1], E. Mingarelli[1], C. Saponaro[2], M. Gaggini[2], E. Buzzigoli[2], I. Pierantonelli[1], S. Saccomanno[1], C. Pinto[1], L. Trozzi[1], A. Benedetti[1], S. De Minicis[1], M. Marzioni[1], A. Gastaldelli[2], G. Svegliati-Baroni[1]. [1]*Gastroenterology, Polytechnic University of Marche, Ancona,* [2]*Institute of Clinical Physiology, National Research Council, Pisa, Italy*
E-mail: gsvegliati@gmail.com

Background and Aims: Non-Alcoholic Fatty Liver Disease (NAFLD) is the most common form of chronic liver disease and can lead to cirrhosis and hepatocellular carcinoma. Gut microflora alterations and bacterial translocation induced by specific dietary habits can elicit a proinflammatory and profibrogenic response. The NLRP3 inflammasome regulates intestinal homeostasis and mediates the release of IL1β and IL18 in response to cellular danger signals. Its role in NAFLD development is controversial. Thus aim of the study was to investigate the role of NLRP3 inflammasome in a Western lifestyle diet model of NAFLD.
Methods: Wild-type (WT) C57BL/6 and Nlrp3A350VneoR ($Nlrp3^{-/-}$) mice were fed either a chow diet (controls) or a high-fat diet with fructose in drinking water (HFHC) for 12 weeks.
Results: $Nlrp3^{-/-}$ HFHC gained more weight ($p < 0.01$), showed reduced energy expenditure and more fat mass (both measured by doubly labeled water, all $p < 0.05$) with increased adipose tissue TNFα expression ($p < 0.05$), and developed more hepatic steatosis measured by triglyceride content ($p < 0.01$) compared to WT HFHC. HFHC increased intestinal permeability, as showed by reduced zonulin-1 expression in the caecum, that led to higher hepatic expression of TLR4 ($p < 0.01$) and TLR9 ($p < 0.05$) in $Nlrp3^{-/-}$ HFHC compared to WT HFHC. In the liver no differences were observed between $Nlrp3^{-/-}$ HFHC and WT HFHC in the expression of downstream SREBP-1c effectors of de novo lipogenesis (ACC, FAS and SCD-1) that were significantly increased in both groups. On the other hand, compared to WT HFHC, $Nlrp3^{-/-}$ HFHC showed higher expression of the lipogenic transcription factor PPARγ2 ($p < 0.01$) and of its downstream effectors FABP-4 ($p < 0.05$) and CD36 ($p < 0.01$) that regulate lipid uptake and storage. In addition $Nlrp3^{-/-}$ HFHC showed increased mitochondrial-oxidation of fatty acid (i.e., higher CPT1A expression) that, associated to the reduced expression of the "master regulator" of the antioxidant response NRF2, led to increased superoxide production (measured by dihydroethidium staining) (all $p < 0.01$). These series of events were associated to increased macrophage infiltration, type I collagen and MCP1 gene expression ($p < 0.05$) in $Nlrp3^{-/-}$ HFHC mice only.
Conclusions: In the Western lifestyle diet, lack of NLRP3 inflammasome is associated with translocation of bacterial products that leads to severe metabolic alterations in both adipose tissue and the liver, and to NASH development.

MECHANISTIC STUDY OF TM6SF2 IN NAFLD PATHOGENESIS: STABLY TRANSFECTED Huh7 CELLS OVER-EXPRESSING THE TM6SF2 E167K VARIANT EXHIBIT GREATER LEVELS OF OXIDATIVE STRESS

J. Palmer[1], Y.-L. Liu[1], C.P. Day[1], A. Daly[1], Q.M. Anstee[1]. [1]*The Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom*
E-mail: quentin.anstee@newcastle.ac.uk

Background and Aims: Non-Alcoholic Fatty Liver Disease (NAFLD) is a complex disease trait influenced by genetic modifiers. We, and others, have recently reported that minor (T) allele carriage of a non-synonymous polymorphism in *TM6SF2* (rs58542926 C>T, p.E167K), a gene of unknown function, is associated not only with steatosis, but also with NASH and clinically relevant advanced liver fibrosis. Carriage of the C allele is associated with dyslipidaemia and cardiovascular disease. To better understand the mechanisms underlying these associations, we examined the effects of *TM6SF2* over-expression in vitro.
Methods: Huh7 human hepatoma cell-lines stably transfected to overexpress wild-type (E167) or variant (167K) forms of TM6SF2 were generated. Cells were cultured in standard medium or oleic acid enriched media. Hepatocyte lipid accumulation was assessed by oil red O staining, cellular oxidative stress (ROS) measured by FACS after DCFDA staining and the expression profile of relevant genes involved in lipid metabolism, fatty acid oxidation, inflammation and fibrogenesis were measured by rtPCR.
Results: Following stable transfection, *TM6SF2* expression was >50-fold increased relative to resting Huh7 cells both at mRNA and protein levels. As previously noted, protein expression of the E167 form was approximately twice that of the 167K variant, likely reflecting protein misfolding or accelerated intracellular degradation. Whilst overexpression of either *TM6SF2* form was associated with increased hepatic lipid accumulation in oleic acid enriched media, oil red O staining was substantially greater in cells expressing 167K. Consistent with development of NASH, carriage of the 167K variant was also associated with greater levels of ROS. At the transcriptome level, overexpression of *TM6SF2* suppressed several lipogenic and pro-inflammatory genes. However, relative to E167, the 167K variant promoted differential expression of key genes including *DGAT1, CYP2E1, IL6* and *TNFA*.
Conclusions: These in vitro data suggest that *TM6SF2* has profound effects on hepatocyte lipid metabolism. They provide the first evidence that the TM6SF2 p.E167K variant induces increased hepatocyte oxidative stress, possibly by favoring extra-mitochondrial omega- fatty-acid oxidation, and also promotes hepatocyte inflammatory cytokine expression. Work to further characterize the functional effects of TM6SF2 p.E167K carriage and the mechanisms through which it promotes liver injury and NASH are underway.

Bcl-3 REGULATES HEPATIC GLUCOSE AND LIPID METABOLISMS THROUGH INSULIN AND ASSOCIATED METABOLIC TRANSCRIPTION FACTORS

N. Gehrke[1], M.A. Wörns[1], A. Schad[2], Y. Alt[1], A. Waisman[3], N. Hoevelmeyer[3], P.R. Galle[1], J.M. Schattenberg[1]. *[1]I. Department of Medicine, [2]Institute of Pathology, [3]Institute of Molecular Medicine, University Medical Center of the Johannes Gutenberg University, Mainz, Germany*
E-mail: NadineGehrke@gmx.net

Background and Aims: The NFkB-cofactor gene B cell leukemia-3 (Bcl-3) plays a critical role in altering the transcriptional capacity of the NFkB-subunits p50 and 52 and thus regulates inflammation. Beyond that Bcl-3 was also identified as a transcriptional coregulator of genes involved in cellular energy metabolism. However, its regulatory role in non-alcoholic fatty liver disease (NAFLD) has not been investigated yet.
Methods: 8–12 week old male mice exhibiting a hepatocyte-specific overexpression of Bcl-3 (Bcl-3hepar) and wild type (wt) littermates were fed with a high-fat diet [HFD; 35.5% w/w crude fat (58kJ%)] plus drinking water enriched with fructose (55% w/v) and glucose (45% w/v) for 12 weeks to induce NAFLD. Gender- and age-matched mice received a corresponding control diet [CD; 5.4% w/w crude fat (13kJ%)] and normal drinking water. After the dietary period, biometric, serological, histological, FACS, Western Blot and qRT-PCR analyses were performed.
Results: HFD-feeding induced a pronounced metabolic derangement in Bcl-3hepar mice which was characterized by enhanced hepatic cell death and steatosis from increased de novo lipogenesis (ACC, FAS, SREBP-1), and decreased b-oxidation (CPT1, PPARa), hydrolysis (FXR, CES1) and release (MTTP) of fatty acids. In addition, Bcl-3hepar mice exhibited hyperinsulinaemia, but still a decreased expression of gluconeogenetic enzymes. Interestingly, the transcription factors PGC-1a, PPARa and PPARg, that regulate hepatic glucose and lipid metabolism and also promote anti-inflammatory processes, were down-regulated in the liver of HFD-fed Bcl-3hepar mice as compared to the wt. Ex vivo-treatment of primary hepatocytes from Bcl-3hepar mice with oleic acid, fructose and glucose for 48 h to induce intracellular lipid accumulation led to a diminished expression of PGC-1a, PPARa and PPARg, whereas these genes were not affected in wt hepatocytes. Moreover, metformin improves the metabolic and injurious phenotype of Bcl-3hepar mice in vivo by reducing hepatic steatosis via a decrease in lipogenesis (FAS) and elevated expression of PGC-1a, PPARa and PPARg. In parallel, metformin caused a marked reduction of serum TNF-a and CCL2 levels and of intrahepatic leukocytes, in particular T cells, NK cells and macrophages.
Conclusions: In a high-fat dietary model of NAFLD, Bcl-3 is a hepatocellular factor that promotes metabolic dysfunction and insulin resistance by suppressing transcription factors of hepatic lipo- and gluconeogenesis.

HEMATOPOIETIC OVEREXPRESSION OF CYP27A1 REDUCES HEPATIC INFLAMMATION INDEPENDENTLY OF 27-HYDROXYCHOLESTEROL LEVELS IN LDLR$^{-/-}$ MICE VIA NPC-MODULATED CHOLESTEROL TRANSPORT

T. Hendrikx[1], M.L. Jeurissen[1], S.M. Walenbergh[1], T. Houben[1], P.J. van Gorp[1], F. Verheyen[1], M.J. Gijbels[1], E. Leitersdorf[2], M. Hofker[3], D. Lütjohann[4], R. Shiri-Sverdlov[1]. *[1]Maastricht University, Maastricht, Netherlands; [2]Hadassah-Hebrew University Medical Center, Jerusalem, Israel; [3]UMC Groningen, Groningen, Netherlands; [4]University of Bonn, Bonn, Germany*
E-mail: t.hendrikx@maastrichtuniversity.nl

Background and Aims: Non-alcoholic steatohepatitis (NASH) is characterized by hepatic lipid accumulation and inflammation. Currently, the underlying mechanisms leading to hepatic inflammation are still unknown. The breakdown of free cholesterol inside Kupffer cells (KCs) by the mitochondrial enzyme CYP27A1 produces 27-hydroxycholesterol (27HC). We recently demonstrated that administration of 27HC to hyperlipidemic mice reduced hepatic inflammation. In line, hematopoietic deletion of CYP27A1 resulted in increased hepatic inflammation. In the current manuscript, the effect of hematopoietic overexpression of CYP27A1 on the development of NASH and cholesterol trafficking was investigated. We hypothesized that CYP27A1 overexpression in KCs will lead to reduced hepatic inflammation.
Methods: Irradiated *Ldlr*$^{-/-}$ mice were transplanted (tp) with bone marrow from mice overexpressing CYP27A1 (*Cyp27a1*^{over}) and wild-type (Wt) mice and fed either chow or high-fat, high-cholesterol (HFC) diet for 3 months. Additionally, gene expression was assessed in bone marrow derived macrophages (BMDM) from *Cyp27a1*^{over} and Wt mice. Electron microscopy anaylis was performed to study intracellular cholesterol distribution.
Results: In line with our hypothesis, hepatic inflammation in HFC-fed *Cyp27a1*^{over}-tp mice was reduced and KCs were less foamy compared to Wt-tp mice. Remarkably, these changes occurred even though plasma and liver levels of 27HC did not differ between both groups. BMDM from *Cyp27a1*^{over} mice revealed reduced inflammatory gene expression and increased expression of cholesterol transporters compared to Wt BMDM after LPS stimulation. In addition, 27HC increased expression of NPC proteins, thereby reducing lysosomal cholesterol accumulation.
Conclusions: Our data suggest that overexpression of CYP27A1 in KCs reduces hepatic inflammation independently of 27HC levels in plasma and liver via increased NPC-mediated cholesterol transport. This study further points towards KCs as specific target for improving therapy of NASH.

LYSOSOMAL CHOLESTEROL IN KUPFFER CELLS, PARTICULARLY WHEN OXIDIZED, CONTRIBUTES TO MURINE STEATOHEPATITIS

S. Walenbergh[1], T. Houben[1], T. Hendrikx[1], P. van Gorp[1], M. Jeurissen[1], V. Bieghs[1], M.-H. Lenders[2], M. Gijbels[1], J. Plat[3], M. Hofker[4], C. Binder[5,6], D. Luetjohann[7], F. Verheyen[2], G. Koek[8], R. Shiri-Sverdlov[1]. *[1]Molecular Genetics, [2]Molecular Cell Biology and Electron Microscopy, [3]Human Biology, Maastricht University, Maastricht, [4]Pathology and Medical Biology, University of Groningen, Groningen, Netherlands; [5]Laboratory Medicine, Medical University of Vienna, [6]Center for Molecular Medicine, Austrian Academy of Sciences, Vienna, Austria; [7]Institute of Clinical Chemistry and Clinical Pharmacology, University of Bonn, Bonn, Germany; [8]Internal Medicine, Maastricht University Medical Center, Maastricht, Netherlands*
E-mail: s.walenbergh@maastrichtuniversity.nl

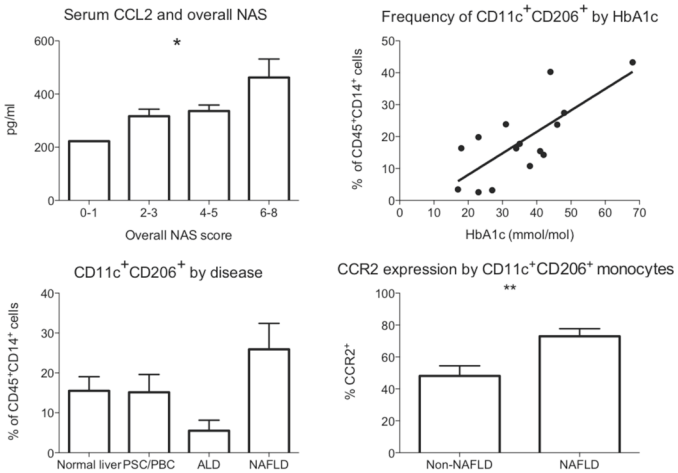
Background and Aims: Recently, the importance of lysosomes within the metabolic syndrome, including fatty liver disease, is gaining increasing attention. It has been suggested that macrophages during atherosclerosis as well as Kupffer cells (KCs) during hepatic inflammation demonstrate properties of an acquired lysosomal storage disorder. So far, it is unclear whether there is a causal relationship between lysosomal cholesterol accumulation (LCA) in KCs and hepatic inflammation. Additionally, the specific contribution of the oxidized LDL (oxLDL) fraction to LCA, its concomitant effect on lysosomal function, and on hepatic inflammation is unexplored.
Methods: Hematopoietic deficiency of the mutant Niemann-Pick type C1 (NPC1^{mutant}) protein was used as a tool to induce LCA in KCs of hyperlipidemic mice. To induce high levels of anti-oxLDL antibodies, NPC1^{mutant}-transplanted mice were immunized every two weeks with heat-inactivated pneumococci until the end of the experiment.

Results: Compared to wildtype, NPC1^{mutant}-transplanted mice displayed severe hepatic inflammation and fibrosis. Anti-oxLDL immunization of NPC1^{mutant}-transplanted mice improved cholesterol metabolism, lysosomal dysfunction and liver inflammation, in contrast to non-immunized NPC1^{mutant}-transplanted mice.
Conclusions: A direct causal link exists between LCA in KCs and hepatic inflammation. Rather than total cholesterol, we specifically show that oxLDL significantly contributes to lysosomal dysfunction, cholesterol homeostasis and the hepatic inflammatory response.

O069
EVIDENCE FOR A ROLE OF CCR2 IN HUMAN NON-ALCOHOLIC FATTY LIVER DISEASE

R. Parker[1], C. Corbett[2], C. Weston[1], M. Armstrong[1], P. Newsome[1], D. Adams[1]. [1]*Centre for Liver Research, University of Birmingham, Birmingham,* [2]*Gastroenterology, Royal Wolverhampton Hospitals NHS Foundation Trust, Wolverhampton, United Kingdom*
E-mail: richardparker@nhs.net

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is closely associated with the metabolic syndrome. Chemokine-C-receptor 2 (CCR2) has been shown to be expressed on myeloid cells that infiltrate human adipose tissue in obese individuals where they play a role in causing insulin resistance. CCR2+ cells have been demonstrated in murine models of obesity and NAFLD. We sought to define the role of CCR2 in human fatty liver disease.
Methods: Serum and liver tissue was collected from patients at University Hospitals Birmingham NHS Foundation Trust with appropriate ethical approval, and from healthy volunteers. Serum concentration of CCL2 was assessed by ELISA and compared to histological assessment of liver disease. Whole liver tissue CCL2 gene expression was analysed by rt-PCR. CCR2 expression on liver-infiltrating cells was assessed with immunohistochemistry of paraffin embedded liver sections and flow cytometry of cells isolated from liver tissue.
Results: Serum CCL2 concentration was elevated in patients with NAFLD compared to healthy volunteers (mean concentration 330 ng/ml, SD 157.2 vs. 207 ng/ml SD 90.6, $p = 0.030$), where CCL2 concentration correlated with inflammation assessed by Kleiner-Brunt system (one way ANOVA $p = 0.025$). Gene expression of CCL2 was markedly upregulated in NASH cirrhosis compared to normal liver tissue (mean fold increase 56.5 $p < 0.01$). CCR2$^+$ cells were observed particularly around areas of steatosis in NAFLD liver tissue. Flow cytometry of liver infiltrating cells demonstrated CCR2 expression predominantly on CD14$^+$ monocytes. A subset of CD14$^+$ monocytes expressed CD11c and CD206, and was associated with insulin resistance (correlation with HbA1c r^2=0.56, $p < 0.001$). This subset was more frequent in NAFLD liver [% of CD14$^+$, 26.42% (SEM 4.7) vs. 14.31% (2.70), $p = 0.035$] where CCR2 expression was also greater [76.32% (3.32) vs. 45.48% (6.48), $p = 0.002$].



Conclusions: CCL2 expression is greater in NAFLD and correlates with inflammation. A subset of CCR2 monocytes associated with insulin resistance are seen more frequently in NAFLD. These results demonstrate a role for CCR2 in human fatty liver disease that complement observations made in murine models. Further work to investigate the effects of targeting this axis in humans may provide a novel therapeutic method for this common disease.

O070
CX3CR1 IS A GATEKEEPER FOR INTESTINAL BARRIER INTEGRITY: LIMITING STEATOHEPATITIS BY PROMOTING INTESTINAL HOMEOSTASIS

K.M. Schneider[1], V. Bieghs[1], F. Heymann[1], W. Hu[1], L. Liao[1], N. Gassler[2], O. Pabst[3], E. Latz[4,5,6], G. Sellge[1], J. Penders[7], F. Tacke[1], C. Trautwein[1]. [1]*Department of Medicine III, University Hospital RWTH Aachen, Aachen,* [2]*Institute of Pathology, Klinikum Braunschweig, Braunschweig,* [3]*Institute of Molecular Medicine, University Hospital RWTH Aachen, Aachen,* [4]*Institute of Innate Immunity, University Hospital, University of Bonn, Bonn, Germany;* [5]*Department of Medicine, University of Massachusetts Medical School, Worcester, United States;* [6]*German Center for Neurodegenerative Diseases, Bonn, Germany;* [7]*Department of Medical Microbiology, School for Nutrition, Toxicology and Metabolism, Maastricht University Medical Center, Maastricht, Netherlands*
E-mail: Kai.Markus.Schneider@gmail.com

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) represents the most common liver disease in Western societies and is regarded as the hepatic manifestation of the metabolic syndrome. The G-Protein-coupled chemokine receptor CX3CR1 has been shown to play a central role in many metabolic syndrome related diseases including type-2 diabetes, atherosclerosis and obesity. However, the role of CX3CR1 in relation to NAFLD progression remains unclear. Recent data indicate that intestinal dysbiosis drives NASH development and CX3CR1 is essential for intestinal homeostasis. Based on these findings, we hypothesized that CX3CR1 plays a role in regulating the gut–liver axis and therefore has implications for the progression of NASH.
Methods: Male wildtype (WT) and CX3CR1$^{-/-}$ mice were fed either a normal chow diet (NCD), high-fat diet (HFD) or methionine-choline-deficient (MCD) diet to induce steatohepatitis. For eradication of the intestinal microbiota, the drinking water of the mice was supplemented with a broad-spectrum antibiotic cocktail.
Results: CX3CR1$^{-/-}$ mice demonstrated more pronounced liver steatosis, inflammation and glucose intolerance compared to controls. Surprisingly, the experimental diets induced a marked reduction of intestinal resident macrophages in CX3CR1$^{-/-}$ mice, which was associated with significant alterations in the intestinal microbiota composition, a leaky epithelial barrier and a reduced phagocytic capacity of intestinal macrophages. Collectively, these intestinal changes led to an increased translocation of endotoxin and stronger activation of pathogen recognition receptors (PRRs) in livers of CX3CR1$^{-/-}$ mice, thereby triggering an enhanced inflammatory response in the liver. Strikingly, depletion of the intestinal microbiota by administration of broad-spectrum antibiotics (AB) suppressed the number of infiltrating macrophages and promoted a restorative phenotype of liver macrophages. Consequently, AB-treated mice demonstrated a marked improvement of steatohepatitis and glucose tolerance.
Conclusions: CX3CR1 dampens the microbiota-mediated activation of the hepatic innate immune response and thus limits the progression of steatohepatitis. Hence, CX3CR1 is a gatekeeper by promoting intestinal homeostasis.
K.M. Schneider and V. Biegs contributed equally.

TELOMERASE REVERSE TRANSCRIPTASE MUTATIONS ARE ASSOCIATED WITH HEPATOCELLULAR CARCINOMA IN NASH

B. Donati[1], E. Vanni[2], P. Dongiovanni[3], M. Iavarone[4], R. Rametta[1], C. Rosso[2], A. Carnelutti[5], S. Petta[6], A.L. Fracanzani[1], H.L. Reeves[7], J.F. Dofour[8], L. Miele[9], Q. Anstee[10], E. Bugianesi[11], G. Soardo[5], S. Fargion[1], L. Valenti[1]. *[1]Pathophysiology and Transplantation, Università degli Studi di Milano, Milano, [2]Medical Sciences, University of Turin, Turin, [3]Internal Medicine, [4]Gastroenterology, Fondazione IRCCS Ca' Granda, Milano, [5]Internal Medicine, University of Udine, Udine, [6]Gastroenterology, University of Palermo, Palermo, Italy; [7]Medicine, Freeman Hospital, Newcastle Upon Tyne, United Kingdom; [8]Clinical Research, University of Bern, Bern, Switzerland; [9]Internal Medicine, Catholic University, Rome, Italy; [10]Cellular Medicine, Newcastle University, Newcastle Upon Tyne, United Kingdom; [11]Gastroenterology, University of Turin, Turin, Italy*
E-mail: donatibenedetta@gmail.com

Background and Aims: In an increasing proportion of cases, hepatocellular carcinoma (HCC) develops in nonalcoholic steatohepatitis (NASH). Mutations in telomerase reverse-transcriptase (hTERT), the main regulator of telomere length, have been associated with a spectrum of progressive familial liver disease characterized by steatosis, and telomere attrition characterizes cirrhosis and cancer development. Aim was to determine whether shortened telomeres and functional hTERT mutations predispose to HCC in NASH.
Methods: In 40 consecutive Italian unrelated patients with HCC occurring in NASH-related liver disease (78% with cirrhosis), 40 patients with NASH-related cirrhosis, and 60 healthy subjects with normal liver enzymes, telomere length was evaluated by qRT-PCR and hTERT coding regions and intron-exon boundaries were analyzed by Sanger sequencing on DNA from peripheral blood leukocytes. Prediction of functional consequences of genetic variants was estimated in silico by consulting Telomere Database (http://telomerase.asu.edu) and bioinformatic algorithms.
Results: Telomere length was reduced in HCC patients (median: 1.01 IQR: 0.76–1.42; calculated as ratio of telomere repeat copy number to 36B4 single gene copy number) vs. cirrhosis (median: 1.12 IQR: 0.83–1.70;p = 0.1) and vs. healthy subjects (median: 1.40 IQR: 1.00–1.72;p = 0.002). We detected novel rare coding variants of hTERT in NASH HCC patients, while no mutations were found in those with cirrhosis and healthy controls (prevalence 10%; p = 0.040 vs. cirrhosis, p = 0.012 vs. healthy subjects; p = 0.001 vs. controls overall). Three HCC patients were carriers of missense mutations: Ala67Val in homozygosity and Pro193Leu in heterozygosity located in the N-terminal (template binding domain, possibly damaging), while one was heterozygous for the Glu668Asp (catalytic domain, likely damaging). One patient presented a heterozygous frameshift mutation (Glu113Arg_fs*79, likely damaging). All patients positive for hTERT mutations had cirrhosis and were carriers of the I148M PNPLA3 variant predisposing to HCC in NASH; mortality at 24 months was 100% (vs. 65% in negative patients).
Conclusions: These data suggest that multiple rare hTERT mutations may frequently contribute to the pathogenesis of HCC in NASH by favouring telomere attrition, with possible clinical implications for relatives of the probands. We are currently validating these findings in an independent European cohort.

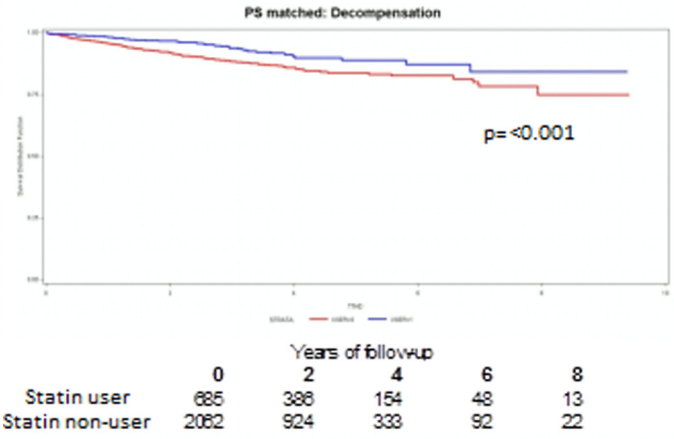
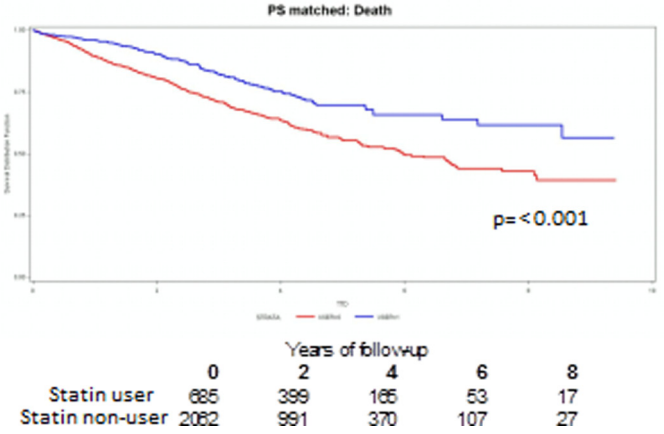
STATIN USE SIGNIFICANTLY DECREASES DECOMPENSATION AND DEATH IN VETERANS WITH HEPATITIS C-RELATED COMPENSATED CIRRHOSIS

A. Mohanty[1,2], J.P. Tate[3,4], G. Garcia-Tsao[1,2]. *[1]Section of Digestive Diseases, VA Connecticut Healthcare System, West Haven, [2]Section of Digestive Diseases, Yale School of Medicine, New Haven, [3]Department of Internal Medicine, VA Connecticut Healthcare System, West Haven, [4]Department of Internal Medicine, Yale School of Medicine, New Haven, United States*
E-mail: arpanmohanty1@gmail.com

Background and Aims: Statin use has been shown to decrease portal pressure in patients with cirrhosis, and improve survival in patients who have bled from varices. However, the long-term effect of statin use on cirrhosis decompensation and mortality in patients with compensated cirrhosis is unknown.
Aim: To study the effect of statin use on decompensation and mortality in hepatitis C virus (HCV)-infected patients with compensated cirrhosis.
Methods: Using the Veteran Affairs clinical case registry from 01/1996 to 12/2009 (n = 342,157), we identified a cohort of HCV mono-infected patients with compensated cirrhosis and no statin use at baseline. New statin users (median time of use was 2.8 years) were propensity matched to up to 5 non-users. The propensity score was created using variables associated with statin prescription: demographics, calendar year of index visit, site of statin prescription, site prescribing pattern, number and type of lipid tests, laboratory data including liver tests, and





comorbid conditions. As previously validated, decompensation was defined by the presence of one inpatient or two outpatient ICD-9 codes for esophageal varices with bleeding, ascites and/or spontaneous bacterial peritonitis. The association between statin use and decompensation and death was estimated using cox proportional hazards model with adjustment for age + Child score and age + MELD score.

Results: Among 40,512 patients with HCV compensated cirrhosis (98% male, median age 56 years), 2,802 statin users were identified. From this group 685 statin users were propensity score matched with 2,062 non-users. Discrimination of propensity score model was excellent (c = 0.92). The figure shows plots of time to decompensation (A) or death (B) by statin use in the matched cohort. Statin use was associated with lower risk of decompensation [HR 0.55 (95% CI 0.39, 0.77)] or death [HR 0.56 (95% CI 0.46, 0.69)] compared to non-users. These findings persisted after adjustment for age + Child score [decompensation HR 0.53 (95% CI 0.37, 0.74); death HR 0.54 (95% CI 0.44, 0.66)] or age + MELD score [decompensation HR 0.53 (95% CI 0.38, 0.75); death HR 0.54 (95% CI 0.44, 0.66)].

Conclusions: Statin use in U.S. Veterans with HCV compensated cirrhosis is associated with over 40% lower risk of hepatic decompensation and death.

O073

NON-SELECTIVE BETA-BLOCKERS AND MORTALITY IN CIRRHOSIS PATIENTS WITH OR WITHOUT REFRACTORY ASCITES: POST HOC ANALYSIS OF THREE LARGE RCT'S WITH 1198 PATIENTS

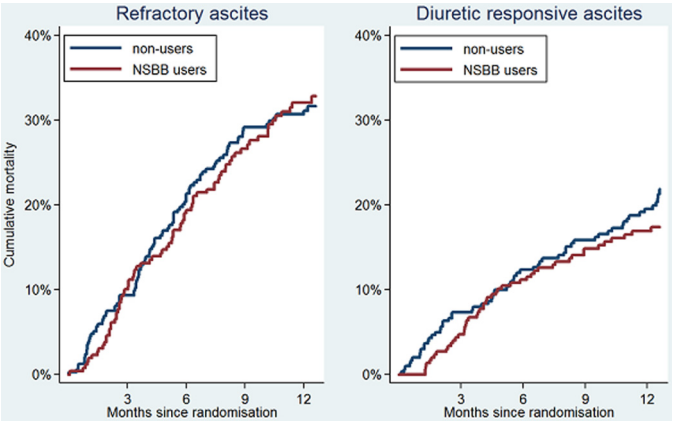
L. Bossen[1,2], A. Krag[3], H. Vilstrup[1], H. Watson[4], P. Jepsen[1,2].
[1]Department of Hepatology and Gastroenterology, [2]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, [3]Department of Medical Gastroenterology, Odense University Hospital, Odense, Denmark; [4]Sanofi Aventis R&D, Sanofi, Paris, France
E-mail: larsbossen@clin.au.dk

Background and Aims: Non-selective β-blockers (NSBB) are the standard treatment to prevent bleeding from esophageal varices, but their safety in patients with refractory ascites has been questioned. We used data from randomised trials to examine the effect of NSBB on mortality in cirrhosis patients with or without refractory ascites.

Methods: In 2006–2008, 1198 patients were enrolled in three multicentre randomised trials to determine the efficacy of satavaptan in treating ascites. Two of the trials were stopped early, but even so all participants' vital status was assessed after the planned 52 weeks of treatment. We used these data to compare the mortality of NSBB users vs. non-users. With Cox regression we adjusted for confounding by age, gender, MELD score, Child–Pugh score, serum sodium, history of variceal bleeding, cirrhosis aetiology and refractory ascites.

Results: NSBB users (n = 562) were more likely than non-users (n = 636) to have a history of variceal bleeding (30% vs. 13%), but they were less likely to have Child–Pugh class C cirrhosis (class A/B/C = 8%/68%/24% vs. 8%/64%/28%) or refractory ascites (46.4% vs. 52.5% among non-users of NSBB). MELD scores (median 12 [IQR 8–15] vs. 11 [IQR 8–15]) and serum sodium (median 137 [IQR 134–140] vs. 136 [IQR 133–139]) were similar in the two groups. During the follow-up (median follow-up for survival = 52.5 weeks) 129 NSBB users and 163 non-users died, and the cumulative mortality was 24.2% vs. 27.1%. Confounder adjustment did not change this overall impression that NSBB use did not affect mortality (adjusted HR = 0.92, 95% CI 0.72 to 1.18). When we examined patients with refractory ascites separately, NSBB use still had no effect on mortality (n = 595, adjusted HR = 1.02, 95% CI 0.74 to 1.39). Nor did it affect mortality among patients with diuretic-responsive ascites (n = 603, adjusted HR = 0.78, 95% CI 0.53 to 1.16) (Figure). We also examined the effect of NSBB in subgroups defined by a daily NSBB dose ≥80 mg or <80 mg, a MELD score ≥18 or <18, a mean arterial pressure ≥82 mmHg or <82 mmHg, or with or without a history of spontaneous bacterial peritonitis: NSBB use did not increase mortality in any of these subgroups.

Conclusions: NSBB use did not affect mortality in these cirrhosis patients with ascites.



O074

A METABOLOMIC STUDY OF SERUM FROM PATIENTS WITH CIRRHOSIS IDENTIFIES 2 METABOLITES THAT ACCURATELY PREDICT THE ACUTE HVPG RESPONSE TO β-BLOCKER THERAPY

E. Reverter[1,2], J.J. Lozano[2], C. Alonso[3], A. Berzigotti[1,2], S. Seijo[1,2], F. Turon[1,2], M.L. Martínez-Chantar[4], J. María Mato[4], V. Hernández-Gea[1,2], J. Bosch[1,2], J.C. García-Pagán[1,2]. *[1]Hepatic Hemodynamic Laboratory, Liver Unit, IDIBAPS. Hospital Clínic, [2]Centro de Invetigaciones en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Barcelona, [3]OWL Genomics, [4]CIC bioGUNE, Bizkaia, Spain*
E-mail: ereverte@clinic.ub.es

Background and Aims: Complications of cirrhosis (ascites, encephalopathy, variceal bleeding) are related to the presence of portal hypertension (PHT). A decrease in hepatic venous pressure gradient (HVPG) greater than 10% (HVPG responders) after the acute i.v. administration of propranolol is associated with a lower risk for these complications to appear and with a better survival. However, only about a half of patients are HVPG responders to propranolol and, up to now, there are not non-invasive markers to identify them. Thus, an invasive study of HVPG is needed. The present study aims at identifying a metabolomic serum profile in patients with cirrhosis and PHT that allows predicting a good HVPG response to acute i.v. propranolol.

Methods: 40 patients with cirrhosis (Child–Pugh A/B/C=21/12/7) and HVPG≥10 mmHg, in whom HVPG response to i.v. propranolol was assessed, were prospectively included. HVPG was measured at baseline and 20 minutes after i.v. propranolol (0.15 mg/kg). A targeted metabolomic analysis of serum samples using UPLC-MS (ultra-performance liquid chromatography coupled to mass spectrometry; 562 metabolites) was performed. The best combination of metabolites to identify HVPG responders (HVPG reduction >10%) was obtained using stepwise logistic regression (LR) from the subset of metabolites with a p value <0.1. Baseline clinical variables associated to a good response to propranolol were also studied.

Results: 25 of 40 patients (63%) were HVPG responders. The metabolomic study identified 65 metabolites that were significantly different among HVPG responders and non-responders. LR analysis identified 2 lipidic metabolites that showed a good prediction of the response to propranolol (AUC=0.872, CI=0.754–0.989), being a robust model at internal cross-validation (mean AUC 0.841). This model had a specificity of 80%, sensibility of 84%, Positive PV of 88% and Negative PV of 75% to identify HVPG responders, with a

positive and negative likelihood ratio of 4.2 and 0.2, respectively. The addition of clinical variables to the model did not improve its performance.

Conclusions: the combination of 2 lipidic serum metabolites accurately identifies patients with a good response to the acute administration of propranolol. The analysis of these metabolites could be a useful non-invasive tool to identify these patients.

O075

ASSESSMENT OF THE TRANSJUGULAR PORTO-SYSTEMIC SHUNT (TIPSS) IN THE MANAGEMENT OF COMPLICATIONS OF NONCIRRHOTIC PORTAL HYPERTENSION

J. Bissonnette[1,2], J.-C. Garcia-Pagán[3], A. Albillos[4], C. Ferreira[3], F. Turon[3], L. Téllez[4], J.-C. Nault[5], M. Abdel Rehim[6], A. Sibert[6], P. Perreault[7], L. Bouchard[7], N. Carbonell[8], F. Trottier-Tellier[2], P.-E. Rautou[1], D. Valla[1], A. Plessier[1]. *[1]Liver Unit, Hôpital Beaujon, Clichy, France; [2]Liver Unit, Hôpital Saint-Luc, Montreal, Canada; [3]Liver Unit, Hospital Clinic, Barcelona, [4]Liver Unit, Hospital Universitario Ramón y Cajal, Madrid, Spain; [5]Hôpital Jean Verdier, Bondy, [6]Radiology, Hôpital Beaujon, Clichy, France; [7]Radiology, Hôpital Saint-Luc, Montreal, Canada; [8]Liver Unit, Hôpital Saint-Antoine, Paris, France*

E-mail: julien.bissonnette@umontreal.ca

Background and Aims: Noncirrhotic portal hypertension (NCPHT) is a heterogeneous group of diseases characterized by portal hypertension without cirrhosis or a cause of chronic liver disease and no venous obstruction. The efficacy of the TIPSS in this population has not been reported.

Methods: We analyzed the charts of patients with NCPHT undergoing a TIPSS procedure in 5 reference centers between 1994 and 2013. Survival, presented as means ± SD, was assessed using the log-rank test and the Cox model.

Results: Thirty-eight patients (16 F, 22 M, aged 45±16 years) were included. Associated conditions were prothrombotic states in 9 patients (protein C and S deficiency, myeloproliferative disease, pregnancy, antiphospholipid syndrome), immune disorders in 12 (inflammatory myositis, rheumatoid arthritis, HIV, common variable immune deficiency, Crohn's disease), exposure to toxins in 9 (oxaliplatine, hematopoietic stem cell graft) and idiopathic in 8. Patients were grouped as low-risk thrombophilia or idiopathic (n = 12) and others (n = 26). Indication for TIPSS was uncontrolled variceal hemorrhage in 22 patients, refractory ascites in 12, exsudative enteropathy in 1, hepatic hydrothorax in 1 and preparation for abdominal surgery in 2. The porto-systemic gradient decreased from 20±7 to 6±3 mmHg. During follow-up (average 34±32 months), 10 patients died 16±20 months after TIPSS insertion, 5 from complications of the procedure or of the liver disease and 5 from the associated conditions. In the refractory ascites group, 6/12 (50%) died, including 5 in the first 6 months. Among patients with uncontrolled hemorrhage, 7 (31%) rebled, including 3 with early TIPSS thrombosis. Fourteen patients (38%) were hospitalized for encephalopathy. Using univariate analysis, serum creatinine ($p = 0.003$), MELD score ($p = 0.006$) and ascites as the indication ($p = 0.03$) at the time of the procedure predicted death. Survival was higher in the group of patients with low-risk thrombophilia or idiopathic NCPHT than in the other group ($p = 0.04$). Among deceased patients, mean MELD score was 14±5 and Child–Pugh score ranged from 6 to 9 at the time of the procedure.

Conclusions: Outcome was good after TIPSS in NCPHT patients with low-risk thrombophilia or idiopathic disease. Patients with bleeding as the indication for TIPSS had good long-term outcome despite frequent rebleeding. In patients with refractory ascites, TIPSS is associated with a high short-term mortality.

O076

CARDIAC VOLUME OVERLOAD AND PULMONARY HYPERTENSION AFTER LONG-TERM FOLLOW-UP IN TIPS PATIENTS

T.A. Hippchen[1], A. Wannhoff[1], K. Friedrich[1], C. Rupp[1], K.-H. Weiss[1], P. Schemmer[2], B. Radeleff[3], W. Stremmel[1], D.N. Gotthardt[1]. *[1]Department of Internal Medicine IV, [2]Department of General and Transplant Surgery, [3]Department of Diagnostic and Interventional Radiology, University Hospital Heidelberg, Heidelberg, Germany*

E-mail: Theresa.Hippchen@med.uni-heidelberg.de

Background and Aims: Insertion of transjugular intrahepatic portosystemic shunt (TIPS) might induce significant cardiac overload and in rare cases lead to acute cardiac decompensation. Yet little is known about long-term cardiac outcome. Therefor we conducted a study to analyze cardiac function in long-term follow-up after TIPS.

Methods: Between 2000 and May 2014, patients with liver cirrhosis who underwent successful TIPS creation, were seen for follow-up or underwent TIPS creation in another hospital while waiting for liver transplantation at the University Hospital Heidelberg were included. Findings on echocardiography from the last one before and first one at 1 to 5 years after TIPS were analyzed and included. A control group of patients with liver cirrhosis were matched to TIPS patients with available echocardiography after TIPS. Results are expressed as median and interquartile range. For comparison Mann–Whitney and Wilcoxon's test were used.

Results: The final study cohort consists of 158 (103 male) patients after 23 were excluded due to BCS and 51 because no follow-up after TIPS was available. Median age at TIPS was 56 years (49–64) and 29 patients were Child A, 92 Child B and 37 Child C at time of TIPS.

Significant change was found for pulmonary-arterial systolic pressure (PASP) increasing from 25 mmHg (22–33) to 30 mmHg (25–36) ($p = 0.038$; $N = 22$) and septal thickness ($p = 0.009$; $N = 34$) as well as for left atrial diameter (LAD) ($p = 0.001$; $N = 33$) changing from 37 mm (33–43) to 40 mm (36–47) and end-diastolic diameter (EDD) ($p < 0.001$; $N = 33$). No differences were found for the end-systolic diameter ($p = 0.266$; $N = 23$), posterior wall ($p = 0.354$; $N = 32$), early to late diastolic tissue velocity ratio (E'/A') ($p = 0.123$; $N = 9$) and right ventricular diameter ($p = 0.562$; $N = 12$).

Comparison of echocardiographic findings between TIPS ($N = 55$) and control group ($N = 110$) revealed a significantly larger LAD ($p < 0.001$), VCI ($p = 0.009$), EDD ($p = 0.004$) and an increased PASP ($p < 0.001$) in the TIPS group. Incidence of pulmonary hypertension (PH) in the TIPS group was 6 out of 158 (3.8%) patients during mean follow-up of 28.6 (±27.8) months whereas in the control group no patient developed PH during mean follow-up of 24.3 (±22.8) months.

Conclusions: In conclusion, TIPS is accompanied by long-term effects on cardiac function in cirrhotic patients. Signs of volume overload after insertion of TIPS is seen even after >1 year, causing pulmonary hypertension in some patients. Therefor we recommend regular echocardiography in the long-term follow-up in these patients.

O077

USE OF DIRECT ORAL ANTICOAGULANTS (DOACS) IN PATIENTS WITH SPLANCHNIC VEIN THROMBOSIS AND/OR CIRRHOSIS

A. De Gottardi[1], S. Seijo[2], A. Plessier[3], J. Schouten[4], J. Trebicka[5], B. Terziroli[6], L. Magenta[6], D. Semela[7], P. Langlet[8], F. Turon[9], R. Arya[2], M. Peck-Radosavljevic[10], D. Valla[3], J.C. Garcia-Pagan[9], EASL-VALDIG Consortium. *[1]Hepatology, Inselspital, Berne, Switzerland; [2]Hepatology, King's College, London, United Kingdom; [3]Hepatology, Hôpital Beaujon, Paris, France; [4]Gastroenterology, AZ Nikolaas, St. Nikolaas, Belgium; [5]Gastroenterologie, University of Bonn, Bonn, Germany; [6]Epatocentro, Lugano, [7]Gastroenterology, Kantonsspital, St. Gallen, Switzerland; [8]CHIREC, Brussels, Belgium; [9]Liver Unit, Hospital Clinic, Barcelona, Spain; [10]Hepatology, Medical University, Vienna, Austria*
E-mail: andrea.degottardi@ikp.unibe.ch

Background and Aims: DOACs are increasingly used off label in patients with splanchnic vein thrombosis and/or cirrhosis. Since efficacy and safety remain a concern in these patients, our aim was to describe the indications of DOACs, the reasons for switching from other anticoagulants and the possible adverse effects.
Methods: A questionnaire including demographic information, laboratory data, DOACs treatment characteristics and complications was sent to the members of the VALDIG Consortium from 42 centers in 15 countries.
Results: Thirty-three centers (79%) answered the questionnaire. The use of DOACs in patients with splanchnic vein thrombosis (SVT) and/or cirrhosis was reported for 35 cases (8 centers in 6 European countries). Patients (21 men/14 women) were aged 52 (range 16–82 years). Indications for anticoagulation were SVT (22), peripheral deep vein thrombosis (1), Budd-Chiari syndrome (3), atrial fibrillation (5) and others (4). The DOACs used were rivaroxaban (31), dabigatran (3) and apixaban (1) for a median of 7 months (range 1–42). The reasons for choosing DOACs were no need for INR monitoring (17), to avoid injections (4), previous complications of other anticoagulants (7) and unknown (7). There were 13 patients with cirrhosis and median Child–Pugh score B7 (range 6–9), MELD 8 (range 7–13). In cirrhotic patients the median daily dose of rivaroxaban was 15 mg (n = 11), of apixaban 10 mg (n = 1) and of dabigatran 220 mg (n = 1).
During treatment, creatinin, bilirubin, albumin, platelet counts and ALT did not change significantly, while INR increased from 1.72 to 2.19 (p = 0.002).
Adverse events included 1 case of anemia probably due to portal hypertensive gastropathy, 1 case of dizziness and disorientation and 1 case of progression of SVT. In 1 patient rivaroxaban was stopped due to hepato-renal syndrome.
Conclusions: A limited number of patients with SVT and/or cirrhosis are currently treated with DOACs. The most frequent reason for choosing DOACs is no need for INR monitoring. DOACs seem to be safe because no major bleeding episodes or liver deterioration occurred during treatment, but there is a compelling need for more data in this field.

O078

THE PREVALENCE AND MORTALITY OF ACUTE-ON-CHRONIC LIVER FAILURE DEFINED BY APASL VS. EASL–CLIF CONSORTIUM: A MULTICENTER, RETROSPECTIVE COHORT STUDY IN KOREA (KACLIF STUDY)

D.S. Song[1], T.Y. Kim[2], D.J. Kim[3], H.Y. Kim[1], D.H. Shinn[4], E.L. Yoon[5], J.H. Sohn[2], C.W. Kim[1], Y.K. Jung[6], K.T. Suk[3], J.M. Yang[1], H.J. Lee[7]. *[1]Internal medicine, College of Medicine, The Catholic University College of Korea, Seoul, [2]Internal medicine, Hanyang University Guri Hospital, Guri, [3]Internal medicine, Hallym University, Chunchon Sacred Heart Hospital, Chunchon, [4]Internal medicine, Samsung Medical Center, [5]Internal medicine, Inje University Sanggye Paik Hospital, Seoul, [6]Internal medicine, Korea University Ansan Hospital, Ansan, [7]Internal medicine, Yeungnam University College of Medicine, Daegu, Korea, South*
E-mail: dsman@catholic.ac.kr

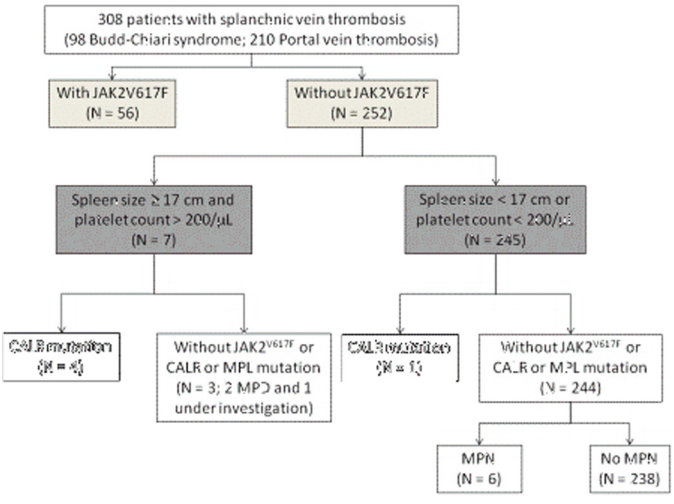
Background and Aims: Acute-on-chronic liver failure (ACLF) is defined differently between Eastern (APASL) and Western countries (EASL-CLIF consortium). This study aimed to investigate the prevalence of ACLF according to the APASL vs. EASL-CLIF definitions as well as short-term mortality.
Methods: We collected data for 1470 hospitalized patients (male 1092, median age 55±12 years) with chronic liver disease (CLD) and acute decompensation (AD) from January 2013 to December 2013 from 21 academic hospitals in Korea.
Results: The most common underlying cause of CLD was alcohol (63.1%) and the main forms of decompensation were ascites (33.0%) and variceal bleeding (32.2%). The prevalence of ACLF development based on the APASL and EASL-CLIF consortium were 155 (10.5%) and 197 (13.4%) at admission, and 45 (3.1%) and 77 (5.2%) within 28 days of enrollment, respectively. The 28-day and 90-day mortality were higher in patients with ACLF at enrollment than in those without ACLF at enrollment (by APASL definition: 19.4% vs. 4.3%, and 35.7% vs. 6.6%, respectively, $P < 0.001$; by EASL-CLIF definition: 32.0% vs. 3.9%, and 46.5% vs. 8.4%, respectively, $P < 0.001$). Of the 207 patients who satisfied the APASL or EASL-CLIF definition at the time of admission, only 54 (26.1%) patients satisfied both definitions, while the remaining patients (73.9%) satisfied only one (with APASL definition, 92 patients; with EASL-CLIF definition, 61 patients). In patients with ACLF, the 28-day and 90-day mortality in patients who satisfied both definitions were significantly higher than in those who satisfied just one definition (44.4% and 53.7%, respectively). The enrolled patients with previous AD within 1 year had higher short-term mortality than those with no previous AD or AD more than 1 year before (28-day mortality: 10.1% vs. 7.8% vs. 5.8%, $P = 0.037$, 90-day mortality: 20.2% vs. 12.0% vs. 8.8%, $P < 0.001$). And, of the 118 AD patients at enrollment who had chronic liver disease but not cirrhosis, the 28-day mortality in patients with ACLF at enrollment was not statistically different from that in patients without ACLF at enrollment (by APASL definition: 11.1% vs. 2.8%, $P = 0.275$, by EASL-CLIF definition: 6.3% vs. 2.9%, $P = 0.446$).
Conclusions: Development of ACLF is associated with high short-term mortality. However, the prevalence and mortality are significantly different when ACLF is defined by the two different APASL vs. EASL-CLIF definitions. Thus, refinement of the two ACLF definitions or a consensus definition is urgently needed.

O079

CALR SOMATIC MUTATIONS IN A PROSPECTIVE COHORT OF 308 PATIENTS WITH SPLANCHNIC VEIN THROMBOSIS

C. Marzac[1], A. Plessier[2], J.-J. Kiladjian[3], A. Andreoli[3], E. De Raucourt[4], O. Goria[5], K. Zekrini[2], C. Bureau[6], F. Lorre[1], F. Durand[2], N. Casadevall[1], D.-C. Valla[2], P.-E. Rautou[2]. *[1]Laboratoire d'Immunologie et Hématologie Biologique, Hôpital Saint-Antoine, Paris, [2]Service d'Hépatologie, Hôpital Beaujon, Clichy, [3]Centre d'Investigations Cliniques, Hôpital Saint-Louis, Paris, [4]Service d'Hématologie Biologique, Hôpital Beaujon, Clichy, [5]Service d'Hépato-gastroentérologie, CHU Rouen, Rouen, [6]Liver-Gastroenterology Department, University Hospital and Paul Sabatier University, Toulouse, France*
E-mail: pierre-emmanuel.rautou@inserm.fr

Background and Aims: Myeloproliferative neoplasms (MPN) are the leading cause of splanchnic vein thrombosis (SVT). Due to its excellent specificity for MPN, JAK2V617F analysis is very helpful in this setting. Still, 5 to 10% of SVT patients have a JAK2V617F-negative MPN, requiring bone marrow biopsy and/or cultures of erythroid progenitors for diagnosis. Recently, somatic mutations of the calreticulin (*CALR*) gene have been described in MPN patients. The aim of this study was to determine the prevalence as well as the features associated with CALR mutations in a large prospective cohort of SVT patients.
Methods: CALR, JAK2V617F and MPL mutations were analyzed in all patients with SVT prospectively included in our center. Bone marrow biopsy (searching for clusters of dystrophic megakaryocytes) and/or cultures of erythroid progenitors (searching for endogenous colonies) were performed when spleen size was ≥17 cm by imaging and platelet count >200/μL (Chait, Brit J Haematol 2005) or when considered relevant by the physician.
Results: 308 patients (162 F, 146 M), aged 43±16 years have been included (Figure). Facteur II or V gene mutations were detected in 18 (6%) and 20 (7%) patients, respectively. Antiphospholipid syndrome and paroxysmal nocturnal haemoglobinuria were diagnosed in 31 (10%) and 5 patients (2%), respectively. A MPN was diagnosed in 69 patients (23%), including 56 with JAK2V617F. None of the 308 patients had MPL mutation. CALR mutations were found in 5 (2%) patients (3F, 2M; aged 33±5 years; 4 idiopathic myelofibrosis and 1 essential thrombocythemia). All 5 patients had a spleen size ≥17 cm, except for one who had a spleen size of 16.6 cm. None of the 5 patients had JAK2V617F, factor II or V gene mutation, protein C, S or antithrombin deficiency, antiphospholipid syndrome or paroxysmal nocturnal haemoglobinuria. Patients with CALR mutations had more commonly a portal vein involvement than other patients (5/5 *vs.* 145/300; p = 0.028).



Conclusions: CALR mutations are detected in 2% of SVT patients. When present, these mutations are the only risk factor for thrombosis suggesting that this is a major determinant for SVT. CALR mutations should thus be investigated in patients with SVT without JAK2V617F. These results reinforce the diagnostic strategy based on spleen size and platelet counts since a MPN is present in virtually all JAK2V617F-negative patients with a spleen size ≥17 cm and platelet count >200/μL, *vs.* only in 3% of other patients.

EARLY CLINICAL FEATURES ASSOCIATED WITH LONG-TERM RISK OF TRANSPLANTATION IN PRIMARY SCLEROSING CHOLANGITIS: RESULTS FROM THE UK-PSC CONSORTIUM

E.C. Goode[1], B. Srivastava[2], A.B. Clark[3], K. Spiess[4], G.M. Hirschfield[5], W.T.H. Gelson[6], P.J. Trivedi[5], G.F. Mells[4], R.N. Sandford[4], G.J. Alexander[2], R.W. Chapman[7], S.M. Rushbrook[1], UK-PSC Consortium. *[1]Department of Gastroenterology, Norfolk and Norwich University Hospital, Norwich, [2]Division of Gastroenterology and Hepatology, Department of Medicine, University of Cambridge, Cambridge, [3]Norwich Medical School, University of East Anglia, Norwich, [4]Academic Department of Medical Genetics, University of Cambridge, Cambridge, [5]Centre for Liver Research and NIHR Biomedical Research Unit, University of Birmingham, Birmingham, [6]Department of Hepatology, Addenbrooke's Hospital, Cambridge University Hospitals NHS Foundation Trust, Cambridge, [7]Department of Gastroenterology, John Radcliffe Hospital, Oxford, United Kingdom*
E-mail: elizabeth.goode@doctors.org.uk

Background and Aims: Early assessment of new therapies in PSC will be aided by better surrogates of disease outcome. We determined baseline and follow up factors associated with transplantation in a representative UK cohort.
Methods: Detailed phenotypic data were collated on patients recruited to the UK-PSC national cohort (August 2008-July 2014). Unadjusted hazard ratios (HR) were estimated using the proportional hazards model; adjusted HRs were estimated using forward selection to identify variables associated with transplantation (Stata 11.2/SE).
Results: From a 1700 patient cohort, detailed phenotypic data were analysed in 500 patients (77 hospitals; 5 transplant centres; 59.4% male). Median age at diagnosis was 49.5 years, median follow-up 5.7 yrs. 68.4% had IBD (75.1% UC), 13.4% had another autoimmune disease. 87% were prescribed ursodeoxycholic acid (UDCA) (mean dose 12.8 mg/kg/day). 100 (20%) had a transplant (median age 51 yrs); need for transplantation was associated with cholangiographic disease burden with only 9.4% of patients without cholangiographic changes at baseline undergoing transplantation. 14% of females had transplants compared to 23.9% of males. 9.2% died without transplant, 4.4% due to PSC. 8.8% developed a GI cancer, most commonly colorectal (4.2%) and cholangiocarcinoma (3%). By univariate analysis, factors associated with increased need for transplantation were baseline ALP >2×ULN (p = 0.005; HR = 1.87, 95% CI 1.21, 2.89) and male gender (p = 0.03; HR 1.63, 95% CI 1.05, 2.53). At 1 and 2 years post diagnosis, ALP >1.5 and >2×ULN were associated with transplantation need (p < 0.001; see table). Absence of cholangiographic changes at baseline was protective (p = 0.023; HR 0.38, 95% CI 0.16, 0.87). After multivariate analysis, ALP >2×ULN at baseline (p = 0.001; HR 2.32, 95% CI 1.43, 3.77) and year 2 (p = 0.015; HR 2.96, 95% CI 1.23, 7.13) and ALP >1.5×ULN at year 1 (p < 0.001; HR 2.92, 95% CI 1.85, 4.59) remained associated with need for transplantation. Absence of cholangiographic changes

(p = 0.008; HR 0.28, 95% CI 0.11, 0.72) and older age at diagnosis (p = 0.01; HR 0.98, 95% CI 0.97, 1.0) appeared protective. Of note, UDCA use and IBD had no effect on transplantation need.

Variable	Univariate		Multivariate	
	p	HR (95% CI)	p	HR (95% CI)
Age at diagnosis	0.088	0.99 (0.98, 1.00)	0.01	0.98 (0.97, 1.00)
Gender	0.03	1.63 (1.05, 2.53)		
IBD	0.537	1.15 (0.73, 1.82)		
Autoimmune disease	0.90	0.97 (0.61, 1.77)		
UDCA use	0.94	1.03 (0.55, 1.92)		
Intra- and extra-hepatic disease		1		
Intra-hepatic disease only	0.006	0.52 (0.33, 0.83)	0.027	0.57 (0.35, 0.94)
No cholangiographic changes	0.023	0.38 (0.16, 0.87)	0.008	0.28 (0.11, 0.72)
Baseline ALP >1.5×ULN	0.155	1.39 (0.88, 2.19)		
Baseline ALP >2.0×ULN	0.005	1.87 (1.21, 2.89)	0.001	2.32 (1.43, 3.77)
Year 1 ALP >1.5×ULN	<0.001	2.57 (1.67, 3.95)	<0.001	2.92 (1.85, 4.59)
Year 1 ALP >2.0×ULN	<0.001	2.49 (1.63, 3.79)		
Year 2 ALP >1.5×ULN	<0.001	2.71 (1.58, 4.66)	0.059	1.96 (0.97, 3.96)
Year 2 ALP >2.0×ULN	<0.001	2.53 (1.55, 4.11)	0.015	2.96 (1.23, 7.13)

Conclusions: Long-term outcome in patients with PSC is associated with cholangiographic disease burden and ALP at baseline and follow up, with no effect of UDCA use. These emerging data from a representative UK cohort help inform models for disease stratification and choice of early exploratory endpoints for clinical trials.

O081
VAP-1 IS ELEVATED IN PSC, CORRELATES WITH CLINICAL OUTCOME AND EXHIBITS AMINE OXIDASE ACTIVITY IN A SUBSTRATE-DEPENDENT MANNER

P.J. Trivedi[1,2], J. Tickle[1], J. Vainio[3], D. Smith[3], G.M. Hirschfield[1,2], C.J. Weston[1], D.H. Adams[1,2]. *[1]NIHR Centre for Liver Research, University of Birmingham, [2]Liver Unit, Queen Elizabeth Hospital, Birmingham, United Kingdom; [3]Biotie Therapies Corp, Turku, Finland*
E-mail: p.j.trivedi@bham.ac.uk

Background and Aims: Vascular adhesion protein (VAP)-1 is an adhesion molecule possessing potent amine-oxidase activity. Activation on hepatic sinusoidal endothelium (HSEC) leads to H_2O_2 production, NFκB activation and expression of the gut-homing receptor mucosal addressin cell-adhesion molecule-1, which promotes homing of gut-tropic lymphocytes to the liver. Given the proposed role this pathway has in hepatic disorders complicating inflammatory bowel disease (IBD), our aim was to quantify circulating soluble (sVAP-1) titre in blood and determine intrahepatic/colonic enzyme activity in patients with primary sclerosing cholangitis (PSC)/IBD, and investigate consequences of activating VAP-1 with variant amine substrates.
Methods: Soluble VAP-1 was measured by ELISA in blood samples from patients with PSC (n = 105); primary biliary cirrhosis/PBC (n = 60); autoimmune hepatitis/AIH (n = 99); IBD-alone (n = 50) and healthy controls (n = 21). Correlations with clinical outcome were assessed using Cox proportional hazards assumption and KM estimates. Protein lysates were extracted from (a) explanted liver (PSC=9, PBC=10, AIH=5, normal donor, n = 10); and (b) colonic resections (ulcerative colitis=7) and VAP-1 activity quantified using the Amplex-Red assay. Putative VAP-1 substrates were selected based on their inclusion in the human metabolome database (www.hmdb.ca).
Results: PSC patients had higher circulating VAP-1 concentrations (median 517 ng/mL) than those with AIH (475), PBC (472), IBD-alone (413) and healthy controls (425) (p < 0.0001). VAP-1 levels >540 ng/mL in PSC were associated with significantly worse transplant-free survival (HR:2.94, p = 0.008). Intrahepatic VAP-1 enzyme activity was significantly greater in patients with PSC (227pmol H_2O_2/min/mg protein) compared with PBC (124), AIH (128) and healthy controls (109) (p < 0.001) and comparable to activity in inflamed colonic tissue (220). The substrate associated with highest VAP-1 enzymatic efficiency was cysteamine (k_{cat}^{app}/K_m^{app}: 5.4×10^7); an amine secreted by Escherichia spp. which induces colitis in the murine colon.
Conclusions: High levels of circulating sVAP-1 in PSC are predictive of poor prognosis. Intrahepatic VAP-1 enzyme activity is also increased in PSC akin to that seen in inflamed colon. The ability of VAP-1 to catabolise amine substrates secreted by gut commensals/enteric pathogens, provides a theoretical link between altered colonic microbiota and mucosal immunity in the pathogenesis of PSC.

E-mail: martin.kummen@medisin.uio.no

Background and Aims: The gut microbiota has been hypothesised to influence primary sclerosing cholangitis (PSC) because of its role in bile acid homeostasis and the strong association between PSC and inflammatory bowel disease (IBD). We aimed to characterize the gut microbiota of PSC in a cross-sectional cohort.
Methods: After excluding participants with antibiotics the last 4 weeks, elimination diets and previous bowel resections, we extracted DNA from stool samples collected from 90 PSC patients (n = 58 [64%] with concurrent IBD), 263 healthy controls (HC) and 36 ulcerative colitis (UC) patients without PSC. The median age (male %) for PSC patients was 50 (63), UC patients 40 (44) and HC 46 (41). All groups had similar body mass index. The V3-V4 region of the 16S rRNA gene was then sequenced from all stool samples on the Illumina MiSeq platform. Quantitative Insights Into Microbial Ecology (QIIME) was used for subsequent quality control and analysis. PSC patients and HC were randomized to a discovery and a replication panel for a two-stage design, followed by a joint analysis for comparison with UC patients.
Results: The PSC patients and HC exhibited large global differences in microbiota composition as measured by beta diversity in both the discovery and replication panel (unweighted UniFrac, PERMANOVA: p = 0.001). In PSC, there was reduced alpha diversity (i.e. richness and evenness) compared to HC in both panels (phylogenetic diversity, Chao1 and Shannon index, p < 0.001). On the taxonomic level, 12 bacterial genera had significantly different abundance in PSC and HC in the discovery panel (p < 0.05), out of which 6 were validated in the replication panel. In the joint analysis PSC patients differed from both HC and UC patients in regard to beta diversity (p < 0.01), whereas both PSC and UC differed from HC in alpha diversity (p < 0.001), with no differences between UC and PSC. In PSC patients, however, the IBD status did not influence beta and

alpha diversity. Most genera separating PSC and HC were similar in PSC and UC. However, PSC patients exhibited a significantly increased abundance (2.8 fold) of the *Veillonella* genus compared to both HC and UC ($p < 0.02$).
Conclusions: The fecal microbial profile in PSC patients was different from HC and UC patients without PSC, while the profiles in PSC patients with and without IBD were similar. Compared with HC and UC, PSC patients exhibited a marked increase in abundance of the *Veillonella* genus, which has also been linked to other conditions of fibrosis.

ABSENCE OF BSEP/ABCB11 PROTECTS FROM CHOLESTATIC LIVER AND BILE DUCT INJURY IN A MOUSE MODEL OF SCLEROSING CHOLANGITIS

C.D. Fuchs[1], G. Paumgartner[1], A. Wahlström[2], P. Chiba[3], T. Stojakovic[4], T. Claudel[1], H.-U. Marschall[2], M. Trauner[1].
[1]Internal Medicine III, Medical University of Vienna, Vienna, Austria; [2]Department of Molecular and Clinical Medicine, University of Gothenburg, Gothenburg, Sweden; [3]Institute of Medical Chemistry, [4]Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University of Vienna, Vienna, Austria
E-mail: claudia.fuchs@meduniwien.ac.at

Background and Aims: Cholestasis, characterized by intrahepatic accumulation of potentially cytotoxic bile acids (BAs) leads to liver injury reflected by disruption of hepatocellular integrity, inflammation and fibrosis. Bile salt export pump (BSEP/ABCB11) is the main canalicular BA transporter and therefore rate limiting step for hepatobiliary BA secretion. Here we investigate the role of ABCB11 in development of cholestatic liver and bile duct injury in a model of sclerosing cholangitis.
Methods: Wildtype (WT) and ABCB11 knockout (KO) mice were subjected to common bile duct ligation (CBDL) (7 days) and DDC feeding (4 weeks) as models for acute and chronic cholestasis (sclerosing cholangitis), respectively. RNA profiling was performed by RT-PCR. BA transporter expression was assessed at protein level. Serum biochemistry, hepatic hydroxyproline (HP) levels, BA composition as well as liver histology were assessed.
Results: In contrast to WT, ABCB11 KO mice where protected from cholestatic liver injury after CBDL or DDC feeding, reflected by unchanged serum levels of ALT, AST, AP, total cholesterol and BA. ABCB11 KO mice where protected from inflammation (reflected by unchanged mRNA levels of F4/80 and MCP1) and fibrosis (reflected by unchanged mRNA levels of Col1a1, Col1a2 and aSMA protein levels) while WT mice display significant up-regulation of both inflammatory (F4/80 4-fold and Mcp1 60-fold) and fibrotic (Col1a1 2-fold, Col1a2 2.5-fold, HP levels 2-fold) markers. Polyhydroxylated BAs (PHBA) were increased 4-fold in ABCB11 KO CBDL mice compared to WT CBDL mice ($p < 0.01$). mRNA expression of Cyp2b10, downstream target of CAR, a nuclear receptor regulating BA detoxification, was increased (10-fold) in ABCB11 KO mice under cholestatic conditions. Protein levels of BA transporter such as NTCP, OATP (sinusoidal uptake) and MRP2 (canalicular export) were reduced in WT and increased in ABCB11 KO mice under cholestatic conditions. MRP3 and MRP4 (sinusoidal export) protein levels were increased in WT CBDL mice and not changed in ABCB11 KO mice. Notably, the phosphorylated form of STAT3 – essential for the differentiation of pro-inflammatory TH17 cells – was exclusively found in WT BDL mice.
Conclusions: Changes in BA metabolism favouring detoxification and efflux of potentially toxic BAs protects ABCB11 KO mice from development of acute and chronic cholestatic liver injury. Therefore PHBAs may open a new therapeutic avenue against cholestasis and subsequent progression toward fibrosis in cholangiopathies such as PBC and PSC.

O084
NOVEL TREATMENT OPTIONS TO IMPROVE ABERRANT PRE-MESSENGER RNA SPLICING AND PROTEIN FOLDING IN ATP8B1 DEFICIENCY

W. van der Woerd[1,2], J. Mulder[1], F. Pagani[3], U. Beuers[1,4], R. Houwen[2], S. van de Graaf[1,4]. *[1]Tytgat Institute for Liver and Intestinal Research, Academic Medical Center, Amsterdam, [2]Department of Pediatric Gastroenterology, Wilhelmina Children's Hospital, University Medical Centre Utrecht, Utrecht, Netherlands; [3]Human Molecular Genetics, International Centre for Genetic Engineering and Biotechnology, Trieste, Italy; [4]Department of Gastroenterology & Hepatology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands*
E-mail: wvanderwoerd@hotmail.com

Background and Aims: ATP8B1 deficiency is a severe autosomal recessive liver disease due to mutations in the *ATP8B1* gene and characterized by intrahepatic cholestasis. Many *ATP8B1* mutations are predicted to affect pre-messenger RNA splicing. The most common missense mutation (p.I661T) leads to protein misfolding and disturbed protein homeostasis (proteostasis). Current therapeutic options are insufficient. The aim of our study was to elucidate the molecular consequences of *ATP8B1* mutations at exon-intron boundaries and the development of mutation-specific therapies for ATP8B1 deficiency.
Methods: Fourteen *ATP8B1* mutations at exon-intron boundaries, associated with ATP8B1 deficiency, were analysed for their effect on pre-messenger RNA splicing using an *in vitro* minigene system. Modified versions of U1 small nuclear RNA (snRNA) matching donor splice sites were expressed and subsequent splice rescue was evaluated by reverse transcription PCR. The potential of 13 proteostasis regulators to restore ATP8B1 p.I661T plasma membrane expression was evaluated by cell surface biotinylation.
Results: Eleven mutations resulted in aberrant splicing and a complete absence of correctly spliced product. Three mutations led to partially incorrect splicing. Expression of modified U1 snRNA complementary to the mutated splice donor sites strongly improved or completely rescued splicing for several *ATP8B1* mutations located at donor, as well as acceptor, splice sites. Furthermore, six proteostasis regulators caused a significant upregulation of ATP8B1 p.I661T plasma membrane expression.
Conclusions: The majority of *ATP8B1* mutations at exon-intron boundaries resulted in total exon skipping and compensatory modified U1 snRNAs were able to improve exon definition very efficiently. In addition, proteostasis regulators were able to improve ATP8B1 p.I661T plasma membrane expression. Modified U1 snRNAs as well as proteostasis regulators could be a novel therapeutic strategy in ATP8B1 deficiency and other genetic diseases.

LANREOTIDE REDUCES LIVER VOLUME YET ACCELERATES MUSCLE WASTING AND WEIGHT LOSS IN SYMPTOMATIC POLYCYSTIC LIVER DISEASE

F. Temmerman[1], T.A. Ho[2], R. Vanslembrouck[3], W. Coudyzer[3], J. Billen[4], F. Dobbels[5], J. van Pelt[1], B. Bammens[6], Y. Pirson[2], F. Nevens[1]. *[1]Hepatology, University Hospital KULeuven, Leuven, [2]Nephrology, Université Catholique de Louvain, Brussels, [3]Radiology, [4]Laboratory Medicine, [5]Public health and Primary care, [6]Nephrology, University Hospital KULeuven, Leuven, Belgium*
E-mail: frederik.temmerman@uzleuven.be

Background and Aims: Polycystic liver disease (PCLD) can induce malnutrition due to extensive hepatomegaly, forming an indication for liver transplantation (LTx). The somatostatin analogue (SA) lanreotide 120 mg (LAN) given for 6 months reduces liver volume (LV). We aimed to investigate the efficacy and long-term safety of LAN.

Methods: In this 18 month prospective trial performed in 2 tertiary centers, patients were administered LAN 90 mg/4 weeks for 6 months. If a LV reduction ≥100 mL (responders) was induced, patients continued to receive LAN 90 mg for an additional year. Non-responders were offered dose-escalation to LAN120 mg. LV and body composition were measured by CT-scan.
Results: Of 67 patients screened, 59 were included. 21/53 patients (40%) were responders at month 6 of which 19 (90%) reached the 18-month endpoint. The absolute LV change after 18 months was −430 mL (SE: 92). In non-responders, LV increased with +120 mL (SE: 42), yet no further increase was observed after dose-escalation in the 24 patients who reached the endpoint. All subscales of the PCLD complaints specific assessment (POLCA) improved including an improved food intake ($p = 0.04$). A significant decrease of weight and total muscle mass was observed; whereas subcutaneous and visceral fat mass were not affected. This was congruent with a significant reduction of insulin-like growth factor 1 level: from 19% to 50% below the age-adjusted normal range level ($p = 0.002$).
Conclusions: This study demonstrates that low doses of LAN induce LV reduction and relief of complaints. Weight loss and muscle wasting may limit the long-term use of SA due to the induction of growth-hormone deficiency and needs further exploration (clinicaltrials.gov.identifier NCT01315795).

O086
BUDESONIDE FOR AUTOIMMUNE HEPATITIS: RESPONSE RATE AND LIMITATIONS IN A LARGE REAL LIFE COHORT

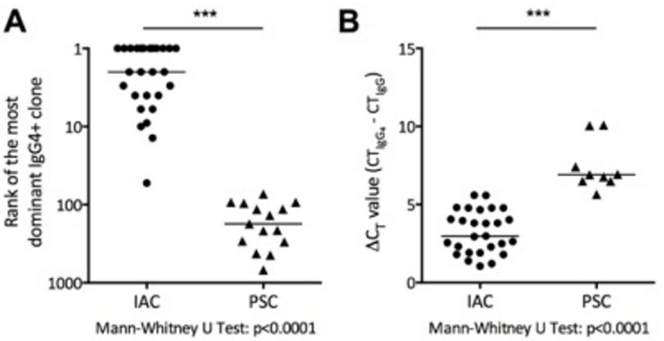
M. Peiseler[1], T. Liebscher[1], N. Pannicke[1], M. Sebode[1], R. Zenouzi[1], J. Hartl[1], H. Ehlken[1], C. Weiler-Normann[1], A.W. Lohse[1], C. Schramm[1]. *[1]I. Department of Internal Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*
E-mail: moritz.peiseler@gmx.de

Background and Aims: Autoimmune hepatitis (AIH) responds well to immunosuppressive treatment with prednisolone and azathioprine, yet many patients (pts) suffer from steroid-specific side effects. Budesonide was shown to be effective in inducing and maintaining remission with fewer steroid-specific side effects in a controlled clinical trial (Manns et al. 2010 Gastroenterology). In order to assess the usefulness of budesonide in real life we here report on a large cohort of pts with AIH or AIH/PBC overlap syndrome treated with budesonide at our unit.
Methods: 83 pts (67 AIH and 16 overlap) were identified who had received budesonide for at least 6 months (mos). Treatment response was evaluated at 6, 12 and 24 mos. For comparison with the published study, treatment response was defined as normal levels of aminotransferases.
Results: Start of treatment was with 9 mg/d and the mean maintenance dose of budesonide was 6.2 mg. 38 (46%) pts were given budesonide due to steroid-specific side effects, 35 (42%) because of steroid-dependency and 10 (12%) pts as initial therapy. After 6, 12 and 24 mos, 55%, 69% and 64% of all pts achieved remission. Pts who were given budesonide due to steroid-specific side effects, demonstrated remission in 58% after 6 mos, in 64% after 12 mos and in 64% after 24 mos. The steroid-dependent group reached remission in 54% after 6 mos, in 70% after 12 mos and in 63% after 24 mos. The group of pts who were given budesonide as initial therapy achieved remission in 50% after 6 mos, in 85% after 12 mos and in 67% after 24 mos. At last follow up, 66% (55/83) of all pts were in remission. A total of 36 pts (43%) were still on budesonide, but 22 pts (26%) had changed back to prednisolone. 13 pts received neither prednisolone nor budesonide and 9 pts had stopped treatment. We identified 13 pts with steroid-induced osteopenia at the beginning of budesonide treatment. In follow up DXA we saw improvement in 5 pts, stable results in 5 pts and worsening in only 1 pt. 18 pts were treated with budesonide alone, including 8 pts with an overlap. Overlap pts responded favourably to budesonide treatment with 75% reaching remission after 6 mos compared to only 40% of AIH pts.
Conclusions: Budesonide can be considered as an alternative to conventional steroids for the treatment of AIH. However, efficacy may be lower than prednisolone since one quarter of pts had to be switched back due to insufficient response. Pts with an overlap syndrome may demonstrate a more favourable response to budesonide treatment.

O087
IgG4+ B-CELL RECEPTOR CLONES IN PERIPHERAL BLOOD DISTINGUISH IgG4-ASSOCIATED CHOLANGITIS/AUTOIMMUNE PANCREATITIS FROM PRIMARY SCLEROSING CHOLANGITIS

L.M. Hubers[1,2], M.E. Doorenspleet[3,4], E.L. Culver[5,6], L.J. Maillette de Buy Wenniger[1,2], P.L. Klarenbeek[3,4], S.F. Van de Graaf[2], J. Verheij[7], T.M. Van Gulik[8], F. Baas[9], E. Barnes[5,6,10], N. De Vries[3,4], U. Beuers[1,2]. *[1]Gastroenterology and Hepatology, [2]Tytgat Institute of Liver and Intestinal Research, [3]Clinical Immunology and Rheumatology, [4]Laboratory of Experimental Immunology, Academic Medical Center, Amsterdam, Netherlands; [5]Translational Gastroenterology Unit, John Radcliffe Hospital, [6]NDM, Oxford University, Oxford, United Kingdom; [7]Pathology, [8]Experimental Surgery, [9]Genome Analysis, Academic Medical Center, Amsterdam, Netherlands; [10]Oxford NIHR Biomedical Research Center, Oxford University, Oxford, United Kingdom*
E-mail: l.m.hubers@amc.uva.nl

Background and Aims: Immunoglobulin G4-related disease (IgG4-RD) predominantly affects the biliary tract (IgG4-associated cholangitis, IAC) and pancreas (autoimmune pancreatitis, AIP). Its clinical presentation often mimics primary sclerosing cholangitis (PSC) and/or pancreatobiliary malignancies, and an accurate diagnostic marker is lacking. Recently, we identified dominant IgG4+ B-cell receptor (BCR) clones in blood of 6 patients with active IAC, but not in controls, using next-generation sequencing (NGS; Hepatology 2013;57:2340). Here, we aimed to validate our findings in larger patient cohorts and to test a novel qPCR protocol in comparison to NGS.
Methods: 27 patients with IAC/AIP fulfilling HISORt criteria were included in one Dutch (n = 17) and one English (n = 10) academic hospital. Also, 15 PSC controls were included. The total BCR heavy-chain repertoire was analysed using primers for all V(ariable)-genes and total RNA from peripheral blood. All amplified products encoded CDR3, the region defining a unique clone. The number of identical sequences reflects the size of the BCR clone. In addition, qPCR was performed on 27 IAC/AIP patients and 9 disease controls using forward primers for all IgG subtypes and IgG4 specifically; one generic reverse primer was used within the constant region of the receptor. Differences between the specific IgG4 and total IgG message in peripheral blood were calculated and expressed as differences in CT value.



Results: IgG4+ BCR clones were detected in all individuals included. 25/27 of all IAC/AIP patients had IgG4+ BCR clones that were among the 10 most dominant IgG+ BCR clones in blood (median 2nd, range 1–53; Figure 1A), whereas the most dominant IgG4+ BCR clone in

PSC patients ranked 176th (median, range 73–686, $p < 0.0001$). All IgG4+ clones together covered 16.6% of all IgG+ clones, and 19.9% of the IgG+ repertoire (compared to 1.6% and 1.0% resp. in PSC controls). This difference was confirmed using qPCR: in IAC/AIP patients the median ΔCT value was 3.0 (1.0–5.6), compared to 6.9 in PSC patients (range 5.6–10.1, $p < 0.0001$).

Conclusions: Identification of highly dominant IgG4+ BCR clones by NGS in patients with active IAC/AIP clearly distinguishes IAC/AIP from PSC. Our novel qPCR protocol, in comparison to NGS, could be a simple and inexpensive alternative diagnostic tool. Expansion of patient cohorts (IAC/AIP, PSC, pancreatobiliary malignancies) for test validation is underway.

OMBITASVIR/PARITAPREVIR/RITONAVIR FOR TREATMENT OF HCV GENOTYPE 1b IN JAPANESE PATIENTS WITH OR WITHOUT CIRRHOSIS: RESULTS FROM GIFT-I

K. Chayama[1], F. Suzuki[2], K. Ikeda[2], H. Toyoda[3], K. Sato[4], Y. Karino[5], Y. Matsuzaki[6], K. Kioka[7], T. Pilot-Matias[8], C. Setze[8], X. Zhang[8], P. Badri[8], T. Yanke[8], T. Matsuda[9], R.A. Vilchez[8], L. Rodrigues-Jr[8], H. Kumada[2]. *[1]Hiroshima University, Hiroshima, [2]Toranomon Hospital, Tokyo, [3]Ogaki Municipal Hospital, Gifu, [4]Gunma University Hospital, Maebashi, [5]Sapporo Kosi General Hospital, Sapporo, Hokkaido, [6]Tokyo Medical University, Ibaraki Medical Center, Ibaraki, [7]Osaka City General Hospital, Osaka, Japan; [8]AbbVie Inc, North Chicago, United States; [9]AbbVie GK, Tokyo, Japan*
E-mail: kristina.kligys@abbvie.com

Background and Aims: Sustained virologic response (SVR) rates of 99–100% have been achieved with the 3 direct acting antivirals ombitasvir (OBV), paritaprevir (PTV, formerly ABT-450, identified by AbbVie and Enanta, co-dosed with ritonavir [PTV/r]) with dasabuvir (DSV) in multinational phase 3 clinical trials of treatment-naïve (TN) and treatment-experienced (TE) HCV genotype 1b (GT1b)-infected patients (pts). Since PTV levels are higher in Japanese than Western pts, the Phase 3 trial, GIFT-1, evaluated the efficacy and safety of PTV/r with OBV (2D) without DSV in Japanese HCV GT1b-infected pts.

Methods: In the double-blind (DB), placebo (PBO)-controlled substudy, TN and TE adult Japanese HCV GT1b-infected pts without cirrhosis were randomized 2:1 to receive DB co-formulated 2D (OBV/PTV/r; 25 mg/150 mg/100 mg QD) or PBO for 12 weeks. Pts with cirrhosis received 12 weeks of open-label (OL) 2D. SVR was defined as HCV RNA < lower limit of quantification (<25 IU/ml) 12 weeks post-treatment (SVR12). The primary efficacy population (PEP) was TN, non-cirrhotic pts eligible for interferon (IFN) therapy with HCV RNA ≥100,000 IU/ml. Treatment-emergent adverse events (TEAEs) were captured from first dose through 30 days after last dose of study drug.

Results: A total of 363 pts were randomized/enrolled (DB 2D, N = 215; DB PBO, N = 106; OL 2D, N = 42). Demographics and baseline disease characteristics were generally similar between DB treatment arms. Among non-cirrhotic pts, SVR12 rates were 94.6% in the PEP, 94.2% in TN, and 96.1% in TE pts. SVR12 rates were >90% in all subpopulations based on stratification factors at randomization (Tables). Reasons for not achieving SVR12 are shown in the table. Most TEAEs were mild or moderate in severity. The most common TEAEs in non-cirrhotic pts were nasopharyngitis (16.7%), headache (8.8%), and peripheral edema (5.1%). Peripheral edema occurred significantly more frequently with DB 2D (5.1%) than PBO (0%) and all pts were using concomitant calcium-channel blockers. Nasopharyngitis (14.3%) was the most common TEAE in cirrhotic patients. Of the patients receiving DB or OL 2D, 9 had serious TEAEs and 3 discontinued treatment due to TEAEs.

Table 1. Virologic response in HCV GT1b-infected patients treated with ombitasvir/paritaprevir/r

Population (ITT)	SVR12 [#], n/N (%)	95% CI
Non-cirrhotic treatment-naïve patients	131/139 (94.2)	89.1, 97.1
Primary efficacy population	106/112 (94.6)	90.5, 98.8
Low viral load [¶]	6/6 (100)	61.0, 100
IFN ineligible [¶]	21/23 (91.3)	73.2, 97.6
Non-cirrhotic treatment-experienced patients	73/76 (96.1)	89.0, 98.6
Relapse	21/22 (95.5)	78.2, 99.2
Non-response	28/28 (100)	87.9, 100
IFN intolerant	24/26 (92.3)	75.9, 97.9
Cirrhotic patients	38/42 (90.5)	77.9, 96.2

IFN, interferon.
[#] Patients with missing data after imputations were applied were counted as failures.
[¶] These categories are not mutually exclusive.

Table 2. Reasons for not achieving SVR12

	Non-cirrhotic ITT population		Cirrhotic ITT population
	Treatment naïve (N = 139)	Treatment experienced (N = 76)	All patients (N = 42)
On-treatment virologic failure*, n	0	1	1
Relapse [†], n	4	1	2
Other [‡], n	4	1	1

*Confirmed viral breakthrough or failure to suppress with at least 6 weeks of treatment.
[†] Confirmed HCV RNA ≥25 IU/mL post-treatment through SVR12 out of the patients completing treatment with HCV RNA <25 at end of treatment and post treatment HCV RNA data.
[‡] Patients not achieving SVR12 without on-treatment viral failure or relapse (e.g. early discontinuation or lost to follow-up).

Conclusions: High response rates were achieved with the IFN- and RBV-free once-daily regimen of OBV/PTV/r in Japanese HCV GT1b-infected pts with or without cirrhosis. The 2D regimen was generally well-tolerated with few treatment discontinuations due to TEAEs.

G14

SYSTEMIC INFLAMMATORY RESPONSE SYNDROME (SIRS) IS A MAJOR DETERMINANT OF TREATMENT RESPONSE TO TERLIPRESSIN FOR HEPATORENAL SYNDROME TYPE 1 (HRS-1)

F. Wong[1], S.C. Pappas[2], T.D. Boyer[3], A.J. Sanyal[4], K. Jamil[5], on behalf of The REVERSE Study Investigators. *[1]University of Toronto, Toronto, Canada; [2]Orphan Therapeutics, Lebanon; [3]University of Arizona, Tucson, [4]Virginia Commonwealth University, Richmond, [5]Ikaria, Hampton, United States*
E-mail: spappas1@comcast.net

Background and Aims: Infection is a common precursor of HRS-1 and may be associated with SIRS. The presence of SIRS in patients with decompensated cirrhosis and acute kidney injury (AKI) has been associated with a poorer prognosis, and therefore possibly also a lower response to treatment for AKI. The REVERSE study, a randomized placebo controlled study of terlipressin in patients with HRS-1 included enrollment of patients with ≥2 SIRS criteria in the

absence of untreated infection. The aim of the current study was to evaluate the effect of SIRS on the response to terlipressin in HRS-1.
Methods: SIRS was defined as the presence of ≥2 of 3 SIRS criteria: WBC <4000 or >12,000 cells/μL; HR >90 bpm and HCO_3 <21 mmol/L (an approximation of the SIRS criterion PaCO2 of <32 mmHg). Subjects with HRS-1 were randomized to terlipressin (1 mg IV every 6 hours) or placebo, plus albumin in both groups. Efficacy endpoints evaluated included confirmed HRS reversal (CHRSR) defined as 2 SCr values ≤1.5 mg/dL, at least 48 hours apart, and HRS reversal defined as a decrease in SCr to ≤1.5 mg/dL, change in SCr and survival.
Results: SIRS was present in 58/196 (30.0%) of subjects. Baseline clinical characteristics were similar between SIRS and non-SIRS groups; there was slightly higher WBC and heart rate, and slightly lower HCO3 in the SIRS group, as expected. In the SIRS group, CHRSR was observed in 9/28 subjects (32.1%) with terlipressin vs. 1/30 subjects (3.3%) with placebo ($p < 0.005$). In subjects treated with terlipressin (n = 97), CHRSR was observed in 9/28 subjects with SIRS (32.1%) vs. 10/69 subjects (14.5%) without SIRS ($p < 0.05$); HRS reversal with terlipressin was observed in 12/28 (42.9%) subjects with SIRS compared with 11/69 (15.9%) subjects without SIRS ($p < 0.005$). The change from baseline to end of treatment in SCr in response to terlipressin was significantly greater for SIRS subjects (−1.4 mg/dL) vs. non-SIRS subjects (−0.8 mg/dL, $p < 0.05$). For subjects treated with terlipressin, survival estimates (Figure) and the percentage of subjects alive and transplant-free at Day 90 were higher in the SIRS subjects (13/28, 46.4%) compared to the non-SIRS subjects (17/69, 24.6%) ($p = 0.0517$)
Conclusions: SIRS is common in patients with HRS-1. Despite the presence of SIRS, the response of these subjects to terlipressin is significantly better than that in subjects without SIRS and those treated with placebo. Terlipressin is effective in improving renal function and achieving HRS reversal in patients with HRS-1 and SIRS.

E-mail: jean-charles.duclos-vallee@pbr.aphp.fr

Background and Aims: HCV recurrence is a main complication following liver transplantation (LT) impacting graft and patient survival. The recent approval of IFN-free regimen using direct antiviral agents (DAA) has radically changed the management of liver transplant recipients. However, the optimal strategy remains to be determined. The aim of this study was to assess efficacy and safety of sofosbuvir (SOF) and daclatasvir (DCV)-based regimens in this setting.
Methods: The ANRS CO23 CUPILT study is a prospective cohort including currently 335 patients (pts) with HCV recurrence and treated with 2nd generation DAA. All pts treated with SOF+DCV±ribavirin (RBV) between Jul. 2013 and Nov. 2014 were included in the present study.
Results: This study enrolled 190 liver recipients (male: 76%, mean age 59±9years [33–83]), with an active HCV recurrence (G1:116, G3:17, G4:12, G5:1), in 19 centers. The mean delay between LT and starting therapy was 74.2±73.5 months [1.8–339.4]. Treatment duration was 24 weeks (wk) in 84% of pts. RBV was given in 67 (38%) pts. Indication was severe HCV recurrence, including 32 cirrhotic pts, and 11 cholestatic hepatitis. Eighty-three (46%) pts were non-responders to a previous course of therapy post-LT [including Peg-FN/RBV: 64 (77%); 1st generation PI based regimen: 16 (19%)]. Eighty-nine percent of pts received cyclosporine (32%) or tacrolimus (68%).
At baseline, HCV viral load, GGT and hemoglobin levels were 6.4±0.7log10 IU/mL [4.2–8.4], 381.8±573.4 IU/L [16–3561], 12.8±2.3 g/dL [7.8–17.9], respectively. After 4 wks, a complete virological response was obtained in 36/178 (23%) pts. One pt experienced a virological breakthrough (wk 8); among 115 pts who have completed the treatment, the end of treatment response was achieved in 114 (99%). One pt relapsed at wk 4 post-treatment; 62/64 (97%) and 42/44 (95%) pts achieved SVR4 and 12, respectively.
Twenty-three (12%) pts experienced serious adverse events (SAE), leading to 2 premature discontinuations (wk 1 and 2) including 1 death (diabetic coma). Most common SAE were hematological toxicity. Anemia occurred in 6 (3%) pts, all treated with RBV. Eight non-severe infections occurred. Two non-severe biopsy-proven acute rejections occurred after treatment discontinuation. No drug–drug interaction was reported.

Conclusions: SOF and DCV based regimens showed excellent results combining high rate of SVR4 and 12 (97% and 95%, respectively) and a good tolerance. Final results will be presented.

G16

THE COUNFOUNDING ROLE OF SEVERE COMORBIDITIES AND ALCOHOL USE DISORDERS ON PROGNOSIS IN CHRONIC HEPATITIS C VIRUS INFECTION: AN ANALYSIS OF THE 2008–2012 FRENCH NATIONAL HOSPITAL DISCHARGE DATABASE

M. Schwarzinger[1], S. Thiébaut[1], V. Mallet[2], J. Rehm[3]. *[1]THEN (Translational Health Economics Network), Paris, France; [2]Hepatology, Assistance Publique-Hôpitaux de Paris, Hôpital Cochin, Paris, France; [3]Social and Epidemiological Research (SER) Department, Centre for Addiction and Mental Health, Toronto, Canada*
E-mail: michael.schwarzinger@transhealthecon.net

Background and Aims: There is an epidemiological relationship between chronic hepatitis C virus (HCV) infection and alcohol use disorders (AUD). AUD is a leading cause of liver disease and death. However, burden of chronic HCV infection analyses barely take into account the potential confounding role of AUD on prognosis. Our aim was to compare the prognostic value of chronic HCV infection and AUD in the general population.
Methods: In 2008–2012, 28,953,755 adult individuals residing in Metropolitan France were hospitalized and 1,506,453 died at hospital (51.6% and 55.7% of National Vital Statistics, respectively). We characterized all hospitalized patients by severe comorbidities (see Table), and tracked their trajectory according to chronic HCV infection and/or AUD (including withdrawal/abstinence). Age at death was analyzed in multivariate Cox proportional hazards model from January 2008 to last discharge or transplantation with stratification by gender, main French regions, and having received care in teaching hospitals.
Results: Chronic HCV infection was present in 112,146 (0.39%) of hospitalized patients, AUD in 705,259 (2.44%), both chronic HCV infection and AUD in 23,351 (0.08%; i.e., 20.8% of HCV and 3.3% of AUD). Overall, the adjusted hazard ratio of in-hospital death (aHR) was 1.90 (95% confidence interval 1.86–1.94) for chronic HCV infection and 3.13 (3.10–3.15) for AUD, with a negative interaction effect between chronic HCV infection and AUD (aHR: 0.93; 0.90–0.97). Alcohol withdrawal or abstinence was significantly associated with lower mortality risks (HR, 0.66; 0.65–0.67). Subgroup analyses by severe comorbidities revealed that chronic HCV infection was only associated with higher mortality risks in presence of severe comorbidities (Table: groups 1 to 4, and 7 to 12). In absence of severe comorbidities, the prognostic value of chronic HCV infection was not statistically significant among patients with cirrhosis and milder liver disease stage (groups 13 to 17). In contrast, AUD was associated with higher mortality risks in all prognostic subgroups, including all liver disease stages.
Conclusions: AUD has a dismal prognostic value in the general population and in the minority group of patients with chronic HCV infection. Alcohol withdrawal and abstinence increase survival regardless of HCV treatment.

Table (abstract G16): Sequential characterization of patients

	Characteristic	Patients, n (%)	HCV (%)	AUD (%)	HCV & AUD (%)	In-hospital death (%)	Mortality risk, aHR (95% CI) HCV	AUD	Interaction HCV & AUD	Withdrawal or abstinence among AUD

A DISTINCT PROFILE OF LYSO-PHOSPHATIDYLCHOLINES AND AMINO ACIDS CHARACTERIZES NAFLD IN LEAN SUBJECTS

A. Feldman[1,2], S. Eder[1], T.K. Felder[3], A. Stadlmayr[2,4], C. Datz[2,4], E. Aigner[1,2]. *[1]First Department of Medicine, [2]Obesity Research Unit, [3]Department of Laboratory Medicine, Paracelsus Medical University, Salzburg, [4]Department of Internal Medicine, General Hospital, Oberndorf, Austria*
E-mail: alexandra.feldman@outlook.com

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is typically associated with obesity and the metabolic syndrome, however, approximately 10% of lean subjects (BMI <25) also have NAFLD. The aim of this study was to identify clinical and metabolic features of NAFLD in lean Caucasian subjects.
Methods: Data from 247 patients allocated to one of 4 groups according to BMI and hepatic steatosis on ultrasound were obtained: lean healthy (BMI ≤25 kg/m^2, no steatosis, N = 76), lean steatosis (BMI ≤25 kg/m^2, steatosis, N = 57), obese healthy (BMI ≥30 kg/m^2, no steatosis, N = 52), obese steatosis (BMI ≥30 kg/m^2, steatosis; N = 62). A detailed clinical and laboratory examination including oral glucose tolerance test (oGTT) was performed. Metabolite profile was obtained by API 4000 triple quadrupole mass spectrometer (ABSciex) using the AbsoluteIDQ™ p180 kit (BIOCRATES Life Sciences). Significant differences between groups were calculated using the false discovery rate (FDR) approach for metablomics analyses and ANOVA for comparison of clinical characteristics.
Results: Lean NAFLD subjects had fasting glucose concentrations and HOMA-IR similar to lean healthy subjects. However, lean NAFLD subjects had markedly impaired glucose tolerance as assessed by oGTT similar to obese NAFLD patients, and significantly different from lean healthy subjects (P < 0.001). In the metabolomics analysis significantly lower levels of sphingomyelin (OH) C14:1, lysophosphatidylcholine (lysoPC) C18:0, lysoPC C17:0, phosphatidylcholine with diacryl residue sum (PC aa) C34:2 and higher levels of glutamic acid (FDR < 0.001 for all analytes) were found in lean NAFLD compared to lean healthy subjects. A sum of lysoPC C18:0 and lysoPC C17:0 can separate lean healthy from lean NAFLD with a ROC area under the curve (AUC) of 0.76. Additionally, in lean NAFLD subjects higher levels of phosphatidylcholine with acyl-alkyl residue sum (PC ae) C 42:3, lysine and lower levels of alanine, tyrosine, valine and butyrylcarnitine (FDR < 0.001 for all analytes) were found when compared to obese NAFLD. ROC analysis of lysine, alanine and tyrosine discriminated lean and obese NAFLD subjects with an AUC of 0.88.
Conclusions: Although lean NAFLD patients have normal fasting glucose concentrations, the degree of glucose intolerance is similar to obese NAFLD patients. Furthermore, a distinct profile of lysoPCs and amino acids may be distinguishing indicators of the metabolic alterations linked to NAFLD in lean subjects.

G18

THE FXR AGONIST PX20606 REDUCES LIVER DAMAGE, FIBROSIS AND PORTAL HYPERTENSION IN CIRRHOTIC RATS

P. Schwabl[1], E. Hambruch[2], B.A. Payer[1], T.L. Schubert[1], B. Strobel[1], S. Fida[1], M. Wagner[1], L. Garnys[1], M. Trauner[1], M. Peck-Radosavljevic[1], C. Kremoser[2], T. Reiberger[1], Hepatic Experimental Hemodynamic Laboratory of Vienna. *[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [2]Phenex Pharmaceuticals AG, Heidelberg, Germany*
E-mail: philipp.schwabl@meduniwien.ac.at

Background and Aims: Steroidal FXR agonists attenuate liver injury and reduce portal hypertension in experimental models of cirrhosis. We aimed to assess the impact of the nonsteroidal FXR agonist PX20606 (PX) on liver histology, inflammation and hemodynamics in cirrhotic rats.
Methods: Cirrhosis was induced by carbontetrachloride (CCl_4) injections (2× weekly i.p. for 12 weeks) in Sprague Dawley rats. Controls received corn oil. PX (10 mg/kg/day) or placebo (DMSO) were gavaged daily from week 4. Blood was sampled at week 6 and 11. At end of treatment, mean arterial pressure (MAP), heart rate (HR), portal pressure (PP) and superior mesenteric artery blood flow (SMABF) were measured. Liver fibrosis was assessed by Sirius Red area (SRA) and content of hydroxyproline (HP), collagen-I (Col1) and α-smooth muscle actin (αSMA). Col1 and αSMA were assessed by immunofluorescence staining. Hepatic expression of fibrogenic genes was quantified by qRT-PCR [shown as x-fold (×) of control].
Results: CCl_4 rats presented with marked cirrhosis, elevated transaminases and portal hypertension compared to corn oil-treated animals. In CCl_4 rats, PX treatment significantly ameliorated fibrosis (SRA: 6.99±3.15 vs. 3.97±1.64%; p < 0.001. HP: 415±86 vs. 134±14 μg/g liver; p = 0.002) and reduced Col1 (12.28±1.78 vs. 4.93±0.28; p < 0.05) and αSMA (7.78±1.41 vs. 2.08±0.49; p < 0.05) content. Accordingly AST (555±30 vs. 227±83 IU/ml; p < 0.001) and ALT (538±233 vs. 193±86 IU/ml; p = 0.008) significantly decreased under PX treatment, while plasma cholesterol or triglycerides levels remained unaffected. In cirrhotic rats, PX treatment significantly decreased PP (11.9±1.4 vs. 9.7±1.4 mmHg; p = 0.037) and increased SMABF (8.88±2.62 vs. 13.81±2.81 ml/min/100g; p = 0.021), while not affecting MAP (125±14 vs. 116±25 mmHg) nor HR (330±29 vs. 333±52bpm). Livers of CCl_4-PX rats significantly overexpressed FXR target genes including bile salt export pump (2.5×), small heterodimer partner (2.3×), cystathionase (2.1×) and dimethylargininase (1.7×). Expression of endothelin-1 (0.45×), PDGF-Rβ (0.51×) and αSMA (0.61×) were significantly reduced. In corn oil-treated animals PX did not affect liver histology, transaminases, MAP or HR.
Conclusions: PX20606 treatment reduces hepatic inflammation, stellate cell activation and fibrogenesis and thus significantly reduced portal pressure in cirrhotic rats. PX20606, as a selective,

HIGH-THROUGHPUT SEQUENCING OF THE HUMAN HEPATIC PROGENITOR CELL NICHE REVEALS DIFFERENT SIGNALLING PATHWAYS DEPENDING ON THE UNDERLYING CHRONIC LIVER DISEASE

O. Govaere[1], J. Wouters[1], W. van Delm[2], R. van Eijsden[2], A. Ceulemans[1], W. van Steenbergen[3], D. Monbaliu[4], F. Nevens[3], T. Roskams[1]. *[1]Department of Imaging and Pathology, KU Leuven and University Hospitals Leuven, [2]VIB Nucleomics Core, KULeuven, [3]Department of Hepatology, [4]Department of Abdominal Transplant Surgery, KU Leuven and University Hospitals Leuven, Leuven, Belgium*
E-mail: olivier.govaere@med.kuleuven.be

Background and Aims: Hepatic progenitor cells (HPCs) can differentiate into cholangiocytes or hepatocytes, depending on the underlying aetiology. Though some pathways are known to be involved in the process of differentiation, it still is unclear how HPCs interact with their surrounding niche.
Methods: Using laser microdissection, the HPC niche was isolated from samples obtained from patients diagnosed with primary sclerosing cholangitis (PSC n = 6) or hepatitis C virus (HCV n = 5), as models for biliary or hepatocellular regeneration. Isolated mRNA was amplified using the Clonetech SMARTer kit and processed for Illumina HiSeq sequencing. Differentially expressed genes were integrated with Ingenuity Pathway analysis. Immunohistochemistry was used for protein validation on a set 40 FFPE samples (PSC n = 20, HCV n = 20).
Results: In total 304 genes were significantly differentially expressed. Recruitment and homing of inflammatory cells was distinctly different. The niche in PSC was characterised by neutrophil attractant chemokines (CXCL5, CXCL6, IL-8) together with CCL28, whereas HCV was identified by T- and B-lymphocyte infiltration and a strong interaction with macrophages (as HPCs in HCV expressed the macrophage receptor MARCO). In addition the composition of the niche's extracellular matrix differed depending on the disease (e.g. FN1, LAMC2 in PSC and COL17A1 in HCV) but also reflecting the stage of the disease. Even the neighbouring endothelial cells proved to have a different phenotype (e.g. RORB, FOXJ1, INHBA). Transcriptional regulators (e.g. KLF4, ERK1/2, HNF4A) and growth factors (e.g. IGF2, TGFB2, BMP9) were also differentially expressed.
Conclusions: Our data sheds light on the different signalling pathways in human biliary vs hepatitis chronic liver disease.

O089

INCREASED NEURONAL EXPRESSION OF K-TYPE GLUTAMINASE POTENTIATES BRAIN EDEMA IN ACUTE LIVER FAILURE MICE THROUGH A TLR4 DEPENDENT PATHWAY

Y. Sharifi[1], G. Wright[1], M. Jover[1], N. Shah[1], F. Scaravilli[2], R. Jalan[1], on behalf of Liver Failure Group, Institute for Liver and Digestive Health, UCL: Royal Free Hospital. *[1]Liver Failure Group, Institute for Liver and Digestive Health, UCL: Royal Free Hospital, [2]UCL Institute of Neurology, Queen Square, UCL, London, United Kingdom*
E-mail: yalda.sharifi@ucl.ac.uk

Background and Aims: *Introduction:* In the brain Ammonia is detoxified to glutamine through the action of astrocytic glutamine synthase. This glutamine transported to the neurons serves as an energy source via neuronal mitochondrial glutaminase (K-glutaminase) producing ammonia. Accumulating ammonia may become neurotoxic, an effect partly modulated by TLR4. Therefore increasedbrain K-glutaminase activity and ammonia generation could produce neuronal dysfunction.
Aim: To assess the expression and activity of neuronal K-glutaminase in ALF and determine whether this involves TLR4-dependent pathways.
Methods: *Study 1*: 3 groups of mice studied. Healthy: n = 6; ALF induced by acetaminophen (APAP) (500 mg/kg IP): n = 7; and ALF treated with STM 28, a TLR4 antagonist. The animals were sacrificed after 8-hour or at coma. *Study 2*: 4 groups of mice studied [*WT control*: n = 10, *WT* (NH_3), n = 10 (using NH_4Cl in diet); *TLR4 ko control* ($TLR4^{-/-}$), n = 6; $TLR4^{-/-}$(NH_3) n = 13]. Arterial ammonia and frontal cortex brain water were measured. Brain was snap frozen for PCR and brain sections were stained for Glase.
Results: *Study 1*: ALF induced significant increase in ammonia and brain water in the APAP group compared with controls (345±32 vs. 132±11 umol/L, p = 0.002) (83.6±2.3% vs. 76.3±2.6%, p = 0.05) respectively. Immunohistochemistry of brain slices showed significantly increased K-Glase expression in the neurons in the frontal cortex, hippocampus and cerebellum of the ALF treated animals compared with healthy controls. Glase activity was significantly increased in ALF treated groups compared with controls (7.9±0.2 vs 6.2±0.7 p < 0.03) and reduced significantly in the STM 28 animals (p < 0.03) in parallel with reduced brain water and time to coma (p < 0.01 each). *Study 2*: Hyperammonemia resulted in a significant increase in brain water in WT animals compared with $TLR4^{-/-}$ cohort (p 0.02), Glase expression and activity was significantly reduced in the $TLR4^{-/-}$ hyperammonemic animals compared with the WT hyperammonemic group (8.5±0.4 vs 7.2±0.1, p = 0.01).
Conclusions: The study shows for the first time a potential role of neuronal production of ammonia by increased expression of Glase. Reduction of brain inflammation using TLR4 antagonist or a knocking out TLR4 results in reduction of Glase expression, activity and reduction in brain edema suggesting a potential role of TLR4 signalling in the modulation of increased neuronal Glase in ALF. Further studies should address the mechanisms involved and whether Glase may be a target of therapy.

O090

HUMANIZATION OF GERM-FREE MICE WITH ALCOHOLIC CIRRHOTIC MICROBIOTA, BUT NOT HEALTHY MICROBIOTA, INDUCES BACTERIAL TRANSLOCATION AND A PRO-INFLAMMATORY MILIEU, WHICH IS AMELIORATED WITH LACTOBACILLUS GG

D.J. Kang[1], P.B. Hylemon[1], R.B. Sartor[2], G. Kakiyama[1], P. Gillevet[3], D.M. Heuman[1], W.M. Pandak[1], J.M. Ridlon[1], O. Fiehn[4], D. Grapov[4], J.S. Bajaj[1]. *[1]Virginia Commonwealth University and McGuire VAMC, Richmond, [2]University of North Carolina, Chapel Hill, North Carolina, [3]George Mason University, Manassas, [4]NIH West Coast Metabolomics Center, Davis, California, United States*
E-mail: jasmohan@hotmail.com

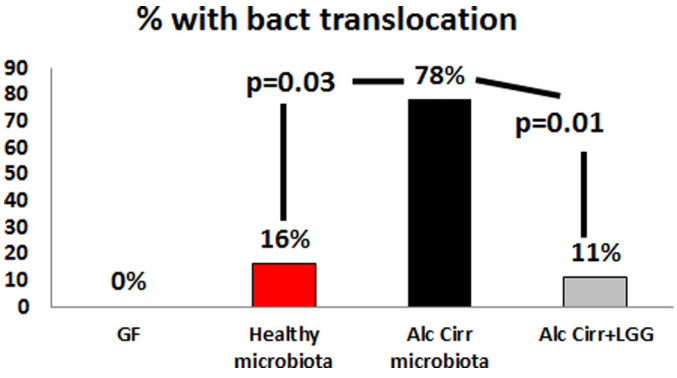
Background and Aims: A pro-inflammatory milieu with altered gut microbiota exist in alcoholic cirrhosis however, the contribution of the microbiota versus liver disease on this milieu is unclear. *Aims:* (1) impact of humanization with alcoholic cirrhotic compared to healthy stool, on bacterial translocation, microbial content/function and inflammation in germ-free (GF) mice and (2) changes with lactobacillus GG (LGG).
Methods: 4 gps of 10wk-old C57BL/6 GF mice were studied for 30 days; *Gp 1*: GF, *Gp 2*: humanized with healthy human stool, *Gp 3*: humanized with alcoholic cirrhotic stool, *Gp 4*: half of Gp 3 received LGG for last 15 days. At day 30, intestines, mesenteric lymph nodes (MLN), stool, blood, liver and brain were analyzed.

We analyzed microbiota in MLN (*bacterial translocation*), stool, intestines using multi-tagged sequencing. Microbial function was studied with cecal content metabolomics and stool bile acid (BA) profile. *Inflammation*: studied in liver, intestine, blood and brain. We compared all changes between Gps 1, 2 3 and between Gp 3 4.

Results: 6 mice each were in Gps 1 2 while 9 mice each were in Gps 3 4. *Cross-sectional analysis*: *Bacterial translocation*: was seen in 0 in Gp 1, 1/6 in Gp 2 and 7/9 in Gp 3 ($p = 0.03$, Figure). *Microbiota* in the stool and tissues showed dysbiosis in Gp 3 vs 2 (higher Porphyromonadaceae, Rikenellaceae and lower commensals: Lachnospiraceae, Ruminococcaceae and Clostridiales XIV). *Microbial function*: Gp 3 had higher fecal secondary BA deoxycholate (DCA) and significantly increased cecal content amino-acid metabolism, especially glutamine (100 fold) on metabolomics than Gp 2. *Inflammation:* higher endotoxemia (79 vs. 45 EU/ml, $p = 0.03$), cecal MCP-1 & IL-1 and cerebellar IL-6, TGR-5 & IL-1 seen in Gp 3 vs Gp 2. No liver inflammation was seen.

Before/after LGG: Bacterial translocation reduced (1/9 vs 7/9, $p = 0.01$) while stool/intestinal microbiota showed reduced dysbiosis (increased commensal taxa). *Microbial function*: DCA reduced significantly while, on metabolomics, LGG reduced glutamine by 80% and increased the anti-oxidant tyrosol by 56-fold. *Inflammation*: There was reduced endotoxemia (79 vs. 56 EU/ml, $p = 0.04$), cecal wall IL-6 & MCP-1 and cerebellar IL-1/IL-6 after LGG.

Conclusions: These results demonstrate that alcoholic cirrhosis-associated microbiota, but not healthy human microbiota, results in a pro-inflammatory milieu through dysbiosis and bacterial translocation, even without causing liver disease, and LGG supplementation may ameliorate these effects through altered anti-oxidant and glutamine metabolism.



O091

ORAL THERAPY WITH NON-ABSORBABLE CARBONS OF CONTROLLED POROSITY (YAQ-001) SELECTIVELY MODULATES STOOL MICROBIOME AND ITS FUNCTION AND THIS IS ASSOCIATED WITH RESTORATION OF IMMUNE FUNCTION AND INFLAMMASOME ACTIVATION

J. Macnaughtan[1], I. Ranchal[2], J. Soeda[2], R. Sawhney[1], J. Oben[1], N. Davies[1], R. Mookerjee[1], J. Marchesi[3], J. Cox[4], R. Jalan[1]. *[1]Institute of Liver and Digestive Health, [2]University College London, [3]Imperial College London, [4]Institute of Hepatology, London, United Kingdom*
E-mail: j.macnaughtan@ucl.ac.uk

Background and Aims: The host-microbiome interaction is pathological in cirrhosis promoting a dysregulated inflammatory response resulting in organ injury and diminished survival. Yaq-001 is an oral non-absorbable carbon shown to result in improvement in hepatic hemodynamics and markers of liver injury but the mechanism how it achieves these beneficial effect is unknown. The aims of this study were to determine whether the beneficial effects of Yaq-001 was related to the composition and associated functional state of the microbiome in bile-duct ligated cirrhotic animals.

Methods: BDL (n = 12) or sham (n = 12) animals were randomised to treatment with Yaq-001 (Yaqrit ltd. UK) from weeks 2–4. Analysis of urine samples was performed using ^{1}HNMRs. Bacterial DNA from stool was extracted, amplified and sequenced. Arterial plasma was co-incubated with HEK-Blue hTLR4 and IL-1β/IL-18 reporter cell lines. Constitutive ROS and LPS-induced ROS production from circulating monocyte and neutrophil populations was determined using flow cytometry.

Results: BDL was associated with a significant reduction in Peptidostreptococcaceae and Clostridium XI ($p < 0.05$) in stool compared to sham controls. Carbon therapy was associated with significant increases in firmicutes, in particular clostridia populations in stool with significant reductions in bacteroides populations ($p < 0.05$).

Functionally, BDL rats were found to have significantly higher urinary bile acids, trimethylamine oxidase, benzoate, glycine, acetate and lactate than sham controls ($p < 0.05$). Significantly lower levels of citrate, dimethylarginine and creatinine were observed in BDL compared to sham animals ($p < 0.05$). Carbon treatment results in a significant increase in urinary creatinine and bile acids and reduction in urinary glycine ($p < 0.05$).

A significant increase in IL18/IL1B expression was observed in untreated BDL rats compared to sham which was significantly attenuated with Yaq-001 ($p < 0.05$). Monocyte LPS-induced ROS production was significantly higher in BDL rats but attenuated with carbon treatment ($p < 0.05$).

Conclusions: The results of this study show that Yaq-001, which is a non-specific adsorbent has substantial effects of the composition and function of the microbiome in cirrhotic rats and positively modulates the function of neutrophils and monocytes reducing ROS production and inflammasome activation. These data provide compelling evidence that the gut bacterial products are important in mediating immune dysfunction of cirrhosis and is a target of therapy.

O092

MICROBIOLOGICAL ASSESSMENT OF ASCITIC FLUID IN LIVER DISEASE: CULTURE TECHNIQUES, SENSITIVITIES AND INTERPRETATION

D. Sutherland[1], F. Buckle[1], U. Altmeyer[2], M. Priest[3], S. Barclay[4], A. Stanley[1], E. Forrest[4]. *[1]Gastroenterology, [2]Microbiology, Glasgow Royal Infirmary, [3]Gastroenterology, Gartnavel General Hospital, [4]Hepatology, Glasgow Royal Infirmary, Glasgow, United Kingdom*
E-mail: ewan.forrest@ggc.scot.nhs.uk

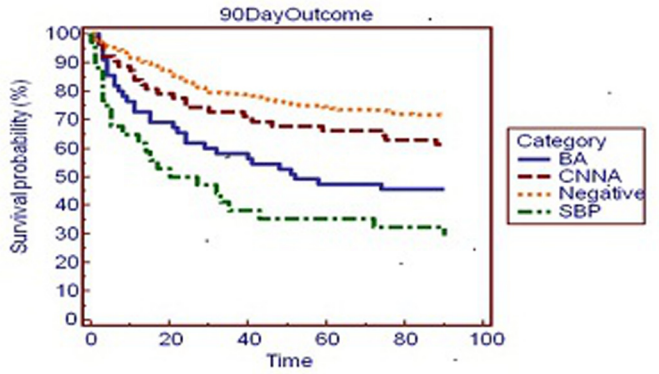
Background and Aims: Diagnostic paracentesis is a routine procedure for the assessment ascitic patients and the diagnosis of spontaneous bacterial peritonitis (SBP). It is recommended that samples are sent in blood culture bottles (BC) as well as universal containers (UC) for the best culture yield. However there is uncertainty regarding the significance of bacterascites (BA). We aimed to determine the culture yield of paired BC and UC samples and to assess outcome relative to the presence of SBP, BA or culture negative neutrocytic ascites (CNNA).

Methods: This was a retrospective review of all the ascitic fluid samples sent for microbiology analysis in North Glasgow between November 2010 and December 2013. Measured white cell count (WCC) and bacterial cultures were noted. Positive samples were defined as follows: **BA**, positive culture with WCC <250; **CNNA**, WCC >250 but negative culture; **SBP**, positive culture with WCC >250. Samples were classified on the basis of the initial sample or if >3 months since the previous sample.

Results: A total of 4131 samples were received from patients with liver disease. Of these there were 1520 BC and UC paired cultures in 503 individual patients; the majority having alcoholic

liver disease (74%). Pathogens were cultured in 118 paired samples: 47% only in BC; 34% in both BC and UC; 19% only in UC. Commensals were more common in UC: 72% compared with BC, 34%. 90 positive samples had had previous negative samples: 24 had negative samples less than 1 week prior to positive sample. 69% of pathogens cultured were sensitive to co-amoxiclav. BA and SBP were associated with a worse outcome compared with negative samples: HR 3.46 (2.0, 5.98); p < 0.0001 and HR 0.082 (0.039, 0.175); p < 0.0001 respectively. SBP, CNNA and BA samples had a worse 28 day outcome if the pre-ascitic tap C-reactive protein was >20: HR 0.476 (0.253, 0.895); p = 0.02. Culture of any pathogen was associated with a reduced 90 day survival compared with negative samples: HR 0.244 (0.159, 0.374); p < 0.0001.

Conclusions: Both BC and UC samples yield relevant pathogen cultures and both should be requested for the best chance of a positive culture. BA is not a benign finding. Direct culture of any pathogen irrespective of WCC is associated with a worse 90 day outcome.



O093

THE EMPIRICAL ANTIBIOTIC TREATMENT OF NOSOCOMIAL SPONTANEOUS BACTERIAL PERITONITIS IN PATIENTS WITH DECOMPENSATED LIVER CIRRHOSIS: RESULTS OF A RANDOMIZED CONTROLLED CLINICAL TRIAL

S. Piano[1,2], F. Salinas[3], F. Morando[2], M. Cavallin[2], A. Romano[2], S. Rosi[2], M. Stanco[2], S. Fasolato[1], A. Sticca[2], M. Senzolo[4], P. Burra[4], G. Zanus[4], U. Cillo[4], A. Gatta[2], P. Angeli[1,2]. *[1]Unit of Hepatic Emergencies and Liver Transplantation, [2]Department of Medicine, University of Padova, Padova, [3]Giovanni XXIII Hospital of Monastier, Treviso, [4]Department of Surgical, Oncological and Gastroenterological Sciences, University of Padova, Padova, Italy*
E-mail: pangeli@unipd.it

Background and Aims: Spontaneous bacterial peritonitis (SBP) is a common and life-threatening complication of liver cirrhosis. Third generation cephalosporins are the first line empirical treatment of SBP. In recent years it has been observed an increasing rate of SBP due to third generation cephalosporins resistant bacteria, in particular in nosocomial SBP. Up to now a broader spectrum antibiotic regimen such as carbapenems and glicopeptides or lipopeptides have never been compared to third generation cephalosporins in the treatment of nosocomial SBP. The aim of our study was to compare the efficacy of meropenem plus daptomycin versus ceftazidime in the treatment of nosocomial SBP.

Methods: Consecutive patients with cirrhosis, ascites and nosocomial SBP were randomized to receive meropenem (1 g/8 hours) plus daptomycin (6 mg/kg/day) or ceftazidime (2 g/8 hours) plus albumin in both groups (1.5 g/kg on day 1 and 1 g/kg on day 3). A diagnostic paracentesis was performed after 48 h of antibiotic treatment. A reduction in ascitic fluid neutrophil count >25% of the pre-treatment value and/or isolation of bacteria resistant to the assigned treatment were considered a treatment failure and antibiotic therapy was changed accordingly. The primary outcome was the efficacy of the treatment defined by the resolution of SBP after 7 days of treatment.

Results: 32 patients were randomized and 31 were analyzed. The combination of meropenem plus daptomycin was significantly more effective than ceftazidime in the treatment of nosocomial SBP (86.7% vs 25%; p < 0.001). Third generation cephalosporin resistant bacteria and multidrug resistant bacteria were isolated in 81.3% and 37.5% of positive cultures, respectively. In the multivariate Cox regression analysis, ineffective response to first line treatment (hazard ratio [HR]=20.6; p = 0.01), development of acute kidney injury during hospitalization (HR = 23.2; p = 0.01) and baseline mean arterial pressure (HR = 0.92; p = 0.01) were found to be independent predictors of 90-day transplant free survival. The incidence of global adverse events (73.3 vs 81.3%; p = 0.68) and drug related adverse events (20.0 vs 25.0; p = 1.0) were similar between the two groups.

Conclusions: The combination of meropenem plus daptomycin is more effective than ceftazidime in the treatment of hospital acquired SBP. The efficacy of the first line treatment is associated with improved 90 days survival in these patients.
ClinicalTrials.gov Identifier: NCT01455246

O094

THE PRESENCE OF ECHOCARDIOGRAPHIC ABNORMALITIES INCREASES MORTALITY IN PATIENTS WITH SPONTANEOUS BACTERIAL PERITONITIS

M. Mandorfer[1], S. Bota[1], P. Schwabl[1], N. Pfisterer[1], G. Goliasch[2], V. Fuhrmann[1], T. Horvatits[1], A. Ferlitsch[1], W. Sieghart[1], M. Trauner[1], M. Peck-Radosavljevic[1], T. Reiberger[1], on behalf of Vienna Hepatic Hemodynamic Lab. *[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine III, [2]Division of Cardiology, Department of Internal Medicine II, Medical University of Vienna, Vienna, Austria*
E-mail: mattias.mandorfer@meduniwien.ac.at

Background and Aims: Cirrhosis was found to be associated with echocardiographic abnormalities (ECHOABNs) such as left ventricular hypertrophy (LVH), systolic dysfunction (LVSD) and diastolic dysfunction (LVDD), as well as left atrial enlargement (LAE). Recent studies have highlighted the importance of the cardiac reserve for the adaptive response to acute circulatory stress in advanced cirrhosis, e.g. in patients with infections such as spontaneous bacterial peritonitis (SBP). We assessed the impact of abnormalities in cardiac structure and function in routine echocardiography on mortality in patients with cirrhosis and ascites (A) without SBP and (B) after a SBP episode.

Methods: One hundred twenty-seven patients with cirrhosis who underwent their first paracentesis at the Medical University of Vienna and did not develop SBP during the follow-up (group: no-SBP), as well as 78 patients diagnosed with SBP (group: SBP) with available information on routine echocardiography were included in this retrospective cohort study. Cox models were calculated to investigate the effect of echocardiographic abnormalities on transplant-free survival (TFS) and adjusted for all factors showing a trend toward a statistically significant difference ($P \leq 0.1$) between the no-SBP and the SBP group.

Results: *Patient characteristics:* Child–Pugh stage A:3%, B:47%, C:50%; median MELD score 19.3 (interquartile range:8.87); varices:75%; previous variceal bleeding:18%; hepatocellular carcinoma:15%; non-selective beta-blocker treatment: 42%. The prevalence of significant ECHOABNs was: LVH: 20%; LVSD: 2%; LVDD: 16%; LAE: 18%. The proportion of patients with ECHOABNs in the SBP group (55%) was higher, when compared to no-SBP patients (37%, $P = 0.011$).
While the presence of ECHOABNs had no impact on TFS in the no-SBP group [hazard ratio (HR): 1.183, 95% confidence interval (95% CI): 0.711–1.969; $P = 0.776$], it was associated with

substantially increased mortality in the SBP group (HR: 1.914, 95% CI: 1.026–3.571; *P* = 0.041).
Conclusions: The prevalence of ECHOABNs in patients with cirrhosis and ascites is high and further increases in patients with more advanced stages of cirrhosis, such as patients with SBP. Development of SBP may reveal impairments in the adaptive response to acute circulatory stress due to latent cardiac dysfunction, as the presence of ECHOABNs was associated with increased mortality in this subgroup of patients.

O095
HIGH TRANSFERRIN SATURATION DURING MAINTENANCE VENESECTION THERAPY IN HFE HEMOCHROMATOSIS IS ASSOCIATED WITH INCREASED MORBIDITY REGARDLESS OF SERUM FERRITIN LEVELS

E. Bardou-Jacquet[1], C. Jezequel[1], J. Morcet[1], F. Laine[1], D. Guyader[1], Y. Deugnier[1]. [1]*CHU Pontchaillou Rennes, Rennes, France*
E-mail: edouard.bardou-jacquet@chu-rennes.fr

Background and Aims: Current international guidelines on the management of maintenance venesection therapy in *HFE* hemochromatosis (HH) recommend to keep serum ferritin (FRT) between 50 and 100 μg/l regardless of transferrin saturation (SAT). Our aim was to assess the impact of elevated SAT during maintenance therapy on HH-related morbidity
Methods: C282Y homozygotes were included if they had at least 3 years of follow-up after achievement of low body iron stores and at least one FRT and SAT determinations available per year.
A self-administered questionnaire assessing the onset or worsening of HH-related morbidity during maintenance therapy was sent to patients. Main questions concerned fatigue, joint and liver symptoms, and quality of life based on the assessment of libido, ability to work and to practice sport. Decreased quality of life was defined by a positive answer at 2 or 3 of these 3 questions.
Areas under the curves of SAT and FRT throughout maintenance therapy were determined to obtain mean SAT (mSAT) and FRT (mFRT)
Results: 268 patients (57% men, 78% probands) were included. Mean follow-up was 13.5±6 years. A number of 29±15 FRT and SAT values were available during this period. Median mSAT and mFRT were 47.6% [40.2–53.2] and 38.9 μg/L [27.7–59.4] respectively, with 40% of patients having mSAT >50%. 31% of women and 35% of men with mFRT <50 μg/L had mSAT >50%. Correlation between mSAT and mFRT was weak but significant (rho = 0.28, p < 0.001).
At multivariate analysis: (1) mSAT >50% was associated with mFRT >50 μg/L, smoking, BMI <27, absence of tea consumption, serum transferrin <1.7 g/L, and follow-up >15 years; (2) mFRT >50 μg/L was associated with mSAT >50%, overweight, alcohol consumption, and BMI >27; (3) worsening of hand arthropathy was associated with mSAT >50%, arthropathy at diagnosis, serum transferrin <1.7 g/L and follow-up >15 years; (4) worsening of quality of life was associated with mSAT >50%, age at diagnosis >55, arthropathy at diagnosis, and serum ferritin >50 μg/L at the end of the initial iron removal treatment.
Conclusions: In HH patients on maintenance venesection therapy, high transferrin saturation – regardless of serum ferritin level – is associated with increased HH-related morbidity, especially worsening of hand arthropathy. Further controlled studies are required to assess the potential benefit of tuning maintenance therapy according to SAT.

E-mail: ogirigoyen@alumni.unav.es

Background and Aims: Matrix metalloproteinases (MMPs) play an important role in wound healing during acute liver injury. However, in chronic liver damage MMPs may be involved in hepatocellular carcinoma (HCC) development, contributing to a pro-tumorigenic microenvironment. This microenvironment is characterized by hypoxia and reactive oxygen species (ROS) production. The chemokine (CXC) receptor 4 (CXCR4)/stromal derived factor 1 (SDF1) axis promotes HCC cell proliferation, motility, angiogenesis and metastasis. Here we have characterized the expression and function of MMP10 (stromelysin 2) in hepatocarcinogenesis, and identified a new functional crosstalk between MMP10 and the CXCR4/SDF1 axis in HCC cells.
Methods: Hepatic MMP10 and CXCR4 expression were examined in diethylnitrosamine (DEN)-induced hepatocarcinogenesis in mice. The role of MMP10 was evaluated in DEN-treated $Mmp10^{+/+}$ and $Mmp10^{-/-}$ mice. A HCC cell line (Huh7) stably expressing MMP10 was generated (Huh7-MMP10). The functional crosstalk between MMP10 and the CXCR4/SDF1 axis was evaluated in human HCC cells.
Results: Hepatocellular MMP10 expression was progressively induced during hepatocarcinogenesis. Compared to $Mmp10^{+/+}$ animals $Mmp10^{-/-}$ mice showed less HCC incidence, smaller histological lesions, reduced tumor microvascular density and less lung metastases. CXCR4 expression in $Mmp10^{-/-}$ mice livers was significantly lower than in $Mmp10^{+/+}$. Huh7-MMP10 cells had increased CXCR4 expression levels and enhanced migratory capacity than control Huh7 cells. Up-regulation of CXCR4 expression in Huh7-MMP10 cells was attenuated by the antioxidant N-acetyl cysteine. Pharmacological inhibition of CXCR4 significantly reduced Huh7-MMP10 cell migration. On the other hand, MMP10 gene expression was induced by hypoxia and this response was enhanced by the CXCR4 ligand SDF1. Hypoxia/SDF1 triggered MMP10 expression through the MEK/ERK1/2 signaling pathway involving an AP-1 site in the proximal *MMP10* gene promoter.
Conclusions: To our knowledge this is the first report addressing the role of a MMP in hepatocarcinogenesis in the corresponding knockout mouse. MMP10 plays an important part in HCC development, participating in tumor angiogenesis, growth and dissemination. We have identified a new functional and reciprocal crosstalk between MMP10 and the CXCR4/SDF1 axis that can contribute to HCC progression and metastasis.

MUTATION OF RELA THR505 ENHANCES LIVER REGENERATION FOLLOWING PARTIAL HEPATECTOMY

A. Moles[1], J. Butterworth[2], J. Hunter[2], A. Sanchez[2], D. Mann[1], F. Oakley[1], N.D. Perkins[2]. [1]*Institute of Cellular Medicine,* [2]*Institute for Cell and Molecular Biosciences, Newcastle University, Newcastle Upon Tyne, United Kingdom*
E-mail: ana.moles@ncl.ac.uk

Background and Aims: NF-κB is a family of transcription factors that are key regulators of the immune and inflammatory responses. NF-κB regulation is complex and occurs at many levels, including direct post-translational modifications (PTMs) of the subunits. Phosphorylation of RelA (p65) at Thr505 regulates proliferation, migration and autophagy in *in vitro* cellular systems; however its role and relevance in an *in vivo* system still remains unclear. Thus, the aim of this study was to analyse the role of RelA phosphorylation in vivo by mutating this site through creating a knock in mouse.
Methods: Knock in mutant mice where generated where Thr505 was substituted by Alanine, thus preventing phosphorylation. Partial hepatectomy (PhX) and acute CCl_4 administration was performed in WT and knock in mice. Animals were culled at 36, 72 hours and 5 days or at 24, 48 and 72 hours respectively. Paraffin stainings for BrdU and PCNA were used as markers of proliferation and γH2AX for DNA damage. Western blot was used to determined p53 and p-JNK expression.
Results: Thr505 mutation of RelA resulted in an increased liver to body weight ratio after PhX at 36, 72 hours and 5 days. Hepatocyte proliferation was increased after both injuries, PhX and acute CCl_4, at all the time points in RelA T505 mice versus WT, as assessed by PCNA and/or BrdU staining. Furthermore, mitotic body counts were also higher in RelA T505 mice after both injuries. Of note, proliferation after PhX was sustained for longer in RelA T505 mice, pointing towards an inefficient resolution of the proliferative response. Increased DNA damage, as determined by γH2AX staining, was seen in both WT and RelA T505 after 36 hours of PhX. However, the DNA damage was significantly higher in RelA T505 mice in comparison with WT. Finally, western blot analysis of these samples revealed increased expression of the p53 tumour suppressor and active JNK in RelA T505 mice.
Conclusions: RelA Thr505 phosphorylation provides an important and novel regulatory mechanism to control the proliferative response and prevent genomic damage in the liver.

LONG TERM NLRP3 INFLAMMASOME ACTIVATION LEADS TO SEVERE LIVER FIBROSIS VIA INFLAMMATORY MACROPHAGE POLARIZATION AND DIRECT ACTIVATION OF HEPATIC STELLATE CELLS

A. Wree[1], M.D. McGeough[1], E. Inzaugarat[2], C.A. Peña[1], A. Cherñavsky[2], H.M. Hoffman[1], A.E. Feldstein[1]. [1]*Department of Pediatrics, University of California – San Diego, La Jolla, United States;* [2]*Institute of Immunology, Genetics and Metabolism, CONICET-UBA, Buenos Aires, Argentina*
E-mail: awree@ucsd.edu

Background and Aims: The NLRP3 inflammasome, a caspase-1 activation platform critical for the processing of key pro-inflammatory cytokines has been implicated in the development acute and chronic liver diseases. However, the source and mechanisms of inflammasome mediated liver damage remains poorly understood. Therefore, our *aim* was to test the hypothesis that chronic NLRP3 inflammasome activation is a central mechanism for innate immune activation and the progression of liver disease.
Methods: *Nlrp3*^{D301NneoR} knock-in mice on a C57BL/6 background were crossed to C57BL/6.Cg-Tg(*Cre*/Esr1)–Estrogen Receptor Cre (CreT) mice to induce temporal *in vivo* expression of mutant NLRP3 in adult mice through administration of tamoxifen. After 16 weeks of inflammasome activation, mice were sacrificed and liver tissue and serum were harvested. To dissect cell specific effects of inflammasome activation, primary hepatic cells – hepatocytes, macrophages, and hepatic stellate cells (HSC) – were isolated from *Nlrp3*^{D301NneoR} CreT mice and activation of the NLRP3 inflammasome was induced *in vitro* in cultured cells via 4OH-tamoxifen treatment.
Results: Activation of the Nlrp3 inflammasome in Nlrp3^{KI} CreT over 16 weeks resulted in hepatomegaly while tamoxifen-injected control mice showed regular liver weights (liver to body weight % – 6.1±0.32% vs. 4.6±0.03%, $p < 0.05$). Analysis of liver histology revealed increased inflammation with neutrophilic infiltration and increased mRNA levels of myeloperoxidase (fold-change to WT 52.8±13.75, $p < 0.05$). Liver sections of *Nlrp3* mutant mice displayed significantly increased collagen deposition and expression of TIMP1 (fold-change to WT 7.5, $p < 0.05$) when compared to tamoxifen-injected controls. Activation of NLRP3 in isolated hepatocytes resulted in a 2-fold increase in the expression of proliferating cell nuclear antigen (PCNA). Studies on isolated hepatic macrophages revealed inflammatory polarization upon NLRP3 activation with elevated expression levels of iNOS, pro-IL-1β, and TNF-α, while levels of arginase 1 were reduced. Moreover, we found that activation of the NLRP3 inflammasome in isolated HSC resulted in increased expression of α-SMA and tissue inhibitor of metalloproteinase-1 (TIMP-1).
Conclusions: Our study uncovers a crucial role for the NLPR3-inflammasome in the development of liver injury and fibrosis and provides unique models to assess novel therapeutic strategies aimed at halting the progression of chronic liver diseases.

O099
CYSTEINE CATHEPSINS CONTROL LIVER INFLAMMATION THROUGH REGULATION OF SIRTUIN-1 ACTION ON P65-NFκB SUBUNIT

A. de Mingo[1], A. Morales[1], J. Fernandez-Checa[1], M. Mari[1]. [1]*IIBB-CSIC/IDIBAPS/CEK, Barcelona, Spain*
E-mail: monmari@clinic.ub.es

Background and Aims: Sirtuin-1 (SIRT1) is a nuclear protein deacetylase that controls hepatic lipid metabolism in hepatocytes and modulates the acetylation status of the RelA/p65 subunit of NFκB, thus playing a pivotal role in regulating the inflammatory, and apoptotic responses in the liver. Cysteine cathepsins were originally believed to participate exclusively in terminal protein degradation during necrotic and autophagic cell death. However, nowadays it is well established that they execute numerous specific functions participating in important physiological processes, such as MHC-II-mediated antigen presentation, pro-hormones activation, and others. To our knowledge, however, the potential participation of cysteine cathepsins (such as Cathepsin B, CtsB or S, CtsS) on SIRT1 regulation of inflammation in the liver has not been reported, and is the aim of this study.
Methods: Hepatocytes (HC), Kupffer cells (KC) and hepatic stellate cells (HSCs) were isolated and cultured in plastic. Human LX2 activated HSCs, RAW264.7 macrophages, and Hep3B cells were also used. Cells were exposed to LPS (50 ng/ml) or TNF (50 ng/ml), in the presence of CtsB or CtsS inhibitors (Ca074Me, 25μM and Z-FL, 10μM). SIRT1, p65 (NF-κB), α-SMA, β-actin, Lamin A/C, among others, were evaluated by western blotting. κB-dependent genes (A20, MCP1, and IL6) were detected by RT-qPCR.
Results: SIRT1 levels increased during the activation of primary mouse HSCs (from days 1 to 8) paralleling CtsS, CtsB, and α-SMA expression. Challenging HSCs or LX2 cells with TNF or LPS resulted in SIRT1 downregulation followed by p65-NFκB nuclear translocation, and enhanced κB-dependent gene expression (MCP1 and IL-6). In this setting, CtsB or CtsS inhibition resulted

in decreased p65 nuclear translocation and κB-dependent gene expression, which was accompanied by enhanced SIRT1 expression. Similar results were observed in murine primary Kupffer cells and hepatocytes, and were replicated in RAW264.7 and Hep3B cells. In addition, *in vivo* LPS challenge in mice was accompanied by enhanced expression of MCP1 and IL6 mRNA, which was greatly reduced after CtsB or CtsS inhibition. Thus indicating that inhibiting cysteine cathepsins limits hepatic inflammation through the regulation of SIRT1 deacetylation of p65-NFκB and down-regulation of κB-dependent gene expression.

Conclusions: Cysteine cathepsins modulate liver inflammation by controlling SIRT1-dependent deacetylation of p65-NFκB subunit.

THE HEPATIC MICROENVIRONMENT INDUCES A CSC PHENOTYPE AND DETERMINES THE PROGNOSIS OF HCC PATIENTS

D. Castven[1], M. Fischer[1], S. Heinrich[2], J.B. Andersen[3], M.F. Sprinzl[1], I. Gockel[4], S. Heilmann[5], M.A. Wörns[1], S.S. Thorgeirsson[6], P.R. Galle[1], H. Lang[2], J.U. Marquardt[1]. *[1]Department of Medicine I, [2]Department of Surgery, University of Mainz, Mainz, Germany; [3]5Biotech Research and Innovation Centre (BRIC), University of Copenhagen, Copenhagen, Denmark; [4]Department of Visceral, Transplant, Vascular and Thoracic Surgery, University of Leipzig, Leipzig, [5]Institute of Human Genetics, University of Bonn, Bonn, Germany; [6]CCR/NCI/NIH, NIH, Bethesda, United States*

E-mail: marquarj@uni-mainz.de

Background and Aims: The cancer stem cell (CSC) hypothesis is an emerging concept in cancer research that provides a plausible explanation for the observed phenotypic heterogeneity of many cancers including hepatocellular carcinoma (HCC). However, despite profound therapeutic implications the prognostic relevance of CSCs and their cellular localization within the tumor formation remain controversial.

Methods: Expression levels and localization of established CSC markers were assessed in pre-neoplastic lesions as well as 30 HCCs using qRT-PCR, imunohistochemistry and Western-Blotting. Integrative whole genome and transcriptome analyses of different tumor regions as well as tumor-surrounding liver (SL) were performed to identify associated molecular alterations and integrated with our existing HCC database.

Results: Expression patterns of established CSC markers were surprisingly heterogeneous. While classical markers such as GPC3 were induced in tumor tissue, activation of CSCs was predominantly observed in SL and continuously decreased from pre-neoplastic lesions to HCC. Consistently, genomic and transcriptomic profiles between SL and different tumor regions were quite distinct. Progressive increase in genetic alterations and activation of pathways related to proliferation as well as apoptosis was observed in the tumor tissue, while the invasive tumor margin (TM) was characterized by inflammatory and EMT-related gene sets as well as activation of pro-survival signaling such as ERK and FOS. Consistently, integration of the different signatures with our database of 53 HCC revealed that the TM signature was associated with the survival of HCC patients.

Conclusions: CSCs in HCC are heterogeneous. The CSC phenotype is predominantly determined by the permissive tumor microenvironment. However, pro-oncogenic properties might originate in the TM. The activation of key oncogenic features as well as immune-response signaling indicates that the cross-talk between tumor and microenvironment might be a promising therapeutic and/or preventive target.

HISTONE VARIANT macroH2A1 ORCHESTRATES ESCAPE FROM HEPATOCYTE SENESCENCE DURING AGEING AND CANCER

M. Borghesan[1,2], C. Panebianco[3], F. Rappa[4], J.M. Sedivy[5], M. Buschbeck[6], F. Cappello[4], T. Mazza[7], V. Pazienza[3], M. Vinciguerra[1,3]. *[1]UCL-Institute of Liver and Digestive Health, London, United Kingdom; [2]IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy; [3]Gastroenterology Unit, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, [4]Department of Experimental Biomedicine and Clinical Neurosciences, Section of Human Anatomy, University of Palermo, Palermo, Italy; [5]Department of Molecular Biology, Cell Biology and Biochemistry, Center for Genomics and Proteomics, Brown University, Providence, United States; [6]Institute for Predictive and Personalized Medicine of Cancer, Barcelona, Spain; [7]Bioinformatic Unit, IRCCS Casa Sollievo della Sofferenza, Rome, Italy*

E-mail: m.vinciguerra@ucl.ac.uk

Background and Aims: The epigenetic basis of age-associated progression of liver diseases towards hepatocellular carcinoma (HCC) is unclear. MacroH2A1 is a variant of histone H2A1, present in the two isoforms macroH2A1.1 and macroH2A1.2, with fundamental roles in cell homeostasis. MacroH2A1 protein levels are upregulated in human HCC. MacroH2A1 is also marker of senescence associated heterochromatic foci (SAHF) and synergizes with DNA demethylating agent 5-aza-2′-deoxycytidine (5-aza-dC) in silencing tumor suppressor genes in human fibroblasts. Its role in cell senescence during HCC is unknown.

Methods: We used liver tissues from aged wild type mice, naked mole rats and human HCC to analyze macroH2A1 levels during hepatocyte senescence. Stable HepG2 cell line overexpressing macroH2A1.1 and macroH2A1.2 tagged with GFP, HepG2 cells stably silenced (knock-down) for macroH2A1 and macroH2A1 knock-out mice were generated for biochemical studies and to study the effects of macroH2A1 on 5-aza-dC induced cell senescence by B-gal assay, quantitative RT-PCR, chromatin immunoprecipitation sequencing (ChIP-Seq) and RNA sequencing (RNA-Seq). Cell cycle was assessed by FACS analyses, while cell proliferation and migration was evaluated by MTT and scratch assay, respectively. SAHF were analyzed by confocal microscopy.

Results: We show that protein levels of macroH2A1 isoforms are increased in the livers of old rodent and humans, and in HCC tissue of both young and old age. Human HCC HepG2 cells overexpressing macroH2A1 escape 5-aza-dC-induced senescence, as determined by cell proliferation/migration/cell cycle assays, B-gal staining and SAHF marker HP-1 cellular localization, and exhibit a synergistic global DNA hypomethylation. Deletion of macroH2A1 in HepG2 cells and in old mice had opposite, pro-senescence, effects as determined by cell cycle assays and hepatic X-gal staining, respectively. System analysis of ChIP-Seq combined with RNA-Seq data in HepG2 cells revealed complex macroH2A1 genome occupancy correlated with anti-senescence transcriptional patterns.

Conclusions: Together with our previous report indicating both macroH2A1 isoforms as HCC markers (Rappa F et al., PLOS ONE 2013), our data demonstrate that both macroH2A1 isoforms are oncogenic in the liver. In fact, they allow HCC cells to escape senescence induced by a chemotherapy drug, increasing their aggressiveness. We propose macroH2A1 as a strong candidate target for epigenetic- and senescence-based HCC chemotherapy.

O102

GALECTIN-1 EXPRESSION IS ESSENTIAL FOR AN EFFECTIVE LIVER REGENERATION

T. Potikha[1], E. Ella[1], L. Mizrahi[1], O. Pappo[2], G. Rabinovich[3], E. Galun[1], D. Goldenberg[4]. *[1]Gene Therapy Institute, Hadassah Ein Kerem hospital Jerusalem Israel, [2]Department of Pathology, Hadassah-Hebrew University Medical Center, Jerusalem, Israel; [3]3Laboratory of Immunopathology, Institute of Biology & Experimental Medicine, Buenos Aires, Argentina; [4]Goldyne Savad Institute of Gene Therapy, Hadassah-Hebrew University Medical Center, Jerusalem, Israel*

E-mail: eithang@hadassah.org.il

Background and Aims: Galectin-1 (Gal1) protein is encoded by the *Lgals1* gene and acts both extracellularly and intracellularly as an immune/inflammatory regulator, modulating innate and adaptive immune responses. In the liver, it is expressed mainly by non-parenchymal cells and acts mostly as an inducible anti-inflammatory regulator. Here, we explored the role of Gal1 in liver regeneration (LR) using a murine model.

Methods: We performed 70% partial hepatectomy (PHx) in the C57BL/6 WT and Gal1-knockout (Gal1-KO, *Lgals1*$^{-/-}$) mice and monitored the process of LR in both strains at 2, 6, 24, 48, 72 and 96 hours following operation. Expression of several known PHx-induced genes was monitored by RT-PCR at 2, 6 and 24 hours following operation. Expression of selected proteins was validated by immunohistochemistry and immunoblotting.

Results: We demonstrate an early Gal1 induction in the liver tissue of WT mice upon PHx, and report a significant delay in LR following PHx in the Gal1-KO compared to the WT liver. This delay was accompanied by a decreased monocyte/macrophage recruitment; a decreased level of nuclear cyclin D1 protein in all liver cells analyzed, and by an increased level of hepatocyte nuclear p21 protein in the Gal1-KO versus WT livers at 24 and 48 hours following PHx. Transcriptional analysis revealed a significantly decreased expression of the *Il6* and *Atf3*, both indispensable for LR, at two hours post-PHx, and a significantly increased expression of the anti-inflammatory *Tnfaip3* and *Zfp36* genes at six hours post-PHx, in Gal1-KO compared to WT livers. Transient steatosis, which is imperative for LR following PHx, was significantly delayed and decreased in the Gal1-KO compared to the WT liver. This was accompanied by a significantly decreased expression in the mutant liver of several genes encoding lipid metabolism regulators.

Conclusions: Our findings reveal for the first time that the Gal1 protein is essential for efficient LR following PHx through its known regulatory activities on liver inflammation and cell proliferation, and possibly through its newly discovered regulation of lipid storage in the regenerating liver.

O103

METASTASIS DEVELOPMENT IN A NOVEL MOUSE MODEL OF ADVANCED LIVER CANCER

C. Lechler[1], B. Kohnke-Ertel[1], J. Sage[2,3], R.M. Schmid[1], U. Ehmer[1]. *[1]II. Medizinische Klinik und Poliklinik, Klinikum rechts der Isar, TU München, München, Germany; [2]Department of Pediatrics, [3]Department of Genetics, Stanford University, Stanford, CA, United States*

E-mail: ursula.ehmer@tum.de

Background and Aims: Liver cancer is one of the leading causes of cancer related mortality worldwide. With limited treatment options, especially in the advanced stages of the disease, the development of novel therapies is urgently needed. The absence of reliable mouse models has been a major limitation in the study of advanced, metastatic liver cancer in the past. Here, we present a novel genetically engineered mouse model of primary liver cancer. Combining expression of oncogenic Kras with inactivation of the tumour suppressors RB and p53 we mimic molecular events that occur in the majority of human liver cancers and achieve rapid formation of hepatic tumours with extrahepatic metastases in our mice.

Methods: Adult *Rb*$^{lox/lox}$;*p53*$^{lox/lox}$;*Kras*$^{LSL-G12D/+}$ (RPK) mice were injected intravenously with liver specific AAV-Cre. Upon liver tumour formation, individual lesions were microdissected and analysed. mRNA microarray analysis was performed on an Affymetrix platform and validated using qPCR. Protein expression was visualized by immunohistochemistry and SDS page gel electrophoresis.

Results: The RPK mouse model combines liver specific inactivation of RB and p53 with activation of Ras signalling. After gene recombination, RPK mice rapidly develop hepatic tumours within 3 to 4 months. Cancer lesions in this mouse model express hepatocytic (AFP$^+$ and/or ALB$^+$) as well as biliary (CK19$^+$) differentiation markers. Comparison of gene expression microarrays from RPK tumours with data from human liver cancer samples confirmed clustering with human un-differentiated hepatocellular carcinomas and cholangiocarcinoma. Interestingly, selective targeting of hepatocytes in RPK mice showed that liver tumours of mixed or even biliary differentiation arise from mature hepatocytes. On the molecular level, RPK liver tumours showed activated ERK and AKT signalling downstream of Kras, as well as expression of metastasis associated genes. Strikingly, extrahepatic metastases to the abdominal lymph nodes or lung were found in the majority of mice with advanced tumour lesions.

Conclusions: The RPK mouse model presents a novel platform to study key molecular mechanisms in liver carcinogenesis. Importantly, the highly consistent occurrence of metastatic lesions gives the unique opportunity to investigate molecular drivers of metastasis development in vivo. The RPK model will help to answer important question in liver tumour biology and aims to identify novel targets in the treatment of human liver cancer.

Liver transplantation

PREDICTIVE MODEL FOR THE NEED FOR LIVER TRANSPLANTATION IN SYMPTOMATIC POLYCYSTIC LIVER DISEASE

F. Temmerman[1], M. Oliverius[2], J. Lerut[3], J.P. Drenth[4], H. Metselaar[5], W. Coudyzer[6], R. Vanslembrouck[6], J. van Pelt[1], B. Bammens[7], J. Pirenne[8], F. Nevens[1], on behalf of the European Liver and Intestine Transplant Association (ELITA). *[1]Hepatology, University Hospital KULeuven, Leuven, Belgium; [2]Transplant Surgery, Institute for Experimental and Clinical Medicine, Prague, Czech Republic; [3]Abdominal and Transplantation Surgery, Université Catholique de Louvain, Brussels, Belgium; [4]Gastroenterology and Hepatology, Radboud University, Nijmegen, [5]Gastroenterology and Hepatology, Erasmus Medical Center, Rotterdam, Netherlands; [6]Radiology, [7]Nephrology, [8]Abdominal Transplant Surgery, University Hospital KULeuven, Leuven, Belgium*

E-mail: frederik.temmerman@uzleuven.be

Background and Aims: Polycystic liver disease (PCLD) with massive hepatomegaly can become an indication for liver transplantation (LTx). To prioritize these patients on the LTx-waiting list, exception criteria based on simple, objective and highly reproducible factors are needed. We aimed to explore the parameters contributing to the severity of the PCLD disease which could be used in the decision/prioritization for LTx.

Methods: We performed a large retrospective cohort analysis of PCLD patients referred to 5 European tertiary centers. Existing

clinical and abdominal scan data were re-analysed for liver volume and index (estimates how many times the liver has been enlarged), stage of malnutrition (sarcopenia), and extra-hepatic and local cyst complications.

Results: The study population consisted of 216 patients: 87% (n = 187) were women, 83% (n = 180) had ADPKD and 36% (n = 67) suffered from sarcopenia. 137 patients (63.4%) were deemed eligible for LTx based on clinical judgement of the transplant teams; of them 50 (36%) received a combined liver and kidney transplantation (cLTKTx). The indication for LTx was severe hepatomegaly related complaints in 85% (n = 116). In patients with a previous kidney transplantation the most frequent indication for LTx (47%) was recurrent liver cyst infection. Factors which predicted the need for LTx (PCLD severity score) were: liver volume index >5, serum albumin <4.1 g/l, age <47 yrs and the presence of ascites. A multivariable model combining these factors had an area under the curve of 0.81 (SE: 0.05; 95% CI: 0.72 to 0.88, p < 0.0001) and correctly classified 92% of the patients. In cLTKTx patients, a creatinine clearance <32 ml/min/1.73m^2 correctly classified 92% of the patients with the need for KTx.

Conclusions: In patients with PCLD, factors which can be assessed only by one scan (liver volume, nutritional stage, ascites) provide objective information that could be used for the decision/prioritization for LTx. In patients with kidney transplantation, recurrent liver cyst infections is also an indication for LTx.

O105

COMPARISON OF SHORT-TERM AND LONG-TERM OUTCOMES AFTER DCD AND DBD DONOR LIVER TRANSPLANTATION

M. Cortes[1], S. Khorsandi[1], D. Chasiotis[1], R. Patcha[1], B. Amir Sayed[1], M. Tedeschi[1], Y. Puri[1], B. Reyes[1], M. Diaz[1], G. Rompianesi[1], M. Heneghan[1], J. O'Grady[1], H. Vilca-Melendez[1], K. Menon[1], A. Prachalias[1], P. Srinivasan[1], M. Rela[1], N. Heaton[1], W. Jassem[1]. [1]*Institute of Liver Studies. Liver Transplantation, King's College Hospital, London, United Kingdom*
E-mail: miriam_corcer@yahoo.es

Background and Aims: The increasing demand for suitable organs for liver transplantation (LT) has expanded the use of donation after cardiac death (DCD) allografts, despite evidence of higher incidence of primary non-function (PNF) and primary ischaemic cholangiopathy (PIC) with these grafts. To evaluate our experience, we compared the outcome of LT with donation after brain death (DBD) and DCD grafts in a large single centre cohort.

Methods: The outcomes of 293 controlled DCD liver transplants were compared to 293 matched DBD controls, performed at a single institution over a 15 year time period. DCD livers were allocated to adult patients with no previous major abdominal surgery. There were no age cut-offs for DCD grafts, but warm ischaemic time (WIT) was limited to 30 minutes or less.

Results: There was no difference in gender and recipient's BMI between DBD and DCD transplants, however DBD donors were older and had longer cold ischaemic times (CIT). Patients that received DCD grafts had higher levels of post-transplant serum AST ($p < 0.0005$), however, there was no significant difference in duration of intensive care unit or hospital stay for recipients of either type of allograft. PNF was significantly higher in DCD allografts ($p < 0.0005$), nevertheless there were no statistically significant differences in the incidence of renal replacement therapy usage, rejection episodes, vascular or biliary complications, including PIC, between the 2 groups. Although more patients with hepatocellular carcinoma (HCC) were allocated a DCD graft, there was no difference in HCC recurrence. Overall patient and graft survival was higher in the DBD group (p = 0.025, p = 0.002) but when transplants for HCC were excluded, no difference in overall patient and graft survival were observed.

Conclusions: The data shows a favourable outcome of LT using DCD allografts with no increase in biliary or vascular complications. Minimising CIT and optimising donor/recipient matching are crucial in order to achieve good outcome. More work is required to explore the impact of DCD status on HCC recurrence.

THERAPEUTIC PLASMA EXCHANGE MODULATES INNATE IMMUNE ACTIVATION AND IMPROVES OUTCOME IN PATIENTS WITH ACUTE LIVER FAILURE

C. Bernsmeier[1], V.C. Patel[1], A. Singanayagam[1], M. Yuksel[1], X. Huang[1], C. Willars[1], W. Bernal[1], G. Auzinger[1], Y. Ma[1], F.S. Larsen[2], J.A. Wendon[1], C.G. Antoniades[1,3]. [1]*Institute of Liver Studies, King's College Hospital, King's College London, London, United Kingdom;* [2]*Department of Hepatology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark;* [3]*Hepatology Department, St. Mary's Hospital, Imperial College London, London, United Kingdom*
E-mail: christine.bernsmeier@kcl.ac.uk

Background and Aims: Acute liver failure (ALF) involves a mortality of >40% despite transplantation. Overwhelming hepatocyte death induces a systemic inflammatory response (SIRS) and confers adverse outcome. Monocytes are key effectors of SIRS in the pathogenesis of ALF. A multicentre study evaluating therapeutic plasma exchange (TPE) demonstrated a 20% survival benefit. TPE has been established for various immunologically driven disorders. Recent data highlight its ability to dampen innate inflammatory responses. We evaluated the effect of TPE on phenotype and function of immune effector cells.

Methods: Plasma samples from ALF patients admitted to Rigshospitalet (n = 11) and King's College Hospital (n = 9) who underwent TPE were taken before and after the first exchange. Healthy peripheral blood mononuclear cells were cultured for 24 hours in medium containing 25% plasma from ALF patients. The effect of plasma obtained before/after TPE was compared to plasma from patients who did not receive any therapeutic intervention (natural course, n = 11). Immunophenotyping (CD14, CD16, HLA-DR, CD86, MERTK, CD163, CD64, CCR7, AnnexinV) and TNF-α/IL-6 production of monocytes in response to lipopolysaccharide (LPS) and phenotyping of lymphocytes (CD4, CD8, CD56, CD127, CD25, FoxP3) and LPS-induced IFN-γ/IL-2/TGF-β/IL-10 production were assessed by flow cytometry.

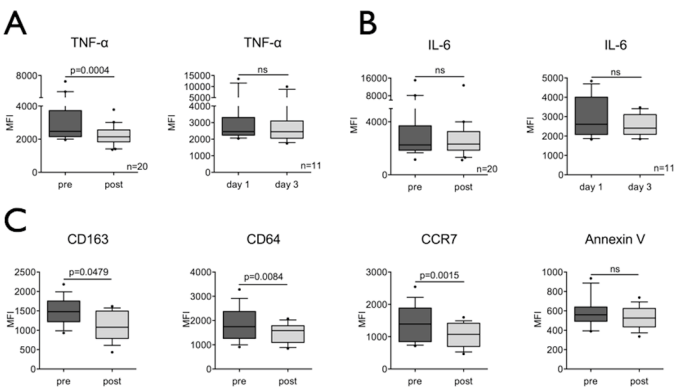

Figure: (A) Monocytes TNFα production in response to lipopolysaccharide in ALF patients pre- and post-TPE (left) and without therapeutic intervention (right). (B) Monocyte IL-6 production. (C) Reduced inflammatory activation markers on monocytes pre- and post-TPE (CD163, CD64, CCR7) and Annexin V staining excluding apoptosis.

Results: Across TPE, a significant reduction of disease severity markers such as MELD (p = 0.0156), lactate (p = 0.0078) and AST (p = 0.0078) was observed. Monocyte counts (p = 0.8125) and apoptosis rates (AnnexinV; p = 0.1354) before and after TPE were comparable. Monocyte pro-inflammatory response (TNF-α) to LPS

was significantly reduced in plasma post- compared to pre-TPE ($p = 0.004$; CD14+16-:$p = 0.0003$/CD14+16+:$p = 0.0014$), there was no change following natural course of disease. IL-6 production was unaffected. Immunophenotyping of monocytes in post TPE plasma revealed reduced expression of activation markers CD64 ($p = 0.0084$), CCR7 ($p = 0.0015$) and CD163 ($p = 0.0479$), but no changes following natural course. Numbers of CD4/CD8, regulatory T-cells, NK-cells were unchanged, however CD4-cell secretion of IL-10 ($p = 0.0144$) and TGF-β ($p = 0.0332$) was significantly reduced.
Conclusions: Clearance of inflammatory mediators from the plasma by TPE reduces disease severity, SIRS activation and extrahepatic organ dysfunction through suppression of innate immune cell activation in ALF; providing a mechanistic explanation for the beneficial effect of TPE on outcome in ALF.

O107

IL-22 SECRETION IS REQUIRED FOR LIVER REGENERATION AND IS MODULATED BY EXTRACELLULAR NUCLEOTIDES

R. Kudira[1], T. Malinka[1], M. Gomez de Agüero[2], A. Keogh[1], D. Stroka[1], D. Candinas[1], G. Beldi[1]. *[1]Department for Visceral Surgery and Medicine, [2]Department of Gastroenterology/Mucosal Immunology, Bern University Hospital, University of Bern, Bern, Switzerland*
E-mail: guido.beldi@insel.ch

Background and Aims: Liver regeneration after hepatic resection is a complex and highly coordinated process between various cell types including innate immune cells. Nucleotides, such as ATP are released by such cellular injury bind to specific purinergic receptors expressed and further modulate effector functions of various immune cells including cytokine secretion. The cytokine IL-22 exhibits specific hepatoprotective and proliferative properties in various models of liver injury and repair.
Methods: Partial hepatectomy is performed in mice null for IL-22 and CD39 and assessed using PCNA and Ki67 staining. Cytokine sercretion ex vivo was assessed in response to IL-23 or PMA and ionomycin
Results: Serum levels of IL-22 are elevated at early time points post partial hepatectomy. Specific fractions of IL-22 producing cells are shown in the liver that include innate lymphoid cells like conventional NK cells, Rorgt positive ILC3 cells and other cells fractions include NKT cells, T cells and lineage negative cells. Further, IL-22 is required for optimal liver regeneration as hepatocellular proliferation was assessed by Ki67 and PCNA staining was significantly delayed and liver injury was increased in mice null for IL-22 compared to wild type mice. Interestingly, cell fractions that produce IL-22 express CD39 a major vascular ectonucleotidase that hydrolyzes extracellular ATP to ADP and AMP. In CD39 null mice NK cells, CD4 T cells, NKT cells, Rorgt positive ILC3 cells and lineage negative cells exhibit lower secretion of IL-22 in response to IL-23 or PMA/Ionomycin. In vivo secretion of IL-22 post partial hepatectomy was significantly reduced in mice lacking CD39 compare to wild type mice. Dysregulated activation of P2 type receptors in response to extracellular nucleotides was explored using P2 receptor agonists. Administration of ATPgammaS, ADPbetaS (non-hydrolysable ATP analogs) stimulates IL-22 expression that is not dependent on IL-23 stimulation. Further IL-23 dependent secretion of IL-22 is modulated by extracellular ATP. These findings were substantiated in vivo by showing that elevated hydrolysis of extracellular ATP by soluble ectonucleotidase apyrase is associated with significant decrease of IL-22 expression in response to IL-23.
Conclusions: We show that IL-22 secretion is required for liver regeneration and that the secretion of IL-22 by various subsets of hepatic immune cells is modulated by CD39 and extracellular nucleotides.

O108

RESIDUAL HCV-RNA IN LIVER EXPLANTS FROM PATIENTS UNDERGOING SOFOSBUVIR AND RIBAVIRIN TREATMENT WHILE AWAITING LIVER TRANSPLANTATION IS NOT ASSOCIATED WITH HCV RELAPSE

M. Gambato[1], S. Pérez-del-Pulgar[1], C. Hedskog[2], J. Svarovskia[2], M.S. Paulson[2], J. Denning[2], M.P. Curry[3], N. Caro-Pérez[1], M.C. Londoño[1], X. Forns[1]. *[1]Liver Unit, Hospital Clinic, IDIBAPS, CIBERehd, Barcelona, Spain; [2]Gilead Sciences Inc., Foster City, CA, [3]Beth Israel Deaconess Medical Center, Boston, MA, United States*
E-mail: martina.gambato@gmail.com

Background and Aims: Sofosbuvir (Sovaldi™, SOF) in combination with ribavirin (RBV) administered to HCV-infected patients with hepatocellular carcinoma awaiting liver transplant (LT) prevented recurrence of HCV post-LT in 70% in those individuals with undetectable serum HCV-RNA at time of LT (Curry et al Gastroenterology 2014). The present study examined the presence of HCV-RNA in available liver explants from patients in the Phase 2 clinical study.
Methods: Liver explant samples were collected from 38 HCV-infected cirrhotic patients that underwent LT. All patients received 3 to 52 weeks of SOF+RBV while awaiting LT. HCV-RNA levels in the liver were determined by quantitative real-time PCR in triplicate experiments. The limit of detection was 6 copies per reaction (S 86%, Sp 91%). Liver explants from 39 HCV-RNA negative patients were used as controls.
Results: Thirty-four patients were included in the final analysis. Twenty-three out of 34 (68%) patient liver explants were HCV-RNA positive (range 0.7–67566 copies/ug) and 11 (32%) were HCV-RNA negative. HCV-RNA was not detected in any of the control explants. Treatment duration and time with undetectable HCV-RNA in serum before LT were significantly lower in patients with HCV-RNA in liver explants (16 and 7 weeks, respectively), compared to those with undetectable HCV-RNA (24 and 13 weeks, $p = 0.037$ $p = 0.045$, respectively). Twenty-four out of 34 patients (71%) achieved SVR12 after LT and 10 patients (29%) presented recurrent HCV infection. Interestingly, HCV-RNA was detected in liver explants from 16 (68%) of the 24 responders and in 7 (70%) of the 10 non-responders ($p = 0.850$).
Conclusions: SOF+RBV regimen is an efficacious therapy for preventing HCV recurrence. The presence of HCV-RNA in liver explants did not significantly correlate with the likelihood of recurrent HCV infection post-LT. Residual HCV in liver explants may represent non-functional HCV-RNA (incomplete genomes versus unfit viral strains) in the context of HCV-RNA polymerase inhibition by SOF.

E-mail: jerome.dumortier@chu-lyon.fr

Background and Aims: Recurrence of HCV after liver transplantation (LT) can rapidly lead to liver graft cirrhosis, and therefore graft failure and re-transplantation or death.

Study aim was to assess efficacy and tolerance of sofosbuvir (SOF)-based regimens for the treatment of HCV recurrence in patients with severe fibrosis after LT.

Methods: The ANRS CO23 CUPILT study is a prospective nationwide cohort including patients with HCV-recurrence following LT treated by second-wave direct antivirals. The present study focused on patients included between Oct 2013 and Feb 2014 and diagnosed with HCV recurrence and liver graft extensive fibrosis (METAVIR F3/F4). Treatment regimens were prescribed according investigator's discretion. Patients were followed at W0, W2, W4, W12 and W24.

Results: A sofosbuvir (SOF)-based regimen was administered to 35 patients fulfilling inclusion criteria. The median delay from LT was 65 months [29–111]. The characteristics of patients at W0 were: median age: 61 years [53–67]; male: 77%, G1: 77%, G2: 3%, G3: 14%, G4: 6%; ALT: 84 IU/L [43–126], gGT: 137 IU/L [58–290], bilirubin: 15.5 micromol/L [10–33], albumin: 37.7 g/L [31.1–40.6], median HCV RNA: 6.3 log IU/ml [5.8–6.6]. Ascites was present in 1 (3%) patient. Three (9%) were HIV-co-infected and 33 (94%) failed to previous antiviral therapy containing first generation protease inhibitors in 6 (17%) cases. The following regimens were used: Peg-IFNa + SOF + ribavirin (n = 3), SOF + ribavirin (n = 7), SOF + daclatasvir (n = 11) and SOF + daclatasvir + ribavirin (n = 14) for 24 weeks. All patients were alive without re-transplantation at W24. HCV RNA was not detectable at W2 and W4 in 3 (12%) and 5 (15%) patients, respectively. At W12, 6 (17%) patients had HCV RNA <15 IU/ml and 28 (80%) were not detectable. At W24, HCV RNA was not detectable in all patients. The rates of ALT and gGT normalization at W12 were 85% and 62%, respectively. Median bilirubin serum level decreased from 15.5 to 12.2 at W24. Albumin level increased from 37.7 to 39.8 g/L at W24. This was accompanied by clinical improvement including nutritional status (weight gain from 72.2 to 75.3 kg). Ascites was present at W24 in 2 patients. Severe adverse-events occurred in 11 (31%) patients before W24.

Conclusions: SOF-based regimens show very promising results regarding high rates of end of treatment virological response in patients with severe HCV recurrence after LT. Sustained virological response rates will be presented during the meeting.

O110

SIMEPREVIR + SOFOSBUVIR COMBINATION THERAPY FOR RECURRENT GENOTYPE-1 HEPATITIS C IN LIVER TRANSPLANT RECIPIENTS: A REAL-LIFE MULTICENTER EXPERIENCE

H. Te[1], J. Ahn[2], T. Schiano[3], A. Diesing[4], A. Aronsohn[1], S. Robertazzi[4], L. Myers[2], R. Satoskar[4]. *[1]Medicine, University of Chicago Medicine, Chicago, IL, [2]Medicine, Oregon Health and Science University, Portland, OR, [3]Medicine, The Mount Sinai Medical Center, New York, NY, [4]Georgetown University Hospital, Washington, D.C., United States*
E-mail: hte@medicine.bsd.uchicago.edu

Background and Aims: Recurrent hepatitis C (HCV) after liver transplantation (LT) remains a major cause of morbidity and mortality. Data on the safety and effectiveness of simeprevir + sofosbuvir (SMV+SOF) therapy in "real-life" patients with HCV after LT are limited.

Aim: To evaluate the safety and effectiveness of SMV+SOF therapy in patients with genotype (GT)-1 HCV recurrence after LT.

Methods: All GT-1 HCV patients who underwent LT and received, or are receiving, SMV+SOF for 12–24 weeks were retrospectively identified at 4 centers. Treatment response by HCV RNA during therapy and at weeks 4 and 12 after completion of therapy (sustained virologic response, SVR4 and SVR12, respectively) were determined. Adverse events (AE), significant AE (SAE), changes to immunosuppression and survival were recorded.

Results: 40 patients were included in the study, 82% male, 62.5% Caucasian, with a mean age of 61.3±6.2 years; 60% had GT-1a, 35% had GT-1b and 5% had no subtype. The median time from LT to SMV+SOF initiation was 991 days (44–4563 days). 63% had F0–2 fibrosis, and 37% had F3–4 fibrosis. 90% were on tacrolimus. All patients (n = 22) who completed 12 weeks of therapy achieved undetectable HCV RNA at this time point. SVR4 was achieved in 77% (10/13). There were 2 relapses after completion of 12 weeks of SMV+SOF, and one patient truncated therapy at 6 weeks due to progression of hepatic decompensation and later died. Adverse events were reported in 53% of patients with the most common: constitutional (42%), anemia (10%), and gastrointestinal symptoms (10%). There were 4 SAEs consisting of syncope due to dehydration (n = 1), renal insufficiency (n = 2), and progressive hepatic decompensation leading to death (n = 1). There were no significant changes required on immunosuppression while on therapy.

Conclusions: SMV+SOF is an effective regimen for the treatment of HCV recurrence after LT, with no significant impact on dosing of immunosuppression. Adverse events were manageable in almost all patients, with SAEs being uncommon. However, given the rapidly evolving treatment landscape of HCV, the future utility of SMV+SOF in LT recipients with hepatic decompensation from recurrent HCV appears uncertain.

OPERATIONAL TOLERANCE CAUSES A LONG LASTING ACTIVE IMMUNOREGULATION WITHIN THE GRAFT

R. Taubert[1], R. Danger[2], M.-C. Londono[3], M. Martinez[3], A. Rimola[4], M.P. Manns[1], A. Sanchez-Fueyo[4], E. Jaeckel[1]. *[1]Dept. E-mail: jaeckel.elmar@mh-hannover.de

Background and Aims: Immunosuppression (IS) can be discontinued from selected, stable patients after liver transplantation resulting in operational tolerance (OT). While biomarkers can predict the outcome of IS withdrawal, the mechanisms mediating OT remain elusive.

Methods: In the current study, we analyzed serial liver biopsies obtained from adult liver recipients enrolled in a prospective multi-center IS withdrawal trial employing immunophenotyping and transcriptional profiling. Liver samples were collected before the initiation of IS withdrawal, at the time of rejection, or 1 and 3 years after complete drug discontinuation. In parallel immune cells from peripheral blood were analysed by flow analysis.

Results: Out of the 102 recipients participating in the trial, IS withdrawal was successful in 41 recipients. We analyzed mechanisms of tolerance in 15 patients with serial biopsies. The number of liver infiltrating T cell subsets did not differ at baseline between patients who rejected and those who successfully discontinued IS, However, to our surprise the tolerated grafts exhibited portal tract expansion with increased T cell infiltration despite normal transaminases and no signs of rejection one year after IS withdrawal. This was associated with preferential accumulation of CD4+Foxp3+ T cells, a shift in the CD4/CD8 T cell ratio and a trend towards up-regulation of immune activation and regulatory genes. At three years after induction of operational tolerance the grafts had still large inflammatory infiltrates, but with reduced CD8+ T cells leading to an increased CD4/CD8 ratio suggestive of additional deletional mechanisms. The inflammatory gene signature returned to baseline 3 years after IS withdrawal. Changes within the graft were not paralleled by analysis of PBMCs

Conclusions: We report here for the first time data suggesting that in human liver transplant recipients OT is an active, long-lasting phenomenon in which IS withdrawal elicits dominant immunoregulatory mechanisms that restrain effector alloimmune

responses. The results will need to be taken into account when designing future diagnostic and therapeutic clinical studies aiming at achieving allograft tolerance in clinical organ transplantation.

Background and Aims: Uncontrolled studies suggest that addition of PEGIFN in CHB patients receiving NUCs with undetectable serum HBV DNA may increase HBsAg clearance. We conducted a multicenter randomized controlled study to evaluate this strategy.
Methods: The key inclusion criteria were: HBeAg negative CHB and documented negative HBV DNA while on stable NUC regimens for at least 1 year. Patients with PEGIFN contra-indications were excluded.
From January 2011 to July 2012, 183 patients [86% male, mean age 47.6 years (range 28–74), HBV DNA undetectable for 198 weeks (range 13–1074)], were randomized to receive a 48 weeks course of 180 μg/w PEGIFN-alfa-2a (Pegasys) in addition to the backbone NUC regimens (Group 1: n = 90) or no additional therapy (Group 2: n = 93). Patients were stratified according to the HBsAg titers (< or ≥2.25 log IU/ml). NUC regimens remained unchanged during the study period up to week 144. Treatments discontinuation was allowed if HBsAg clearance was sustained for 24 weeks. Patients were seen monthly during the first 48 weeks, then every 3 months.
The primary end point was the proportion of patients with serum HBsAg clearance at week 96. Secondary endpoints included HBsAg clearance at week 48.
Results: 85 patients initiated PEGIFN in group 1, 17 patients discontinued prematurely PEGIFN due to adverse events, and 4 patients had a dose reduction to 135 μg/w or 90 μg/w. There was no discontinuation of the NUC regimens in group 1 and only one patient in group 2. At week 48, 7 patients had an HBsAg clearance in group 1 and 1 in group 2 (p = 0.032). Demographic and baseline characteristics, CHB history and history of anti-HBV therapies were studied. HBsAg clearance at the end of PEGIFN treatment (W48) was associated with (1) baseline HBsAg titer (p = 0.020) and (2) history of HBeAg seroconversion prior to randomization [4/19 (21%) vs 3/64 (4.6%), p = 0.038].
Final results regarding primary end point at week 96 will be presented in this meeting.
Conclusions: Addition of a 48 weeks course of PEGIFN alfa-2a to oral anti-HBV therapy in HBeAg negative CHB patients with undetectable serum HBV DNA for at least 1 year: (1) Results in a low rate of HBsAg clearance [7/90 (8%)] and (2) Suggests that low baseline HBs Ag titers and a history of HBeAg seroconversion either spontaneaously or under HBV therapy may increase HBsAg clearance rate.

O113

HLA DPB1 rs9277535 POLYMORPHISM STRONGLY PREDICTS HBsAg CLEARANCE IN IFN TREATED GENOTYPE D HBeAg-NEGATIVE PATIENTS WITH CHRONIC HEPATITIS B

P. Lampertico[1], E. Galmozzi[2], F. Facchetti[1], C. Cheroni[3], F. Invernizzi[1], V. Valveri[3], R. Soffredini[1], M. Viganò[4], S. Abrignani[3], R. De Francesco[3], M. Colombo[2]. *[1]Division of Gastroenterology and Hepatology, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, [2]Division of Gastroenterology and Hepatology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, [3]INGM Istituto Nazionale Genetica Molecolare, [4]Division of Hepatology, Ospedale San Giuseppe, Università degli Studi di Milano, Milan, Italy*
E-mail: massimo.colombo@unimi.it

Background and Aims: HLA DP polymorphisms have recently been associated to spontaneous hepatitis B virus (HBV) clearance in Asians patients. Whether these SNPs influence IFN-induced HBsAg response in difficult to cure HBeAg-negative genotype D chronic hepatitis B Caucasian patients, is currently unknown.
Methods: 126 such patients with compensated disease (46 years, 82% males, 90% genotype D, HBV DNA 6.2 log cp/ml, ALT 132 IU/L, 40% with cirrhosis) were followed for a median of 11 (1–23) years after 22 (6–48) months of either standard or pegylated (Peg)IFN alfa treatment. The primary endpoint was HBsAg clearance. HLA DPA1 rs3077, HLA DPB1 rs9277535 and rs9277534, and IL28B rs12979860 genotypes were assessed by using TaqMan SNP Genotyping Assays.
Results: Twenty-eight (22%) patients ultimately cleared serum HBsAg with a 15-year cumulative probability of 30%, with a preference for patients with baseline lower HBV DNA levels, higher ALT levels, IL28B rs12979860 CC, HLA DPB1 rs9277534 AG/GG and HLA DPB1 rs9277535 AG/GG. At multivariate analysis, HLA DPB1 rs9277535 AG/GG genotype was the strongest independent predictor of HBsAg seroclearance (HR: 6.88; 95% CI 2.82–16–7, p < 0.000) along with baseline ALT levels (HR 1.00, 95% CI 1.00–1.00, p = 0.001), baseline HBV DNA levels (HR 0.54, 95% CI 0.37–0.79, p = 0.002), and IL28B rs12979860 CC genotype (HR 2.2, 95% CI 1.02–5.0, p = 0.044). The 15-year cumulative rates of HBsAg clearance were 62% in carriers of the HLA DPB1 rs9277535 AG/GG genotype compared to 13% in carriers of the AA genotype (p < 0.0000).

Conclusions: HLA DPB1 rs9277535 polymorphism strongly predicts IFN-induced HBsAg clearance in HBeAg-negative patients chronically infected by genotype D HBV. This genetic signature may help to select patients to IFN based regimen.

O114

SERUM HBV-RNA LEVELS DECLINE SIGNIFICANTLY IN CHRONIC HEPATITIS B PATIENTS DOSED WITH THE NUCLEIC-ACID POLYMER REP2139-CA

L. Jansen[1,2], A. Vaillant[3], F. Stelma[1,2], N.A. Kootstra[2], M. Bazinet[3], M. Al-Mahtab[4], H.W. Reesink[1,2]. *[1]Gastroenterology and Hepatology, [2]Experimental Immunology, Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands; [3]REPLICor Inc., Montreal, Canada; [4]Bangabandhu Sheikh Mujib Medical University, Dhaka, Bangladesh*
E-mail: l.jansen@amc.uva.nl

Background and Aims: Treatment of chronic hepatitis B (CHB) patients with the HBsAg release inhibitor REP2139-Ca may be a promising new option for achieving therapy-induced HBsAg loss (functional cure), however its effect on circulating hepatitis B pregenomic RNA (HBV-RNA) is not known. For this, we determined HBV-RNA levels during treatment with REP2139-Ca and compared these with HBV-DNA and HBsAg levels.
Methods: 12 Patients with HBeAg positive CHB (mean HBV-DNA 8.21 logC/mL) participating in a phase 2 study were dosed with the nucleic-acid based amphipathic polymer REP2139-Ca for 20–38 weeks. Responders to REP2139 (defined as decline in serum HBsAg) were subsequently treated with add-on peginterferon alpha-2a and/or thymosin alpha-1. HBsAg (Architect), HBV-DNA, and HBV-RNA levels were determined in baseline serum samples, after 20–24 weeks of REP2139-Ca monotherapy, and either during a treatment-free follow-up (for responders) or during entecavir treatment (for non-responders). HBV-RNA isolated from 140 μL of plasma was quantified by RT-qPCR using HBV-specific primers. Lower limit of quantification of RNA was set at 3.00 logC/mL. Variables were evaluated with a paired T-test.
Results: HBV-RNA was detectable in all 12 patients before treatment [mean 6.70 logC/mL (SD 0.83)], and was significantly associated with HBsAg (r^2 0.33, $p = 0.049$) and HBV-DNA (r^2 0.74, $p < 0.001$). After 20–24 weeks of REP2139-Ca treatment, mean HBV-RNA, HBV-DNA, and HBsAg levels declined significantly compared to baseline (−2.54, −3.34, and −3.12 log C or IU/mL, respectively, all $p < 0.001$). At week 20–24, HBV-RNA was undetectable in 8/12 patients. In 7 of these 8 patients, HBV-RNA remained undetectable during the treatment-free follow-up period (mean 21.9 weeks, range 7–27). HBsAg loss and anti-HBs seroconversion was achieved in 4/8 patients during treatment-free follow-up (anti-HBs range 200–766 U/L).
In contrast, 3/4 patients with detectable HBV-RNA at week 20–24 of REP2139-Ca treatment also showed no decline in HBV-DNA or HBsAg, after which entecavir therapy was initiated. After 21–32 weeks of entecavir treatment HBV-DNA had declined significantly (−4.39 logC/mL, $p = 0.029$), whereas HBV-RNA levels remained unchanged (+0.23 logC/mL, $p = 0.188$).
Conclusions: Treatment of CHB patients with REP2139-Ca resulted in a pronounced decline of serum HBV-RNA, HBV-DNA and HBsAg in the majority of patients, and may be a promising new option for improving the chance of functional cure in CHB patients.

O115

HIGH ANTIVIRAL ACTIVITY OF THE HBV CORE INHIBITOR NVR 3-778 IN THE HUMANIZED UPA/SCID MOUSE MODEL

K. Klumpp[1], T. Shimada[2], L. Allweiss[3], T. Volz[3], M. Luetgehetman[3,4], O. Flores[1], G. Hartman[1], A. Lam[1], M. Dandri[3,5]. *[1]Novira Therapeutics Inc., Doylestown, United States; [2]PhoenixBio Co., Ltd., Higashi-Hiroshima, Japan; [3]Department of Internal Medicine, [4]Institute of Microbiology, Virology and Hygiene, University Medical Center Hamburg-Eppendorf, [5]German Center for Infection Research, Hamburg-Lübeck-Borstel Partner Site, Hamburg, Germany*
E-mail: kklumpp@noviratherapeutics.com

Background and Aims: NVR 3-778 represents a new class of HBV core inhibitors and is in clinical development for the treatment of chronic hepatitis B. We determined the antiviral activity of NVR 3-778 alone or in combination with PEG-IFN or entecavir in the humanized uPA/SCID mouse model of HBV infection.
Methods: Thirty-six mice infected with HBV genotype C, with serum HBV viremia $>10^6$ copies/ml and human serum albumin levels >6 mg/ml were randomized into 6 treatment groups: (1) NVR 3-778, (2) vehicle, (3) entecavir, (4) PEG-IFN, (5) NVR 3-778 + entecavir and (6) NVR 3-778 + PEG-IFN. Virologic endpoints included serum and intrahepatic HBV DNA, HBV antigen, cccDNA and HBV RNA levels.
Results: All 6 mice in the NVR 3-778 group showed >1.7 log serum viral load reduction from baseline at day 14 [mean (median) viral load reduction 1.9 (1.9) log]. This effect was similar to that obtained with entecavir ($p > 0.05$) and larger than that obtained with PEG-IFN treatment ($p < 0.05$). The largest viremia reduction across all groups was obtained when NVR 3-778 was combined with PEG-IFN, resulting in a mean (median) viral load reduction of 2.4 (2.4) log at day 14, significantly larger than that obtained with either NVR 3-778 or PEG-IFN alone ($p < 0.05$). The combination of NVR 3-778 and PEG-IFN also showed the largest reduction in intrahepatic HBV DNA loads (median 3.0 log; $p < 0.005$) as compared to other treatment groups (NVR 3-778 alone 2.0 log, entecavir 2.2 log and PEG-IFN 1.8 log). Intrahepatic HBV RNA loads were reduced significantly in the PEG-IFN groups only. As expected, serum levels of HBsAg were reduced most strongly in the PEG-IFN groups and were only minimally affected by NVR 3-778 alone. Levels of cccDNA were similar across treatment groups. Treatment with NVR 3-778 was not associated with any significant changes in the levels of human serum albumin, serum alanine aminotransferase (ALT) levels, or intrahepatic amounts of human β-globin, indicating that the number of human hepatocytes remained stable during the treatment period.
Conclusions: The HBV core inhibitor NVR 3-778 demonstrated high intrinsic antiviral activity in HBV infected humanized mice. Serum HBV viral load reduction was larger than that obtained with PEG-IFN and similar to entecavir alone. The combination of NVR 3-778 and PEG-IFN showed higher antiviral activity as compared to NVR 3-778 or PEG-IFN alone, indicating a functionally beneficialinteraction between a core inhibitor and interferon alpha.

O116

PREDICTIVE VALUE OF BASELINE AND ON-TREATMENT qHBsAg LEVEL IN HBeAg POSITIVE CHB PATIENTS WHO SWITCHED FROM NUCS TO PEGYLATED INTERFERON A-2A: A FURTHER ANALYSIS FROM NEW SWITCH STUDY

E-mail: hp_cq@163.com

Background and Aims: qHBsAg level, which has been used to predict IFN response in treatment naïve patients, is rarely studied in NUC-treated CHB patients. Aim of this study is to investigate the predictive value of baseline and on-treatment qHBsAg levels on treatment response in patients who switched from a long-term treatment of NUC to pegylated interferon a-2a (PEG-IFN a-2a).
Methods: HBeAg positive CHB patients who achieved partial responses (defined as HBV DNA<200 IU/ml and HBeAg loss) with a prior NUC history for 1–3 years were included in NEW SWITCH study. All participants were switched to PEG-IFN a-2a treatment for either 48 or 96 weeks (with the first 12 weeks overlapping NUC therapy) at a randomization ratio of 1:1 and followed-up to 48 weeks after the discontinuation of PEG-IFN a-2a. The predictive values of qHBsAg levels at baseline, 12wks and 24wks on treatment response (defined as HBsAg loss at week 48) were analyzed in the retrospective analysis.
Results: 271 patients, who had completed 48wks of treatment, were recruited in this analysis, including 47 (17.3%) patients achieved HBsAg loss at week 48. Significantly lower qHBsAg levels at baseline (720.97 IU/ml *vs* 5456.16 IU/ml, $P < 0.001$) and reduction of qHBsAg during treatment ($P < 0.001$) were observed in patients with HBsAg loss comparing with those without.
Patients with qHBsAg<1500 IU/ml at baseline achieved higher HBsAg loss rate than those with qHBsAg≥1500 IU/ml (33.3% *vs* 4.1%, $P < 0.0001$). Similarly, those with qHBsAg levels <200 IU/ml at week 24 achieved higher HBsAg loss rate than those with qHBsAg≥200 IU/ml (48.4% *vs* 0.6%, $P < 0.0001$).
Analysis of the combinative prediction value of baseline and on-treatment qHBsAg levels has shown that patients with qHBsAg<1500 IU/ml at baseline and qHBsAg <200 IU/ml at week 24 had the highest response rate (PPV 51.35%), while those with qHBsAg≥1500 IU/ml at baseline and qHBsAg≥200 IU/ml at week 24 had the lowest response rate (NPV 100%, Figure 1).
Conclusions: Combination of qHBsAg levels at baseline and week 24 might be able to predict HBsAg loss at week 48 in HBeAg positive CHB patients who switched to PEG-IFN a-2a after achieving partial responses in NUC treatment.

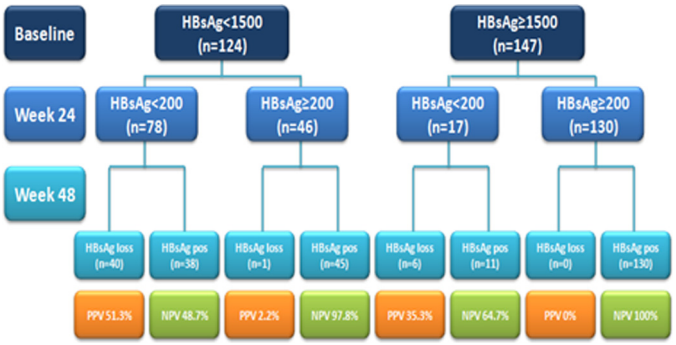

Figure 1. The algorithm for the predictive value of qHBsAg levels.

E-mail: hlychan@cuhk.edu.hk

Background and Aims: There are scarce on-treatment data on HBsAg and HBV DNA kinetics with concomitant nucleos(t)ide

analog and immunomodulator HBV therapy. Predictors of clinical response may help manage patients on combination therapy.
Methods: From study GS-US-174-0149, 740 CHB patients without advanced disease were randomized 1:1:1:1 to receive (TDF+PEG) x48 weeks (arm A); (TDF+PEG) x16 weeks followed by TDFx32 weeks (arm B); continuous TDF (arm C); PEGx48 weeks (arm D). Associations between baseline and on-treatment variables with change in HBV DNA (log_{10} IU/ml) or HBsAg (log_{10} IU/ml) levels from baseline to week 48 or HBsAg loss at Week 72 were examined via linear regression or Cox regression analyses, respectively, in univariate models as well as multivariate models.
Results: In a multivariate analysis, treatment arms A, B, and C compared to arm D, baseline HBeAg-negative status, higher baseline HBV DNA, and lower baseline HBsAg levels were associated with greater HBV DNA decline at Week 48. For every 1 log_{10} IU/ml increase in baseline HBV DNA or 1 log_{10} IU/ml decrease in baseline HBsAg, there is an expected greater HBV DNA decline by 0.85 or 0.31 log10 IU/mL, respectively, at Week 48. On multivariate analysis, achieving HBsAg loss was associated with treatment Arm A, GT A, early ALT flare on treatment, and, at Week 12, with HBsAg decline from baseline >1 log_{10} IU/ml (table). The positive predictive values for achieving HBsAg loss at week 72 with (TDF+PEG) $\times$48 weeks with either 1 log_{10} IU/ml decline or HBsAg <100 IU/ml at week 12 were 43% and 50%, respectively, and the negative predictive values (NPV) were 97% and 95%, respectively. TDF+ PEG combination for 48 weeks exhibited the largest HBsAg decline (log_{10} IU/ml) as compared to other treatment arms (Arm A: −1.1, B: −0.5, C: −0.3, D: −0.8; $p < 0.01$ for all comparisons of arm A versus others). Similar levels of HBsAg decline were observed in genotypes (GT) A and B (mean log_{10} IU/ml $\pm$ SD: −1.2$\pm$2.0 and −1.1$\pm$1.2, respectively), both of which exhibited a greater decline than GT C and D (−0.5$\pm$0.9 and −0.4$\pm$1.0, respectively) ($p < 0.05$).

Table: Predictors of HBsAg loss at Week 72 – Multivariate Cox Regression Analysis (Number of observations: 625)

Predictors	Hazard ratio	95% CI	p-value
Arm A vs. B	3.68	(1.25, 13.32)	0.033
Arm A vs. D	3.82	(1.29, 13.97)	0.032
GT A vs. B	8.90	(2.63, 32.22)	<0.001
GT A vs. C	15.51	(3.95, 73.96)	<0.001
GT A vs. D	7.88	(1.84, 46.78)	0.015
Achieving >1 log_{10} IU/ml decline in HBsAg at week 12: Y vs. N	7.80	(2.05, 29.22)	0.003
ALT flare in 1st 12 weeks: Y vs. N	4.65	(1.54, 14.46)	0.009

Conclusions: Higher baseline HBsAg levels appear to impact negatively on-treatment HBV DNA response. HBsAg decline on TDF plus PEG combination therapy x48weeks was synergistically greater than on either TDF or PEG monotherapy. HBsAg decline appears to favor HBV GT A and B. Moreover, HBsAg decline at week 12 shows high NPV for week 72 HBsAg loss and may provide a valuable tool for response-guided therapy in PEG+TDF combination treatment.

OPTIMIZING THE PRENYLATION INHIBITOR LONAFARNIB USING RITONAVIR BOOSTING IN PATIENTS WITH CHRONIC DELTA HEPATITIS

C. Yurdaydin[1], R. Idilman[1], I. Choong[2], C. Kalkan[1], O. Keskin[1], M.F. Karakaya[1], A.E. Tuzun[1], E. Karatayli[3], M. Bozdayi[4], D. Cory[5], J.S. Glenn[6]. *[1]Gastroenterology, Ankara University School of Medicine, Ankara, Turkey; [2]University of California, Berkeley, United States; [3]Institute of Hepatology, [4]Institute of Hepatology, Ankara University School of Medicine, Ankara, Turkey; [5]University of Waterloo, Ontario, Canada; [6]Gastroenterology, Stanford School of Medicine, California, United States*
E-mail: cagdas.kalkan@hotmail.com

Background and Aims: Chronic delta hepatitis (CDH) is the most severe form of chronic viral hepatitis. Interferons are effective in only a quarter of patients and alternative treatment options are urgently needed. Prenylation inhibitors (PI) function by impeding virion assembly. In a proof of concept study, 100 mg BID or 200 mg BID of the PI lonafarnib (LNF) led to a 0.7 log and 1.6 log reduction in serum HDV RNA, respectively, after 4 weeks of treatment (Koh et al, AASLD 2014). AIM: To explore and identify an optimal LNF-based treatment regimen for further development.
Methods: To date, a total of 15 patients have received LNF alone, or in combination (**LO**nafarnib **W**ith **R**itonavir for **HDV** – **LOWR HDV-1**). 9 patients received LNF as monotherapy (LNF 200 mg BID, n = 3; LNF 300 mg BID, n = 3; LNF 100 mg TID, n = 3). 3 patients received LNF 100 mg BID in combination with 180 ug pegylated interferon alfa 2a QW, and 3 patients in combination with ritonavir 100 mg QD. Treatment durations ranged from 4 to 12 weeks. All patients underwent 72-hour pharmacokinetic and pharmacodynamic evaluations Biochemical parameters, quantitative HDV RNA and HBV DNA were tested at days 1, 2, 3, 7, 14, 28 and at 2–4 week intervals thereafter, as well as post-treatment.
Results: LNF + RTN produced the most optimal regimen with HDV RNA decline, ALT normalization and and acceptable safety and tolerability. LNF + RTN combination achieved the best HDV RNA decline after 4 weeks (mean reduction: 2.21 log_{10} copies/mL $\pm$ 0.53 [x$\pm$SD], $p < 0.001$ vs baseline). After 8 weeks of LNF + RTN combination, mean reduction of HDV RNA was 3.45 log, with 1 of 3 patients becoming HDV RNA negative. In other treatment groups, mean HDV RNA decline after 4 weeks ranged between 1.18 and 1.52 log_{10} copies/mL. Adverse events during treatment included anorexia, nausea, diarrhea and weight loss of grade 1 and 2 (according to CTCAE criteria). Mean serum LNF concentrations increased by more than 3 times with RTN boosting compared to LNF monotherapy at all time points tested. RTN-boosted LNF 100 mg BID not only achieved the greatest reductions in HDV RNA, but this regimen was better tolerated than higher doses of LNF.
Conclusions: 1. LNF is effective in human CDH. 2. Based on the results to date, it was decided to further develop LNF with RTN boosting and 12 additional HDV infected patients are currently receiving LNF + RTN (**LOWR HDV-2**). The data from **LOWR HDV-1** and the ongoing **LOWR HDV-2** trials will be presented at the EASL meeting.

STOPPING TENOFOVIR DISOPROXIL FUMARATE (TDF) TREATMENT AFTER LONG TERM VIROLOGIC SUPPRESSION IN HBeAg-NEGATIVE CHB: WEEK 48 INTERIM RESULTS FROM AN ONGOING RANDOMIZED, CONTROLLED TRIAL ("FINITE CHB")

T. Berg[1], K.-G. Simon[2], S. Mauss[3], E. Schott[4], R. Heyne[5], D. Klass[6], C. Eisenbach[7], T.M. Welzel[8], R. Zachoval[9], G. Felten[10], J. Schulze zur Wiesch[11], M. Cornberg[12], E.B. Martins[13], L. Gallo[13], T. Warger[13], J. Petersen[14]. *[1]Innere Medizin, Sektion Hepatologie, Universitätsklinikum, Leipzig, [2]Gastroenterologische Gemeinschaftspraxis, Leverkusen, [3]Zentrum HIV and Hepatogastroenterologie, Düsseldorf, [4]Charite, [5]Leberzentrum Checkpoint, Berlin, [6]Innere Medizin I, Universitätsklinikum, Ulm, [7]Universitätsklinikum, Heidelberg, [8]J.W.-Goethe Universität, Frankfurt a. Main, [9]Klinikum der LMU, München, [10]Gastroenterologische Gemeinschaftspraxis, Herne, [11]University Hamburg Eppendorf, Hamburg, [12]Medizinische Hochschule, Hannover, Germany; [13]Gilead Sciences, Foster City, United States; [14]IFI Institut, Hamburg, Germany*
E-mail: lothar.gallo@gilead.com

Background and Aims: Long-term effective NUC therapy may lead to partial restoration of HBV-specific T cell functions. Stopping therapy in HBV-DNA suppressed HBeAg-negative patients may lead to initial viral rebound and hepatic flare followed by HBsAg clearance. We investigated HBsAg kinetics after controlled stopping of long-term TDF therapy.
Methods: Subjects on effective TDF therapy for at least 4 years were randomized to either stop or to continue TDF therapy for 144 weeks (advanced fibrosis/ cirrhosis excluded). Primary endpoint is HBsAg loss at Week 144. TDF could be restarted in case of clinically significant hepatitis B flares.
Results: 45 subjects were randomized in this open-label study at 13 sites in Germany (median age 45 years, 79% male, 88% Caucasian). 21 Stop-TDF subjects and 21 Continue-TDF subjects completed Week 48 (3 subjects withdrew consent – data excluded). At W48, Continue-TDF subjects maintained viral suppression, stable ALT, none lost HBsAg. 19 of 21 Stop-TDF subjects had early (first 12 weeks) substantial HBV DNA rebound (median 205,380 IU/mL, [Q1 59,995 IU/mL; Q3 444,147 IU/mL]) accompanied by ALT elevations (median 106 IU/mL; [Q1 76 IU/ml; Q3 233 IU/mL]). 2 subjects had minimal HBV DNA rebound (max 259 IU/mL) and normal ALT; both had HBsAg levels <500 IU/ml at baseline (BL), while HBsAg levels in the other 19 subjects were substantially higher (median 52,640 IU/mL; [Q1 26,518 IU/mL; Q3 95,240 IU/mL; range 4,400–221,840 IU/mL]). At W48, 3 subjects had restarted TDF and all had returned to normal ALT and HBV DNA <LLQ, 18 subjects remained off TDF, 15/18 had normal ALT, 14/18 had HBV DNA <2000 IU/mL, and 2/18 lost HBsAg (both male, ages 46 and 58 years, BL HBsAg 7,308 and 15,276 IU/mL, respectively). Among subjects that did not restart TDF, BL HBsAg levels were lower in those with HBsAg decline >1 log (n = 5, median −1.62 log) compared those with decline <1 log (n = 13, median −0.23 log); median BL HBsAg levels were 14,888 IU/ml vs 52,280 IU/ml, respectively. Continue-TDF subjects had only small declines in HBsAg (median: −0.09 log).
Conclusions: Stopping TDF in chronic HBV HBeAg negative long-term suppressed subjects with defined restarting criteria appears to be safe and led to a significantly greater early HBsAg decline as compared to a continued TDF monotherapy. HBsAg loss was observed so far in two subjects (9.5%). If necessary, TDF can be effectively restarted. Lower HBsAg level at BL seems to be a predictive factor for HBsAg decline.

ADVANCED FIBROSIS IS COMMON IN INDIVIDUALS WHOSE HEPATITIS C HAS NOT BEEN DIAGNOSED: RESULTS FROM THE NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY 2001–2012

P. Udompap[1], A. Mannalithara[1], N.-Y. Heo[1], W.R. Kim[1]. *[1]Division of Gastroenterology and Hepatology, Stanford University, Stanford, United States*
E-mail: wrkim@stanford.edu

Background and Aims: Hepatitis C virus (HCV) infection is a global public health problem – while it is common, its consequences may be severe, including end stage liver disease and hepatocellular carcinoma. Moreover, most individuals with HCV remain asymptomatic, which makes the diagnosis difficult. With the hypothesis that individuals whose HCV is not diagnosed are less likely to have advanced fibrosis than those who have been diagnosed, we compare liver fibrosis between respondents to the National Health and Nutrition Examination Survey (NHANES) with diagnosed and undiagnosed HCV infection.
Methods: Testing for HCV was incorporated in NHANES 2001–2012. In a subgroup of the respondents with HCV infection, follow-up questionnaires were administered. Awareness of HCV infection was assessed by the question whether they had known they had HCV before receiving a letter from NHANES. Liver fibrosis was estimated by the FIB-4 and APRI scores. Based on the published cut-off values for advanced fibrosis, the proportion of respondents with a high probability of advanced fibrosis was compared between respondents with known and undiagnosed HCV.
Results: Out of 30,140 respondents of the NHANES survey, 360 tested positive for HCV RNA. There were 355 participants with complete laboratory data needed for the FIB-4 and APRI scores, of whom 130 had completed the full hepatitis C follow-up questionnaires. Slightly less than half (47.7%, n = 62) knew that they had hepatitis C infection before the survey, whereas in the remainder (52.3%), HCV was only discovered from the survey. In the figure, the two groups were comparable with respect to age, sex, aminotransferase and platelet counts. BMI was higher in those with known diagnosed, the significance of which is uncertain. The raw FIB-4 and APRI scores were similar between the two groups. Among the respondents with known HCV infection, the proportion with a high, intermediate, and low probability of advanced fibrosis was 14.5%, 40.3%, 45.2%, respectively. The corresponding data in those with undiagnosed HCV were 19.1%, 30.9%, 50.0%, respectively. A similar pattern was seen with the APRI score.

	Aware	Not aware	p
N	62	68	0.59
Age	52.1	51.2	0.64
Male %	66.7%	76.5%	0.21
AST	57.1	58.0	0.89
ALT	58.1	61.7	0.62
Platelets	216	236	0.18
BMI	30.3	27.1	<0.01
FIB-4 score	2.32	2.14	0.62
	14.5% Advanced	19.1% Advanced	0.53
APRI score	0.90	0.82	0.63
	17.7% Advanced	17.7% Advanced	0.21

Conclusions: While more than half of survey respondents did not know of their HCV infection, their liver fibrosis was no less advanced than those whose HCV had been diagnosed prior to

participation in the survey. These data further justifies the current recommendation for HCV screening in asymptomatic individuals.

E-mail: mfraquelli@yahoo.it

Background and Aims: The performance of pocket-sized ultrasound devices (PUDs) is comparable with that of standard ultrasonography, whereas the accuracy of a physical examination is often poor requiring further tests to assess diagnostic hypotheses. Adding the use of PUD to physical examination could lead to an incremental benefit. Accordingly, present cohort impact study was aimed at assessing whether the use of PUD in the context of physical examination could reduce the request rate of additional tests when used by physicians in different clinical settings.
Methods: The study involved medical wards (#4), hepatological outpatient clinic (#1) and 90 GPs operating in the same geographical area. After a short predefined training course 135 physicians used PUD in addition to physical examination in 1962 consecutive patients to investigate ten well-defined clinical hypotheses (biliary-duct dilation/ gallstones, ascites, splenomegaly, pleural /pericardial effusion, urinary retention/ stones, abdominal mass/ aortic aneurysm). PUD related findings were recorded. and the decision as to whether to request further tests was left to the physician clinical judgement. The main outcome was to define the proportion of cases undergoing additional tests after PUD. An accurate report of the frequency of the clinical questions in the different settings was also planning, using logistic regression analysis to assess the determinant(s) of the primary outcome.
Results: Of the 1962 patients included 726 (37%) were inpatients, 510 (26%) hepatology outpatients and 726 (37%) recruited from GPs. Gallstones (37%), ascites (17%), pleural effusion (13%), urinary stones (13%) and urinary retention (12%) accounted for >90% of the clinical questions, confirmed by PUD in 66% of cases. The overall frequency of further tests after PUD was 37%; and logistic was associated with both the clinical questions and settings ($p < 0.01$). The rate of agreement between findings at PUD and additional tests was 89%, with a sensitivity of 91% and a specificity of 83% (LR+ 5.4; LR− 0.11).
Conclusions: After a simple and short training, a PUD examination can be used in addition to a physical examination in both in- and outpatients to improve the answer to ten common clinical questions, thus reducing the need further testing.

E-mail: sandracoenen80@yahoo.com

Background and Aims: Chronic hepatitis B virus (HBV) and hepatitis C virus (HCV) infection represent a global public health problem resulting in significant morbidity and mortality. In high endemic regions primary prevention in the form of HBV vaccination has led to a decrease in morbidity and mortality. In low endemic countries it is debated whether it is useful to screen for chronic HBV and HCV in first generation migrants from high endemic countries. In the current report, we describe the outcome in terms of clinical impact of five large-scale Dutch screening projects in which screening for HBV and HCV was offered to first generation Chinese migrants aiming at secondary prevention.
Methods: Between 2009 and 2013 five outreach screening projects for viral hepatitis targeting first generation Chinese migrants were conducted in five main Dutch cities. In three cities all HBsAg positive patients were referred for further evaluation to a medical specialist, in two cities only when either HBeAg was positive or ALT was elevated. To explore the relevance of our screening projects we defined clinical impact as the presence of an indication for: 1. start of antiviral therapy within one year of follow-up 2. strict follow-up because of high HBV DNA levels (HBV DNA >20,000 IU/ml) and/or 3. surveillance for HCC according to the AASLD and Dutch guidelines.
Results: In total, 4423 persons participated in the screening projects of which 6% (n = 264) was HBsAg positive. The total number of newly diagnosed HBsAg positive patients who were analysed in specialist care was 129. Among these patients prevalence of cirrhosis was 7%. Within one year of initial consultation, antiviral therapy for HBV was started in 32 patients (25%). In patients without an initial treatment indication, strict follow-up because of high HBV DNA levels and/ or HCC surveillance was considered indicated in 64 patients (50%). Three patients (0.7%) were newly diagnosed with chronic HCV infection (two of these with HBV co-infection). Overall, 75% of all HBsAg and HCV positive patients needed antiviral treatment within one year of follow up or were thought to need strict follow up or HCC surveillance.
Conclusions: In our screening project in first generation Chinese migrants, in 75% of all positive HBsAg and HCV patients analysed

in referral centres, antiviral treatment, strict follow-up because of high HBV DNA levels and/ or HCC surveillance were considered indicated. These data show that detection of HBV infection had considerable impact on patient care.

TEN YEARS OF HOSPITAL ADMISSIONS FOR LIVER CIRRHOSIS IN PORTUGAL

M.J. Silva[1], M.V. Rosa[2], P. Nogueira[2,3], F. Calinas[1]. [1]*Gastroenterology Department, Central Lisbon Hospital Centre,* [2]*Directorate of Analysis and Information, Directorate-General of Health,* [3]*Statistical Council, Lisbon, Portugal*
E-mail: mariojorgesilva01@gmail.com

Background and Aims: Robust data on epidemiology of liver diseases in Europe are lacking. Furthermore, recent changes in alcohol and drug consumption may be affecting the burden of liver cirrhosis (LC). We aimed at characterizing hospital admissions for LC in Portugal in the past decade.

Methods: We analyzed all hospital admissions for LC at Portugal Mainland from patients aged ≥20 years between 2003 and 2012 registered in the Diagnosis-Related Group database from the Portuguese Health System's Central Administration. Selected admissions had LC as main diagnosis; or a complication of LC as main diagnosis with a concomitant secondary diagnosis suggestive of LC. Cirrhosis was classified according to etiology considering alcohol, hepatitis B and hepatitis C.

Results: Between 2003 and 2012 there were 63,910 admissions for LC in public institutions in Portugal Mainland, 74.4% were from male patients. Causes of admitted cirrhosis were: 76.0% alcoholic, 1.1% hepatitis B, 1.4% hepatitis B plus alcohol, 3.6% hepatitis C, 4.0% hepatitis C plus alcohol. There was a significant decline ($p < 0.001$) in admissions for alcoholic cirrhosis, whereas hospitalizations for cirrhosis due to hepatitis C or hepatitis C plus alcohol raised by 50% ($p < 0.001$). Admitted patients with alcoholic plus hepatitis B or C cirrhosis were significantly younger than those with either alcoholic or viral cirrhosis (53.1 years vs 59.4 years respectively, $p < 0.001$). Hospitalization rates for LC in 2011 were 124.4/100,000 in men and 32.6/100,000 in women. Hepatocellular carcinoma and fluid retention were more common in viral cirrhosis, while encephalopathy and variceal bleeding were more frequent in alcoholic cirrhosis. Hepatorenal syndrome was the strongest predictor of in-hospital mortality (OR 13.09; 95% CI 12.07–14.22) compared to spontaneous bacterial peritonitis (OR 2.05; 95% CI 1.86–2.26), hepatocellular carcinoma (OR 1.92; 95% CI 1.82–2.03), hepatic encephalopathy (OR 1.92; 95% CI 1.85–1.99), hepatic hydrothorax (OR 1.52; 95% CI 1.41–1.64), esophageal variceal bleeding (OR 1.34; 95% CI 1.27–1.42), age ≥50 years (OR 1.20; 95% CI 1.14–1.26), ascites (OR 1.00; 95% CI 0.93–1.06) and patient gender (OR 1.01; 95% CI 0.96–1.05). In-hospital mortality was 15.2% in LC from all causes.

Conclusions: Despite the decline in admissions for alcoholic cirrhosis and the rise of those related to hepatitis C, the burden of hospitalized liver cirrhosis in Portugal was essentially attributable to alcoholic liver disease.

O124

IS INCREASED HCV CASE-FINDING COMBINED WITH 8 OR 12 WEEK INTERFERON-FREE DIRECT-ACTING ANTIVIRAL TREATMENT COST-EFFECTIVE IN UK PRISONS? A COST UTILITY ANALYSIS INCLUDING TREATMENT AS PREVENTION BENEFITS

N.K. Martin[1], P. Vickerman[1], I.F. Brew[2], J. Williamson[2], W.J. Irving[3], S. Sakshena[4], S.J. Hutchinson[5,6], M. Hickman[1]. [1]*University of Bristol, Bristol,* [2]*Leeds Community Healthcare NHS Trust, Leeds,* [3]*University of Nottingham, Nottingham,* [4]*County Durham and Darlington NHS Trust, Durham,* [5]*Glasgow Caledonian University,* [6]*Health Protection Scotland, Glasgow, United Kingdom*
E-mail: natasha.martin@bristol.ac.uk

Background and Aims: Hepatitis C virus (HCV) prevalence is high among incarcerated populations, and in 2014 England introduced opt-out HCV testing in prisons. However, short sentences for people who inject drugs (PWID) in the UK combined with long HCV treatments meant case finding was unlikely to be cost-effective without considerable continuity of care between prison and the community, which could not be guaranteed. We assess the cost-effectiveness of increased testing and treatment in UK prisons using 8–12 week interferon-free direct-acting antiviral (DAA) HCV regimens including prevention benefits.

Methods: A previously developed dynamic model of incarceration and HCV transmission was used to assess the cost-effectiveness of doubling HCV case-finding in UK prisons (achieved in one site) when combined with 12 or 8 week IFN-free DAAs including individual and population prevention benefits. The intervention is compared to a baseline of current prison testing and IFN/RBV treatment. Costs (in GBP £) and health utilities (in quality-adjusted life-years, QALYs) were used to calculate mean incremental cost effectiveness ratios (ICERs). We assume 95% SVR and a cost of £3200/wk for DAAs. Based on UK prison data, we model a baseline testing rate of 1.5% per month, 15% yield, and a 56% referral rate. We assume 25%/2.5% exPWID/PWID who attend referral, respectively, are initiated onto treatment within 2 months of diagnosis, PWID and ex/nonPWID are in prison an average 4 and 8.5 months, respectively, We assume no continuity of treatment between prison and community. Multivariate probabilistic sensitivity analyses were performed.

Results: Doubling prison testing rates and treatment with 12 week DAAs produces a mean ICER of £25,766 per QALY gained compared to current testing and treatment, and is 65% likely to be cost-effective under a £30,000 willingness to pay threshold (Figure 1a). Doubled prison treatment rates (achieved in the community) lowers the ICER to £21,678/QALY due to additional individual and population prevention benefits. With 8 week DAAs, the ICER drops to £18,715/QALY and is 88% likely to be cost-effective under a £30,000 threshold (Figure 1b).

Conclusions: Increased HCV case-finding and treatment using short duration DAAs is likely to be cost-effective in UK prisons due to

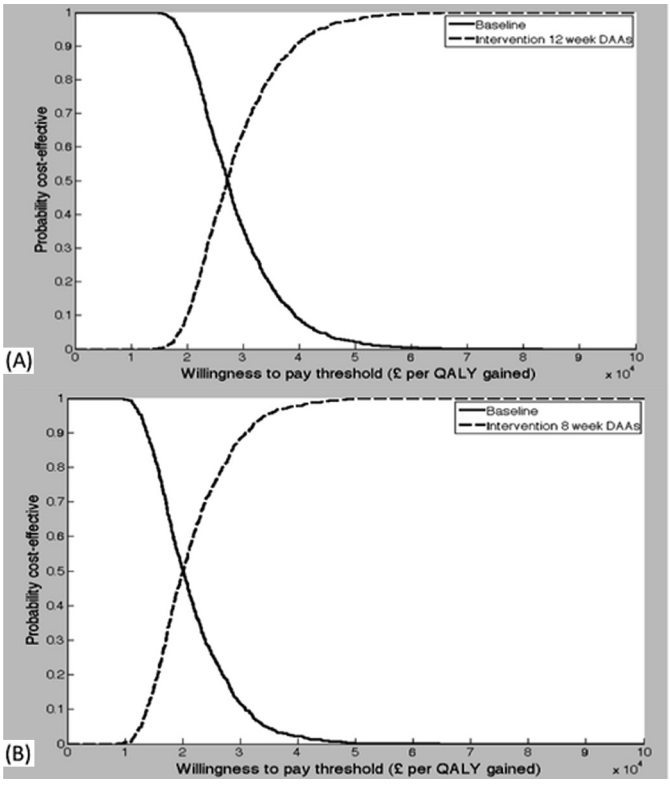

Figure 1. Cost-effectiveness acceptability curves for doubled HCV case-finding in prison combined with (A) 12- and (B) 8-week IFN-free DAAs.

higher completion rates. Greater cost-effectiveness can be achieved through scale-up of treatment due to treatment as prevention benefit, but the affordability of scaling up treatment sufficiently to reduce community transmission is unclear.

O125
A SYSTEMATIC REVIEW OF HEPATITIS B AND C TESTING IN THE COUNTRIES OF THE WHO EUROPEAN REGION

J.V. Lazarus[1], I. Sperle[1], J.K. Rockstroh[2], A. Spina[3], L. Wiessing[4].
[1]CHIP, Rigshospitalet, University of Copenhagen, Copenhagen Oe, Denmark; [2]Department of Medicine I, University Hospital Bonn, Bonn, Germany; [3]Centre for Infectious Disease Epidemiology, Austrian Agency for Health and Food Safety (AGES), Vienna, Austria; [4]European Monitoring Centre for Drugs and Drug Addiction, Lisbon, Portugal
E-mail: Jeffrey.Lazarus@regionh.dk

Background and Aims: Growing awareness of the threat posed by hepatitis B and C has been accompanied by important biomedical advances in their treatment. However, in Europe as elsewhere, there is the potential for hepatitis drugs to be greatly underutilised because many people who might benefit from them are undiagnosed. We reviewed scientific studies reporting hepatitis B and C testing as a step toward informing public health strategies to reduce the number of individuals who remain undiagnosed.
Methods: Using PRISMA criteria, we conducted a systematic review of the MEDLINE and EMBASE databases to identify original research studies reporting levels of hepatitis B and C testing in the 53 Member States of the WHO European Region. English-language peer-reviewed articles and conference abstracts published between January 2007 and June 2013 were included.
Results: This review identified 154 studies from 28 (52.8%) of 53 countries. More than two-thirds of the studies (67.7%) were from six countries: Turkey, Germany, Italy, France, the Netherlands and the United Kingdom. The populations studied most frequently were people who use drugs (32 studies), health care patients (28) and populations tested for reasons relating to pregnancy or use of assisted reproductive technology (18) (Figure 1). Median testing uptake levels ranged from 100% for eight types of populations (Figure 1) to 79.9% for people born to HBsAg-positive mothers and 70.5% for current or former prison inmates. Four studies reported testing uptake of 75.0% or lower in people living with HIV, and six studies reported testing uptake of less than 50% in people who use drugs. The highest median HBsAg prevalence (14.9%) and HCV RNA prevalence (49.7%) were both found in people who use drugs.

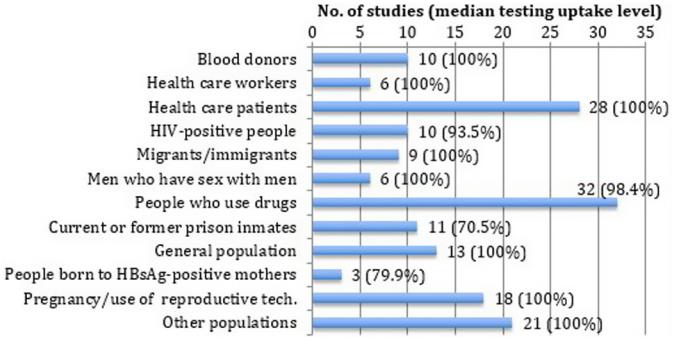

Figure 1. Number of studies reporting on each type of population. [Numbers sum to more than the total number of studies in the review because some studies reported on more than one type of population.]

Conclusions: An evidence base on hepatitis B and C testing appears to be lacking in many European countries. The results indicate that some high-risk populations have been studied much more than others, but mostly only in a small number of countries. Since almost all studies utilised methodologies that required or encouraged study participants to undergo testing, high median testing uptake levels are not likely to be representative of overall testing uptake in most populations. Low testing uptake in some studies raises the question of whether key opportunities to identify infected individuals are being missed. Public health officials need much more comprehensive information in order to plan effective responses to hepatitis B and hepatitis C in Europe.

O126
IMPACT OF SUCCESSIVE HBV-VACCINATION PUBLIC POLICIES ON THE VACCINATION COVERAGE AND INCIDENCE OF HBV INFECTION IN A LARGE FRENCH COHORT OF INDIVIDUALS BORN BETWEEN 1960 AND 1994

C. Ramière[1,2,3], L. Roche[4], C. Scholtès[1,2,3], J. Saison[5], R. Ecochard[4], P. André[1,2,3]. *[1]Laboratoire de Virologie, Hôpital de la Croix-Rousse, Hospices Civils de Lyon, [2]Université de Lyon, [3]Centre International de Recherche en Infectiologie, [4]Service de Biostatistiques, [5]Département des Maladies Infectieuses, Hôpital de la Croix-Rousse, Hospices Civils de Lyon, Lyon, France*
E-mail: christophe.ramiere@inserm.fr

Background and Aims: Hepatitis B remains a pandemic with 240 million chronically infected persons at risk of developing cirrhosis or hepatocellular carcinoma despite the existence of efficient and safe vaccines. To control HBV transmission, the WHO recommends universal vaccination rather than targeting only high risk groups as preferred by several European countries. The French health authorities targeted these risk groups from 1982 to 1994, switched to universal vaccination of infants and catch-up immunization of the general population, to finally abandon catch-up vaccination in 1998. The study aimed at assessing the consequences of these successive vaccination policies on vaccination coverage (VC) and virus circulation among populations at risk of contracting HBV.
Methods: HBV status of 57,113 individuals attending HIV and hepatitis infection screening facilities in Grand Lyon, France, was established by serum HBsAg, anti-HBs, and anti-HBc determination between 2005 and 2010. VC and HBV incidence were calculated for each birth cohort from 1960 to 1995 using statistical "survival" models.
Results: VC increased during the first period corresponding to birth cohorts from 1960 to 1985, reaching a maximum of 60–70% vaccinated individuals in 1983–1985 cohorts. VC then decreased dramatically in post-1985 birth cohorts and fell below 30% in the most recent cohort studied. The incidence of HBV infection in non-vaccinated individuals fluctuated between 5 and 7‰ in pre-1986 birth cohorts, decreased to 2.5‰ in 1986–1991 cohorts but rebounded up to 5‰ in post-1991 birth cohorts.
Conclusions: Reaching a VC above 50% reduced strongly the incidence of HBV infection but the modification of HBV vaccination policies following public controversies in France was sanctioned by a dramatic decline in VC of young adults and a sharp rebound of HBV circulation. These data support the idea that efforts combining universal and catch-up campaigns are essential to control HBV circulation in low endemic countries with the persisting risk to virus resurgence if VC shrinks.

A WORLDWIDE STUDY REVEALS THAT THE AMOUNT OF DAILY ALCOHOL INTAKE IS A BETTER PREDICTOR OF THE WEIGHT OF ALCOHOL IN THE CIRRHOSIS BURDEN THAN THE TOTAL PER CAPITA COMSUMPTION

R. Bataller[1], E. Stein[2], J.T. Altamirano[3], M. Cruz-Lemini[4], J. Cheong[2]. *[1]Gastroenterology and Hepatology, University of North Carolina at Chapel Hill, Chael Hill, [2]Gastroenterology and Hepatology, University of North Carolina at Chapel Hill, Chapel Hill, United States; [3]Institut d'Investigacions Biomediques August Pi i Sunyer (IDIBAPS), [4]Institut d'Investigacions Biomediques August Pi i Sunyer (IDIBAPS), Barcelona, Spain*
E-mail: bataller@med.unc.edu

Background and Aims: Approximately 6% of global deaths are caused by alcohol consumption, with a major contribution from

alcoholic cirrhosis (Global Status Report on Alcohol and Health, WHO, 2014). Moreover, of diseases not explicitly defined by alcohol consumption, cirrhosis has the highest alcohol-attributable fraction (50% of all cases worldwide). Most studies assessing the prevalence of alcohol abuse as a risk factor for alcoholic cirrhosis focus on total annual per capital consumption. However, clinical studies indicate that high daily consumption is the strongest predictor of alcoholic cirrhosis. We hypothesize that the counties with the highest daily alcohol consumption are at highest risk of having a greater burden of alcoholic cirrhosis.

Methods: We performed a comprehensive analysis of the WHO Global Status Report on Alcohol and Health, which included parameters of alcohol consumption and drinking patterns from 193 countries. We categorized countries by heavy or moderate drinking using the average daily consumption among drinkers, according to the US Dietary Guidelines threshold for heavy drinking (up to 1 drink/day for women, up to 2 drinks/day for men). Moreover, global rates of HCV and HBV were obtained from published seroprevalence estimates, and obesity data were obtained from the WHO Data Repository. Uni- and multivariate models were fitted to determine the correlation between alcohol parameters and the outcome measure of alcohol-attributable fraction (AAF) of cirrhosis, adjusting for the cofactors' effects.

Results: In an integrative model that adjusted for cirrhosis cofactors, the classification of countries by moderate or heavy daily drinking had the strongest influence on the weight of alcohol in the cirrhosis burden. Of note, the cirrhosis burden due to alcohol increased by 11.13% with a transition from the moderate to heavy classification ($p < 0.001$). In contrast, total yearly per capita consumption had a correlation coefficient of only 2.22 with the AAF of cirrhosis ($p < 0.001$). Importantly, drinking patterns such as heavy episodic drinking and the type of alcoholic beverages (wine, beer or spirits) did not independently correlate with AAF.

Conclusions: The presence of heavy daily drinkers in a population most significantly and independently influences the weight of alcohol in a country's cirrhosis burden. Reducing heavy drinking should therefore be considered as an important target for public health monitoring and policies.

E-mail: laurinda.cooker@abbvie.com

Introduction: Limited data are available on the safety of direct-acting antivirals (DAAs) for treating hepatitis C virus (HCV) infection in patients with severe renal impairment or end-stage renal disease; many go untreated and are vulnerable to disease progression. RUBY-I is an ongoing, open-label study evaluating the interferon-free 3 DAA (3D) combination of ombitasvir/paritaprevir*/ritonavir (25/150/100 mg QD) and dasabuvir (250 mg BID) with or without ribavirin (RBV, 200 mg QD) in patients with stage 4 or 5 chronic kidney disease (CKD) and HCV genotype (GT) 1 infection. We report preliminary safety results from Cohort 1 of this study.

Material and Methods: Treatment-naïve, non-cirrhotic adults with HCV GT1 infection and CKD classified using estimated glomerular filtration rate (eGFR) as stage 4 (eGFR 15–30 mL/min/1.73m^2) or stage 5 (eGFR <15 mL/min/1.73m^2 or requiring dialysis) receive 12 weeks of treatment with 3D with RBV (GT1a) or without RBV (GT1b), with 24 weeks post-treatment follow-up. On-treatment adverse events (AEs), serious AEs and notable laboratory abnormalities through 18 Feb 2015 are reported.

Table: Baseline characteristics

Variable	3D±RBV (N = 17)
Age, yr; mean (SD)	59.5 (5)
Male; n (%)	14 (82)
Race; n (%)	
Black	11 (65)
White	6 (35)
Hispanic or Latino Ethnicity; n (%)	3 (18)
Degree of fibrosis: n (%)	
F0–F1	9 (53)
F2	5 (29)
F3	5 (18)
HCV viral load, $\log_{10}$(IV/ML); median (minimum, maximum)	6.57 (5.47, 7.64)
GT1a; n (%)	12 (71)
CKD stage; n (%)	
4 (eGFR 15–30 mL/min/1.73m^2)	7 (41)
5 (eGFR <15 mL/min/1.73m^2 or requiring dialysis)	10 (59)
On dialysis; n (%)	11 (65)
eGFR, ml/min/1.73m^2; median (minimum, maximum)	10.6 (5.4, 29.9)
Creatinine, mg/dL; median (minimum, maximum)	6.5 (2.2, 10.8)

Results: 17 (of 20 planned) patients in Cohort 1 received study drug as of 18 Feb 2015; six have completed treatment. 13 of 17 patients reported at least 1 AE, mainly mild or moderate in severity. Two patients experienced serious AEs considered unrelated to DAAs (1 patient: diskitis, respiratory failure. 1 patient: pseudoaneurysm, hemoperitoneum, small bowel obstruction). Both briefly interrupted 3D due to complications of hospitalization; no other patient had an interruption or discontinuation of 3D. Six patients met hemoglobin criteria for interruption of RBV (hemoglobin decrease >2 g/dL during any 4-wk period, or a value <10 g/dL at any time). There was one case of hemoglobin <8 g/dL (hospitalized patient with diskitis). No blood transfusions were performed. All viral loads suppressed rapidly on treatment and there are no cases of virologic rebound or relapse to date.

Conclusions: Among HCV GT1-infected patients with stage 4 or 5 CKD in this ongoing trial, the regimen of 3D±RBV has been well tolerated to date, with no treatment-related serious AEs, one hemoglobin decline to <8 g/dL, and no premature discontinuations of DAAs. All viral loads suppressed rapidly on treatment and there are no virologic failures to date. Available pharmacokinetic and SVR data will be presented.

*Paritaprevir was identified by AbbVie and Enanta.

LO2

SIGNIFICANT REDUCTION OF HBsAg AND HDV RNA BY THE NUCLEIC ACID POLYMER REP 2139 IN CAUCASIAN PATIENTS WITH CHRONIC HBV/HDV CO-INFECTION

M. Bazinet[1], V. Pantea[2], V. Cebotarescu[3], L. Cojuhari[3], P. Jimbei[3], A. Vaillant[1]. *[1]REPLICor Inc., Montreal, Canada; [2]Department of Infectious Diseases, Testemitanu State University of Medicine and Pharmacy, [3]Toma Ciorba Infectious Clinical Hospital, Chisinau, Moldova, Republic of*
E-mail: availlant@replicor.com

Introduction: Nucleic acid polymers (NAPs) block the assembly of HBV subviral particles (SVP), thereby inhibiting their release from infected hepatocytes and eliminating the HBsAg protein from the

blood. The NAP REP 2139 has previously been shown to efficiently clear HBsAg from the blood of patients with HBV mono-infection and improve the ability of immunotherapy to elicit SVR in Asian patients.

Material and Methods: In a phase II proof of concept trial (NCT02233075), the safety and antiviral efficacy of REP 2139 (first in monotherapy and then with add on PEG IFN at week 16) in 12 Caucasian patients with chronic HBV / HDV co-infection is being assessed. Recruitment in this trial is now complete and preliminary safety and efficacy data from for the first 7 patients to reach 13 weeks of REP 2139-Ca monotherapy exposure are disclosed.

Patients with chronic HBV / HDV co-infection are being treated once weekly with 500 mg REP 2139-Ca (calcium chelate complex) by 2h IV infusion. Viremia (HDV RNA and HBV DNA), HBsAg and anti-HBs are followed every two weeks using standard assays (Robogene RT-PCR, Abbott RealTime HBV, Abbott Architect) and performed at the Institute of Virology, University of Duisburg-Essen, Germany.

Results: REP 2139-Ca treatment in all patients is currently well tolerated. All patients have experienced reductions in serum HBsAg and HDV RNA on treatment as outlined in the table below. Four patients have achieved HBsAg reductions of 4–5 logs from baseline with accompanying 5–8 log reductions in HDV RNA (currently undetectable). More moderate HBsAg reductions (1–2 logs) in the other three patients were accompanied by similarly moderate (1–3 log) reductions in HDV RNA. Significant elevations in serum free anti-HBs are detectable in 6/7 patients and are >10 mIU/ml in 4 patients. In the 5 patients with pre-treatment HBV DNA <10 IU/ml, small amounts of detectable HBV DNA are now present.

Patient	HBsAg (IU/ml)		HDV RNA (U/ml)*		Anti-HBs (mIU/ml)		HBV DNA (IU/ml)**	
	Baseline	Week 13	Baseline	Week 13	Baseline	Week 13	Baseline	Week 13
1	13,988	1.17	394,000	TND	1.0	7.9	<10	33
2	27,264	0.34	47,100,000	TND	1.2	25	<10	20
3	28,261	0.01	697,000	TND	0	20.6	<10	25
4	17,511	130	5,490,000	21,500	2.1	6.0	726	66
5	16,426	2,335	211,000	21,100	0	11	104	55
6	12,382	0.07	12,100,000	TND	0.5	26	<10	29
7	20,869	1,732	23,000,000	75,500	0.2	1.3	<10	50

*LLOQ = 1800 U/ml, **LLOQ = 10 IU/ml; TND = RT-PCR target not detected.

Conclusions: REP 2139-Ca is able to achieve rapid reductions in serum HBsAg in Caucasian patients with HBV / HDV infection, demonstrating the reliability of the NAP pharmacological effect (HBsAg reduction or complete clearance) in Caucasian patients. HDV RNA reductions were correlated with HBsAg reductions, suggesting a link between SVP formation and HDV formation. REP 2139-Ca may become an important new therapeutic option for patients with chronic HBV / HDV infection.

E-mail: helene.fontaine@cch.aphp.fr

Introduction: Real-life results of the Sofosbuvir/Simeprevir combination have been extensively reported but there are few data regarding the Sofosbuvir/Daclatasvir combination. In January 2015, 3003 patients of the French observational cohort ANRS CO22

HEPATHER were given the new oral antivirals in 32 centers: we report the preliminary results of the Sofosbuvir/Daclatasvir combination in Genotype 1-infected patients.

Material and Methods: Demographics, history of liver disease were collected at entry in the cohort. Clinical, adverse events, and virological data were collected throughout treatment and post-treatment follow-up.

Results: 409 HCV Genotype 1 mono-infected patients were given a combination of Sofosbuvir (SOF: 400 mg/d) and Daclatasvir (DCV: 60 mg/d) without ribavirin (n = 318) or with ribavirin (1–1.2 g/d, n = 91). 318 patients had cirrhosis and 306 were previously treated with PR (n = 134) or PR + a first generation PI (n = 172).

The overall SVR4 rate was 81.6, 93.9, 100 and 96.6% in those who were given for 12 and 24 weeks SOF/DCV and SOF/DCV/RBV, respectively. The overall SVR4 rate differed according to the prior history and fibrosis (Table). The 12-week combination SOF/DCV/RBV achieved a 100% SVR4 rate in cirrhotics without additive effect of extension of the treatment to 24 weeks with or without RBV (95.7 and 92.5, respectively) and this was also true in experienced patients; all non-cirrhotic patients achieved 100% SVR4 at 12 weeks and, thus, the 12-week combination of SOF/DCV is a good therapeutic option. Serious adverse events were only reported in 9% and treatment discontinuation related to adverse events in 3.1%.

	SOF/DCV (n = 318)		SOF/DCV/RBV (n = 91)	
	12 weeks	24 weeks	12 weeks	24 weeks
% SVR4	81.6	93.9	100.0	96.6
% SVR12	86.8	94.0	100.0	100.0
% SVR4 cirrhotic	69.0	92.5	100.0	95.7
% SVR4 noncirrhotic	100.0	100.0	100.0	100.0
% SVR4 naïve	87.0	86.8	100.0	100.0
% SVR4 experienced	76.9	95.3	100.0	95.9

Conclusions: The Sofosbuvir/Daclatasvir combination is associated with a high rate of SVR4 in difficult-to-treat patients infected by Genotype 1. The combination of Ribavirin increases the SVR rate in cirrhotic or experienced patients without additive effect of the extension of the treatment from 12 to 24 weeks.

*The ANRS CO22 Hepather cohort is supported by MSD, Janssen, Gilead, BMS, Roche, Abbvie and conducted in collaboration with AFEF.

E-mail: cikennedy@shire.com

Introduction: Alagille syndrome (ALGS) is a rare, life-threatening genetic disorder characterized by cholestatic liver disease (CLD) and extrahepatic manifestations. Children with ALGS experience severe pruritus and markedly reduced quality of life and may require liver transplantation. Numerous pharmacological therapies have been tried, with limited success. Partial external biliary diversion (PEBD), which interrupts the enterohepatic circulation, can improve biochemical markers of cholestasis and ameliorate pruritus, but is disfiguring and can be associated with frequent complications. LUM001 is a potent, selective, minimally absorbed inhibitor of the apical sodium-dependent bile acid transporter (ASBT); it blocks bile acid reabsorption in the terminal ileum and increases faecal bile acid excretion, thereby reducing recirculation of bile acids to the liver. We report safety and efficacy data from IMAGO, the first study of LUM001 in children with ALGS.

Material and Methods: Children aged 1–18 years with ALGS, cholestasis (total serum bile acid [sBA] >3 times upper normal limit) and intractable pruritus, who had not undergone liver transplantation or PEBD, were randomized 2:1 to once-daily LUM001 (140 or 280 μg/kg/day) or placebo. LUM001 dosing started at 14 μg/kg/day and increased weekly for 5 weeks to reach the target dose in each group. The primary endpoint was change in fasting sBA level from baseline to Week 13. Secondary endpoints were change in pruritus, assessed twice daily with a novel reported outcome measure (the ItchRO) using a hand-held electronic diary, and liver enzymes (ALT, AST and ALP). Safety assessments included adverse events, laboratory values and vital signs. Comparisons between LUM001 and placebo were made using an analysis of covariance model and descriptive statistics.

Results: In total, 20 patients were enrolled in IMAGO, with 19 completing 13 weeks of therapy. All patients who completed IMAGO elected to enter a 72-week extension study (IMAGINE-I). Results from IMAGO will be available in early April.

Conclusions: This is the first report of the use of the novel pharmacological therapy LUM001 to inhibit ASBT for the treatment of CLD and severe pruritus in children with ALGS. The results of this study will have significant implications for ALGS treatment. LUM001 may substitute for PEBD, an invasive and disfiguring surgery, and prevent or delay the need for liver transplantation.

Study funded by Lumena (part of the Shire Group of Companies).

SOFOSBUVIR + PEGINTERFERON/RIBAVIRIN FOR 12 WEEKS VS SOFOSBUVIR + RIBAVIRIN FOR 16 OR 24 WEEKS IN GENOTYPE 3 HCV INFECTED PATIENTS AND TREATMENT-EXPERIENCED CIRRHOTIC PATIENTS WITH GENOTYPE 2 HCV: THE BOSON STUDY

G.R. Foster[1], S. Pianko[2], C. Cooper[3], A. Brown[4], D. Forton[5], R.G. Nahass[6], J. George[7], E. Barnes[8], D.M. Brainard[9], B. Massetto[9], M. Lin[9], J.G. McHutchison[9], G.M. Subramanian[9], K. Agarwal[10].

E-mail: kellie.chu@gilead.com

Introduction: Sofosbuvir (SOF) in combination with ribavirin with or without peginterferon (PEG) has demonstrated high efficacy in genotype 2 or 3 HCV-infected patients. However, these regimens have not been directly compared. The phase 3 BOSON study evaluated the safety and efficacy of SOF+PEG/RBV for 12 weeks vs SOF+RBV for 16 or 24 weeks in treatment-experienced genotype 2 (GT2) HCV-infected patients with cirrhosis, and in treatment-naïve and -experienced genotype 3 (GT3) HCV-infected patients with and without cirrhosis.

Material and Methods: Patients were randomized 1:1:1 to receive either SOF+RBV for 16 or 24 weeks or SOF+PEG/RBV for 12 weeks and stratified by HCV genotype and cirrhosis status. All patients received SOF 400 mg daily and RBV 1000–1200 mg in a divided daily dose. PEG was administered as 180 μg weekly injection. The primary end point was sustained virologic response 12 weeks after treatment (SVR12).

Results: Of 592 patients randomized and treated, 92% had GT3 HCV, 67% were male, 84% white, 53% treatment experienced, 62% had non-CC IL28B genotypes, and 37% had cirrhosis. GT2 treatment-experienced patients with cirrhosis had high SVR12 rates in all treatment groups: 87% of those receiving SOF+RBV for 16 weeks, 100% of those receiving SOF+RBV for 24 weeks, and 94% of those receiving SOF+PEG/RBV for 12 weeks. Among GT3 patients, SVR12 rates were highest in those receiving SOF+PEG/RBV for 12 weeks (93%) as compared to SOF+RBV for 24 (84%, p 0.008) or 16 weeks (71%, p < 0.001) (Table). The most common adverse events in all arms were fatigue, headache, insomnia, and nausea. Overall, 6 (1%) patients discontinued treatment due to adverse events; one of them was treated with SOF+PEG/RBV.

Table: SVR12 in GT3 patients

	SVR, % (n/N)		
	SOF+RBV 16 weeks N = 181	SOF+RBV 24 weeks N = 182	SOF+PEG/RBV 12 weeks N = 181
Overall	71% (128/181)	84% (153/182)	93% (168/181)
Treatment-naive	77% (70/91)	88% (83/94)	95% (89/94)
Cirrhotic	57% (12/21)	82% (18/22)	91% (21/23)
Non cirrhotic	83% (58/70)	90% (65/72)	96% (68/71)
Treatment-experienced	64% (58/90)	80% (70/88)	91% (79/87)
Cirrhotic	47% (17/36)	77% (26/34)	86% (30/35)
Non cirrhotic	76% (41/54)	82% (44/54)	94% (49/52)

Conclusions: GT2 treatment-experienced patients with cirrhosis had high SVR12 rates in all treatment arms. In GT3 patients, including a large proportion of treatment-experienced patients with cirrhosis, SOF+PEG/RBV for 12 weeks resulted in the highest SVR12 rates observed to date in a Phase 3 study. Overall and in all subgroups, GT3 patients receiving 24 weeks of SOF+RBV had higher SVR12 rates than those receiving 16 weeks of treatment, confirming that 24 weeks is the optimal duration for this combination in GT3 patients. SOF+PEG/RBV for 12 weeks was well tolerated with a high rate of treatment completion. These data suggest SOF+PEG/RBV treatment should still be considered for IFN-eligible GT3 patients, particularly for those with cirrhosis and/or prior treatment failure.

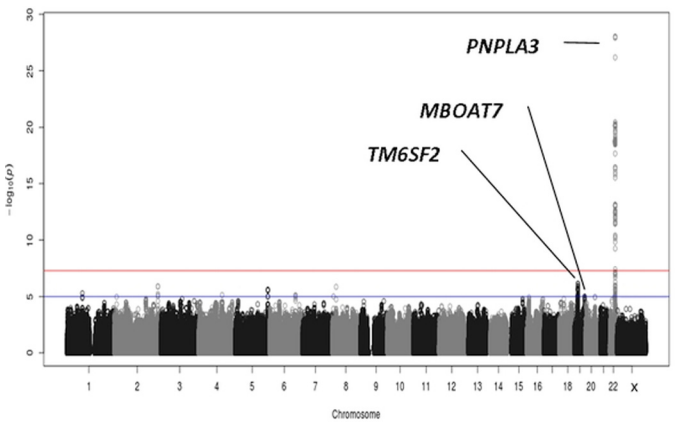
E-mail: felix.stickel@ikp.unibe.ch

Introduction: Alcohol misuse is a major cause of cirrhosis in the Western world, but only <20% of alcohol misusers eventually develop significant liver disease. Multiple lines of evidence suggest that the risk of developing alcohol-related cirrhosis is genetically modulated. Nevertheless, the only robust, replicated finding to date is of a strong risk association with a genetic variant in *PNPLA3*, but no systematic genome-wide association studies (GWAS) of alcohol-related cirrhosis risk have been undertaken to date.

Material and Methods: A two-stage GWAS was performed comparing cases with alcohol-related cirrhosis with alcohol dependent controls with no evidence of liver disease. In the first stage, individuals recruited from Germany (410 cases *vs.* 1119 controls) and the UK (302 cases *vs.* 347 controls) underwent separate genome-wide association analysis followed by meta-analysis implemented in META v.1.5.0. In the second stage, the top

GWAS hits were validated in independent cohorts from Germany (529 cases *vs.* 761 controls) and Belgium (619 cases *vs.* 161 controls) and the results of the joint analyses combined. Genotyping was undertaken using Illumina BeadChips (Illumina Inc., San Diego, CA, USA); SNP replication was undertaken using Taqman chemistry (Applied Biosystems, Foster City, Ca, USA) on an automated platform.

Results: The strongest association signal in the initial meta-analysis was observed between the rs738409 variant in *PNPLA3* ($P_{meta} = 1.17 \times 10^{-28}$, OR = 2.38 [2.08–2.69]); 102 separate variants at the *PNPLA3* locus associated with genome-wide significance ($P_{threshold} < 5 \times 10^{-8}$). In addition, nine other independent loci provided borderline association signals ($P_{threshold} \leq 1.1 \times 10^{-5}$). Validation genotyping for rs738409 in *PNPLA3* and lead markers for the top 10 associated regions confirmed disease association for rs738409 in *PNPLA3*, and for (*MBOAT7:* rs641738 $P_{replication} = 1.35 \times 10^{-4}$; $P_{combined} = 9.25 \times 10^{-10}$; OR = 1.63 [1.46–1.80] and *TM6SF2:* rs10401969 $P_{replication} = 3.29 \times 10^{-5}$; $P_{combined} = 1.73 \times 10^{-8}$; OR = 1.35 [1.25–1.44]).



Conclusions: This first multicenter GWAS in alcoholic liver disease identifies variants within the genes coding for *PNPLA3, TM6SF2* and *MBOAT7* as significant risk loci for cirrhosis. All play a role in lipid metabolism suggesting that dysfunctional lipid signalling pathways – partly overlapping with non-alcoholic fatty liver disease – play an important role in the pathogenesis of alcohol-related cirrhosis.

Reesink[1]. *[1]Department of Gastroenterology and Hepatology, Academic Medical Center, Amsterdam, [2]Department of Gastroenterology and Hepatology, University Medical Center Groningen, Groningen, [3]Department of Gastroenterology and Hepatology, Onze Lieve Vrouwe Gasthuis, [4]Department of Medical Microbiology, Clinical Virology Laboratory, Academic Medical Center, Amsterdam, [5]PRA Healthsciences, Zuidlaren, Netherlands; [6]Regulus Therapeutics, San Diego, CA, United States*
E-mail: meike.vanderree@amc.uva.nl

Introduction: MicroRNA-122 (miR-122) is an important host factor for hepatitis C virus (HCV) replication. Binding of miR-122 to the HCV 5′-UTR RNA protects the genome from degradation and prevents induction of an innate immune response against the virus. RG-101 is a hepatocyte targeted carbohydrate conjugated oligonucleotide with potent antagonist activity against miR-122. The aim of this study was to evaluate the safety and efficacy of RG-101 in chronic HCV patients with various genotypes.

Material and Methods: In this multicenter phase 1 study, we included 32 chronic HCV patients with genotype 1, 3 or 4 infection. The first cohort of 16 patients received a single subcutaneous injection of 2 mg/kg RG-101 (n = 14) or placebo (n = 2), the second cohort received a single subcutaneous injection of 4 mg/kg (n = 14) or placebo (n = 2). Both cohorts were followed until 57 days after randomization, and patients with HCV RNA levels below the limit of quantification (BLOQ) at day 57 were included in an extended follow-up study. HCV RNA levels were measured using Roche COBAS AmpliPrep/COBAS Taqman HCV v2.0 assay, with a reported LLOQ of 15 IU/mL.

Results: Thirty-two patients infected with HCV genotype 1 (n = 16), genotype 3 (n = 10) or genotype 4 (n = 6) were included. Twenty-three patients were treatment naive and 9 patients were virological relapsers to a prior interferon-based therapy. None of the patients had cirrhosis. At baseline, mean HCV RNA levels were comparable between RG-101 dosed patients versus placebo (6.2 versus 6.4 log 10 IU/mL, p = 0.53). The mean viral load reduction at day 29 was 4.1 log10 IU/mL (range 2.3–5.8) in patients dosed with 2 mg/kg, and 4.8 log10 IU/mL (range 3.0–5.8) in patients dosed with 4 mg/kg RG-101, as compared with a reduction of 0.0 in the placebo group (p < 0.001). At day 57, 15/28 patients (gt 1 n = 6, gt 3 n = 5, gt 4 n = 4) dosed with RG-101 had HCV RNA levels BLOQ, and 12 of these 15 patients had HCV RNA levels that could not be detected. In 10/15 patients (gt 1 n = 3, gt 3 n = 3, gt 4 n = 4) HCV RNA levels remained BLOQ at day 85. No dose-limiting adverse events were observed and none of the patients discontinued the study.

Conclusions: A single administration of 2 mg/kg or 4 mg/kg RG-101 was well tolerated and resulted in significant reductions in HCV RNA levels in patients infected with various chronic HCV genotypes and prior treatment history. Patients with HCV RNA levels BLOQ will be followed up to six months to assess if viral cure can be established with one single administration of RG-101.

DACLATASVIR, SOFOSBUVIR, AND RIBAVIRIN COMBINATION FOR HCV PATIENTS WITH ADVANCED CIRRHOSIS OR POSTTRANSPLANT RECURRENCE: PHASE 3 ALLY-1 STUDY

F. Poordad[1], E.R. Schiff[2], J.M. Vierling[3], C. Landis[4], R.J. Fontana[5], R. Yang[6], F. McPhee[7], E. Hughes[6], S. Noviello[6], E.S. E-mail: christiaan.wallett@articulatescience.com

Introduction: The pangenotypic combination of daclatasvir (DCV) and sofosbuvir (SOF) achieves high rates of SVR in patients with chronic HCV infection. DCV+SOF has favorable safety and drug interaction profiles and a high resistance barrier. These attributes support the ALLY-1 study of DCV+SOF with ribavirin (RBV) in patients with advanced cirrhosis or post-liver transplant HCV recurrence, who have a high unmet therapeutic need.

Material and Methods: This open-label study enrolled treatment-naive or experienced adults with HCV infection of any genotype (GT) in 2 cohorts: (1) advanced cirrhosis, (2) post-liver transplant recurrence. Patients received 12 weeks of treatment with once-daily DCV 60 mg + once-daily SOF 400 mg and RBV (initially 600 mg/d, adjusted for hemoglobin and creatinine clearance). In the cirrhosis cohort, patients transplanted during treatment could receive 12 weeks of extended treatment immediately posttransplant,

regardless of treatment duration before transplant. The primary endpoint was HCV RNA <LLOQ (25 IU/mL) at posttreatment Week 12 (SVR12) in patients with GT1 in each cohort.

Results: The cirrhosis (N = 60) and posttransplant (N = 53) cohorts were, respectively, 40% and 42% treatment-naive and 75% and 77% GT1. The Child–Pugh class in the cirrhosis cohort was 20% A, 53% B, and 27% C. MELD score ranged from 8 to 27. No posttransplant patients had cholestatic recurrence or hepatic decompensation. Overall, 83% of patients in the cirrhosis cohort achieved SVR12, with higher SVR12 rates in patients with Child–Pugh class A or B disease than in those with class C (Table). In the posttransplant cohort, 94% achieved SVR12. Twelve of the 13 patients without SVR12 relapsed posttreatment. SVR12 rates were comparable regardless of prior treatment experience or baseline demographic characteristics. Four cirrhotic patients received a liver transplant during treatment; 3 of 4 extended treatment posttransplant and all 4 achieved SVR12. The most common AEs (any grade) were headache, fatigue, anemia, diarrhea, and nausea. There were no treatment-related serious AEs. One posttransplant patient discontinued all therapy after 31 days due to headache but achieved SVR12.

	SV12, % (n/N)	
	Advanced cirrhosis cohort	Posttransplant cohort
All patients	83 (50/50) [a,b]	94 (50/53)
GT 1 [95% CI]	82 (37/45) [c] [68, 92]	95 (39/41) [c] [84, 99]
GT 1a	76 (26/34)	97 (30/31)
GT 1b	100 (11/11)	90 (9/10)
GT 1, Child–Pugh A	91 (10/11)	–
GT 1, Child–Pugh B	92 (22/24)	–
GT 1, Child–Pugh C	50 (5/10)	–
GT 3	83 (5/6) [a]	91 (10/11)
GT 2, 4, or 6	89 (8/9) [b]	100 (1/1)

[a] Includes 1 patient (GT3) who had SVR12 documented after database lock.
[b] Includes 1 patient (GT4) who discontinued after 3 weeks for liver transplantation and achieved SVR12 off study.
[c] Primary endpoints.

Conclusions: DCV+SOF+RBV for 12 weeks was safe and well tolerated in both cohorts. SVR12 rates were >90% in patients with Child–Pugh class A or B cirrhosis but lower in Child–Pugh class C. SVR12 was achieved by 94% of liver transplant recipients with HCV recurrence.

DACLATASVIR PLUS SOFOSBUVIR FOR TREATMENT OF HCV GENOTYPES 1–4 IN HIV–HCV COINFECTION: THE ALLY-2 STUDY

D.L. Wyles[1], P. Ruane[2], M.S. Sulkowski[3], D. Dieterich[4], A.F. Luetkemeyer[5], T.R. Morgan[6], K.E. Sherman[7], Z. Liu[8], S. Noviello[8], P. Ackerman[8]. *[1]University of California, San Diego, CA, [2]Ruane Medical and Liver Health Institute, Los Angeles, CA, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]Icahn School of Medicine at Mount Sinai, New York, NY, [5]University of California and San Francisco General Hospital, San Francisco, CA, [6]VA Long Beach Healthcare System, Long Beach, CA, [7]University of Cincinnati College of Medicine, Cincinnati, OH, [8]Bristol-Myers Squibb, Princeton, NJ, United States*

E-mail: neslihan.oz@articulatescience.com

Introduction: Daclatasvir (DCV; NS5A inhibitor) and sofosbuvir (SOF; nucleotide NS5B inhibitor) are potent, pangenotypic, well-tolerated, once-daily, oral HCV antivirals with limited pharmacokinetic interactions with other agents. DCV+SOF has demonstrated high rates of sustained virologic response (SVR) in HCV monoinfection. Efficacy and safety of DCV+SOF in HIV–HCV coinfection was assessed in a phase 3 study.

Material and Methods: ALLY-2 was a randomized, open-label study in HCV treatment-naive (n = 151) or -experienced (n = 52) adults coinfected with HIV and HCV (any genotype). Naive patients were randomized 2:1 to receive 12 or 8 weeks of SOF 400 mg + DCV 60 mg (dose adjusted for concomitant combination antiretroviral therapy (cART): 30 mg with ritonavir-boosted protease inhibitors [PI], 90 mg with nonnucleoside reverse transcriptase inhibitors [NNRTI] except rilpivirine). Experienced patients received DCV+SOF for 12 weeks. Primary endpoint was SVR at posttreatment week 12 (SVR12) in treatment-naive GT-1 patients who received 12 weeks of DCV+SOF.

Results: Patients were 87% male, 62% white, 34% black, and 14% cirrhotic, had a median age of 52 years, and were infected with HCV GT-1 (83%), GT-2 (9%), GT-3 (6%), or GT-4 (2%). Median baseline (BL) HCV RNA was 6.7 $\log_{10}$ IU/mL and median BL CD4 count was 565 cells/μL. Nearly all patients (98%) were on cART: 50% PI based, 25% NNRTI based, and 25% other regimens (primarily integrase inhibitors). A total of 98% of patients completed study treatment. Among GT-1 patients, SVR12 was achieved by 96% of naive and 98% of experienced patients after 12 weeks of DCV+SOF and by 76% of naive patients after 8 weeks; SVR12 rates for non-GT-1 patients in these groups were 100%, 100%, and 78%, respectively. SVR12 was similar in patients with or without cirrhosis and across other demographic and disease subgroups (Table). There were no HCV virologic breakthroughs, and HIV control was not compromised throughout the study period. Posttreatment HCV relapse occurred in 1–2% of patients in the 12-week treatment groups and 20% in the 8-week group. There were no treatment-related serious AEs or discontinuations for AEs.

		SVR12, % (n/N)

[a] Primary endpoint.

Conclusions: Treatment of HIV–HCV coinfected patients with DCV+SOF once daily for 12 weeks resulted in an overall 97% SVR12, and was well tolerated. DCV+SOF was effective in cirrhotics, in other demographic and disease categories, and across a broad range of cART regimens without compromising HIV virologic control.

E-mail: d.roth@med.miami.edu

Introduction: HCV infection in patients with chronic kidney disease stages 4 and 5 (CKD4/5), defined as CrCl <30 mL/min ± dialysis-dependence, is associated with an increased risk of death and

kidney transplant failure. HCV-infected patients with CKD4/5 have limited HCV treatment options. Ribavirin-containing regimens are poorly tolerated; other treatments rely on renal clearance so are unsuitable. In a Phase 2 trial, grazoprevir (GZR; NS3/4A protease inhibitor) and elbasvir (EBR; NS5A inhibitor) was highly efficacious in treating HCV genotype 1 (G1) infection. Both medicines are cleared by the liver. We conducted a Phase 3 trial of GZR/EBR in HCV G1-infected patients with CKD4/5.

Material and Methods: 224 HCV G1-infected patients with CKD4/5 were randomized to immediate treatment with GZR 100 mg / EBR 50 mg once daily for 12 weeks or deferred treatment (placebo then active dosing). The trial also included an open-label GZR/EBR arm in which 11 patients underwent intensive pharmacokinetic (PK) sampling. The primary end point was sustained virologic response at follow-up week (FUW) 12 (SVR12; COBAS TaqMan v2.0 [LoQ 15 IU/mL]). Given the morbidity of CKD4/5, the primary efficacy analysis was done in a modified full analysis set (mFAS) population (patients in the immediate and intensive PK arms who received ≥1 dose of study drug, excluding those who died or discontinued for reasons unrelated to study drug). Safety was evaluated in the GZR/EBR arms and the placebo phase of the deferred arm.

Results: 235 patients received ≥1 dose of study drug (immediate, n = 111; PK, n = 11; deferred, n = 113): 52% had G1a infection, 80% were HCV treatment-naive; 6% were cirrhotic, 73% were male, 46% were African American, 34% had diabetes, 19% had CKD4, 81% had CKD5, and 76% were on hemodialysis. 5/122 (4.1%) patients in the GZR/EBR arms discontinued prior to FUW12 and were excluded from the mFAS population (vs. 6/113 [5.3%] in the deferred [placebo] arm). SVR12 was achieved in 99% (114/115) of patients in the active arms: 1 noncirrhotic patient relapsed at FUW12. Serious AEs occurred in 16 (14%) and 17 (15%) patients in the GZR/EBR and deferred arms, respectively. 0% and 4% of patients in the active and placebo groups, respectively, discontinued therapy due to an AE. The most common AEs in the active arms were headache, nausea, and fatigue.

Conclusions: Once-daily GZR/EBR for 12 weeks was highly effective and generally well tolerated in patients with HCV G1 infection and advanced CKD.

LP03

SAFETY AND EFFICACY OF SHORT-DURATION TREATMENT WITH GS-9857 COMBINED WITH SOFOSBUVIR/GS-5816 IN TREATMENT-NAÏVE AND DAA-EXPERIENCED GENOTYPE 1 PATIENTS WITH AND WITHOUT CIRRHOSIS

E.J. Gane[1], R.H. Hyland[2], Y. Ying[2], E. Svarovskaia[2], L.M. Stamm[2], D.M. Brainard[2], G.M. Subramanian[2], J.G. McHutchison[2], C. Schwabe[1]. *[1]Auckland Clinical Studies, Auckland, New Zealand; [2]Gilead Sciences, Foster City, United States*
E-mail: luisa.stamm@gilead.com

Introduction: GS-9857, a potent pan-genotypic HCV NS3/4A protease inhibitor (PI) with an enhanced resistance profile compared to first generation HCV PIs, demonstrated >3 log reductions in HCV RNA after 3 days of monotherapy in a Phase 1b study in patients infected with HCV genotypes 1–4. Here, we report the safety and efficacy of GS-9857 with SOF/GS-5816, a fixed dose combination of pangenotypic NS5B and NS5A inhibitors, in a regimen with 3 different mechanisms of action for 4 or 6 weeks in treatment-naïve and direct-acting antiviral (DAA)-experienced patients with HCV genotype 1 with and without cirrhosis.

Material and Methods: Treatment-naïve genotype 1 HCV-infected patients without cirrhosis were treated for 4 or 6 weeks with GS-9857 with SOF/GS-5816. Treatment-naïve genotype 1 HCV-infected patients with cirrhosis and those who had failed ≥2 DAAs were enrolled in separate cohorts to also receive 6 weeks of GS-9857 with SOF/GS-5816. HCV RNA was measured using the COBAS® AmpliPrep/COBAS® Taqman® assay V2.0 with a lower limit of quantification (LLOQ) of 15 IU/mL.

Results: 75 patients with HCV genotype 1 were enrolled. The majority were male (51, 68%), had subtype 1a infection (59, 79%), and had the IL28B non-CC genotype (51, 68%). Median HCV RNA in each group ranged from 6.31 to 6.46 log10 IU/mL. All patients completed treatment and 97% achieved rapid viral suppression to <LLOQ by Week 4. SVR4, SVR12 and relapse data are presented in the table. There were no Grade 3 or 4 adverse events, serious adverse events, or deaths. The most frequent adverse events were nausea (19, 25%), headache (18, 24%), and fatigue (12, 16%). Elevated lipase was the only grade 3 or 4 laboratory abnormality that occurred in more than one patient (3, 4%).

Table: Patients with HCV Genotype 1 infection with SVR4, SVR12 and Relapse

Treatment group	Treatment-naïve			Prior DAA failure
	No cirrhosis		Cirrhosis	20% Cirrhosis
	4 weeks	6 weeks	6 weeks	6 weeks
N	15	15	15	30
SVR4, n (%)	11 (73)	15 (100)	12 (80)	26 (87)
SVR12, n (%)	3 (20)	14 (93)	12 (80)	Not available
Relapse, n (%)	11 (73)	1 (7)	2 (13)	4 (13)

Conclusions: GS-9857 with SOF/GS-5816 was well tolerated for 4 or 6 weeks. Treatment for 6 weeks was highly efficacious in GT1 treatment-naïve patients without cirrhosis. Treatment-experienced patients or those with cirrhosis may benefit from longer durations of therapy. Ongoing Phase 2 studies are evaluating GS-9857 with SOF/GS-5816 for durations of 6, 8 and 12 weeks in genotype 1–6 patients.

E-mail: lawitz@txliver.com

Introduction: Hepatitis C virus (HCV)-infected patients (pts) with cirrhosis are historically a difficult-to-treat pt population. In a Phase II study (COSMOS), high sustained virologic response 12 weeks (wks) after end of treatment (EOT; SVR12) rates were achieved in METAVIR F4 treatment-naïve and prior null responder pts treated with an all oral, once-daily (QD) combination of SMV (HCV NS3/4A protease inhibitor)+SOF (HCV nucleotide-analogue NS5B polymerase inhibitor) for 12 or 24 wks, regardless of the presence or absence of ribavirin. The OPTIMIST-2 (NCT02114151) study aimed to demonstrate superiority of 12 wks of SMV+SOF, in treatment-naïve or -experienced (including interferon (IFN)-intolerant) HCV genotype (GT)1-infected pts with cirrhosis compared with a

historical control (composite of the SVR12 rates of approved direct-acting antiviral/IFN+ribavirin regimens).

Material and Methods: Treatment-naïve or -experienced pts with chronic HCV GT1 infection and documented presence of cirrhosis received SMV 150 mg QD+SOF 400 mg QD for 12 wks. The primary efficacy endpoint was SVR12 in the overall population. Safety and pt-reported outcomes were assessed.

Results: 103 pts received treatment (male, 81%; median age, 58 years; Black/African American, 18%; IL28B CC, 28%; GT1a/1b, 70/30%; treatment-naïve [n = 50, 49%]; treatment-experienced [n = 53, 52%]). SVR12 with SMV+SOF (84% [95% confidence interval: 76, 91]) met the primary endpoint of superiority to the historical control (70%). Other endpoints are summarised (Table 1). Adverse events (AEs) were observed in 72 (70%) pts, these were mainly Grade 1/2 (64%). Most frequent AEs: fatigue (20%), headache (20%) and nausea (11%). AEs of interest, increased bilirubin and rash, occurred in 2 (2%) and 16 (16%) pts, respectively. Three (3%) pts discontinued at least 1 drug due to an AE. Serious AEs were infrequent (5 pts [5%]). One pt died in a motor vehicle accident. Pt-reported outcomes improved from baseline to follow-up wk 12 with clinically important improvements in quality of life for pts who achieved SVR12 (Table 2). Additional data will be presented.

Table 1. Results (overall and sub-groups) with 12 weeks of SMV 150 mg QD + SOF 400 mg QD

	n/N (%)
SVR12 [a]	86/103 (84)
Treatment-naïve	44/50 (88)
Treatment-experienced	42/53 (79)
HCV GT1a	60/72 (83)
HCV GT1b	26/31 (84)
IL28B CC	25/29 (86)
IL28B non-CC	61/73 (84)
On-treatment failure [b]	3/103 (3)
Viral relapse [c]	13/103 (13)

[a] HCV RNA <25 IU/mL undetectable 12 wks after EOT.
[b] HCV RNA <25 IU/mL detectable or ≥25 IU/mL at EOT.
[c] HCV RNA <25 IU/mL undetectable at EOT & ≥25 UI/mL during follow-up.

Table 2. Patient-reported outcomes

Patient-reported outcome	Mean (SD) change from baseline	
	Patients with SVR12 (n = 79)	Patients without SVR12 (n = 13)
HCV-SIQv4 OBSS [d]	−5.9 (1.5)	−5.3 (2.9)
FSS [e]	−0.6 (0.2)	−0.7 (0.4)
CES-D [f]	−3.5 (1.1)	−3.5 (1.9)
EQ-5D VAS [g]	10.8 (2.1)	3.7 (5.1)

[d] HCV-SIQv4 OBSS, Hepatitis C Symptom & Impact Questionnaire version 4 Overall Body System Score (range 0 [no symptoms] to 100 [maximum severity for all 29 symptoms]; mean reduction of ≥5 points is clinically important).
[e] FSS, Fatigue Severity Scale (range 1 [no fatigue] to 7 [severe fatigue]; mean reduction of 0.6 points is clinically important).
[f] CES-D, Center for Epidemiologic Studies Depression Scale (range 0 [no depressive symptoms] to 60 [severe depression on 20 symptoms]; mean reduction of ≥3 points is clinically important).
[g] EQ-5D VAS, EuroQol-5 Dimension questionnaire Visual Analogue Scale (range 0 [worst possible health] to 100 [perfect health]; mean increase of ≥5 points is clinically important).

Conclusions: SMV+SOF for 12 wks achieved superiority in SVR12 rates vs the historical control in treatment-naïve and -experienced HCV GT1-infected pts with cirrhosis and was generally well tolerated.

Funded by Janssen.

E-mail: adrienne.tracey@articulatescience.com

Introduction: Treatment options for HCV genotype 3 (GT3) patients are limited. The combination daclatasvir (DCV) and sofosbuvir (SOF) for 12 weeks is associated with high SVR rate in genotype 3 non cirrhotic patients (96% SVR12) and a lower response in cirrhotic (63% SVR12). GT3 cirrhotic remain a difficult to treat population and may benefit from the addition of ribavirin (RBV) or extended treatment duration. This analysis reports interim results from a French multicenter compassionate use program of DCV+SOF±RBV in patients with HCV genotype 3 chronic infection.

Material and Methods: The ATU has been managing over 4000 HCV patients from 221 French centers. Patients received DCV+SOF QD for 12 or 24 weeks, with RBV added at the physician's discretion.

	DCV/SOF +/− RBV			
	12 weeks		24 weeks	
	cirrhotic	Non cirrhotic	cirrhotic	Non cirrhotic
SVR4	22/29 (76%)	11/12 (92%)	52/59 (88%)	5/6 (83%)

Results: 601 HCV genotype 3 patients with severe fibrosis (F3) or cirrhosis (F4), or HCV extrahepatic manifestations or post-liver transplant HCV recurrence or indication for liver or kidney transplantation enrolled in the program. Most patients were male (75%), HCV mono-infected (83%), cirrhotic (77%), and treatment experienced (73%). The median age was 54.3 years (27–83). 64% and 15% planned to receive DCV+SOF for 24 weeks with or without RBV, respectively, 4% and 17% planned to receive DCV+SOF for 12 weeks with or without RBV, respectively. Baseline median HCV RNA level was 6.07 (1.20–7.62) log10 IU/mL, platelets count 118.5x10^9/L (31–387) and albumin was 39.0 g/L (13–56). Treatment discontinuations were related to adverse event in 1 patient, death in 2 patients and patient's decision in 1 patient. The table below shows the interim results in the first 106 patients without liver transplant who

reached the week 4 post-treatment visit according to treatment schedule, fibrosis stage and patient status. Efficacy and safety data will be updated in larger population.

Conclusions: This preliminary analysis is consistent with previous findings and demonstrates that12 weeks of DCV+SOF in GT3 patients results in a high SVR4 in non cirrhotic patient population. Cirrhotic patients appeared to benefit from the extended treatment duration to 24 weeks.

LP06

SUSTAINED VIROLOGIC RESPONSE AFTER ACH-3102 AND SOFOSBUVIR TREATMENT FOR 8 OR 6 WEEKS: A PHASE 2 "PROXY" STUDY

E. Gane[1], C. Schwabe[2], M. Mader[3], V. Suri[2], M. Donohue[3], M. Huang[3], J. Hui[3], J. Yang[3], H. Robison[3], D. Apelian[3], H. Kocinsky[3]. *[1]New Zealand Liver Transplant Unit, Auckland City Hospital, Auckland, [2]Auckland Clinical Studies Ltd, Grafton, New Zealand; [3]Achillion Pharmaceuticals, New Haven, United States*
E-mail: EdGane@adhb.govt.nz

Introduction: ACH-3102 is a 2nd generation NS5A inhibitor in Phase 2 development for the treatment of chronic hepatitis C viral (HCV) infection. ACH-3422, a uridine nucleotide HCV NS5B polymerase inhibitor in Phase 1, is planned for use in combination with ACH-3102. This Phase 2, open-label, randomised, controlled, partial crossover study investigates the efficacy and safety of ACH-3102 plus sofosbuvir (used as a proxy for ACH-3422). Interim and final SVR data from patients (pts) receiving 6-week (wk) and 8-wk treatment durations, respectively, are reported.

Material and Methods: A total of 30 pts with chronic genotype (GT)-1 HCV infection were enrolled in two groups. In the 8-wk treatment group, 12 pts were randomised to active treatment with ACH-3102 (50 mg) and sofosbuvir (400 mg) once daily, and 6 pts were randomised to observation. Based on favorable SVR4 results from this group, a 6-wk treatment group was initiated with the same active treatment. The 6 observational pts from the 8-wk treatment group were assigned to active treatment, 6 new pts were randomised to active treatment, and 6 new pts were randomized to observation.

Results: Of active pts in the 8- and 6-wk treatment groups, 83% and 58% were infected with GT-1a HCV, 75% and 58% were male, and mean ages were 42.6 and 49.2 years, respectively. Baseline viral load in active pts from the 8- and 6-wk treatment groups ranged from 5.5–8.0 $\log_{10}$IU/mL, with 9 and 7 pts in each group, respectively, with values >6,000,000 IU/mL. SVR24 was 100% in the 8-wk treatment group. All active pts in the 6-wk group achieved HCV RNA levels below the limit of quantification by Week 4 and below the limit of detection by Week 6 (end of treatment). The incidence of SVR12 in the 6-wk treatment group was 100%. Treatment was well-tolerated in both groups, with no serious adverse events and no discontinuations.

Conclusions: ACH-3102 is a potent NS5A inhibitor that achieved 100% SVR12 when combined with sofosbuvir in pts with chronic GT-1 HCV infection. Future studies will explore use of ACH-3102 in sofosbuvir-containing regimens for treatment durations as short as 4 weeks, and will also explore sofosbuvir "sparing" regimens using a reduced number of sofosbuvir doses. A parallel development track will explore the combination of ACH-3102 and ACH-3422 +/– sovaprevir (an NS3 protease inhibitor) in interferon- and ribavirin-free regimens with short treatment durations (4–8 weeks) across different patient populations.

E-mail: lawitz@txliver.com

Introduction: Interim analysis (IA) data from IMPACT (NCT02262728), an ongoing Phase II open-label study assessing for the first time an all-oral regimen of SMV (HCV NS3/4A protease inhibitor), in combination with DCV (HCV NS5A replication complex inhibitor) and SOF (HCV nucleotide-analogue NS5B polymerase inhibitor) in chronic HCV genotype (GT)1/4-infected patients (pts) with decompensated liver disease, a population with a high medical need and limited therapeutic options.

Material and Methods: HCV treatment-naïve or (peg)IFN±ribavirin treatment-experienced GT1/4-infected cirrhotic pts ≥18 yrs with Child–Pugh (CP) score <7 (Class A) with evidence of portal hypertension or 7–9 (Class B) were enrolled. Pts received 12 wks of SMV (150 mg QD), DCV (60 mg QD) and SOF (400 mg QD). Primary efficacy endpoint: sustained virologic response 12 wks after end of treatment (EOT, SVR12). Key secondary endpoints: SVR4, on-treatment failure, viral relapse, PK and safety.

Table: Plasma PK parameters

	Mean (SD)			
	Week 2		Week 8	
	Child–Pugh A (n = 19)	Child–Pugh B (n = 9)	Child–Pugh A (n = 18)	Child–Pugh B (n = 9)

AUC (h·ng/mL)	2864 (978)[b]	3768 (1817)	2729 (988)	3769 (1800)

AUC, area under the concentration–time curve; C_{max}, maximum plasma concentration.
[a] n = 8. [b] n = 18.

Results: IA in 28 pts who received treatment (male 64.3%; median age 58.0 yrs; White 96.4%; GT1a/1b/4 71.4/25.0/3.6%; treatment-naive/experienced 50/50%; Fibroscan median score 26.7 kPa [range 14.9–63.9]; CP class A/B 19/9 pts). Baseline Q80K was present in 11/20 GT1a pts and 0 GT1b/GT4 pts. 28 pts reached EOT; 14 reached Wk4 follow-up. Virologic response rates (HCV RNA <15 IU/mL) for CP A/B were 89.5/33.3% at Wk2, 100/77.8% at Wk4 and 100/100% at Wks 8, 10 and 12. All pts with available data achieved SVR4 (CP A 12/12; CP B 2/2). Wk2 mean SMV exposure (AUC) was 1.3 fold higher in CP B vs CP A pts, but individual pt exposures in the CP B group were within the range observed for CP A. Mean SMV exposures in both groups were comparable for Wk2 vs Wk8 (Table). Mean DCV and SOF exposures were each similar within groups and at Wk2 vs Wk8. Adverse events (AEs) occurred in 57.1% of pts (CP A/B 47.4/77.8%); all but one were Grade 1/2 at the time of analysis (1 serious AE [sick sinus syndrome; unrelated to study medication] reported 1 wk after EOT). Most common AEs: pruritus (3 events; CP A/B 1/2) and urinary tract infection (2 events; CP A/B 1/1). At the time of analysis, there were no deaths or discontinuations due to

AEs. Laboratory abnormalities were generally Grade 1/2. Additional data will be presented.

Conclusions: In this Phase II study, the combination of SMV+DCV+SOF resulted in high on-treatment virologic response and SVR4 rates, and was safe and well tolerated in decompensated liver disease pts.

Funding: Janssen

SAFETY AND EFFICACY OF SOFOSBUVIR-CONTAINING REGIMENS IN HEPATITIS C INFECTED PATIENTS WITH REDUCED RENAL FUNCTION: REAL-WORLD EXPERIENCE FROM HCV-TARGET

V. Saxena[1], F.M. Koraishy[2], M. Sise[3], J.K. Lim[4], R.T. Chung[3], A. Liapakis[4], D.R. Nelson[5], M. Schmidt[6], M.W. Fried[6], N. Terrault[1], and HCV-TARGET. *[1]University of California San Francisco, San Francisco, [2]Saint Louis University School of Medicine, St. Louis, [3]Massachusetts General Hospital, Boston, [4]Yale University School of Medicine, New Haven, [5]University of Florida, Gainesville, [6]University of North Carolina, Chapel Hill, United States*

E-mail: varun.saxena@ucsf.edu

Introduction: Renal clearance is the major elimination pathway for GS331007, the major metabolite of SOF, and pharmacokinetic studies show higher drug and metabolite concentrations in those with estimated glomerular filtration rate (eGFR) <30 mL/min/1.73m^2. We assessed the safety and efficacy of SOF-containing regimens in HCV infected patients with varying baseline renal function.

Material and Methods: HCV-TARGET is a longitudinal observational study of patients treated with direct-acting antivirals at academic (n = 43) and community (n = 13) medical centers in North America (n = 51) and Europe (n = 5) with centralized data abstraction and independent data monitoring. Demographic, clinical, adverse events (AEs), and virological data are collected throughout treatment and post-treatment follow-up from enrolled patients. Patients with baseline eGFR (Modification of Diet in Renal Disease equation) ≤30 vs. 31–45 vs. 46–60 vs. >60 mL/min/1.73m^2 were examined.

Table: Treatment regimen, safety and efficacy outcomes by baseline MDRD eOFR

	eGFR ≤30 (n = 18)	eGFR 31–45 (n = 63)	eGFR 46–60 (n = 168)	eGFR >60 (n = 1,641)	p-value

PEG, peg-interferon; SMV, simeprevir.

[a] Includes acute on chronic renal insufficiency. Outcome abstracted from treatment documentation.

[b] Includes acute renal failure, dysuria, hematuria, urinary retention and other similar renal/urinary problems.

Results: 1,890 patients [genotype 1 (71%), 2 (17%), 3 (9%), 4–6 (3%)], of which 129 (7%) are still undergoing therapy, with complete data for baseline eGFR calculation were included: 18 with eGFR ≤30 (5 on dialysis), 63 with eGFR 31–45, 168 with eGFR 46–60 and 1,641 with eGFR >60. Patients with baseline eGFR ≤30 (vs 31–45, 46–60, >60) differed in frequency of being female (72% vs 46%, 46%, 35%), age ≥65 (28% vs 29%, 32%, 18%), of Black race (22% vs 19%, 7%, 12%), having cirrhosis with decompensation (75% vs 69%, 65%, 45%), being post-liver transplant (39% vs 54%, 35%, 8%) and/or being post-kidney transplant (17% vs 8%, 5%, 1%) (all $p < 0.05$). Treatment regimens, safety and efficacy outcomes by baseline eGFR are shown in Table. All patients with eGFR <60 started with SOF 400 mg/day and had standard ribavirin (RBV) dose adjustments. Sustained virologic response (SVR) frequencies were similar across eGFR groups, ranging from 81–88% (Table). The one patient with baseline eGFR ≤30 died from worsening renal failure and hepatic decompensation while on therapy. When limited to patients on RBV-free regimens (n = 839), eGFR ≤30 patients still more frequently experienced anemia, acute renal insufficiency, renal or urinary system AEs and serious AEs (all $p < 0.05$).

Conclusions: Frequencies of SVR with SOF-containing regimens are high and not influenced by renal impairment. However, patients with reduced baseline renal function have a higher frequency of anemia, worsening renal dysfunction and serious adverse events regardless of use of RBV. Close monitoring during treatment is warranted.

LP09

HIGH EFFICACY OF RETREATMENT WITH LEDIPASVIR AND SOFOSBUVIR IN HCV PATIENTS WHO FAILED INITIAL SHORT COURSE THERAPY WITH COMBINATION DAA REGIMENS (NIH SYNERGY TRIAL)

E.M.P. Wilson[1,2], S. Kattakuzhy[3], Z. Sims[1], L. Tang[3], M. McLaughlin[4], A. Price[3], R. Silk[3], C. Gross[3], E. Akoth[3], A. Osinusi[5], H. Masur[1], A. Kohli[1], S. Kottilil[3]. *[1]Critical Care Medicine Department, National Institutes of Health, Bethesda, MD, [2]Clinical Monitoring Research Program, Leidos Biomedical Research, Inc., Frederick, MD, [3]Department of Infectious Diseases, University of Maryland/Institute of Human Virology, Baltimore, MD, [4]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, [5]Gilead Sciences, Foster City, CA, United States*

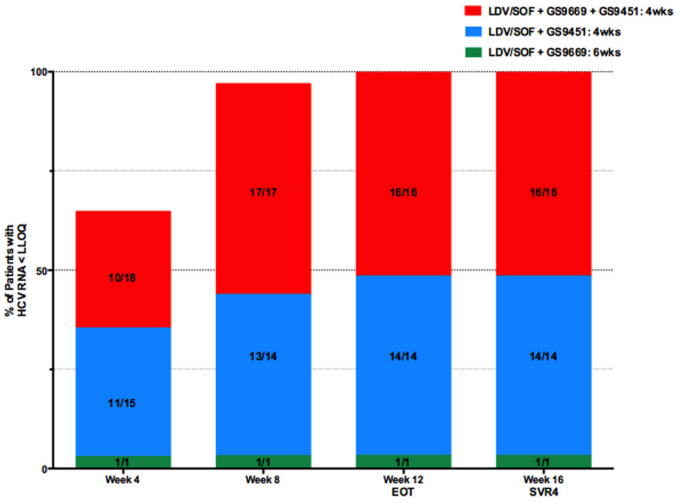
E-mail: eleanor.wilson@nih.gov

Introduction: Directly-acting antivirals (DAAs) have dramatically improved the treatment of Hepatitis C but retreatment strategies for patients who have failed to achieve sustained virologic response (SVR) with combination DAAs have not been studied. The aim of the current study is to determine if HCV genotype-1 patients who have failed short course combination therapy with three or four DAAs can be successfully treated with 12 weeks of ledipasvir (LDV) and sofosbuvir (SOF) in fixed dose combination (FDC).

Material and Methods: In this single-center, open-label, phase 2a trial, HCV mono-infected participants with early stage (F0-F2) liver fibrosis, with previous exposure to combination DAA therapy only (either LDV/SOF in combination with GS-9451 and/or GS-9669) were eligible to enroll and be treated with LDV/SOF for 12 weeks. HCV RNA was measured using the Abbott assay with a lower level of quantitation (LLOQ) of 12 IU/ml. The primary endpoint was defined as HCV RNA viral load (VL) below the LLOQ 12 weeks after completion of therapy (SVR12). Deep sequencing of NS5B, NS3 and NS5A regions were performed at two time points (prior to initial therapy and at the time of relapse, prior to initiation of retreatment) by Illumina next generation sequencing technology.

Results: The study enrolled 34 participants, and 31 (91%) have completed therapy with 12 weeks of LDV/SOF. One patient remains on therapy after a delayed start, one patient was lost to follow up after Day 0 and another withdrew consent at week 4. Participants were predominantly male (82%) and black (85%), with a median age of 60.5 years (IQR 57.0–63.8) and BMI of 26.8 kg/m^2 (IQR 25.3–29.3). Baseline HCV VL was 1.3×10^6 IU/mL (IQR 5.8×10^5–3.9×10^6), 73.5% (25/34) were infected with HCV genotype 1a, and median Metavir fibrosis stage was 1. Median time from relapse to retreatment was

22 weeks (IQR 18–23). We report SVR4 rates of 94% (31/33; ITT) and 100% (31/31, per protocol). For SVR rates by original treatment group in a per protocol analysis, see Figure. Prior to initial therapy, 3 patients had variants consistent with high levels of resistance (>5 fold) in NS3 and 8 in NS5A, and all but one patient lost to follow up went on to achieve SVR4. Data collection is ongoing, and SVR12 data will be presented at the conference.



Conclusions: For the first time, we demonstrate a high SVR rate following retreatment with DAAs in patients who have previously failed DAA-only therapy.

LP10

EFFICACY AND SAFETY OF VITAMIN E FOR NONALCOHOLIC STEATOHEPATITIS: COMBINED ANALYSIS OF THREE CONTROLLED TRIALS

K.V. Kowdley[1], L.A. Wilson[2], M.L. Van Natta[2], R.K. Pai[3], A.J. Sanyal[4], NASH CRN. *[1]Liver Care Network, Swedish Medical Center, Seattle, [2]Johns Hopkins University, Baltimore, [3]Pathology, Cleveland Clinic Foundation, Cleveland, [4]Medicine, Virginia Commonwealth University, Richmond, United States*
E-mail: kris.kowdley@swedish.org

Introduction: Vitamin E (d-alpha-tocopherol) has been part of the treatment for nonalcoholic steatohepatitis (NASH) in three NIDDK-sponsored clinical trials as part of the NASH Clinical Research Network: PIVENS compared vitamin E to pioglitazone and placebo in non-diabetic adults, TONIC compared vitamin E to metformin and placebo in non-diabetic children; FLINT compared obeticholic acid to placebo in diabetic and non-diabetic adults, and 23% of placebo-treated patients were taking vitamin E. We report the combined efficacy and safety of vitamin E in 347 patients; we also compare effect sizes of vitamin E and the other NASH treatments across the three studies.

Material and Methods: Histologic improvement, defined as ≥2 point improvement in NAS with no worsening of fibrosis, and NASH resolution measured effectiveness. Safety measures included incidence of cardiac events and changes in lipid levels. Logistic regression models were used to summarize the odds ratio (OR) effects, confidence limits, and p-values on the combined effect.

Results: NASH patients (n = 155) treated with vitamin E vs. those not treated with vitamin E (n = 192) were more likely to achieve histologic improvement [45% vs 22%, OR = 2.9, 95% CI 1.8, 4.7; p < 0.0001], with an effect size comparable to pioglitazone, metformin, and obeticholic acid (ORs 4.1, 2.7, 3.1, respectively). Vitamin E treated patients also had higher rates of NASH resolution [38% vs 20%, OR = 2.4, 95% CI 1.5, 3.9; p < 0.001], with comparable effect sizes to pioglitazone, metformin, and obeticholic acid (ORs 3.4, 1.8, 1.8, respectively). Incidence of cardiac events was not significantly different in vitamin E vs. no vitamin E groups (6.9% vs. 7.6%, p = 0.85). There were no significant differences in net changes in total cholesterol, HDL cholesterol, LDL cholesterol or triglycerides.

Table 1. Effects of four anti-NASH treatments on histologic improvement and resolution of NASH

Group	%	x/N	OR	95% CI	P
Histologic improvement [a]					
Vitamin E	45%	70/155	2.9	1.8, 4.7	<0.0001
No vitamin E (Placebo)	22%	42/192	1.0		
Pioglitazone	56%	39/70	4.1	2.0, 8.4	0.0001
Placebo	24%	17/72	1.0		
Metformin	48%	24/50	2.7	1.1, 6.4	0.02
Placebo	26%	12/47	1.0		
Obeticholic acid	49%	50/102	3.1	1.7, 5.8	0.0002
Placebo	23%	23/98	1.0		
Resolution of NASH [b]					
Vitamin E	38%	56/148	2.4	1.5, 3.9	<0.001
No vitamin E (Placebo)	20%	37/184	1.0		
Pioglitazone	47%	33/70	3.4	1.6, 7.1	0.001
Placebo	21%	15/72	1.0		
Metformin	41%	16/39	1.8	0.7, 4.6	0.24
Placebo	28%	11/39	1.0		
Obeticholic acid	22%	22/102	1.8	0.8, 3.8	0.13
Placebo	13%	13/98	1.0		

Vitamin E data from PIVENS and TONIC vitamin E treatment groups, and FLINT placebo group patients reporting vitamin E use at baseline. Pioglitazone data from PIVENS; metformin data from TON1C, and obeticholic acid data from FLINT.
[a] Histologic improvement as defined in the FLINT Trial protocol, defined as a decrease of 2 or more points in the NAS and no worsening in the fibrosis score.
[b] Resolution of NASH defined as no NASH at end of treatment biopsy among patients with borderline or definite NASH at baseline.

Conclusions: Vitamin E treatment was associated with significant improvement in NASH histology and resolution of NASH in a pooled analysis of three trials of adult and pediatric NASH. The magnitude of the effect of vitamin E on NASH was comparable to pioglitazone, metformin, and obeticholic acid. No increase in cardiovascular events or adverse lipid profiles was observed with vitamin E treatment. These data support the use of vitamin E as a treatment for NASH.

LP11

WARFARIN ANTICOAGULATION FOR LIVER FIBROSIS IN PATIENTS TRANSPLANTED FOR HEPATITIS C (WAFT-C): RESULTS AT ONE YEAR

A. Dhar[1], E. Tschotazis[2], R. Brown[1], P. Manousou[2], C. Millson[3], M. Aldersley[3], S. Forbes[4], K. Aggarwal[5], A. Gera[5], M. Cramp[6], A. Holt[7], D. Mutimer[7], S. McPherson[8], A. Burroughs[2], Q. Anstee[9], R. Goldin[10], M.R. Thursz[1]. *[1]Department of Hepatology, Imperial College London, [2]Department of Hepatology, Royal Free Hospital, London, [3]Department of Hepatology, St. James University Hospital, Leeds, [4]Department of Hepatology, University of Edinburgh, Edinburgh, [5]Institute of Liver Studies, Kings College Hospital, London, [6]Department of Hepatology, Derriford Hospital, Plymouth, [7]Department of Hepatology, Queen Elizabeth Hospital, Birmingham, [8]Department of Hepatology, Freeman Hospital, [9]Faculty of Medicine, Newcastle University, Newcastle, [10]Department of Histopathology, Imperial College London, London, United Kingdom*
E-mail: a.dhar@imperial.ac.uk

Introduction: Apart from treating the underlying aetiology no therapy is currently licensed for the prevention or treatment of liver fibrosis. In patients transplanted for hepatitis C (HCV) 30% develop rapid fibrosis with progression to cirrhosis within 5 years. FXa and thrombin promote hepatic fibrosis by stellate cell activation and there is an association between pro-thrombotic tendencies

and accelerated fibrosis in HCV pre-transplantation. Direct FXa inhibition and warfarin anticoagulation both ameliorate hepatic fibrosis in animal models. There is now a need to evaluate the effect of anticoagulation on hepatic fibrosis in human studies.

Aims: To evaluate the safety and impact of warfarin anticoagulation on liver fibrosis progression in patients transplanted for HCV infection.

Material and Methods: WAFT-C is a prospective multi-centred, randomised open-label controlled trial designed to investigate the impact of anticoagulation on fibrosis progression over one and two years post liver transplantation. Patients are randomised by centre and gender to standard post transplant care (control group) or standard of care with warfarin anticoagulation maintaining an INR between 2–3 (warfarin group). Interim intention to treat and per protocol analyses were undertaken for fibrosis scores at year one post transplantation. The primary endpoint was the proportion of patients with an increase of ≥2 in their Ishak fibrosis score by per protocol analysis.

Results: 76 patients have been randomised (control group: n = 39; mean age 52.3 yrs; M:F=33:6. warfarin group: n = 37; mean age 53.2 yrs; M:F=30:7). Intentional to treat analysis of year one fibrosis scores (n = 65) indicates a non-significant reduction in the proportion of patients with an increase in fibrosis score between the control and warfarin groups (26% vs 13%, p > 0.05). Per protocol analysis (n = 53) after exclusion of biliary disorders (control group n = 2, warfarin group n = 3) and non compliant patients (failed to start anticoagulation, n = 5; <8 weeks of anticoagulation, n = 2) demonstrated a significant reduction in the proportion of patients with an increase in fibrosis score between the control group and warfarin group at year one (23.3% vs 0%, p = 0.01). No patients were withdrawn due to severe adverse events directly secondary to anticoagulation.

Conclusions: Results of the one year endpoint suggest that warfarin anticoagulation may benefit in reducing HCV related fibrosis one year post transplantation. Two year endpoint data is required to validate these findings.

LP12

SILYMARIN FOR THE TREATMENT OF NON-ALCOHOLIC STEATOHEPATITIS: INTERIM ANALYSIS OF A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL

W.K. Chan[1], N.R. Nik Mustapha[2], S. Mahadeva[1]. *[1]Department of Medicine, University of Malaya, Kuala Lumpur, [2]Department of Pathology, Hospital Sultanah Bahiyah, Alor Setar, Malaysia*
E-mail: wahkheong2003@hotmail.com

Introduction: Silymarin, derived from the milk thistle plant, *Silybum marianum*, has been used as a herbal remedy for diseases of the liver. Its anti-oxidant, anti-inflammatory and anti-fibrotic properties have been demonstrated in various in vitro and animal models, and may be useful for the treatment of non-alcoholic steatohepatitis (NASH).

Material and Methods: This is a randomized, double-blind, placebo-controlled study of silymarin 700 mg t.i.d. for the treatment of NASH. All included patients had biopsy-proven NASH, were given lifestyle advice, and received either silymarin or placebo for 48 weeks. A repeat liver biopsy was performed at the end of the study. Histology was reported using the NASH Clinical Research Network scoring system.

Results: A total of 64 patients completed the study at the time of this interim analysis. Mean age was 50.2±11.4 years and consisted of 43.8% males. The baseline characteristics were comparable between the silymarin (n = 30) and placebo (n = 34) groups. The primary endpoint of the study (defined as at least 30% improvement in the non-alcoholic fatty liver disease activity score, NAS) was met in a higher percentage of patients in the silymarin group compared to the placebo group but this was not statistically significant (33.3% vs. 20.6%, p = 0.517). Patients in both the silymarin and placebo groups experienced significant improvement in NAS ($\Delta = -0.733$, p = 0.003 in the silymarin group; $\Delta = -0.706$, p = 0.006 in the placebo group). The percentage of patients with improvement in NAS was not significantly different between the silymarin and placebo groups (60.0% vs. 58.5%, p = 0.924). However, significantly more patients in the silymarin group experienced NASH resolution (defined as NAS <3) compared to the placebo group (13.3% vs. 0%, p = 0.043). There was also a significant decrease in the fibrosis stage in the silymarin group ($\Delta = -0.367$, p = 0.019). This was not observed in the placebo group ($\Delta = +0.147$, p = 0.282). A significantly higher percentage of patients in the silymarin group had improvement in fibrosis stage compared to the placebo group (36.7% vs. 14.7%, p = 0.043). In addition, four patients in the placebo group developed cirrhosis while none of the patients in the silymarin group did.

Conclusions: A significantly higher percentage of patients experienced NASH resolution and improvement in fibrosis stage after 48 weeks of treatment with silymarin compared to placebo.

LP13

EFFECT OF LONG TERM VIRAL SUPPRESSION WITH SOFOSBUVIR + RIBAVIRIN ON HEPATIC VENOUS PRESSURE GRADIENT IN HCV-INFECTED PATIENTS WITH CIRRHOSIS AND PORTAL HYPERTENSION

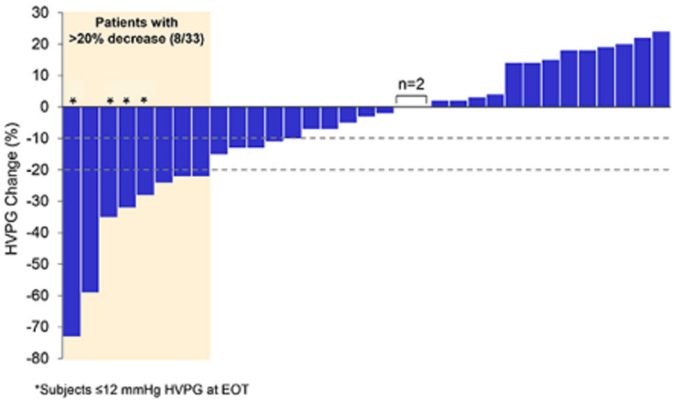
E-mail: jill.denning@gilead.com

Introduction: Portal hypertension is a major predictor of clinical outcomes and anti-viral response in HCV cirrhosis. The effect of viral suppression and SVR on HVPG has not been characterized in patients treated with DAA's.

Material and Methods: FFifty CPT A (n = 18) and B (n = 32) cirrhotic patients with portal hypertension (HVPG >6 mmHg), were randomized to receive 48 weeks of open-label sofosbuvir 400 mg and ribavirin at Day 1 or after a 24 week observation period. The primary endpoint was SVR12. Secondary endpoints included changes in HVPG, laboratory parameter values, MELD and CPT scores.

Results: Patients were predominantly male (76%), Caucasian (90%), prior treatment failures (80%), genotype 1 and 3 (88%) with mean baseline HCV RNA 6.1 $\log_{10}$ IU/mL. In the observation arm, 4 patients discontinued and never received treatment. All patients who completed treatment had viral suppression to undetectable by week 8 on treatment and SVR12 was achieved in 72% (33/46) of patients (2 on-treatment failures and 11 relapses). At study entry mean baseline HVPG was 16.4 mmHg in the observation group and 17.5 mmHg in the treatment group. Over the 24 week observation period the median change in HVPG was 0 mmHg (−7.0 to +4.5 mmHg). Of the 37 patients who had paired baseline and end of treatment (EOT) HVPG measurements there was a median change of −0.5 mmHg. Of the 33/37 (89%) patients with HVPG ≥12 mmHg at baseline, a ≥20% decrease from baseline was observed in 8/33 (24%) patients at the EOT and 4 patients reduced their pressure to less than 12 mmHg (see Figure). Improvements in MELD score from baseline to follow-up week 4 were seen in 37% (15/41) of patients with an average decline of −1.6. Improvement in CPT score was seen in 69% (18/26) of CTP B patients. In an

univariate analysis, a higher baseline MELD score (≥10) was the only factor significantly associated with a ≥20% decrease in HVPG (p = 0.04). 5 of 8 patients who had a ≥20% decrease in HVPG had improvements in MELD (mean decrease, −1.5) and all 8 patients had improvements in albumin (mean increase, +0.50 g/dL).



Conclusions: SOF+RBV for 48 weeks in patients with HCV and portal hypertension was well tolerated with an SVR rate of 72%. Improvement in MELD and CPT were common during and at end of treatment. HVPG at EOT decreased significantly in patients with higher MELD scores, although the full effects of SVR and viral eradication on HVPG may manifest later and is being explored in these patients at 1 year post treatment.

LP14

A PHASE 3, RANDOMISED, OPEN-LABEL STUDY TO EVALUATE THE EFFICACY AND SAFETY OF 8 AND 12 WEEKS OF SIMEPREVIR (SMV) PLUS SOFOSBUVIR (SOF) IN TREATMENT-NAÏVE AND -EXPERIENCED PATIENTS WITH CHRONIC HCV GENOTYPE 1 INFECTION WITHOUT CIRRHOSIS: OPTIMIST-1

Introduction: In a Phase II study (COSMOS), an all oral, once-daily (QD) combination of SMV (Hepatitis C virus [HCV] NS3/4A protease inhibitor) + SOF (HCV nucleotide-analogue NS5B polymerase inhibitor) +/− ribavirin for 12 or 24 weeks (wks) achieved high sustained virologic response (SVR) rates and was well tolerated in treatment-naïve and prior null responder patients (pts), including METAVIR F3–F4 pts. This Phase 3, randomised, open-label study (OPTIMIST-1; NCT02114177) evaluated efficacy and safety of 12 and 8 wks of SMV+SOF, in treatment-naïve or -experienced HCV genotype (GT)1-infected pts without cirrhosis.

Material and Methods: Randomisation (1:1; stratified by HCV GT subtype ±Q80K, *IL28B* GT, treatment history) to 12 or 8 wks of SMV 150 mg QD + SOF 400 mg QD. Superiority of SMV+SOF for 12 and 8 wks, each vs a historical control (HC; derived from published data), was assessed. If both were superior, non-inferiority of 8 vs 12 wks of SMV+SOF was to be assessed. Primary efficacy endpoint was SVR 12 wks after end of treatment (EOT; SVR12). Safety and pt-reported outcomes were assessed.

Results: A total of 310 pts received treatment (male, 55%; median age, 56 years; Black/African American, 18%; *IL28B* CC, 27%; GT1a/1b 75/25%; treatment-naïve [n = 218, 70%]; treatment-experienced [n = 92, 30%]). SVR12 with 12 wks of SMV+SOF (97% 95% confidence interval [CI] 94–100%) was superior to HC (87%). SVR12 with 8 wks of SMV+SOF (83% 95% CI 76–89%]) did not achieve superiority vs HC (83%). Other endpoints are summarised in Table 1.

Adverse events (AEs) occurred in 103 (67%) and 97 (63%) pts receiving 12- or 8-wk treatment, respectively, and were mainly Grade 1/2 (64% and 61%). Most frequent AEs: headache, fatigue and nausea (12-wk arm: 14%, 12% and 15%; 8-wk arm: 17%, 15% and 9%, respectively). AEs of interest, increased bilirubin and rash, occurred in 1 (1%) and 10 (7%) pts in the 12-wk arm vs 1 (1%) and 12 (8%) pts in the 8-wk arm, respectively. No pts discontinued treatment due to an AE. Serious AEs were infrequent (12-wk arm, 1 pt [1%]; 8-wk arm, 3 pts [2%]). No deaths occurred. Patient-reported symptoms and quality of life significantly improved from baseline to SVR12 in both treatment arms (Table 2). Additional data will be presented.

Table 1. SVR12 (overall and sub-groups) with SMV 150 mg QD + SOF 400 mg QD

	n/N (%)	
	12-week arm	8-week arm
SVR12 [a]	150/155 (97)	128/155 (83)
Treatment-naïve	112/115 (97)	88/103 (85)
Treatment-experienced	38/40 (95)	40/52 (77)
HCV GT1a	112/116 (97)	92/116 (79)
HCV GT1b	38/39 (97)	36/39 (92)
IL28B CC	43/43 (100)	38/41 (93)
IL28B non-CC	107/112 (96)	90/114 (79)
On-treatment failure [b]	0	0
Viral relapse [c]	4/154 (3)	27/155 (17)

[a] HCV RNA <25 IU/mL detectable/undetectable 12 weeks after end of treatment.
[b] HCV RNA <25 IU/mL detectable or ≥25 IU/mL at end of treatment.
[c] HCV RNA <25 IU/mL undetectable at end of treatment and ≥25 IU/mL during follow up.

Table 2. Patient-reported outcomes

Patient-reported outcome	Mean (SD) change from baseline			
	12-week arm		8-week arm	
	SVR12	No SVR12	SVR12	No SVR12
HCV-SIQv4 OBSS [a]	−3.9 (0.96)	6.7 (7.07)	−2.9 (0.87)	3.4 (2.82)
FSS [b]	−0.5 (0.15)	1.4 (0.99)	−0.6 (0.12)	−0.0 (0.22)
CES-D [c]	−0.2 (0.73)	5.3 (5.33)	−2.5 (0.61)	4.2 (1.94)
EQ-5D VAS [d]	4.1 (1.40)	−7.0 (7.51)	6.5 (1.39)	−0.6 (2.63)

[a] HCV-SIQv4 OBSS, Hepatitis C Symptom & Impact Questionnaire version 4 Overall Body System Score (range 0 [no symptoms] to 100 [maximum severity for all 29 symptoms]; mean reduction of ≥5 points is clinically important).
[b] FSS, Fatigue Severity Scale (range 1 [no fatigue] to 7 [severe fatigue]; mean reduction of 0.6 points is clinically important).
[c] CES-D, Center for Epidemiologic Studies Depression Scale (range 0 [no depressive symptoms] to 60 [severe depression on 20 symptoms]; mean reduction of ≥3 points is clinically important).
[d] EQ-5D VAS, EuroQol-5 Dimension questionnaire Visual Analogue Scale (range 0 [worst possible health] to 100 [perfect health]; mean increase of ≥5 points is clinically important).

Conclusions: SMV+SOF for 12 wks was superior to HC, and SMV+SOF for 8 wks did not achieve superiority vs HC in treatment-naïve and -experienced HCV GT1-infected pts without cirrhosis. SMV+SOF was well tolerated.

SEPARATE AND COMBINED EFFECTS OF OBETICHOLIC ACID AND WEIGHT LOSS IN NONALCOHOLIC STEATOHEPATITIS (NASH)

B. Hameed[1], N. Terrault[1], R. Gill[1], R. Loomba[2], N. Chalasani[3], J.H. Hoofnagle[4], M.L. Van Natta[5], and Nonalcoholic Steatohepatitis Clinical Research Network (NASH CRN).

E-mail: lwilson9@jhu.edu

Introduction: Obeticholic acid (OCA) is a potent farnesoid-X nuclear receptor agonist. In a 72-week, randomized controlled trial (FLINT) in 283 patients with NASH, OCA was found to be superior to placebo in improving ALT levels, liver histology and resulted in more weight loss (−2.3 kg) than placebo (0.0 kg) (Lancet, 2014). We assessed the separate and combined effects of weight loss and OCA.
Material and Methods: This secondary analysis was limited to the 200 patients with a pre- and end-of-treatment liver biopsy. Liver histology was scored using a standardized system for disease activity (NAS) and fibrosis. Weight loss was defined as ≥ −2 kg decline by end of treatment.
Results: Weight loss occurred in 42% of OCA vs 30% of placebo patients with paired biopsies ($p = 0.08$). Mean change in NAS was greater in OCA patients who lost vs. did not lose weight (−2.5 vs −1.2, $p < 0.001$), an effect seen to a lesser extent with placebo (−1.4 vs −0.4, $p = 0.008$). Fibrosis scores improved in 49% of OCA patients who lost weight vs 25% of those who did not ($p = 0.02$), but fibrosis improvement with placebo was similar with and without weight loss (17% vs 20%). ALT levels decreased more in patients who lost vs. did not lose weight in both OCA (−42 vs −33 U/L) and placebo (−40 vs −7 U/L). In contrast, LDL cholesterol levels rose (+23 mg/dL) in OCA patients who lost weight, but fell in placebo with weight loss (−17 mg/dL) and did not change without weight loss in either OCA or placebo (0 and −2 mg/dL). HDL cholesterol decreased (−0.6 mg/dL) in OCA patients who lost weight, but increased in placebo with weight loss (+3.6 mg/dL).
Conclusions: OCA led to weight loss in 42% of patients. Both OCA therapy and weight loss had beneficial effects on NAFLD severity. Improvements in fibrosis was greatest in OCA patients with weight loss. Paradoxically, weight loss during OCA treatment was associated with potentially adverse changes in the lipid profile.

E-mail: t.grammatikopoulos@nhs.net

Introduction: Cholangiopathies of neonatal onset are typified by biliary atresia (BA), with inflammatory obliteration of bile-duct lumina near the porta hepatis. A similar process without complete occlusion is called neonatal sclerosing cholangitis (NSC). BA and NSC are very alike histopathologically at biopsy of peripheral liver. NSC, unlike BA, is greatly enriched in consanguineous kindreds, strongly suggesting autosomal recessive inheritance. The cause of NSC is not known.
Material and Methods: With ethics-committee approval, archival samples from 13 children with NSC (7 male), 4 from consanguineous families, were selected for whole exome sequencing. The data were analysed using several open source and commercial software packages. Variants were filtered for homozygosity, pathogenicity, minor allele frequency (MAF), and expression pattern of the encoded proteins.
Results: Sequencing data were obtained in all cases. Variants present with MAF >1% in the 1000 Genome Project data, and variants flagged as low quality (quality score <30, long homopolymer runs >5, depth <5) were excluded. Three patients were homozygous for mutations in *DCDC2*, encoding doublecortin domain containing 2 (DCDC2), a ciliary protein expressed in small-duct cholangiocytes, with another 3 patients showing compound heterozygous mutations in *DCDC2*. An additional sibling had the same *DCDC2* mutations. All mutations were confirmed on Sanger sequencing. All mutations were protein truncating. In the 6 patients whose liver tissue was available, immunostaining with monoclonal antibody against human DCDC2 showed no expression. In material suitable for transmission electron microscopy (5 patients, including the siblings), cholangiocytes lacked primary cilia. All patients but one, who developed end-stage renal disease of unknown aetiology, had normal renal function; the sibling pair each had a single small renal cyst. One patient died awaiting liver transplantation (LT). Of 5 who came to LT, one died 2 years later; 4 are well.
Conclusions: DCDC2 is known to be important in ciliary regulation. Among 14 patients with NSC, 7 had mutations in *DCDC2* (6 of 13 families). Our data indicate that mutations in *DCDC2* underlie a substantial proportion of NSC. Histopathologic correlation suggests that NSC is mediated by ciliary abnormalities.

E-mail: Norah.Terrault@ucsf.edu

Introduction: HCV remains the leading cause for liver transplantation (LT) and recurrent HCV disease the most frequent cause of graft loss. Although direct acting antivirals have the potential to reduce HCV RNA levels prior to LT, post-LT recurrence occurs in 30%>50% in patients receiving sofosbuvir/ribavirin pre-LT. Prevention of reinfection independent of genotype and severity

of cirrhosis is highly desirable because it simplifies post-LT management.

Material and Methods: In this adaptive open-label, prospective randomized phase III North American clinical trial (Study 988, NCT01804829) conducted in 2 parts, any antiviral therapy (AVT) pre-LT (resulting in RNA <100 IU/ml prior to transplant) is followed in the active treatment arms by Hepatitis C Immune Globulin (HCIG, Civacir®) peri- and post-LT to prevent HCV infection after LT. In part I (dose finding), patients were randomized 1:1:1 to active (200 or 300 mg/kg) or control arms. Active group patients received 16 infusions of Civacir in the peri- and immediate post-LT period for 10 weeks. Control patients received standard of care (no treatment) immediately after LT. The primary endpoint is sustained virologic response SVR12.

Results: Three quarters (N = 63 as of 27 Jan 2015) of 84 planned patients have been enrolled. Preliminary efficacy evaluations justified continued enrollment in the 300 mg/kg arm but not in the 200 mg/kg low dose arm (closed by amendment). Treatment and control arms are comparable at baseline. Mean age of patients is 61 and 84% are male. 93% of patients were treated with sofosbuvir-based regimens pre-LT, for a median duration of 63.5 days including 9.4% with treatment <4 weeks. To date, 1/21 (5%) reinfection was observed in the 300 mg/kg arm. In the control and 200 mg/kg arm 7/22 (32%) and 6/20 (30%) reinfections occurred, respectively. At day 6, 14, 21 and 28 post-LT the median anti-HCV antibody titer was 440, 312, 274 and 215 U/ml in the 300 mg/kg and 39, 44, 53 and 63 U/ml in the control arm. Civacir has been well tolerated with no drug-related serious adverse events to date. The most frequent reported AEs were those well-known for human immunoglobulins, underlying disease, and surgical associated events.

Table 1. Status of patient recruitment and pre-LT antiviral treatment

Dose group	# pts	Pre-LT sofosbuvir treatment		Reinfections	
		%[a]	Median days[b]	Number	%
Control	22	90%	66	7	32%
200 mg/kg	20	90%	61	6	30% (p = 1.00)
300 mg/kg	21	94%	60	1	5% (p = 0.046)

[a] % of patients recerving sofosbuvir based therapy pre-LT.
[b] Median days of sofosbuvir treatment pre-LT.

Conclusions: Patients with HCV receiving AVT prior to LT are still at risk to reinfect. In this phase III clinical study HCIG therapy is used as a prophylactic approach immediately after LT. Preliminary data suggest that Civacir can prevent HCV-reinfection in patients on pre-LT AVT.

OBETICHOLIC ACID FOR NASH: BENEFITS IN A HIGH RISK SUBGROUP AND THE EFFECTS OF CONCOMITANT STATIN USE

B. Neuschwander-Tetri[1], A. Sanyal[2], R. Loomba[3], N. Chalasani[4], K. Kowdley[5], M. Abdelmalek[6], E. Brunt[7], D. Shapiro[8]. E-mail: dshapiro@interceptpharma.com

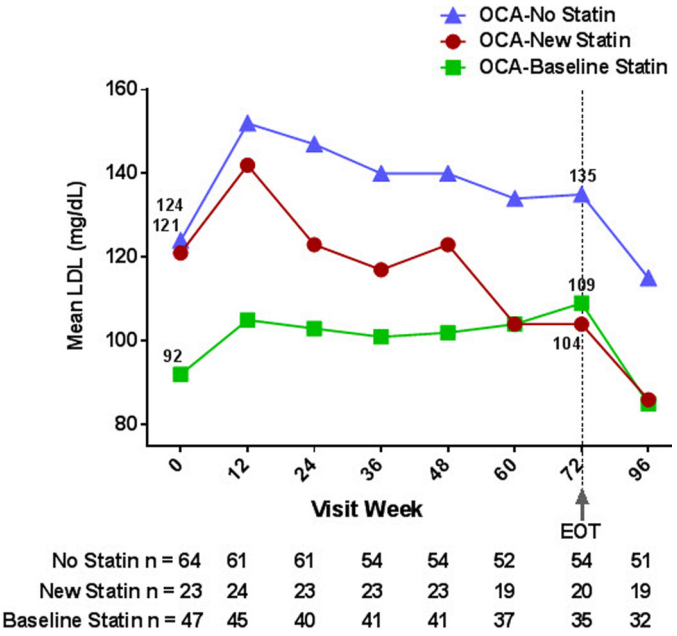
Introduction: The Farnesoid X Receptor Ligand Obeticholic Acid in NASH Treatment (FLINT) Trial was a 72 week placebo-controlled, double-blind trial in patients (N = 283) with non-cirrhotic, nonalcoholic steatohepatitis (NASH). Obeticholic acid (OCA) improved liver histology including fibrosis but was associated with pruritus and elevations of serum total and LDL cholesterol (Neuschwander-Tetri, Lancet 2014). The aims of these secondary analyses were to determine the effect of OCA versus Placebo in the subgroup of patients with more severe NASH and to assess the effects of concomitant statin use on serum LDL cholesterol levels.

Material and Methods: The subgroup of patients at higher risk for liver-related outcomes was defined as those with stage 2–3 fibrosis or stage 1 fibrosis with diabetes, obesity or ALT ≥60 (associated with fibrosis progression) (OCA N = 85; Placebo N = 77). The effect of statin use on changes in LDL cholesterol was assessed in the entire cohort based on patient-reported statin use before and during treatment, initiation during treatment, or no statin use before or during treatment.

Results: Significant histologic improvements were observed in the OCA vs Placebo high-risk subgroup: NAS improved by ≥2 points in 50% OCA vs 31% Placebo (p = 0.001), NASH resolution occurred in 18% OCA vs 6.5% Placebo (p = 0.03), and fibrosis regressed by at least one stage in 39% OCA vs 22% Placebo (p = 0.012). In addition, fibrosis progression with OCA was attenuated (16% OCA vs 29% Placebo [p = 0.047]). The histologic improvement in OCA-treated patients occurred regardless of fibrosis stage at baseline. LDL cholesterol increased during OCA treatment in patients on statins at baseline, but levels did not exceed those of Placebo-treated patients not on statins. Statin initiation during OCA treatment reversed LDL to below pre-OCA baseline levels.



Conclusions: In the subgroup of FLINT patients at higher risk of progression to cirrhosis, OCA treatment improved the features of NASH, NASH resolution, fibrosis regression and decreased fibrosis progression. The OCA-related LDL increase appeared to be reversed by initiating statin therapy during OCA treatment. The clinical significance of these OCA-related treatment effects remains to be determined and warrants further study.

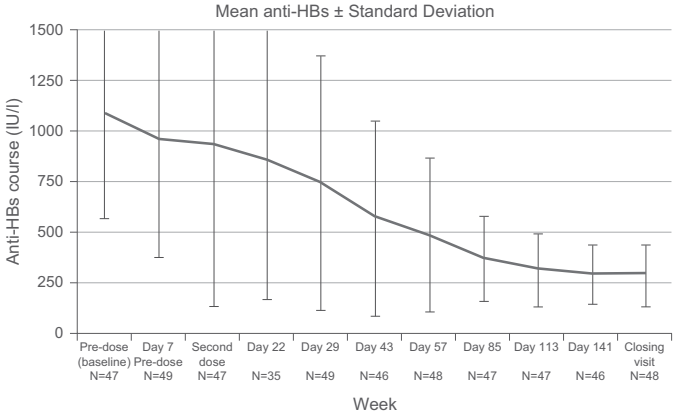
Brotzu" di Cagliari, Cagliari, Italy; [7]NIHR Liver BRU, QE Hospital and Birmingham University, Birmingham, United Kingdom
E-mail: didier.samuel@pbr.aphp.fr

Introduction: Subcutaneous HBIg (Zutectra®) in maintenance liver transplant patients assures hepatitis B surface antibody (anti-HBs) serum trough level >100 IU/l, the minimum threshold for effective HBV reinfection prophylaxis. Data regarding early s.c. administration of HBIg are lacking.
Material and Methods: In a prospective, open-label, single-arm study, HBV DNA-negative patients undergoing liver tx for HBV infection were switched at 8–18 days post-tx from i.v. to s.c. HBIg (500 or 1,000 IU once a week or once every 2 weeks) if they were HBsAg negative at time of switch, and were monitored to month 6 post-tx. All patients received concomitant anti-HBV nucleoside therapy. Self-injection (or by a caregiver) could be started after week 4 if anti-HBs trough level was >100 IU/l and if patients complied with the injection technique. Primary endpoint was failure rate during 6 months, defined as serum anti-HBs ≤100 IU/l or HBV reinfection with serum anti-HBs >100 IU/l.
Results: 49 patients were recruited (20 dosed once a week, 29 dosed once every 2 weeks), of whom 47 (95.9%) continued treatment until month 6. By week 14, 47 patients were self-administering (n = 35) or being injected by a caregiver (n = 12). No treatment failures occurred during the 6-month study treatment period i.e. all patients maintained serum HBs antibody concentrations ≥100 IU/L and remained HBsAg negative. All patients tested for HBV DNA remained negative (45/45). Mean anti-HBs declined successively to month 6 to a protective titer of 250 IU/l (figure). No clinical symptoms consistent with HBV reinfection were observed. Only one non-serious adverse event (mild injection site hematoma) was assessed as treatment-related. No serious drug-related adverse events occurred. All 44 patients who completed an end-of-study questionnaire reported that s.c. injection was convenient and were satisfied with s.c. HBIg.



Conclusions: Early switch to s.c. HBIg (between days 8–18) after liver tx maintained serum anti-HBs at a level which effectively prevented HBV reinfection in all patients. Treatment was well-tolerated. Self-administration of s.c. HBIg as part of combination treatment with HBV virostatic therapy appears a successful and convenient strategy for preventing HBV reinfection.

E-mail: laure.esterle@isped.u-bordeaux2.fr

Introduction: Cirrhotic HIV–HCV coinfected patients have long been considered as difficult-to-treat patients with a high mortality rate. DAA regimens have changed this paradigm in HCV-monoinfected patients. Real-life efficacy and tolerance data with sofosbuvir (SOF)-based combinations in cirrhotic HIV-coinfected patients are scarce and urgently needed.
Material and Methods: Cirrhotic HIV–HCV coinfected patients prospectively enrolled in the CO13 HEPAVIH cohort sponsored and funded by ANRS, and initiating an all-oral DAA regimen were included. Safety and virologic responses (VR: HCV-RNA <15 UI/mL) at week 4 (W4) and end of treatment (EOT) as well as sustained virological response at 4 (SVR4) and 12 (SVR12) weeks were assessed.
Results: 106 patients initiated SOF-based regimen between 01/2014 and 01/2015 (median age: 54; 80% male; CDC A/B/C: 30/36/34%;

Child–Pugh A/B/C: 87/10/3%; 86% with HIV-RNA <50 copies/mL; 104 on continuous antiretroviral treatment (cART); median CD4 at baseline: 462/mm^3 [IQR: 265–628]). History of previous HCV treatment was: naïve 28%, treatment failure with PegIFN+Ribavirin (PR) 57%, treatment failure with PR+first generation protease inhibitor 11%, treatment failure with PR+others 4%. HCV genotype (Gt) were 1a (32%), 1b (12%), 1 other (10%), 2 (4%), 3 (19%) and 4 (23%). Four regimens were used: SOF+R in 22 patients (Gt1 28%; Gt2 18%; Gt3 36%; Gt4 18%), SOF+daclatasvir±R in 75 (Gt1 64%; Gt3 15%; Gt4 21%), SOF+ledipasvir in 3 (2 Gt1 and 1 Gt3) and SOF+simeprevir in 6 (2 Gt1 and 4 Gt4). On February 24th, 2015, 100%, 77%, 69% and 42% of the patients reached W4, EOT, and W4 and W12 post-treatment, respectively. No premature stop of DAA was reported in relation with tolerance or efficiency. Adverse events were reported in 22 patients (digestive 5%, anemia 36%, asthenia 14%, others 45%), and R was stopped in 3 patients and dose-adjusted in 9. During treatment and post-treatment period, clinical events in relation with cirrhosis were reported in 8% (hepatocellular carcinoma in 2 and decompensation in 5) and with HIV in 4% of the patients. VR was observed in 52% of the patients at W4, 100% at EOT. SVR4 and SVR12 were 100% and 93% for the patients reaching this endpoint, respectively.

Conclusions: In this prospective real-life cohort, new all-oral DAA regimens were well tolerated and associated with very encouraging virological efficacy in cirrhotic HIV–HCV coinfected patients. This should not alleviate the surveillance for liver-related events in these patients.

Introduction: Activation of Kupffer cells, constituting >80% of the entire body macrophage population, play a key role in inflammation and may be involved in the development and course of ACLF. We explore this hypothesis by measuring the specific macrophage activation markers sCD163 and sCD206 in plasma and their relationship to short- (1–3 months) and long-term mortality (6 months) in 853 cirrhotic patients from the CANONIC study.

Material and Methods: 86 patients had no ascites and no ACLF, 580 had ascites but no ACLF and 100, 66 and 19 had ACLF-grade I (ACLF-1), ACLF-II, and ACLF-III, respectively. We used in house ELISA for measurement of sCD163 and sCD206

Results: We found a stepwise increase ($p < 0.001$) in sCD163 (7.1±4.5; 9.2±5.6; 11.8±8.2; 16.9±10.3; 24.4±11.3 mg/l, respectively) and sCD206 (0.67±0.4; 0.91±0.5; 0.96±0.5; 1.27±0.5; 1.64±0.8 mg/l) with increasing disease severity. In patients with and without ACLF both sCD206 and sCD163 were independently associated with short and long-term mortality and showed equal or higher predictive accuracy than MELD and CLIF-C Acute Decompensation (AD) and CLIF-C ACLF scores (s). For patients without ACLF, addition of sCD206 to MELDs (data not shown) and CLIF-C-ADs significantly improved their prognostic performance for long-term mortality. For patients with ACLF, addition of sCD163 to MELDs and CLIF-C-ACLFs improved their prognostic performance for short-term mortality (Table 1).

Conclusions: The graded increase in sCD163 and sCD206 and their close association with mortality suggest the importance of liver resident macrophages in the development and course of ACLF. Accordingly, the inclusion of the macrophage biomarkers sCD206 to the CLIF-C-AD and sCD163 to the CLIF-C-ACLF scores improved the prognogstic predictive performance beyond that of the original scores.

LP22

PHASE 1 RESULTS FROM PXS-4728A, A SELECTIVE SSAO/VAP-1 INHIBITOR, FOR THE TREATMENT OF NON-ALCOHOLIC STEATOHEPATITIS

W. Jarolimek[1], B. Charlton[1]. *[1]Drug Discovery, Pharmaxis, Frenchs Forest, Australia*
E-mail: wolfgang.jarolimek@pharmaxis.com.au

Introduction: SSAO/VAP-1 is an ectoenzyme located on endothelial cells, adipocytes and smooth muscle cells that facilitates the migration of leukocytes and lymphocytes to the site of inflammation whilst also inducing oxidative stress through metabolism of primary amines into aldehydes, hydrogen peroxide and ammonia. Plasma SSAO/VAP-1 is shed from the hepatic endothelium into the circulation, and its concentration is positively correlated with liver fibrosis and cirrhosis. Recently, compelling evidence has been provided that the enzymatic activity of SSAO/VAP-1 is involved in the development of fatty liver diseas (Weston et al., J Clin Invest. 2015; 125(2): 501–520. doi: 10.1172/JCI73722).

Results: PXS-4728A is a very selective, mechanism-based small molecule inhibitor of SSAO/VAP-1 with nanomolar potency, good oral bioavailability and desirable developability properties. PXS-4728A reduces infection and lipopolysaccharide, rhinovirus or

carrageenan-induced acute inflammation in rodent models. In the CCl_4-induced liver inflammation and fibrosis model, PXS-4728A was given therapeutically from the halfway point of 4–8 week studies at doses of 2–6 mg/kg in rat or mouse. PXS-4728A improved liver function and reduced the area of fibrosis as measured by picrosirius red staining. In another study, NASH was induced by exposing mice to low-dose streptozotocin and feeding with high-fat diet. PXS-4728A (6 mg/kg oral) was given for the last 3 weeks of a 10 week model. Telmisartan (10 mg/kg) was used as the positive control in this study. PXS-4728A significantly reduced all the components of the NAFLD activity score and collagen deposition, as evidenced by the reduction of picosirius red-positive area.

In a Phase 1 trial PXS-4728A was given orally to healthy male volunteers in a double-blinded, randomised, single ascending dose study. PXS-4728A dose-dependently inhibited plasma SSAO activity for more than 24 hours while the SSAO concentration remained unchanged. In contrast plasma drug concentrations were only measurable for a short period of time consistent with 4728A being an irreversible inhibitor. The safety profile did not identify any signals.

Conclusions: PXS-4728A is an anti-inflammatory and anti-fibrotic drug that reduces the migration of leukocytes and lymphocytes to the site of inflammation and diminishes oxidative stress. PXS-4728A was well tolerated in man and provided significant and long lasting inhibition of enzymatic activity.

E-mail: adrienne.tracey@articulatescience.com

Introduction: All-oral regimen with daclatasvir (DCV; NS5A replication complex inhibitor) + sofosbuvir (SOF; NS5B polymerase inhibitor) ± weight-based ribavirin (RBV) has demonstrated high sustained virologic response (SVR) rates in HCV mono-infected patients. This analysis reports SVR4 results from an ongoing multicenter compassionate use program (ATU) of DCV+SOF ± RBV in HIV–HCV co-infected patients with advanced liver disease in France.

Material and Methods: Since March 2014, more than 4000 HCV patients from 221 French centers were included in the ATU program. We included HIV–HCV co-infected patients with advanced liver disease who received DCV+SOF QD for 12 or 24 weeks, with RBV added at the physician's discretion. Baseline (start of treatment) characteristics were collected through a standardized form as were follow-up data such as virological response rates and adverse events.

Results: This interim analysis includes a total of 733 co-infected patients, 72.3% males, median age 52.3 years 519 (71.4%) cirrhotic (Child Pugh A=85.3%, B=13.1%, C=1.6%) and 585 (80%) treatment-experienced. Genotype (GT) distribution was as follows: 501 GT1 (69.3%), 2 GT2 (0.3%), 95 GT3 (13.1%), 122 GT4 (17.2%) and 1 GT6 (0.1%). HIV–HBV–HCV triple infection was found in 16 patients. Combined antiretroviral therapy (cART) included nucleoside/nucleotide reverse transcriptase inhibitors (NRTI) in 88.3%, protease inhibitors (PIs) in 35.7%, non-nucleoside reverse-transcriptase inhibitors (NNRTIs) in 24.7% and integrase inhibitors in 61.5% of the patients. 21 patients were not on ART. Baseline median CD4 count was 539/mm^3 (0–1922). RBV was added to DCV+SOF in 98 patients (13.6%). Treatment duration was 24 weeks in 573 (79.3%) and 12 weeks in 142 (19.6%) patients. Overall on 86 patients, SVR4 was obtained in 90% of the cases. Detailed efficacy data are depicted in the table. Treatment discontinuations occurred in 14 patients (1.9%) and were related to an adverse event (n = 4), death (n = 3), patient decision (n = 3), contra-indication (n = 3) and unknown reason (n = 1). Efficacy and safety data will be updated with larger population.

	Treatment duration		Genotype status		
	12 weeks	24 weeks	GT1	GT3	GT4
SVR4	29/35 (83%)	48/51 (94%)	53/60 (88%)	7/8 (88%)	18/19 (95%)

Conclusions: In HIV–HCV co-infected patients with advanced liver disease and treated within the ATU program, DCV+SOF ± RBV regimen was well tolerated and demonstrated high antiviral activity at 4 weeks after the end of treatment.

LP24

SAFETY, EFFICACY AND IMPACT ON LIVER FUNCTION OF SIMEPREVIR (SMV) IN COMBINATION WITH DACLATASVIR (DCV) OR SOFOSBUVIR (SOF) IN PATIENTS WITH SEVERE HEPATITIS C RECURRENCE AFTER LIVER TRANSPLANTATION (LT): RESULTS FROM COMPASSIONATE USE IN EUROPE

Introduction: SMV has been approved to treat genotype 1 and 4 hepatitis C infection. There are no data on the use of this drug in the treatment of patients with severe hepatitis C recurrence after LT.

Material and Methods: Retrospective analysis of LT recipients with severe hepatitis C recurrence (high risk of death within the next 12 months) receiving SMV as compassionate use in Europe. The aim of this study was to evaluate the safety, efficacy (SVR4) and impact on liver function of SMV-based therapies.

Results: Data from 64 patients is available, 38 patients had cirrhosis, 22 had clinical decompensation and 3 fibrosing cholestatic hepatitis. SMV was administered with SOF or DCV in 41 (64%) or

23 (36%) cases, respectively. Ribavirin (RBV) was used in 35% and 65% of the patients receiving SOF and DCV, respectively. Most of the patients were male (72%) and genotype 1b (81%). Median age was 59 years. Median baseline MELD and Child–Pugh (CPT) scores were 9 and 6, respectively. Among the patients with cirrhosis, 47% were CPT B/C. Tacrolimus was the immunosuppressant used in the majority of the patients (69%). At the beginning of therapy, 20 patients had ascites and 3 had hepatic encephalopathy (HE). Thirty-four patients completed the treatment course and 30 are still on therapy. End of treatment (EOT) response was 88% (30/34) and SVR12 was 83% (25/30). In patients receiving SMV+DCV±RBV, EOT response was 78% (14/18) due to 4 breakthroughs and SVR4 was 72% (13/18) due to an additional relapse by post-treatment week 4. Four of the non-responder patients had cirrhosis and 3 did not receive RBV. In patients receiving SMV+SOF±RBV, EOT (16/16) and SVR12 (12/12) were 100%. At post-treatment week 12 there was a significant improvement in liver function (Table 1). More importantly, ascites and HE resolved in 15 and 2 patients, respectively. SAEs were reported in 11 patients (anemia [n = 2], infections [n = 5], gastrointestinal bleeding [n = 1], renal dysfunction [n = 1], gastric cancer [n = 1] not considered to be related to SMV). One patient presented eosinophilia considered as possibly related to therapy. Rejection or IS-related toxicity were not reported. No major adjustment in IS drugs were needed. None of the patients died or discontinued therapy due to adverse events.

Table 1. Evolution of liver tests during and after antiviral therapy

Variable (n = 26)[a]	Baseline	On-treatment W12	PTW12	*p*(Baseline vs. PTW12)
Bilirubin (mg/dL)	1 (0.3–4.2)	1.3 (0.4–4.6)	0.8 (0.1–4.8)	0.007
INR	1.1 (0.95–1.85)	1.1 (0.84–2.1)	1.1 (0.93–1.57)	0.308
AST (IU/L)	89 (15–548)	25 (8–83)	28 (14–77)	0.001
ALT (IU/L)	77 (7–296)	20 (7–140)	22 (9–109)	0.001
MELD score	9 (6–18)	10 (6–20)	8 (6–18)	0.006
Child–Pugh score	6 (5–10)	5 (5–11)	5 (5–7)	0.023

Data are expressed as median (range). PTW12, post-treatment week 12.
[a] Patients with available data at PTW12.

Conclusions: SMV in combination with DCV or SOF is effective and safe in patients with severe HCV recurrence after LT. Viral eradication is associated with a fast and significant improvement in liver function.

LP25
ADD-ON PEGINTERFERON ALFA-2A SIGNIFICANTLY REDUCES HBsAg LEVELS IN HBeAg-NEGATIVE, GENOTYPE D CHRONIC HEPATITIS B PATIENTS FULLY SUPPRESSED ON NUCLEOT(S)IDE ANALOGUE TREATMENT: THE HERMES STUDY

P. Lampertico[1], M.R. Brunetto[2], A. Craxì[3], G.B. Gaeta[4], M. Rizzetto[5], G. Palmieri[6], M. Colombo[1], and HERMES Study Group. *[1]Division of Gastroenterology and Hepatology, Ospedale Maggiore Policlinico, University of Milan, Milan, [2]Liver Unit, Reference Centre for Chronic Liver Disease and HCC of the Tuscany Region, University Hospital of Pisa, Pisa, [3]Gastroenterology and Hepatology, Di.Bi.M.I.S., University of Palermo, Palermo, [4]Department of Internal Medicine, Section of Infectious Disease and Viral Hepatitis, Second University of Naples, Naples, [5]Department of Gastroenterology, University of Turin, Turin, [6]Roche, Monza, Italy*
E-mail: giulio.palmieri@roche.com

Introduction: Long-term treatment with nucleos(t)ide analogues (NA) efficiently suppresses viral replication in patients with HBeAg-negative chronic Hepatitis B (CHB), yet minimally affecting serum HBsAg levels. We investigated whether add-on PEG-IFN fosters qHBsAg kinetics in NA suppressed, HBeAg-negative, genotype D, Caucasian CHB patients (HERMES study).

Material and Methods: This phase IIb, open-label, single-arm, multicenter study conducted in 13 sites in Italy included patients who following NA monotherapy, had serum HBV-DNA persistently <20 IU/ml for at least 12 months, HBsAg >100 IU/ml and stable qHBsAg in the 3 months preceding enrollment (<0.5 $\log_{10}$ IU/ml decline). Patients without any HBsAg decline at week 24 or those who completed the add-on treatment period (week 48), discontinued PEG-IFN and were followed-up for additional 48-weeks. Serum HBsAg decline at the end of treatment with PEG-IFN plus NA combination (week 48) was the primary endpoint.

Results: 70 Caucasians started treatment with PEG-IFN. Median age was 50.5 years (range 29–64), 81% were males, 93% were on tenofovir or entecavir, viral suppression lasting for 3.2 years (range 1.1–8.4). Baseline stiffness by FibroScan was 6.1 kPa (range 3.3–12.7) in the 30 tested patients. Median HBsAg levels significantly decreased from 1160 IU/ml at baseline to 308 IU/ml at week 48 ($p < 0.0001$, Table). At week 48 (primary endpoint), serum HBsAg decreased ≥50% from baseline in 30 patients (43%). Likewise, the proportion of patients with HBsAg <1000 or <500 or <100 IU/ml increased from baseline up to week 48 (Table). One patient (1.4%) seroconverted to anti-HBs at week 24 and successfully withdrew from both NUC and IFN treatment and two additional patients (2.8%) reached qHBsAg <10 IU/ml. Sixty-two patients (88.6%) experienced adverse events (AEs), 8 (11.4%) and 7 (10.0%) patients discontinued or temporarily interrupted PEG-IFN due to AEs respectively, while in 8 (11.4%) patients PEG-IFN was downdosed following AEs. Two (2.9%) patients had serious AEs related to PEG-IFN (pyrexia and haemoptysis). Overall, 24 patients (34.3%) discontinued PEG-IFN, 11 (16%) HBsAg non responders, 8 (11%) for AEs, 5 (7.1%) for compliance or consent withdrawal.

Conclusions: In HBeAg-negative, genotype D, CHB patients treated with NA, add-on treatment with PEG-IFN results in a significant reduction of serum HBsAg levels.

LP26
NUCLEIC ACID POLYMERS ARE EFFICIENT IN BLOCKING HEPATITIS DELTA VIRUS ENTRY IN VITRO

D. Poutay[1], M. Sabra[2], G. Abou Jaoudé[1], I. Chemin[2], C. Trepo[2], A. Vaillant[3], C. Sureau[1]. *[1]Institut Nationale de Transfusion Sanguine, Paris, [2]INSERM, Lyon, France; [3]REPLICor Inc., Montreal, Canada*
E-mail: availlant@replicor.com

Introduction: Nucleic acid polymers (NAPs) are phosphorothioated oligonucleotides, which exhibit a sequence-independent, broad-spectrum antiviral activity. NAPs have been previously shown to have antiviral effect against duck hepatitis B virus (DHBV) infection in vitro, having both entry and post-entry activities (Noordeen et al., 2013). Additionally NAPs have been shown to be clinically active against HBV infection where they achieve rapid reductions in both serum HBsAg and HBV DNA.

Material and Methods: HBV and hepatitis delta virus (HDV) are considered to have similar entry mechanisms, therefore the antiviral activity of various NAP compounds was assessed against HDV infection using two *in vitro* cellular infection models.

Table (abstract LP25): HBsAg kinetics during 48 weeks of PEG-IFN and NA combination treatment

	Baseline (n = 70)	Week 12 (n = 67)	Week 24 (n = 66)	Week 36 (n = 50)	Week 48 (n = 46)
HBsAg (IU/mL), median (range)	1160 (133.3–8909)	1317 (1.6–8158)	743 (0.04–5507)*	406 (3.2–6027)	308 (0.5–5202)*
HBsAg <1000 IU/mL, N (%)	33 (47%)	32 (48%)	39 (59%)	34 (68%)	33 (72%)
HBsAg <500 IU/mL, N (%)	16 (23%)	20 (30%)	26 (39%)	24 (48%)	26 (56%)
HBsAg <100 IU/mL, N (%)	0 (0.0%)	3 (4.5%)	9 (14%)	8 (16%)	10 (22%)

*$p < 0.0001$ vs baseline (Wilcoxon Signed Rank test).

The NAPs tested included REP 2006 (a prototypic NAP with a degenerate sequence), REP 2055, REP 2139 (clinically active against HBV) and REP 2165 (an additional clinical candidate NAP). Differentiated HepaRG cells, or NTCP-expressing Huh-7 cells, were inoculated with HDV in the presence of NAPs, and infection was monitored by measuring intracellular HDV RNA levels at day-9 postinoculation. Control experiments consisted of NAP treatment applied postinoculation to specifically monitor for toxicity and inhibition of HDV RNA replication.

Results: Treatment with NAPs resulted in the absence of cytotoxicity at ≤10 μM concentrations. All NAPs demonstrated a dose dependent activity against HDV infection in both HepaRG and NTCP-Huh-7 cells, with an IC50 ≤625 nM for the prototypic NAP. Data show that the antiviral effect was exerted at viral entry and not on HDV RNA replication. The antiviral effect of the prototypic, degenerate REP 2006 was comparable to that of other NAPs with defined sequences.

Conclusions: NAPs display an antiviral activity against HDV entry in vitro, which has the same sequence-independent antiviral effect as that observed for DHBV in vitro. These results suggest that NAPs are potent inhibitors of HDV infection.

LP27

ACH-3422, A NOVEL NUCLEOTIDE PRODRUG INHIBITOR OF HCV NS5B POLYMERASE

E. Gane[1,2], C. Schwabe[1], C. Stedman[3], F. Weilert[4], K. Stuart[5], W. Cheng[6], J. Yang[7], H. Robison[7], J. Hui[7], J. Lahey[7], R. Sorensen[7], D. Apelian[7], R. Hindes[7]. *[1]Auckland Clinical Studies Ltd, Grafton, [2]University of Auckland, Auckland, [3]Christchurch Clinical Studies Trust and Christchurch Hospital, Christchurch, [4]Waikato Hospital, and Waikato District Health Board, Hamilton, New Zealand; [5]Q-Pharm Pty Limited, and Gallipoli Medical Research Foundation, Brisbane, [6]Linear Clinical Research, and Royal Perth Hospital, Perth, Australia; [7]Achillion Pharmaceuticals, New Haven, United States*
E-mail: EdGane@adhb.govt.nz

Introduction: ACH-3422 is a nucleotide inhibitor of hepatitis C virus (HCV) NS5B RNA polymerase, displaying pan-genotypic activity and a high *in vitro* barrier to resistance. This randomized, double-blind, placebo (PBO)-controlled study evaluated the safety, tolerability, pharmacokinetics (PK), and antiviral activity of ACH-3422 after single ascending doses (SAD) and multiple-ascending doses (MAD) in healthy volunteers (HV) and antiviral proof of concept (POC) in patients (pts) infected with genotype 1 (GT-1) HCV.

Material and Methods: This was a 3-phase study whereby 5 different doses of ACH-3422 (50 mg, 150 mg, 300 mg, 500 mg and 700 mg) and PBO were administered in a SAD and 14-day MAD phase with HV, and either a 7 or 14-day POC phase in pts with HCV GT-1. Dose escalation decisions were made in real time based on the emerging safety, PK, and virology assessments.

Results: 104 HV (18–49 years; 73 male) and 37 HCV (IL28 frequency: CC 9, CT 24, TT 4; 27–69 years; 26 male) were randomized. In the SAD/MAD phases, ACH-3422 was well tolerated: no serious adverse events (SAEs), no discontinuations due to adverse events (AEs), no grade 3–4 AEs, and no clinically significant AEs or laboratory or ECG abnormalities were observed. In the POC phase, ACH-3422 was well tolerated: no SAEs or Grade 3 or 4 AEs were considered drug related. No Grade 3 or 4 laboratory abnormalities were observed among active pts, and one discontinuation due to an AE was observed in a PBO patient. There was no significant difference between active and PBO groups in AEs or laboratory abnormalities, and no clinically significant ECG abnormalities were observed. Among active pts, increasing doses of ACH-3422 resulted in increasing viral decline (Figure). In the 700 mg POC group, a mean maximum viral load drop of 3.4 $\log_{10}$, 4.2 $\log_{10}$, and 4.6 $\log_{10}$ was reported after 7, 10, and 14 days of treatment, respectively. Three of 6 pts (50%) achieved viral clearance (target not detected by PCR) with 14 days of 700 mg. Approximate dose-proportional PK was observed for both ACH-3422 (50–700 mg QD) and its corresponding nucleoside metabolite (ACH-3420).

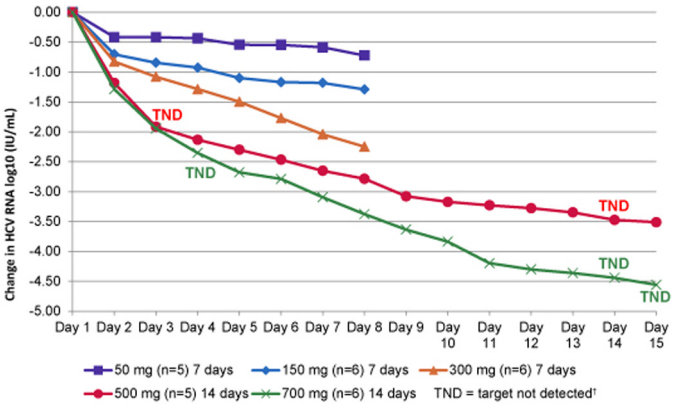

Figure: Mean maximum change in viral load. Maximum change = maximum reduction from Baseline (Day 1 Hour 0) in HCV RNA as of that time point. †2 subjects achieved TND in the 500 mg group; 3 subjects achieved TND in the 700 mg dose group.

Conclusions: In all 3 phases, ACH-3422 was safe and well tolerated at doses up to 700 mg with dose-related virologic responses in pts with HCV GT-1 infection. Together, these results support further investigation of ACH-3422 with ACH-3102, a potent NS5A inhibitor, for the treatment of pts with HCV GT-1 infection.

E-mail: helene.fontaine@cch.aphp.fr

Introduction: Real-life results of the Sofosbuvir (SOF)/Simeprevir (SIM) combination have been extensively reported in genotype 1-infected patients but there are few or no data regarding genotype 4-infected patients for the SOF/SIM or the SOF-Daclatasvir (DCV) combinations. In January 2015, more than 3003 patients of the French observational cohort ANRS CO22 HEPATHER were given the new oral antivirals in 32 centers: we report the preliminary results of the Sofosbuvir-based combinations with DCV or SIM, with or without ribavirin (RBV), in Genotype 4-infected patients.

Material and Methods: Demographics, history of liver disease were collected at entry in the cohort. Clinical, adverse events, and virological data were collected throughout treatment and post-treatment follow-up.

Results: 81 (64 cirrhotic) genotype 4-infected patients were given a combination of 1. SOF (400 mg/d) + DCV (60 mg/d) in 47 patients including 15 patients with ribavirin (1–1.2 g/d) for 12 (n = 11) or 24 weeks (n = 36); 2. SOF (400 mg/d) + SIM (150 mg/d) in 34 patients including 7 patients with ribavirin (1–1.2 g/d) for 12 (n = 23) or 24 weeks (n = 11). Results are given in the table.

The overall SVR4 rate was high from 78 to 100% according to the baseline characteristics and the therapeutic schedule. There was no clear difference between the SOF/DCV or the SOF/SIM combination and there was an additive effect in cirrhotic or experienced patients of either extension of the duration of therapy from 12 to 24 weeks or the addition of RBV, for the 2 combinations. The 12 week combination of SOF/DCVRBV or SOF/SIM/RBV achieved a 100% SVR4 rate in cirrhotics without additive effect of extension of the treatment to 24 weeks and this was also observed in experienced patients; all non-cirrhotic patients achieved 100%SVR4. The 12 week combination of SOF/DCV or SOF/SIM is a good therapeutic option and is generally well tolerated.

	SOF/DCV (n = 32)		SOF/DCV/RBV (n = 15)		SOF/SIM (n = 27)		SOF/SIM/RBV (n = 7)	
Tx duration (weeks)	12 w.	24 w.	12 w.	24 w.	12 w.	24 w.	12 w.	24 w.
% SVR4	88.9	94.7	100.0	100.0	78.3	100.0	100.0	100.0
% SVR12	100.0	90.9	100.0	100.0	88.9	100.0	100.0	100.0
% SVR4 cirrhotic	85.7	92.3	100.0	100.0	69.2	100.0	100.0	100.0
% SVR4 non-cirrhotic	100.0	100.0	–	100.0	100.0	–	–	–
% SVR4 naïve	100.0	100.0	–	100.0	66.7	100.0	100.0	–
% SVR4 experienced	87.5	94.1	100.0	100.0	77.8	100.0	100.0	100.0

Conclusions: The 12 week combination of Sofosbuvir–Daclatasvir or Sofosbuvir–Simeprevir is associated with a high rate of SVR4 in genotype 4-infected patients. The addition of Ribavirin increases the SVR rate in cirrhotic or experienced patients at 12 weeks without additive effect of the treatment extension to 24 weeks.

*The ANRS CO22 Hepather cohort is supported by MSD, Janssen, Gilead, BMS, Roche, Abbvie and conducted in collaboration with AFEF.

Introduction: Chronic hepatitis B (CHB) patients with a low viral load (LVL) are currently not eligible for antiviral treatment. However, they comprise the largest group of hepatitis B virus-infected patients and are still at risk to develop cirrhosis or hepatocellular carcinoma. Here we present the week 48 results of a randomized trial comparing combination treatment of peginterferon alfa-2a (Peg-IFN) and a nucleotide analogue versus no treatment for CHB patients with LVL.

Material and Methods: 134 CHB patients (HBeAg-negative, HBV-DNA <20,000 IU/mL) were randomized 1:1:1 to receive Peg-IFN+adefovir (arm I; n = 46), Peg-IFN+tenofovir (arm II; n = 45) or no treatment (arm III; n = 43) for 48 weeks (ITT population).

Randomization was stratified by HBV genotype A (22%), non-A (B 7%, C 4%, D 26%, E/F/G 20%), or indeterminate (21%). The median age was 43 years, 57% were male. Twelve patients discontinued the study before week 48 (5 in arm I, 6 in arm II, 1 in arm III). HBsAg loss (AxSYM <0.05 IU/mL) and quantitative HBsAg level (Architect) was determined at regular intervals, and were compared using Fisher's, Mann–Whitney U or Wilcoxon test.

Results: At week 48, 4 patients receiving combination therapy had achieved HBsAg loss, compared to none of the untreated patients (ITT 4.4% vs 0.0%, p = 0.31). Patients with HBsAg loss were treated in arm I (n = 1) and arm II (n = 3), and had HBV genotype A (n = 1), B (n = 1), or indeterminate (n = 2). Baseline HBsAg levels were comparable between study arms (median 3.34 log IU/mL). In a per-protocol analysis, HBsAg level had declined significantly in all arms at week 48; −0.33 (p < 0.001), −0.22 (p < 0.001), and −0.07 (p = 0.02) median log reduction for arms I, II, and III, respectively. No difference in HBsAg decline was observed between treatment arms. However, HBsAg declined more in treatment arms I (p < 0.001) and II (p = 0.002) compared to the control arm III. A strong HBsAg decline of >1.0 log IU/mL was observed in 17 treated patients (21%), but in none of the untreated patients (p < 0.001). No unexpected adverse events were observed in the treatment arms.

Conclusions: In CHB patients with a low viral load, 48 weeks of combination treatment with Peg-IFN and adefovir or tenofovir resulted in 4.4% HBsAg loss, compared to 0.0% in the untreated control group. The significant decline in HBsAg at week 48 may indicate a further increase in the rate of HBsAg loss during treatment-free follow-up. Week 72 results are expected in April 2015.

LIVER-DIRECTED ALLOSTERIC INHIBITORS OF ACETYL-CoA CARBOXYLASE FAVORABLY IMPACT PATHOPHYSIOLOGY IN THE PROGRESSION FROM NAFLD TO NASH AND HEPATOCELLULAR CARCINOMA, INCLUDING HEPATIC STEATOSIS, INFLAMMATION, AND FIBROSIS

W.F. Westlin[1], H.J. Harwood[1], D.K. DePeralta[2], O. Moaven[2], L. Wei[2], J. Greenwood[3], S. Bhat[3], B.C. Fuchs[2], R. Kapeller[1], G. Harriman[1].

Introduction: Dysregulated fatty acid (FA) metabolism occurs via elevated FA synthesis (FASyn), impaired FA oxidation, or both. Acetyl-CoA Carboxylase (ACC) occupies a unique position in FA metabolism, responsible for both increased FASyn and reduced FA oxidation. Pharmacologic inhibition of ACC presents an attractive mode for reducing de novo lipogenesis and enhancing FA oxidation. It has been proposed that hepatic steatosis leads to inflammation and production of toxic lipid oxidation byproducts that drive development of fibrosis, cirrhosis, and hepatocellular carcinoma (HCC). We sought to determine the impact of liver-directed, selective ACC inhibition on the pathological processes involved in the progression from hepatic steatosis to NASH and HCC.

Material and Methods: Recently identified selective allosteric inhibitors of ACC, ND-630 and ND-654, were evaluated to determine the effects of ACC inhibition on the specific pathologies associated with NASH and HCC including hepatic de novo lipogenesis, inflammation, and fibrosis. ND-630 and ND-654 inhibit HepG2 FASyn with EC_{50} of 8.7nM and 4 nM, and hepatic FASyn in vivo with ED_{50} of 0.14 mg /kg and 0.3 mg /kg, respectively.

Results: Chronic inhibition of ACC with ND-630 in an in vivo model of high sucrose diet-induced obesity in rats led to potent inhibition of plasma triglycerides, cholesterol, and free fatty acids, and reduced hepatic triglyceride levels with maximal inhibition on Day 14 at 10 mg /kg. Emerging data demonstrate that ND-654 has potent activity to inhibit tumor formation and prolong survival in the diethylnitrosamine (DEN) model of HCC in male Wistar rats treated weekly with 50 mg /kg DEN to induce sequential development of fibrosis, cirrhosis, and HCC. Importantly, ND-654 significantly (p < 0.01) inhibited HCC development in DEN-injured livers from an average of 15.8 tumor nodules in controls to an average of 7.1 tumor nodules in ND-654-treated rats and prolonged survival by several weeks. Interestingly, recent mechanistic studies in the DEN model of HCC demonstrated that inhibition of ACC produced a dose-dependent decrease in fibrosis as assessed by the collagen proportional area (CPA) of Sirius Red stained histological sections, and a decrease in mRNA for markers of inflammation including α-SMA (a marker of stellate cell activation) and CD-68 (a marker of macrophage infiltration).

Conclusions: These data demonstrate that liver-directed inhibition of ACC can impact multiple steps in the pathophysiological cascade during the progression from fatty liver disease to the more advanced diseases of NASH and hepatocellular carcinoma.

STRENGTHENING VIRAL HEPATITIS SURVEILLANCE IN EUROPE: RECOMMENDATIONS FROM TWO GLOBAL HEPATITIS POLICY SURVEYS (2013 AND 2014)

A. Mozalevskis[1,2], I. Sperle[2], K. Safreed-Harmon[2], I. Eramova[1], M.C. Donoghoe[1], J.V. Lazarus[2]. *[1]World Health Organization (WHO) Regional Office for Europe, [2]WHO Collaborating Centre on HIV and Viral Hepatitis, CHIP, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark*
E-mail: antons.mozalevskis@regionh.dk

Introduction: Weak surveillance is a key barrier to evidence-based and country context-adapted responses to growing hepatitis B and C epidemics. We describe surveillance capacity and identify areas where improvements are urgently needed as reported by governments and civil society (CS) from Member States (MS) of the WHO European Region.

Material and Methods: A descriptive and bivariate (comparison between EU/EEA and non-EU/EEA countries) analysis of responses to surveillance-related questions from the WHO Global Hepatitis Policy Survey (2013) was performed and complemented by analysis of corresponding CS responses collected through the Global Community Hepatitis Policy Survey (2014).

Results: 44 of the 53 European MS (83%) responded to the Global Hepatitis Policy Survey and responses from CS were available for 35 countries. Less than one-third (27%) of MS reported having written national strategies containing a surveillance component. While 43 MS (98%) reported the existence of routine viral hepatitis surveillance, only 64% had a national surveillance system for chronic hepatitis B and 61% for chronic hepatitis C. Moreover, in 11 countries (34%) CS respondents disagreed with their governments on this matter. 80% of MS reported having national registries for liver cancer cases and 66% for HIV/hepatitis co-infection. Although 89% of responding MS reported publishing hepatitis reports regularly, this was challenged by 51% of CS responses. Only 45% of MS reported conducting regular viral hepatitis sero-surveys. Of 32 responding countries implementing universal newborn first dose hepatitis B immunisation, 28% reported that data on vaccination coverage for newborns were not available. Areas in which governments would like assistance from WHO included surveillance (23%), viral hepatitis national burden estimation (34%) and development of national plans for viral hepatitis prevention and control (39%), with a higher proportion of non-EU/EEA countries desiring assistance (p = 0.01, p = 0.097 and p = 0.024, respectively).

Conclusions: Many countries in the WHO European Region face limitations in conducting chronic viral hepatitis disease surveillance, assessing the burden of disease and measuring the impact of interventions. Recent treatment advances make it all the more imperative to mobilise political will to develop comprehensive

national strategies supported by the upcoming WHO Global Strategy on Hepatitis (2016–2021) and technical assistance to MS.

LP32

REAL-WORLD EFFECTIVENESS OF LEDIPASVIR/SOFOSBUVIR 8 WEEKS CHRONIC HEPATITIS C TREATMENT

P. Buggisch[1], J. Petersen[1], K. Wursthorn[1], P. Atanasov[2], A. Gauthier[2]. *[1]IFI Institut für Interdisziplinäre Medizin, Asklepios Klinik St. Georg Haus L, Lohmühlenstr. 5, 20099, Hamburg, Germany; [2]Amaris, London, United Kingdom*
E-mail: petar.atanasov@amaris.com

Introduction: Ledipasvir/Sofosbuvir (LDV/SOF) single tablet regimen (STR) is approved in Europe for the treatment of chronic hepatitis C (CHC) patients with genotypes (GT) 1, 3 and 4. The ION-3 study showed that 8 weeks (8w) of LDV/SOF treatment was non-inferior to 12 weeks in previously untreated GT1 patients without cirrhosis with no benefit for the addition of Ribavirin. According to the SPC 8w may be considered in this population. The aim of the present analysis is to characterise the population receiving 8w LDV/SOF and to describe outcomes in clinical practice.
Material and Methods: The first CHC patients treated with 8w LDV/SOF in a single centre in Germany, and for whom sustained virological response after 4 weeks of follow-up (SVR4) will be available in April, were included in the analysis. Baseline characteristics, prior treatment history, safety and effectiveness were investigated. The analysis was performed using descriptive statistics.
Results: 46 patients met the inclusion criteria for this analysis. These patients initiated 8w treatment with LDV/SOF between 24/11/2014 to 27/01/2015. No patient had ribavirin added to the STR. The mean (SD) age was 50.9 (12.4) years and 56.5% were males. The genotype distribution was 52%, 44% and 4% for GT1a, GT1b and GT4, respectively. At entry, 98% of patients had no cirrhosis, one patient had compensated disease. The METAVIR stage distribution of non-cirrhotic patients at baseline was 39.1%, 32.6%, 19.6% and 8.7% for F0, F1, F2 and F3, respectively. Median (range) HCV RNA at baseline was 5.86 (Q1-Q3 5.38–6.22; Min-Max 3.74–6.67) $\log_{10}$ IU/ml, no patient had HCV RNA ≥6 million IU/mL. No patient was HIV co-infected and one patient was HBV co-infected. Overall, 98% of the patients were treatment-naïve. One patient had relapsed after previous IFN/RBV therapy. At baseline, co-morbidities were reported in 93% of patients, with depression (16%) and arterial hypertension (16%) being most common. Up to date, no discontinuations or relevant Adverse Drug Reactions have been observed. Complete results regarding SVR4, adverse events and discontinuations will be available at the time of presentation.
Conclusions: 8w LDV/SOF is predominantly prescribed according to the SPC for treatment-naïve non-cirrhotic CHC patients with HCV RNA <6 million IU/mL at baseline. Preliminary results indicate that LDV/SOF is a safe, well tolerated treatment option with no adverse drug reactions or discontinuations reported so far.

LP33

EFFICACY OF INTERFERON +/− NUCLEOS(T)IDE ANALOG TREATMENT IN CHILDREN WITH CHRONIC HEPATITIS B, IN THE IMMUNOTOLERANT PHASE CONFIRMED BY LIVER BIOPSY

H. Zhang[1], S. Zhu[1], Y. Dong[1], L. Wang[1], Z. Xu[1], D. Chen[1], Y. Gan[1], F. Wang[1]. *[1]The Pediatric Liver Disease Therapy and Research Center, 302 Hospital, Beijing, China*
E-mail: 302zss@sina.com

Introduction: To investigate the efficacyof interferon (IFN) monotherapy or in combination with nucleos(t)ide analogs (NA) in pediatric patients with chronic hepatitis B (CHB), in the immunotolerant phase.
Material and Methods: Ninety-sevenchildren with CHB (HBeAg-positive and HBV-DNA-positive) aged <18 yrs in the immunotolerant phase were included in the analysis. Immunotolerance was defined as low necroinflammatory activity (G ≤ 1 on liver biopsy, Scheuer score) and ALT <2×ULN (40 IU/L). Patients with HBV-DNA >7 log IU/mL received IFN (IFNα 3–5 MIU/m^2 × body surface area once daily, PegIFNα-2a 104 μg/m^2/wk or PegIFNα-2b 1.5 μg/m^2/wk) plus lamivudine (3 mg/kg/day) or adefovir (2–6 yrs: 0.3 mg/kg/day; 7–11 yrs: 0.25 mg/kg/day; >12 yrs: 10 mg/day). Patients with HBV-DNA ≤7 log IU/mL received IFN monotherapy for 12 wks; if, at Wk 12, HBV-DNA declined ≥2 log IU/mL, treatment was continued, but if HBV-DNA declined <2 log IU/mL, patients received IFN plus lamivudine or adefovir. Treatment duration ranged between 72–144 weeks, with a follow-up period of 24 wks post-end of treatment (EOT).
Results: Majority of patients were male (69%) with a mean age of 7.8 years and mean HBV-DNA of 8.76 IU/mL. Eighteen patients (18.6%) received IFN-monotherapy and 79 (81.4%) received IFN/NA combination therapy. At baseline, 39 (40%) patients had ALT levels <ULN and 58 (60%) between 1–2×ULN withHBeAg seroconversion rates of 56.4% (22/39) and 63.8% (37/58) respectively and HBsAg negative/seroconversion were 33.3% (13/39) and 39.7% (23/58) respectively. A summary of virologic response for all subjects during treatment and follow-up are shown in Table 1. Mean treatment duration was shorter among those who relapsed to HBsAg-positivity during follow-up vs. non-relapsers (99±21 vs. 131±20 wks; p = 0.005). Younger age (1–6 vs. 7–17 yrs) was significantly associated with achieving HBeAgor HBsAgseroconversion (p < 0.05). ALT levels (<1×ULN vs. 1–2×ULN) and history of preventing the vertical transmissionwere not significantly associated with efficacy. The main adverse events included pyrexia (68%), neutropenia (51%, mild), rash (13%), hypothyroxinemia (13%), hyperthyroxinemia (11%), and fatigue (10%).
Conclusions: IFN (IFNα or PegIFNα) monotherapy or in combination with NAs is an effective treatmentin pediatric patients in the immunotolerant phase of CHB.

LP34

EX VIVO LIVER RESECTION AND AUTOTRANSPLANTATION: A FEASIBLE AND HIGHLY EFFECTIVE PROCEDURE FOR PATIENTS WITH END-STAGE ALVEOLAR ECHINOCOCCOSIS – 15 CASES EXPERIENCE

H. Wen[1], J.-H. Dong[2], J.-H. Zhang[1], W.-D. Duan[3], J.-M. Zhao[1], Y.-R. Liang[3], Y.-M. Shao[1], X.-W. Ji[1], Q.-W. Tai[1], T. Li[1], H. Gu[1], T. Tuxun[1], Y.-B. He[1], J.-F. Huang[4]. *[1]Department of Liver & Laparoscopic Surgery, Digestive & Vascular Surgery Center, The First Affiliated Hospital of Xinjiang Medical University, Urumqi, [2]Department of Hepatobiliary Surgery, Beijing Tsinghua Chang Gung Hospital, [3]Hospital & Institute of Hepatobiliary Surgery, Chinese PLA General Hospital, [4]Department of Hepatobiliary Surgery, Peking Union Medical College Hospital, Beijing, China*
E-mail: dr.wenhao@163.com

Introduction: The role of *ex vivo* liver resection and autotransplantation in end-stage hepatic alveolar echinococcosis (HAE) is unclear. We aimed to present our experience and propose a selection criteria for this unique technique in patients with end-stage HAE.
Material and Methods: Fifteen patients with end-stage HAE were considered unresectable by conventional resection due to critical invasion to hepatocaval region along with three hepatic veins and retrohepatic vena cava, as well as the tertiary portal and arterial branches. Detailed information was tabulated and the possible criteria was proposed.
Results: All the 15 patients successfully underwent *ex vivo* extended right hepatectomy and autotransplantation without intra-operative mortality. Synchronous lung lobectomy was performed in two cases. The median autograft weight was 706 g (380–1000g); operative time 15.5 hours (11.5–20.5 hours); anhepatic time 283.8

minutes (180–435 min). Median blood transfusion requirement was 7.9 units (0–15 units). Postoperative hospital stay was 32.3 days (12–60 days). Post-operative complication Clavien-Dindo grade IIIa or higher occurred in three patient including one death occurred 12 days after the surgery due to acute liver failure. One patient had lost follow-up after six month. Thirteen patients were followed-up with median period of 21.6 months with no relapse.

Conclusions: This is the largest reported series of patients with end-stage HAE treated with liver autotransplantation. The technique requires neither organ donor, nor post-operative immune suppressant. The early postoperative mortality was low with acceptable morbidity. Preoperative precise assessment and strict patient selection are utmost important.

LP35

A PLACEBO-CONTROLLED, MULTICENTER, DOUBLE-BLIND, RANDOMISED, PHARMACOKINETIC AND PHARMACODYNAMIC TRIAL OF EMRICASAN (IDN-6556) IN SUBJECTS WITH ACUTE-ON CHRONIC LIVER FAILURE (ACLF)

R. Jalan[1], G. Wright[2], S. McPherson[3], C. Frenette[4], M. Cave[5], M. Morris[6], M. Huyghe[7], G. Burgess[8]. *[1]Institute for Liver and Digestive, HealthUniversity College London, Royal Free Campus, London, [2]Basildon & Thurrock University Hospitals NHS-FT, Basildon, [3]Liver Unit, Freeman Hospital, Newcastle upon Tyne Hospitals NHS-FT, Newcastle upon Tyne, United Kingdom; [4]Medical Director of Liver Transplantation, Scripps Center for Organ Transplantation, San Diego, [5]University of Louisville and Jewish Hospital, Louisville, [6]Conatus Pharmaceutical Inc, [7]Conatus Pharmaceuticals Inc, [8]Conatus, San Diego, United States*

E-mail: gary.c.burgess@gmail.com

Introduction: ACLF is characterized by acute deterioration of liver function in subjects with liver cirrhosis. Commonly precipitated by an acute event, it is associated with extra-hepatic organ failure leading to high in-hospital mortality dependent on severity despite maximal support of failing organs. Serum markers of caspase-driven apoptosis are raised in ACLF subjects. Emricasan is an orally active caspase inhibitor with demonstrated efficacy in animal models of liver disease. Emricasan inhibits caspases involved in the maturation of pro-inflammatory cytokines, IL-1β and IL-18. We studied the PK/ PD and safety of emricasan and its effect on caspase activity and apoptosis in subjects with ACLF.

Material and Methods: 21 Subjects with ACLF-1 and -2 were randomised to receive oral emricasan 5 (n = 5), 25 (n = 7) and 50 mg (n = 5), or pbo (n = 4) BID for 28 days. Full PK/PD profiles were obtained on Days 1, 4 and 28. Clinical responders as defined in the table were evaluated at Day 28 or last known follow up.

Results: 7 subjects completed the study: pbo (n = 2), 25 (n = 3) and 50 mg (n = 2). 6 subjects died [pbo (n = 2), 5 (n = 1), 25 (n = 1) and 50 mg (n = 2) respectively] by Day 28; 13/21 subjects reported serious AEs, none of which were considered treatment related. Emricasan blood levels were increased at all doses compared to previous patient populations studied. Baseline values of cCK18 and Caspase 3/7 were significantly higher in ACLF compared to previous populations studied. Clinical responders generally experienced at least 30% reduction in cCK18 and rises in CK18 during the study were generally associated with disease related adverse events. Oral emricasan 25 and 50 mg BID reduced cCK18, flCK18 and Caspase 3/7 levels within 24h post dose by at least 30% in most subjects but only the 50 mg group experienced sustained reductions in cCK18 over the entire dosing period in the majority of subjects. The median reduction in the 50 mg group on Day 1 was 54% compared with 7, 13 and 44 in the pbo, 5 and 25 mg groups respectively.

Conclusions: Biomarkers of apoptosis and caspase activity (cCK18, flCK18, Caspase 3/7) were implicated in ACLF and disease severity, and appeared associated with patient outcome. Emricasan was well tolerated. Increases in cCK18 levels appeared to be associated with disease-related adverse clinical events. The combined PK/PD data suggest higher doses of emricasan may be required in ACLF in future studies to achieve sustained reductions in disease relevant biomarkers.

Introduction: The new prenylation inhibitor lonafarnib (LNF) is a potent antiviral agent that provides a breakthrough for the treatment of HDV and an opportunity to further characterize HDV and hepatitis B surface antigen (HBsAg) dynamics during effective treatment with an oral anti-HDV agent.

Material and Methods: HDV RNA and HBsAg kinetic data were obtained from a Phase 2a study in which 12 patients were treated with LNF 100 mg twice daily (n = 6, Group 1) or 200 mg twice daily (n = 6, Group 2) for 28 days. Blood samples were

Table (abstract LP35): Clinical responders

Criteria	Treatment group assignment				
	Placebo (n = 4)	5 mg BID (n = 5)	25 mg BID (n = 7)	50 mg BID (n = 5)	All subjects (n = 21)
Survival at Day 28 or last known follow-up	2	3	3	3	11
CLIF-SOFA score (improvement by 2 points from baseline)	1	3	2	1	7
MELD score (improvement by 5 points from baseline)	1	2	3	2	8
Total bilirubin (improvement by ~50% from baseline)	2	3	2	1	8
Number of responders	2	3	3	3	11

collected frequently during the first 72 hr, and then weekly until day 28. Viral decline slopes and transition time were estimated by segmented linear regression. A dual mathematical model (Hepatology 2014;60:1902–10) that couples both HDV and HBsAg kinetics was used for the estimation of the LNF pharmacological delay, t_0, HDV clearance rate (c) and LNF effectiveness in blocking HDV production, ε.

Results: The median pretreatment serum HDV RNA and HBsAg levels were estimated as 5.97 (standard error, se = 0.13) log IU/mL and 4.17 (se = 0.12) log ng/mL. While HBsAg remained unchanged, a biphasic decline in HDV RNA during therapy was characterized in all LNF-treated patients, with a first rapid decline phase followed by a second slower decline (or plateau) phase. A short pharmacological delay of t_0=0.73 (se=0.24) day, in which HDV remained at baseline levels, was not associated with LNF dose. The HDV clearance rate in the serum, *c*, was estimated as 0.426 (se=0.04) d^{-1}, corresponding to an HDV half-life of 1.63 (se=0.15) days. LNF effectiveness in blocking HDV production was significantly ($p < 0.001$) higher in Group 2 [ε = 0.952 (se = 0.057)] than Group 1 [ε = 0.739 (se = 0.05)].

Conclusions: The observed stable HBsAg level during LNF treatment suggests that the productively HDV-infected cell number remained unchanged during this relatively short treatment period. The effectiveness of the 200 mg LNF dose in blocking HDV production (ε = 95%) is similar to that previously estimated in patients treated with pegIFN (ε = 96%) [Hepatology 2014; 60: 1902–10]. A strikingly shorter delay was observed with LNF (t_0 = 0.73 day) compared to HDV-infected patients treated with pegIFN (t_0 = 8.5 day), and the refined estimate of HDV $t_{1/2}$ = 1.4 day was about 2-fold shorter than under pegIFN ($t_{1/2}$ = 2.9 day). These findings suggest that LNF might have two mechanisms of action – blocking viral production and assembly/secretion, reminiscent of the dual mechanism of action observed with an HCV NS5A inhibitor [PNAS 2013; 110: 3991–6].

LP37

A PLACEBO-CONTROLLED, MULTICENTER, DOUBLE-BLIND, RANDOMISED TRIAL OF EMRICASAN IN SUBJECTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD) AND RAISED TRANSAMINASES

M. Shiffman[1], B. Freilich[2], R. Vuppalanchi[3], K. Watt[4], G. Burgess[5], M. Morris[5], B. Sheedy[6], E. Schiff[7]. *[1]Liver Institute of Virginia, Bon Secours Health System Richmond and Newport News, Richmond and Newport News, [2]Kansas City Research Institute, Kansas City, [3]3 Division of Gastroenterology and Hepatology, Indiana University School of Medicine, Indianapolis, [4]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, [5]Conatus Pharmaceuticals Inc, [6]Conatus Pharmaceuticals, San Diego, [7]Division of Hepatology, University of Miami, Miami, United States*
E-mail: gary.c.burgess@gmail.com

Introduction: NAFLD and its inflammatory/fibrotic subgroup of non-alcoholic steatohepatitis (NASH), can be considered the hepatic manifestations of the metabolic syndrome and is perhaps the most common cause of chronic liver disease in the US. NASH can progress to cirrhosis, liver failure and increased risk of hepatocellular cancer. Currently, no drugs are approved for the treatment of liver disease associated with NAFLD or NASH. Emricasan (IDN-6556) is an orally available irreversible pan-caspase inhibitor. Caspases are proteases responsible for executing apoptotic pathways, or programmed cell death, and for activation of cytokines (IL-1β and IL-18). Both caspase-mediated apoptosis and inflammation have been shown to play important roles in the development and progression of liver disease associated with NAFLD and NASH. Emricasan has demonstrated efficacy in a number of animal models of liver disease and was also protective in models of NAFLD/NASH where it reduced steatosis, inflammation, apoptosis and fibrosis, suggesting disease-modifying potential. The current study evaluated safety and the impact of emricasan treatment on generic and mechanism specific biomarkers in NAFLD/NASH subjects with elevated liver enzymes.

Material and Methods: Thirty eight subjects with proven NAFLD/NASH and raised ALT (≥1.5×ULN on 2 occasions at least 7 days apart) were entered into the study and randomly assigned to receive oral emricasan 25 mg BID or placebo for 28 days. Subjects were then followed up for an additional 28 days post study for safety assessment. Subjects on statins, fibrates, sulfonylureas and/or metformin were required to be on stable doses of drug for 3 months prior to study entry and for the study duration. The primary endpoint in the study was change from Baseline in ALT at Day 28. Key secondary endpoints included change from Baseline in AST, cCK18, flCK18, caspase 3/7 and HOMA-IR.

Results: All subjects completed the study and the database will be locked in March 2015. The study results will be available for presentation at the meeting.

Conclusions: Effects of emricasan on raised transaminases, caspase activity and markers of apoptosis in subjects with NAFLD/NASH will be discussed in the context of the potential to use this etiology-specific response information to guide future studies in subjects with more advanced liver disease.

Introduction: Patients with hepatitis C virus (HCV) recurrence after orthotopic liver transplantation (OLT) have a high need of antiviral therapy due to accelerated progression of the disease. IFN-free regimens revealed promising efficacy and safety data in clinical studies. We evaluated real-life experience of efficacy and safety of all-oral regimens in patients with HCV-recurrence after OLT.

Material and Methods: 77 OLT-patients and 5 with liver/kidney-transplantation started an all-oral anti-HCV treatment. 68 beyond treatment-week 4 were analyzed (male: 54/79%, age: 59±9 [33–78] years, GT-1: 51 [1a: 13; 1b: 35; 1g: 1, no subtype: 2]; GT-3a: 10; GT-4: 6 [h: 1]; missing: 1). Time from OLT to treatment was 77±67 months. 7 patients had fibrosing cholestatic hepatitis (FCH), 37 cirrhosis (CPS-A: 31; CPS-B/C: 6), 47/69% were treatment-experienced. 53/78% patients received immunosuppression with calcineurin-, the others with mTor-inhibitors.

Treatment regimens were: Sofosbuvir (SOF) with ribavirin (RBV): 18 (27%), SOF/Daclatasvir (DCV): 39, SOF/Simeprevir (SIM): 7, SOF/Ledipasvir (LDV): 3; one patient received SIM/DCV. HCV-RNA-quantification was performed with Abbott Real*Time* HCV ([ART], lower limit of quantification [LLOQ]: 12 IU/ml) or Roche COBAS AmpliPrep/COBAS TaqMan assay (LLOQ: 15 IU/ml).

Results: At present 51 patients reached end-of-treatment and 33 end of follow up. Overall SVR12 rate was 29/33 (88%; see table). 2 FCH-patients died at weeks 8 and 20, respectively. Two patients interrupted treatment before week 12; one was transplanted at week10, the other was hospitalized for hepatic encephalopathy;

treatment was stopped at week8, but the patient reached SVR12. No episode of graft rejection was observed. Compared to baseline (BL) in SVR12-patients transaminases (BL/SVR12: ALT: 139±94.3 *vs.* 44±43.2; AST:133±105 *vs.* 44±48, $p < 0.001$) decreased, platelets (133±72.3 *vs.* 177±77.9 G/L [p = 0.037]), and serum-albumin (34.5±12.3 *vs.* 12:40.6±5.6 g/L [p = 0.048]) increased.

	Week 4 (68 evaluated [100%])		Week 12 (57 evaluated [83.8%])		SVR12 (33 evaluated [49%])
	TnD, n (%)	<LLOQ, n (%)	TnD, n (%)	<LLOQ, n (%)	n (%)
SOF/DCV [a]	12 (67%)	10 (43%)	22 (47%)	5 (71%)	14 (100%)
SOF/RBV	4 (22%)	7 (30%)	15 (32%)	1 (14%)	8 (89%)
SOF/SIM	2 (11%)	2 (9%)	6 (13%)	1 (14%)	4 (80%)
SOF/LDV [b]	–	3 (13%)	3 (6%)	–	3 (100%)
SIM/DAC	–	1 (4%)	1 (2%)	–	0 – relapse
Total	18 (26.5%)	23 (33.8%)	47 (83%)	7 (12%)	29 (88%)

EoT, end of treatment; SVR12, sustained virological response/week 12 follow-up; TnD, target not detected.
[a] + RBV in 1 patient.
[b] + RBV.

Conclusions: Real life-data of IFN-free DAA-based regimens in OLT-patients with HCV-recurrence show high on-treatment and SVR-rates with favorable safety-profile. Additionally, patients with successful treatment experienced improvement of graft function.

LP39

IMPLICATIONS OF BASELINE HCV RNA LEVEL AND INTRAPATIENT VIRAL LOAD VARIABILITY ON OBV/PTV/R + DSV 12-WEEK TREATMENT OUTCOMES

R.S. Brown[1], M. Puoti[2], C. Cooper[3], D.L. Wyles[4], T.E. Sepe[5], R.G. Nahass[6], M. King[7], E. Coakley[7], B.H. McGovern[7], J.J. Feld[8].

E-mail: laurinda.cooker@abbvie.com

Introduction: High levels of pre-treatment HCV RNA may impact the risk of virologic relapse post-treatment. Within the ombitasvir/paritaprevir*/ritonavir and dasabuvir (3D) development program, we examined the effect of viral load on the risk of virologic relapse within various HCV RNA strata.
Material and Methods: Non-cirrhotic treatment-naïve HCV-infected patients who received 12 weeks of 3D (GT1b) or 3D+RBV (GT1a) were included in the analysis. Post-treatment relapse rates were summarized by pre-treatment HCV RNA thresholds. Intrapatient HCV RNA measurement variability was assessed by evaluating differences in HCV RNA levels between screening and baseline (median interval=3 weeks). Plasma samples were analyzed at a central laboratory using the Roche COBAS® TaqMan® RT-PCR assay v2.0.
Results: Among 618 patients, median baseline HCV RNA was 6.56 $\log_{10}$ IU/mL (3.6 million [M] IU/mL); 7/618 (1.1%) had post-treatment relapse. There was no association between baseline HCV RNA and relapse rate for any threshold (Table), with relapse rates of 1.2% and 0.9% below and above baseline HCV RNA of 10 million IU/mL, respectively. In patients who achieved SVR12 or relapsed, the median baseline HCV RNA was 6.55 and 6.66 $\log_{10}$ IU/mL, respectively (p = 0.2). No relapses were observed for any patient with viral load <2.5M IU/mL. Intrapatient variability in HCV RNA measurements increased with rising baseline viremia. Screening and baseline HCV RNA measurements differed by >1M IU/mL in 55%, by >2M IU/mL in 35%, and by >3M IU/mL in 26% of patients. In the subset of patients with a screening HCV RNA above 2M IU/mL, 79% differed by >1M IU/mL, 53% differed by >2M IU/mL, and 40% differed by >3M IU/mL. At the 6M IU/mL threshold, 18% of patients had discordant baseline and screening HCV RNA values.

Table: Relapse rates according to baseline HCV RNA thresholds chosen based on recent FDA analysis

Threshold	Below threshold	Above threshold
1 million IU/mL	0/157 (0%)	7/461 (1.5%)
1.5 million IU/mL	0/201 (0%)	7/417 (1.7%)
2 million IU/mL	0/223 (0%)	7/395 (1.8%)
2.5 million IU/mL	0/248 (0%)	7/370 (1.9%)
3 million IU/mL	1/269 (0.4%)	6/349 (1.9%)
3.5 million IU/mL	1/302 (0.3%)	6/316 (1.7%)
4 million IU/mL	2/324 (0.6%)	5/294 (1.2%)
5 million IU/mL	4/373 (1.1%)	3/245 (1.2%)
6 million IU/mL	4/410 (1.0%)	3/208 (1.4%)
7 million IU/mL	5/443 (1.1%)	2/175 (1.1%)
8 million IU/mL	5/467 (1.1%)	2/151 (1.3%)
9 million IU/mL	5/489 (1.0%)	2/129 (0.9%)
10 million IU/mL	6/502 (1.2%)	1/116 (0.9%)
Total	7/618 (1.1%)	

Conclusions: With this multi-targeted regimen, we did not identify any viral threshold for risk of relapse, suggesting that 12 weeks of therapy is optimal for minimizing the risk of relapse in naïve, non-cirrhotic patients, regardless of underlying host or viral factors. Intrapatient variability in HCV RNA measurements was common, suggesting that a subset of patients may be misclassified if viral thresholds are important for clinical decision-making.
*Paritaprevir was identified by AbbVie and Enanta.

LP40

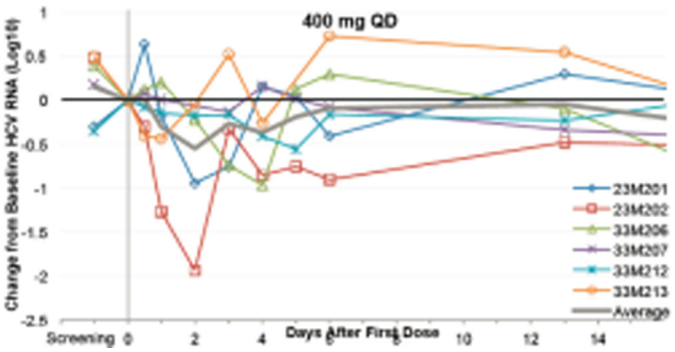
SB 9200, A NOVEL IMMUNOMODULATOR FOR PATIENTS WITH VIRAL HEPATITIS: PHASE 1 MAD STUDY IN PATIENTS WITH HEPATITIS C VIRUS (HCV) INFECTION

A. Thompson[1], S. Roberts[2], W. Cheng[3], P. Angus[4], K. Visvanathan[5], R. Iyer[6], M. Barclay[7]. *[1]Gastroenterology, St Vincent's Hospital and the University of Melbourne, [2]Gastroenterology, Alfred Hospital and Monash University, Melbourne, [3]Gastroenterology, Royal Perth Hospital, Perth, [4]Gastroenterology, Austin Hospital, [5]Innate Immunology, St Vincent's Hospital and the University of Melbourne, Melbourne, Australia; [6]Spring Bank Pharmaceuticals, Inc, Milford, MA, United States; [7]Gastroenterology & Clinical Pharmacology, Christchurch Hospital and University of Otago, Christchurch, New Zealand*
E-mail: alexander.thompson@svhm.org.au

Introduction: The immune response has an important role in the clearance of HCV even in the era of highly potent direct acting antivirals (DAA's) particularly as shorter durations of therapy are explored. SB 9200 is a novel agonist of innate immunity that activates intracellular RIG-1 and NOD2, the cytosolic viral sensors that are important for the regulation of the innate immune response and activation of intracellular interferon (IFN) signaling pathways. SB 9200, a pangenotypic anti-HCV agent, is an oral dinucleotide prodrug that is enzymatically converted to the active Rp-, Sp-SB 9000 isomers in vivo.
Material and Methods: This was a first in man randomized, placebo-controlled, multiple ascending dose study of SB 9200 in treatment-naïve HCV infected adults. Subjects were randomized 6:2 to SB 9200 or placebo for 7 days. Doses evaluated were: 200 mg (N = 8), 400 mg (N = 8), 900 mg (N = 8 HCV-1, N = 6 HCV-3).
Results: Increases in SB 9200 AUC0-t and Cmax were dose-proportional. The terminal plasma half-life (t1/2) on Days 1 and 7 ranged from 0.684 to 1.07 hours for SB 9200, and was slightly longer for the metabolites: Sp-SB 9000 t1/2 was 4.65–8.90 hours, Rp-SB 9000 t1/2 was 4.31–5.94 hours.
SB 9200 Cmax ranged from 0.531 to 6.66 ng/mL at 0.817 and 3.00 hours. Sp-SB 9000 Cmax ranged from 7.13 to 22.0 ng/mL at 1.00 and 12.0 hours. Rp-SB 9000 Cmax ranged from 4.32 to 14.7 ng/mL at 1.00 and 12.0 hours.

Peak individual viral load drop improved from 1.5 to 1.9 $\log_{10}$ when the dose increased from 200 to 400 mg (Figure). Further dose increases did not result in response increases. Inter-individual variability in antiviral response was observed. A significant relationship between SB 9200 Cmax and maximum suppression of HCV RNA on Day 7 was observed (p = 0.015) after exclusion of two subjects with extreme Cmax values for SB 9200.

73 adverse events (AEs) were reported by 25 subjects (83.3%), mostly mild in severity. No dose limiting toxicities or systemic interferon-like side effects were observed and no serious adverse events were reported. There was no relationship between incidences, severity or relationship of AEs and dose of SB 9200 received or placebo.



Conclusions: SB 9200 is a novel oral agonist of innate immunity which achieves therapeutic concentrations of the drug upon once daily administration. Results of this study suggest an anti-viral effect similar to IFN, but without systemic side effects. SB9200 is a novel anti-HCV agent that merits further evaluation in combination trials with DAAs.

LP41

LIVER FIBROSIS EPIDEMIOLOGY REVISITED USING SOFTWARE COMBINED BIOMARKER: PROOF OF CONCEPT USING 1,081,658 CENTRALIZED FIBROTEST (FT) PRESCRIPTIONS

T. Poynard[1,2,3], O. Deckmyn[4], J. Sebastian[5], M. Munteanu[4], Y. Ngo[4], F. Drane[4], J. Queen[5], J.M. Castille[4], on behalf of FibroFRANCE.
[1]Groupe Hospitalier Pitié Salpêtrière APHP, [2]UPMC, [3]INSERM UMR S938, [4]BioPredictive, Paris, France; [5]Labcorp, Burlington, United States
E-mail: tpoynard@teaser.fr

Introduction: The epidemiology of liver fibrosis (LF) was classically described by liver biopsy (LB), therefore limited by bias of LB indication and sample size. Several LF biomarkers have been validated including FT (AIM 2013). We aimed to revisit the epidemiology of LF using the centralized software-combined database (DB) of FT, for assessing the impact of age and sex on LF severity (LFS) as well as the impact of health policy for screening LFS.

Material and Methods: From 2002 to 2014, 1,081,658 interpretable FT, were performed consecutively on fresh serum, mostly for chronic hepatitis C (CHC). In 5 countries, France (Fr), USA, Romania (Ro), Egypt (Eg) and Morocco (Ma), we compare (R software): LFS (METAVIR scoring system F0 to F4 and cirrhosis severity F4.1 compensated, F4.2 bleeding-risk and F4.3 complicated, J Hepatol 2014), the density of LFS according to birth-year (BY) and sex, and the progression of FT dissemination. We used as controls a DB of CHC with LB (Lancet 1997 n = 2235, Gastro 2002 n = 4177).

Results: F4 prevalence varied from 13.8% (Ro), 14.9% (Fr), 18.1% (USA), 22.1% (Ma) to 28.2% (Eg). In France, FT was commonly prescribed, with stable rates since reimbursement (2006); a high number of F4 was detected in women born before 1945 (n = 20,672). In USA, FT (FibroSure) rate dramatically increased in 2013–2014 when the baby-boomer campaign (BY 1945–1965) started, vs 2011–2012 (+132%). In multivariate regression analysis, adjusted for age (OR = 1.06) and sex (0R=3.22) and USA as reference (OR = 1), Eg had the higher risk (OR = 2.3;2.2–2.3) possibly due to associated schistosomiasis; then Ma (OR = 1.3;1.2–1.3) and Ro (1.1;1.1–1.2; masked in univariate (younger age) and lower risk for Fr (0.90; 0.88–0.91); All $P < 10^5$. Sensitivity analyses (excluding age-sex-FT standardization, repeated FT, non-CHC) observed similar results. Associations between LFS age and sex were similar in LB-DB.

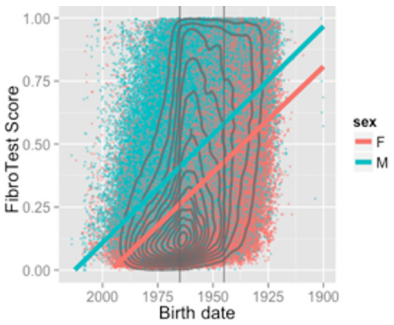


Figure: Density of LFS, according to BY and sex, in Fr (n = 513,762), USA (263,422), Ro (49,812), Eg (34,168) and Ma (16,542). Blue (men) and red lines (women) were regression lines LF/age; vertical black lines were 1945–1965 cutoffs, concentric black lines were density-10percentiles.

Conclusions: Despite possible bias associated with patented biomarker prescription, this proof-of-concept study permitted already to prepare better strategies to reduce the burden of cirrhosis, based on 200 times more patients than biopsy. The first interpretation for France is to prevent without delay a massive burden of death in women born before 1945.

LP42

SAFETY AND EFFICACY OF NOVEL ANTIVIRALS IN KIDNEY TRANSPLANT RECIPIENTS WITH CHRONIC HEPATITIS C VIRUS (HCV) INFECTION

M.V. Lin[1], M.E. Sise[2], M. Pavlakis[3], J.M. Hanifi[4], A.E. Rutherford[1], N. Elias[5], E.C. Heher[2], M.P. Curry[6], L.V. E-mail: mvlin@partners.org

Introduction: Interferon and ribavirin are the mainstay therapy for HCV infection in the post-renal transplant (tx) population. Low treatment efficacy, side effects and concern for interferon-induced acute rejection have limited their use. Several oral direct-acting antivirals (DAA) were recently approved for HCV therapy and have demonstrated high efficacy and good safety profile in the non-tx population. To date, there are no studies evaluating the safety, efficacy, or viral kinetics of DAAs in the renal tx population, thus we sought to characterize our experience with DAA therapy in renal tx recipients.

Material and Methods: Retrospective chart review was conducted on post-renal tx pts with HCV who initiated DAAs between 12/2013–10/2014 at 3 sites. Demographics, clinical information and laboratory values were collected. The primary end point was sustained virologic response (SVR) at 12 wks post-treatment (Rx) (SVR12).

Results: Fifteen pts completed DAA therapy. Mean age was 55.8 yrs (range 34–70 yrs); 80% were male; 53% White, 20% Hispanic, 14% Asian and 13% Black. Mean BMI was 27 (range 21.5–45.5); 73% had diabetes and 87% had hypertension. Genotype distribution: 1a (67%); 1b (13%); 1 without subtype (13%); 2 (7%). Seven pts were Rx naïve; 4 were non-responders; 3 were relapsers; 1

Table 1 (abstract LP42). HCV viral loads and laboratory values at the various treatment time points

	Baseline	Week 4	Week 12	12 weeks post-Rx	p-value [a]
HCV RNA	3.35 million IU/mL (mean) 1060 to 19 million IU/mL (range)	Non-detected: 6 pts (46%) Detected: 7 pts (54%)	Non-detected: 12 pts (100%) Detected: 0 pt	Non-detected: 10 pts (83%) Detected: 2 pts (17%)	
Creatinine (mg/dL), mean (range)	1.26 (0.81–1.76)	1.41 (0.87–2.0)	1.34 (0.98–1.80)	1.40 (0.99–1.99)	0.07
ALT (U/L), mean (range)	86 (14–416)	27 (7–79)	21 (9–58)	31 (7–147)	0.02
Total bilirubin (mg/dL), mean (range)	0.78 (0.30–1.5)	1.05 (0.20–3.5)	0.70 (0.20–1.3)	1.21 (0.20–7.6)	0.5

[a] Calculated based on the comparison between the baseline and 12 weeks post-Rx values.

discontinued Rx. Six pts (40%) had cirrhosis and two (33%) had hepatic decompensation. Nine had kidney tx, 4 pts had combined kidney/liver tx and 2 pts had kidney/pancreas tx. DAA regimens included sofosbuvir (SOF)/simeprevir (SMV) in 9 pts, SOF/SMV/Ribavirin (RBV) in 3 pts, SOF/RBV in 2 pts and SOF/ledipasvir in 1 pt. All were treated for 12 wks. At the time of data analysis, 12 pts (100%) had undetectable end-of-treatment HCV RNA; 10 pts (83%) achieved SVR12 and 2 pts relapsed. The 2 relapsers were black, genotype 1a, had advanced fibrosis/cirrhosis, and received SOF/SMV. Four pts (27%) had potential Rx related side-effects: gout flare, diarrhea, photosensitivity and foot/calf pain. None led to Rx discontinuation. Two pts had worsening proteinuria awaiting work-up. Mean ALT was lower at post-Rx wk 12 and creatinine was not significantly different (Table 1). Calcineurin inhibitor trough levels were stable in all pts and there was no observed allograft rejection.

Conclusions: This is the first reported series of DAA use in renal tx recipients. These agents were efficacious (SVR12 83%), safe and well tolerated in this population. Viral relapse is uncommon and was only observed in pts with HCV genotype 1a and advanced fibrosis/cirrhosis.

LP43

WHAT IS REQUIRED FOR CONTROL AND ELIMINATION OF HEPATITIS B GLOBALLY?

S. Nayagam[1], M. Thursz[1], S. Wiktor[2], D. Low-Beer[3], T. Hallett[4].

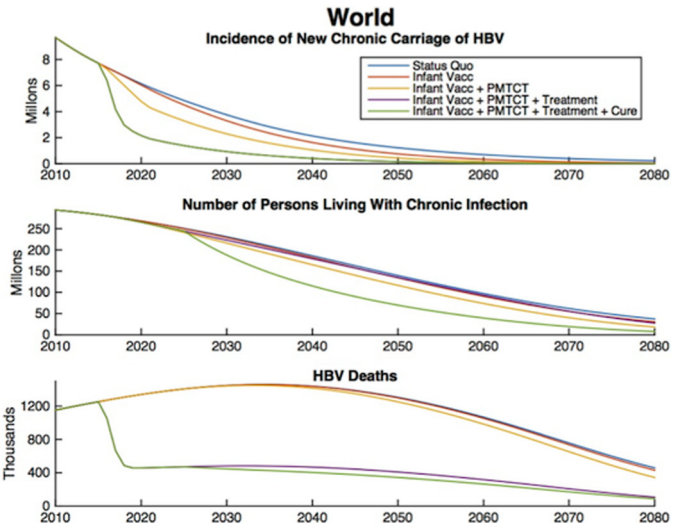
E-mail: s.nayagam01@imperial.ac.uk

Introduction: Despite the availability of a safe and effective vaccine and treatment, variability of coverage means that HBV still accounts for up to one million deaths annually worldwide. Our aim was to evaluate the potential impact of scaling up interventions against HBV, set realistic targets for elimination of transmission and mortality due to HBV and identify key developments needed to achieve them.

Material and Methods: A dynamic, age, sex and region-structured mathematical model of the worldwide HBV epidemic was constructed incorporating data on epidemiology, vaccination coverage, treatment, regional demography and the natural history of HBV. The model was used to generate predictions regarding incidence of new chronic HBV infections, prevalence and HBV related mortality under assumptions that interventions remain at current levels ('status quo'). We then used the model to estimate the impact of scaling up of both prevention and treatment interventions, to establish what would be sufficient to bring HBV to the threshold of control and elimination by 2030.

Results: The scale-up of infant HBV vaccination to date, is already driving a decrease in new infections, and if maintained at current levels, will have averted 1.2M deaths by 2030. This will also result in a greater proportion of transmission being mother-to-child. Without further intervention, the number of persons living with HBV will remain at the same current high levels for the next 40–50 years and there will be 20M HBV-related deaths by 2030. However, a 90% reduction in incidence of new chronic infections and 65% reduction in mortality could be achieved by 2030 with the scale-up of existing interventions: >95% coverage of infant vaccination, 80% coverage of birth dose vaccine and 73% coverage of treatment for all those eligible (implemented from c. 2020). This would amount to 13M deaths averted worldwide by 2030, including 6M cases of cancer. The global cost is forecast to peak at $7.5B annually but decline rapidly after 2030, and could be accelerated if a cure is developed.



Conclusions: The fight against HBV through universal infant vaccination has scored major victories in reducing new infections in some settings but, without further intervention, prevalence and mortality will remain high for decades. However, expansion of vaccination and treatment could significantly reduce deaths and transmission. Although the costs are high, they peak at lower values and decline more rapidly than those projected for other infectious diseases with similar burden.

PHAGOCYTOSIS: HOW THE BEGINNING PROGRAMS THE END IN THE DAMAGED LIVER

L. Campana[1], A. Pellicoro[1], R. Aucott[1], S. Greenalgh[1], S. Anderton[1], J.P. Iredale[1]. [1]*CIR, University of Edinburgh, Edinburgh, United Kingdom*
E-mail: laroz10.84@gmail.com

Introduction: Phagocytosis is a multi-step process that allows the elimination of harmful and dead cells. Professional phagocytes are immune cells, e.g. macrophages, endowed with the ability to process the cargo and present the antigens. Phagocytosis shapes the adaptive immune response and the local microenvironment, generating an anti-inflammatory milieu. The fine tuning of the anti-inflammatory process are not fully understood. In the fibrotic liver two major populations of macrophages exist: inflammatory and restorative macrophages. The formers are recruited at the onset of the injury and the latters mediates fibrosis remodeling later. Our hypothesis is that phagocytosis shapes the switch of the phenotype of inflammatory macrophages to restorative macrophages.

Material and Methods: We have performed *in vitro* and *in vivo* assays using a mouse model defective for the expression of Gpnmb, a protein involved in the formation of the phagosome. Macrophages

from Gpnmb$^-$ mice are able to ingest the cargo but not to process it. As *in vivo* model of liver fibrosis we have used the chronic administration of CCl_4. After CCl_4 withdraw mice experience a fibrotic phase dominated by inflammatory macrophages, followed by a phase of fibrosis remodelling characterised by restorative macrophages.

Results: Gpnmb$^-$ mice show a higher level of plasma transaminases in the phase of fibrosis remodelling, associated with higher proliferation of hepatocytes and higher levels of inflammatory cytokines in the tissue. Concomitantly, Gpnmb$^-$ mice show a lower number of macrophages and T cells. Flow cytometry analysis unveils a skew to a pro-inflammatory phenotype in the recovering liver but not in circulating monocytes. The role of IL6 as pro-proliferative to hepatocytes is established but its regulatory role on phagocytosis is unknown. Both *in vivo* and *in vitro* IL6 shows a pro-phagocytic effect and this effect seems to be mediated by the activation of the STAT3 pathway. After a single CCl4 injection the fraction of phagocytic macrophages in the liver of Gpnmb$^-$ mice increases from 25% to 85% when IL6 is co-administered ($n = 5$, $p < 0.01$, two-way ANOVA followed by Bonferroni's post-hoc test).

Conclusions: Our data suggest that phagocytosis could be the gatekeeper between the phase of initial inflammation and the phase of tissue remodelling and that IL6 could mediate this activity.

Introduction: Chronic hepatitis B virus (HBV) infection is an important cause of liver-related morbidity and mortality worldwide. Impairment of Toll-like receptor (TLR) signalling by the hepatitis B surface antigen (HBsAg) is supposed to attenuate immune responses, thereby facilitating chronicity of infection. Aim of this study was to characterize immune activation in different HBV transgenic mouse strains expressing or lacking the HBsAg.

Material and Methods: Mice expressing the HBsAg (Alb/HBs), mice replicating the complete viral genome but lacking HBsAg (Tg1.4HBV-S-Mut3) and the crossbreed strain (Alb/HBs x Tg1.4HBV-S-Mut3) expressing all viral proteins (HBV-s-rec) were analyzed. HBxAg-targeting small interfering RNAs (siRNAs) or TLR3 ligand polyinosinic-polycytidylic acid (Poly[I:C]) were injected intravenously into Tg1.4HBV-S-Mut3 mice, their HBV-negative littermates, and TLR3$^{-/-}$ and Tg1.4HBV-S-Mut3/TLR3$^{-/-}$ mice. Levels of immune-related genes, HBV DNA, HBcAg, HBeAg, and HBsAg were determined in primary liver cells, liver tissue and serum, respectively.

Results: Tg1.4HBV-S-Mut3 mice but not the HBsAg-recovered strain (HBV-s-rec) exhibited an increased and hepadnaviral replication-dependent expression of interferon beta (IFN-β), interferon-sensitive gene 15 (ISG15), and interferon-induced protein with tetratricopeptide repeats 1 (IFIT1). This antiviral response could be normalized by treatment with HBxAg-targeting siRNA and was completely abrogated in Tg1.4HBV-S-Mut3/TLR3$^{-/-}$ animals. Here, the lack of TLR3 signaling led to increased HBV replication. The HBV replication-induced TLR3 response was confined to non-parenchymal liver cells (NPC). Administration of Poly(I:C) further induced the expression of IFN-β, ISG15, and IFIT1 and thereby suppressed HBV replication *in vivo* and *in vitro*. However, induction of these antiviral genes was significantly lower in Tg1.4HBV-S-Mut3 mice than in control animals, a finding indicating HBs-independent immune evasion.

Conclusions: In contrast to HBV-infected patients mouse models for HBV infection show weak antiviral signals. The present data demonstrate that in the absence of HBsAg hepatic HBV replication leads to TLR3-dependent IFN responses mediated by NPC. We therefore hypothesize that HBsAg is the main evasion mechanism of HBV that controls antiviral innate responses in the liver.

OCCULT HBV IS HIGHLY PREVALENT IN PATIENTS WITH INTRAHEPATIC CHOLANGIOCARCINOMA AND IT IS DETECTED AS BOTH FREE EPISOMAL AND INTEGRATED DNA

T. Pollicino[1], C. Musolino[2], G. Tripodi[2], M. Lanza[2], G. Raffa[2], C. Saitta[2], S. Benfatto[1], C. Beninati[1], G. Navarra[3], P. Invernizzi[4], D. Alvaro[5], G. Raimondo[2]. *[1]Pediatric, Gynecological, Microbiological, and Biomedical Sciences, [2]Clinical and Experimental Medicine, [3]Human Pathology, University Hospital of Messina, Messina, [4]Autoimmune Liver Diseases, Humanitas Clinical and Research Center, Milan, [5]Department of Medico-Surgical Sciences and Biotechnologies, Polo Pontino, Rome, Italy*
E-mail: tpollicino@unime.it

Introduction: Intrahepatic cholangiocarcinoma (ICC) is a fatal primary liver cancer with very poor prognosis. Genome-wide studies have made major advances in understanding the molecular basis of this disease, although most aspects remain unclear. Accumulating evidence indicates that chronic HBV infection is associated with an increased risk of ICC development and suggests an etiological role of HBV in the development of this tumor. Aims of the study were to investigate whether occult HBV infection (OBI) could be involved in ICC development and to characterize the molecular status of HBV in OBI-positive ICC specimens.

Material and Methods: Frozen paired tumor and non-tumor tissue specimens from 40 HBsAg-negative patients with ICC, who underwent surgical resection were tested for OBI by 4 different HBV-specific nested PCR. To reveal HBV cccDNA, DNA extracts were digested with a plasmid-safe ATP-dependent DNase and amplified by nested PCR with cccDNA-specific primers. Finally, for the detection of HBV DNA integrations the Alu-PCR technique was coupled to deep-sequence analysis.

Results: HBV genomic sequences were detected in tumor and/or non-tumor specimens from 28 of the 40 (70%) ICC patients analysed. In particular, 20/40 (50%) tumors and 13/23 (56.5%) non-tumor tissues were HBV DNA positive. HBV cccDNA was detected in tissue specimens from 10/28 OBI-positive patients (36%) (both in tumor and non-tumor specimens in 3 patients; only in tumor tissues in 4 patients; only in non-tumor tissues in 3 patients). HBV integrants were detected in 3 of 10 cases examined so far, and included portions of the HBx gene sequence (including the Basic Core Promoter/Enhancer II) in 2 cases and part of the core gene sequence in one case. The analysis of the integration sites revealed that the HBx sequences were located 3,374 nucleotides upstream the sequence encoding the cat eye syndrome critical region protein 5 isoform and within the coding sequence of the thromboxane A synthase 1, respectively, and that the core gene sequence was located within the cystinosin isoform 1 precursor coding sequence.

Conclusions: Occult HBV infection is highly prevalent in patients with ICC. Both free viral genomes and integrated DNA can be

detected in these cases. These results support the hypothesis of an involvement of HBV in the carcinogenic processes leading to ICC development.

EFFICACY OF TENOFOVIR DISOPROXIL FUMARATE TO PREVENT VERTICAL TRANSMISSION IN MOTHERS WITH LAMIVUDINE-RESISTANT HBV

J. Liu[1], J. Wang[1], F. Cao[1], T. Yan[1], C. Qi[1], T. Chen[1], Y. Zhao[1].

Introduction: In China, many chronically HBV-infected women of childbearing age receive lamivudine antiviral therapy at early ages. Thus, viral resistance becomes a challenge for intervention to prevent mother-to-infant transmission. We prospectively assessed the efficacy of tenofovir in pregnant women with lamivudine-resistant HBV.
Material and Methods: Chronic HBV-infected mothers resistant to lamivudine were enrolled. Tenofovir was administrated beginning at gestation week 24 or 28. HBV load and titers of HBsAg and HBeAg were ascertained every 4 weeks until delivery. All infants received standard combined immunoprophylaxis after birth and were followed for up to 1 year.
Results: Forty-eight mothers and their babies completed the treatment and follow-up, including 21 starting tenofovir therapy at gestation week 24 and 27 starting at week 28. Tenofovir treatment resulted in a mean HBV DNA decline of 5.23 ± 1.68 $\log_{10}$ IU/ml at delivery. Although the group starting therapy at week 24 exhibited more rapid viral inhibition, all mothers had a viral titer $<10^6$ IU/ml, and 73% (35/48) displayed virus <4 $\log_{10}$ IU/ml at delivery, a safe threshold for preventing HBV vertical transmission with combination immunoprophylaxis. No significant difference was found in the percentage of mothers having virus titers <4 $\log_{10}$ IU/ml between the two groups. Congenital abnormalities and neonatal growth were comparable to the normal population. No case of perinatal transmission was diagnosed.
Conclusions: This investigation clarifies the efficacy of tenofovir for blocking vertical transmission of HBV in mothers with lamivudine-resistant HBV strains and demonstrates that tenofovir is well tolerated in the second and third trimesters.

E-mail: b.hullegie@erasmusmc.nl

Introduction: The international epidemic of sexually transmitted acute hepatitis C virus (AHCV) continues to spread within HIV+ men having sex with men (MSM). The incidence rates reported vary between 0.08 and 1.75%. In HIV+ patients with acute HCV, relatively high cure rates (60–70%) are achieved with 24 weeks of peginterferon (P)]+/− ribavirin (R)]. Currently, none of the P-free regimens have been studied or registered for the treatment of AHCV. Furthermore, in most European countries and the USA, the availability of these regimens is restricted to patients with severe fibrosis/cirrhosis. Therefore, if the addition of a direct-acting anti-viral drug (DAA) to P would allow for a higher cure rate or shorter treatment duration, this would still be very valuable. In the DAHH-Study, the efficacy and tolerability of a 12-week boceprevir, P+R regimen in AHCV genotype-1 was evaluated in 10 Dutch HIV treatment centers.
Material and Methods: HIV+ patients with a new ALAT elevation were screened for the presence of HCV RNA. If positive, stored historical plasma samples were tested to prove that the HCV infection was recent. Boceprevir, P+R for 12 weeks was started without a P+R lead-in and was initiated no later than 26 weeks after the day of infection. Primary endpoint is sustained viral response at week 12 (SVR12) in patients with no HCV RNA detected (Roche, CAP/CTM target not detected) at w4 (RVR4) and in all patients included (secondary endpoint).
Results: From 9/2013 to 1/2015 we screened 127 HIV+ patients with a new HCV infection. We excluded 62 patients because of genotype 4 (n = 22), HCV infection >6 months (n = 17), spontaneous clearance before inclusion (n = 8), refusal to participate (n = 13) or other reasons (n = 2). 65 patients were included, 8 cleared HCV or refused before treatment initiation and 57 started therapy. RVR4 was 41/57 (72%) and end of treatment response was 41/45 (91%). In the RVR4 population, 22/23 (96%, 95% CI 76%<>99%) had an SVR12. In the ITT population SVR12 was 26/34 (76%, 95% CI 58%<>89%). Il28B genotype had no impact on RVR4 nor SVR12 results. SVR4 results of all patients and SVR12 results of 44 patients will be presented.
Conclusions: In HIV+ patients with an acute HCV infection, the addition of boceprevir to P+R cured 76% of the patients and as much as 96% of the RVR4 population. At 13,000 €, this shorter therapy is relatively cheap, reasonably tolerated and therefore a relevant therapy to prevent not only future liver disease but also ongoing transmission of HCV in HIV+ MSM.

E-mail: odalgard@medisin.uio.no

Introduction: In registration trials the effect of sofosbuvir (SOF) containing regimes have been modest among patients with genotype 3 infection. Real life data are scarce in this group. We therefore aimed at assessing the effect of SOF containing regimes in genotype 3 patients seen in our daily practices.
Material and Methods: Consecutive patients were included at 8 treatment centers in Denmark, Sweden and Norway if they had genotype 3 infection, had received a SOF containing treatment regime and had at least 4 weeks of follow-up after end of treatment. The following treatments were administered according to local guidelines and availability of drugs: (1) SOF + ribavirin (RBV) for 24 weeks, (2) SOF + Daclatasvir (DCV) +/− RBV for 12 weeks or (3) SOF +pegIFN + RBV for 12 weeks. The

main endpoint was sustained virological response assessed at week 4 (SVR4).
Results: We included 82 patients with genotype 3. The mean age was 55 years (range 20–79), 55/67 (82%) with available staging were cirrhotic and 51% were treatment experienced.
SVR4 was achieved in 62 (83%) while 9 (11%) experienced virological relapse, 4 (5%) non-response and 1 (1%) viral breakthrough. Among 55 cirrhotics SVR 4 was achieved in 44 (80%) compared to 10/11 (91%) of non-cirrhotics. SVR 4 was obtained in 26/33 (81%) who received SOF+RBV for 24 weeks, 19/24 (79%) who received SOF+DCV +/− RBV for 12 weeks and 23/25 (92%) of those treated with SOF+pegIFN+RBV for 12 weeks. Among the 55 patients with cirrhosis SVR4 was achived in 15/22 (68%) who received SOF+RBV for 24 weeks, 16/19 (84%) who received SOF+DCV +/− RBV for 12 weeks and 16/18 (89%) who received pegIFN+SOF+RBV for 12 weeks. Among 50 patients with liverelasticity assessed 10/11 (91%) with <12.5 kPa achieved SVR compared to 14/15 (93%) with 12.5–25 kPa and 17/24 (71%) with >25 kPa.
Conclusions: SOF containing regimes to patients with genotype 3 infection induced SVR 4 in 83%.

E-mail: conti.fabio1@libero.it

Introduction: Hepatitis C virus (HCV) recurrence after liver transplantation (LT) can be associated with a rapid progression to cirrhosis, graft loss and/or death. Sofosbuvir (SOF) has been recently available in a compassionate use program for the treatment of severe HCV recurrence. The aim of this study was to evaluate the efficacy and impact on liver function of SOF based regimen in this setting.
Material and Methods: LT recipients with end stage liver disease (ESLD) or fibrosing cholestatic hepatitis (FCH) and estimated life expectancy ≤6 months were enrolled in a cohort study involving 16 Italian hepatology centers. All patients received 24 weeks of SOF (400 mg daily) in combination with pegylated interferon (PegIFN) and ribavirin (RBV) or an interferon-free regimen. The primary endpoint was the sustained virological response 12 weeks after treatment (SVR12).
Results: Of the 73 patients enrolled (49 ESLD and 24 FCH), 54 (74%) were males, 57 (78.1%) had genotype 1 infection and 46 (63%) had been previously treated. Median baseline MELD and Child–Pugh scores were 15 and 8, respectively. Fifty-nine patients (80.8%) received an interferon-free regimen (54 SOF+RBV, 4 SOF+Daclatasvir, 1 SOF+Simeprevir). To date, 69/73 had completed the study. Of them, 6 patients (8.7%) died (4 during the treatment and 2 during follow-up) and 1 underwent re-LT at week 16 of treatment, all treated with SOF+RBV. 18/69 (26.1%) had a virological failure: 1 breakthrough (treated with SOF+RBV) and 17 relapse (2/14 treated with SOF+PegIFN+RBV and 15/50 with SOF+RBV). SVR12 was achieved in 44 (63.8%): 28/45 (62.2%) in ESLD and 16/24 (66.7%) in FCH. 27/50 patients (54%) receiving SOF+RBV, 12/14 (85.7%) receiving SOF+PegIFN+RBV and 5/5 (100%) receiving SOF+Daclatasvir or Simeprevir obtained SVR12. RBV dose reduction and/or use of erythropoietin and/or blood transfusion due to anaemia were reported in 49.3% of cases. In patients with SVR12, an improvement of liver function was observed (Table). Median baseline MELD and Child–Pugh scores resulted higher in deceased than in survivors (26 vs 15, p = 0.013 and 11 vs 8, p = 0.006, respectively).

	Baseline	Week 12 post-treatment	P
MELD score	13 (7–32)	10 (6–20)	<0.001
Child–Pugh score	7 (5–15)	5 (5–9)	<0.001
INR	1.2 (0.9–4.5)	1.2 (0.9–1.7)	<0.001
Total bilirubin (mg/dl)	2.6 (0.5–12.4)	1.2 (0.4–5.8)	<0.001
Albumin (g/dl)	3.5 (2.4–4.7)	4 (2.7–5.2)	<0.001

Values expressed as median (range).

Conclusions: Treatment schedules with SOF in combination with PegIFN+RBV or a direct-acting antiviral agent provide high virological response rates in patients with severe HCV recurrence after LT. Viral eradication is associated with a significant improvement in liver function. Nevertheless, antiviral treatment seems not beneficial in subjects with very advanced disease.

LP52
NONALCOHOLIC FATTY LIVER DISEASE (NAFLD) AS POTENTIAL RISK FACTOR OF CARDIOVASCULAR DISEASE AND ONCOLOGICAL DISEASE IN DIABETIC TYPE 2 PATIENTS

D. Caroli[1,1], A. Nogara[1], E. Rosa-Rizzotto[2], A. Boscolo Bariga[1], S. Zanoni[1], S. De Boni[1], G. Cavallarin[1], C. Marafin[1], M. Inglese[1], M. Della Loggia[1], L. Peraro[2], S. Lobello[2], F. De Lazzari[2]. *[1]Internal Medicine, Ospedale di Chioggia, Chioggia, [2]Gastroenterology, OSp S. Antonio, Padova, Italy*
E-mail: erik.rosarizzotto@gmail.com

Introduction: NAFLD is an increasingly cause of liver damage in western countries associated with obesity, hypercaloric diet and the sedentary lifestyle. The increasingly high prevalence of Nafld and its possible damage on several organs due to its inflammatory effects (cardiovascular risk and oncological risk) will lead to a prioritary health care problem in the next future. Validated prognostic scores for NAFLD and for cardiovascular risk in diabetics patients were respectively Fatty liver index (FLI) and UK Prospective Diabetes Study (UKPDS risk engine)
Material and Methods: The aims of our study are to assess the real correlation between FLI and UKPDS risk with cardiovascular (CE) and oncological events (OE) in a cohort of diabetic type 2 patients, in order to identify with accurancy the best predictor.
2004 patients referred to our Diabetics Center Ambulatory and in a regular follow-up were retrospectively tested. UKPDS risk and FLI were calcolated for each patient. Data such as CE, OE, anthropometric, biochemical and metabolic features were also

collected. T test for unpaired data and Pearson Chi-squared test were performed.

Results: 304/2004 pt (15%), 211 M and 93 F, were FLI >60; in this group we observed 14 (5%) OE (7 M and 7 F) and 81 (27%) CE (64 M and 17 F). 743/2004 pt (37%), 638 M and 17 F), were FLI <20; in this other group we observed 9 (1%) OE (6 M and 3 F) and 74 (10%) CE (47 M and 27 F). The statistical analysis showed that patients with FLI >60 have a higher risk of OE ($p = 0.0006$) or CE ($p = 0.0001$) compared to patients FLI <20. We identified also two peculiar profiles of cardiovascular risk, in fact male gender patients with FLI >60 presented a significant higher risk of developing CE than female ($p < 0.05$); instead female gender patients with FLI <20 presented a significant higher risk of developing CE than male ($p < 0.001$). No statistical significance was found between FLI >60 + UKPDS >20 and CE ($p = 0.754$). FLI >60 and FLI <20 patients also significantly differed respectively for mean age 62.2 vs 68.4 y ($p = 0.02$), duration of diabetes 4.9 y vs 13.24 y ($p = 0.002$) and mean glycated hemoglobin 8.7 y vs 7.9 ($p = 0.009$).

Conclusions: An early and aggressive program of follow-up and treatment could be established in diabetic type 2 patients with FLI >60 and so with reasonable suspicion of NAFLD because this population have higher risk to develop CE and OE in comparison to FLI <20 (or FLI negative and not suspicion of NAFLD). The simultaneous UKPDS and FLI positivity doesen't improve accuracy in predicting CE.

LP53

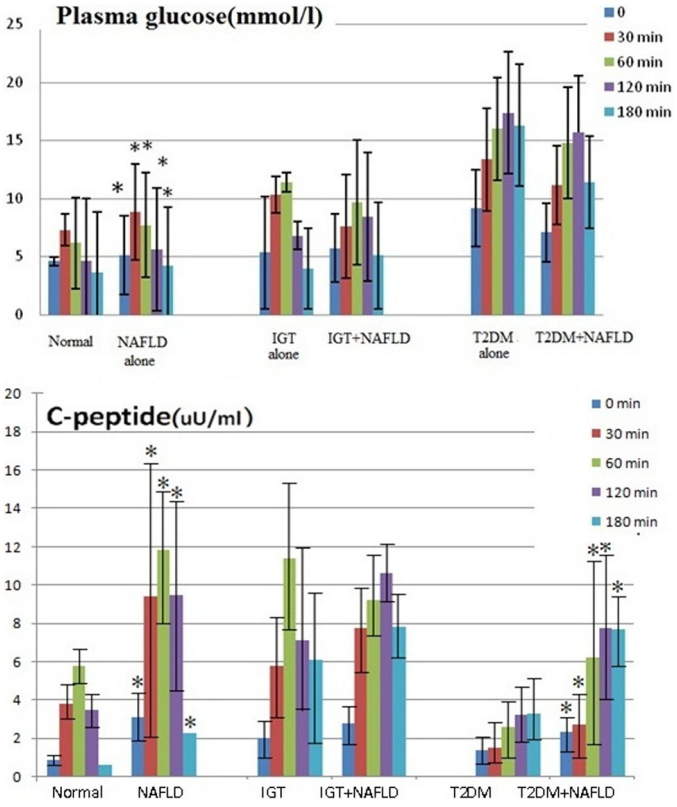
CLINICAL PREDICTIVE VALUE OF INSULIN SECRETION CHARACTERISTICS AND ABNORMAL GLUCOSE METABOLISM OF NAFLD PATIENTS

S.-Y. Chai[1,2], X. Cheng[1], C. Sheng[1], P. Yang[1], H. Li[1], H. Sheng[1], L. Bu[1], W. Li[1], J. Wang[1], X. Wang[1], S. Qu[1,2]. *[1]Endocrinology and metabolism, Shanghai 10th People's Hospital, [2]School of Medicine, Tongji University, Shanghai, China*
E-mail: qushencn@hotmail.com

Introduction: Hyperinsulinemia is a common metabolic characteristic of NAFLD. However, the mechanisms of hyperinsulinemia remain to be fully elucidated. Nonalcoholic fatty liver disease (NAFLD) and type 2 diabetes mellitus (T2DM) often coexist and have adverse outcomes.

Material and Methods: 97 subjects with diagnosed NAFLD by magnetic resonance spectroscopy and 77 Waist circumference and BMI-matched subject were studied. Patients took a 75-g oral glucose tolerance test (OGTT), which measured serum insulin and C-peptide (C-p) levels at baseline (0 min), 30 min, 60 min, and 120 min after glucose challenge. They were classified further as normoglycemia, IGT or T2DM subgroups based on American Diabetes Association criteria. Hepatic insulin clearance, sensitivity and beta cell function were calculated using homeostasis and postprandial models.

Results: β-cell hypersecretion was significantly in the fat liver groups, even fat liver with T2DM compared with those in T2DM alone (HOMA2-B% $P < 0.005$ and $\Delta I_{0-30}\Delta G_{0-30\,min}$ $P < 0.001$). Insulin sensitivity were markedly decreased in fat liver patients, compared to those of normal control subjects (Matsuda index $P < 0.001$ and HOMA2-S% $P < 0.0009$). Slightly, but not significantly, lower in fat liver subjects with IGT or T2DM than those in IGT or T2DM alone. Hepatic insulin clearance was not lower in fat liver patients than nonfat liver patients with normoglycemia and IGT or T2DM alone ($P > 0.05$). Linear regression analysis showed that $\Delta Glucose_{0-120\,min}$ was the best independent predictive variance ($P = 0.002$). $\Delta Glucose_{0-120\,min}$ appeared to be the best diagnostic capacity of NAFLD with a c-statistic 0.901 (95% CI 0.81–0.99) using ROC curve.



Conclusions: Hyperinsulinemia is primarily caused by β-cell hypersecretion in fat liver patients with normoglycemia and IGT, even with T2DM controlled by glycemia-matched subjects, but not reduced hepatic insulin clearance. That give us the impression that NAFLD is not the result of insulin resistance but the complimentary effect of glucose dysregulation. Glycemia indexes such as $\Delta Glucose_{0-120\,min}$ appeared to be the best model to predict the severity of NAFLD than liver injury indices ALT, AST and γGT. In patients with similar levels of insulin resistance and hyperglycemia, DM-NAFLD was associated with higher serum insulin levels than T2DM alone. The present study demonstrates pathophysiological differences in mechanisms of insulin resistance in patients with DM-NAFLD versus T2DM alone.

SOFOSBUVIR INHIBITS HEPATITIS E VIRUS REPLICATION IN VITRO AND RESULTS IN AN ADDITIVE EFFECT WHEN COMBINED WITH RIBAVIRIN

V.L. Dao Thi[1], Y. Debing[2], J. Neyts[2], D. Moradpour[1], J. Gouttenoire[1]. *[1]Division of Gastroenterology and Hepatology, Centre Hospitalier Universitaire Vaudois – University of Lausanne, Lausanne, Switzerland; [2]Rega Institute for Medical Research, Leuven, Belgium*
E-mail: Jerome.Gouttenoire@chuv.ch

Background and Aims: Infection with hepatitis E virus (HEV) of genotype 3 may result in chronic hepatitis in immunocompromised patients. Reduction of immunosuppression or treatment with ribavirin or interferon-α can achieve viral clearance. However, safer and more effective treatment options are needed.

Material and Methods: A selectable subgenomic HEV genotype 3 replicon was derived from the Kernow-C1 strain by partial substitution of the open reading frame 2 (ORF2) and ORF3 sequences with the neomycin phosphotransferase gene. A continuous Huh-7 human hepatocellular carcinoma-derived cell line harboring autonomously replicating HEV RNA was established by transfection of this replicon and selection with neomycin. The antiviral effect of sofosbuvir (SOF), a potent nucleotide inhibitor of the hepatitis C virus (HCV) polymerase, as well as interferon-α,

ribavirin (RBV) and nesbuvir, a non-nucleoside inhibitor of the HCV polymerase, were assessed by quantitative RT-PCR. Findings were validated in a transient luciferase-expressing HEV genotype 3 replication system as well as a full-length infectious clone of HEV. Cell viability was monitored in parallel.
Results: SOF inhibits HEV RNA replication in the selectable subgenomic replicon system, with an IC_{50} of 1.2 μM and without any measurable cell toxicity. As expected, interferon-α and RBV inhibited HEV RNA replication as well, with IC_{50} of 8.5 IU/ml and 8.0 μM, respectively, while nesbuvir as an allosteric inhibitor of the HCV polymerase did not inhibit HEV (negative control). Findings were confirmed in the transient replication system as well as the full-length infectious clone of HEV. Moreover, the combination of SOF and RBV resulted in an additive antiviral effect against HEV.
Conclusions: The HCV polymerase inhibitor SOF inhibits HEV replication and results in an additive effect when combined with RBV. These findings yield potential new avenues for the treatment of persistent HEV infection in immunocompromised patients with chronic hepatitis E.

LP55

RESPONSE GUIDED THERAPY IS NOT DEAD: LOW SUSTAINED VIROLOGIC RESPONSE (SVR) RATES IN PATIENTS WHO HAVE DETECTABLE HEPATITIS C VIRUS (HCV) AT WEEK 4 OF TREATMENT WITH SOFOSBUVIR (SOF) CONTAINING REGIMENS

K. Thornton[1], P. Deming[1], R. Manch[2], A. Moore[2], R. Gish[2], N. Sussman[3], S. Khaderi[4], J. Scott[5], J. Mera[6], T. Box[7], C. Qualls[1], M. Sedillo[1], S. Arora[1]. *[1]University of New Mexico Health Sciences Center, Albuquerque, [2]Dignity Health St. Joseph's Hospital and Medical Center, Phoenix, [3]Baylor College of Medicine & Baylor St. Luke's Medical Center, [4]Baylor St. Luke's Medical Center, Houston, [5]University of Washington, Seattle, [6]Internal Medicine, Oklahoma State University Health Science Center, Tulsa, [7]Gastroenterology and Hepatology, University of Utah, Salt Lake City, United States*
E-mail: kthornton@salud.unm.edu

Introduction: Historically, HCV treatment has been response guided. Clinical trials data with SOF indicated on treatment virologic response was not predictive of SVR. With the introduction of SOF in the United States (US) treatment guidelines eliminated response guided therapy (RGT) that depended on on-treatment viral testing.
Material and Methods: We have a consortium of 6 centers in the US who treat HCV in specialty clinics and also run a Project ECHO (Extension for Community Healthcare Outcomes) program where, through longitudinal videoconferencing, case-based learning and mentoring, primary care clinicians are trained to treat HCV. Members of the consortium and their primary care partners follow shared HCV treatment guidelines. Because of concern that 4 week HCVRNA could be an important predictor of SVR in a real-world setting, we continued to measure on treatment 4 week HCVRNA. Data presented in this abstract are from patients treated either at the specialty clinic or by primary care clinicians through Project ECHO. The purpose is to examine the association between 4 week HCVRNA and SVR in patients treated in real-world practice.
Results: Data on 360 consecutive patients started on treatment between 1/1/2014 and 8/20/2014 with SOF-containing regimens (pegylated interferon + ribavirin (RBV) + SOF; RBV+SOF; SOF + simeprevir) were analyzed. Patients were age 23–80, 46.6% female, 50% had APRI score (AST to platelet ratio index) ≥1.0 and 28.1% had a detectable 4 week HCVRNA. Overall SVR rate was 81.9%. For those with a nondetectable 4 week HCVRNA, SVR was 85.3%. For those with a detectable 4 week HCVRNA, SVR was 73.3%. Detectable 4 week HCVRNA was strongly associated with failure to achieve SVR (Chi-Square 7.14, p-value 0.007). In multivariable logistic regression analysis, detectable 4 week HCVRNA was independently associated with virologic failure with an Odds Ratio of 1.95 (95% Confidence Limits 1.07–3.56). As might be expected, APRI ≥1 was also independently associated with virologic failure with an Odds Ratio of 2.75 (95% Confidence Limits 1.47–5.14).
Conclusions: In a real-world setting, a significant proportion of SOF treated patients have detectable 4 week HCVRNA on treatment. A detectable 4 week HCVRNA is associated with virologic failure. More data are needed to formulate guidance for RGT with newly available HCV therapies.

Liver transplantation/Surgery: a. Experimental

EARLY MONOCYTE DYSFUNCTION IN PATIENTS WHO DEVELOP SYSTEMIC INFLAMMATORY RESPONSE SYNDROME (SIRS) AND SEPSIS AFTER HEPATOPANCREATICOBILIARY SURGERY

R. Lahiri[1,2], Y. Derwa[1], Z. Bashir[1], E. Giles[1], H. Torrance[3], M. O'Dwyer[3], H. Owen[3], A. O'Brien[4], A. Stagg[1], S. Bhattacharya[2], G.R. Foster[1], W. Alazawi[1]. *[1]Blizard Institute, Queen Mary University of London, [2]Barts Health HPB Centre, Royal London Hospital, [3]William Harvey Research Institute, Queen Mary University of London, [4]Department of Medicine, University College London, London, United Kingdom*
E-mail: w.alazawi@qmul.ac.uk

Background and Aims: Patients undergoing major hepatopancreaticobiliary (HPB) surgery are at risk of life-threatening complications including systemic inflammatory response syndrome (SIRS) and sepsis. Early identification of at-risk patients would allow tailored post-operative care and improve survival. Serum interleukin-6 (IL-6) levels are upregulated in patients with poor outcomes after surgery, but the mechanisms that underlie this are unknown. Our aim was to study the pathways involved in IL-6 production in patients undergoing HPB surgery with the goals of understanding mechanisms leading to enhanced inflammatory responses and identifying biomarkers of adverse clinical consequences.
Methods: Two separate cohorts of adult patients undergoing major liver or pancreatic surgery and who gave written informed consent were studied (combined n = 69). Bloods were taken pre-operatively, and on day 1 and day 2 post-operatively. Serum and peripheral blood mononuclear cells were separated and immune phenotype and function were assessed *ex vivo*.
Results: Innate immune dysfunction was evident in blood samples taken from 12 patients who subsequently developed SIRS (on post-operative day 6) compared to 27 who did not, when no clinical evidence of SIRS were apparent (pre-operatively and on post-operative days 1 and 2). In patients who developed SIRS, $CD14^+$ monocytes sampled on post-operative day 1 and 2 expressed higher levels of Toll-like receptor (TLR)4 and TLR5 and produced significantly more IL-6 in response to stimulation with bacterial ligands [lipopolysaccharide (LPS) and flagellin] for these receptors ($p < 0.0001$). TLR-driven phosphorylation of NF-κB was increased on day 1, and interferon alpha-mediated STAT1 phosphorylation was higher pre-operatively in patients who developed SIRS. Increased *TLR4* and *TLR5* gene expression in whole blood was demonstrated in a separate validation cohort of 30 patients undergoing similar surgery. Expression of TLR4/5 on monocytes, particularly intermediate $CD14^{++}CD16^+$ monocytes, on post-operative day 1 or day 2 predicted SIRS

development with accuracy 0.89–1.0 (areas under receiver operator curves).

Conclusions: These data demonstrate the mechanism for IL-6 overproduction in HPB patients who develop post-operative SIRS and identify markers that predict patients at risk of SIRS 5 days before onset of clinical signs.

P0002

LIVER REGENERATION IS NOT IMPACTED IN THE ABSENCE OF INTESTINAL MICROBIOTA

T. Malinka[1], A. Keogh[1], R. Kudira[1], S. Moghadamrad[1], C. McCoy[2], D. Stroka[1], D. Candinas[1], G. Beldi[1]. [1]*Department for Visceral Surgery and Medicine,* [2]*Department of Gastroenterology, Mucosal Immunology, Bern University Hospital, University of Bern, Bern, Switzerland*
E-mail: guido.beldi@insel.ch

Background and Aims: Liver regeneration after partial hepatectomy is a very complex process that involves a variety of different liver cell types via cytokine- and growth-factor-mediated pathways. Bacterial products and LPS circulate in the portal blood stream directly through the hepatic sinusoids and have been proposed to initiate liver regeneration by activation of parenchymal and non-parenchymal cells in liver after partial hepatectomy. Our aim was to evaluate liver regeneration in the absence of microbes and microbial products.

Methods: Two third partial hepatectomy (PH) was performed in germ-free (axenic) mice and mice colonized with altered schaedler flora (ASF) were used as controls. Surgery was performed in axenic conditions to maintain sterility throughout the course of the experiment. Liver regeneration, injury and hepatic fraction of immune cells were assessed in tissue and serum samples 48 hours post partial hepatectomy. Proteomic screen was performed in livers from ASF and axenic mice 2 hours after PH.

Results: Liver injury (ALT/AST) and survival was not significantly different between germ free and ASF colonized mice. Liver regeneration was measured by the number of Ki67 positive cells and there was no significant difference between the germ-free and ASF mice ($p = 0.84$). Absence of microbiota was proved by fluorescence microscopy and faecal cultures. Fractions of CD4 T cells, NKT cells and B cells were altered at baseline between germ-free and ASF mice, but not after partial hepatectomy. The analysis of various protein pathways reveal specific differences between axenic and ASF mice that are present under basal conditions as described before but also persist after PH.

Conclusions: Liver regeneration after PH is not impaired in the absence of microbes and microbial products. These findings contrast with previous studies and reveal that the gut microbiota is not an essential for the priming or maintenance of liver regeneration.

P0003

SEQUENTIAL EXPRESSION PROFILES OF CANNABINOID RECEPTORS ON IMMUNE CELLS AND RELEASE OF CYTOKINES DURING LIVER REGENERATION

A.C. Gupta[1], S. Sharma[1], R. Sehgal[1], P. David[1], S. Sasturkar[1], V. Pamecha[1], N. Trehanpati[1], S.K. Sarin[1]. [1]*Institute of Liver and Biliary Sciences, Delhi, India*
E-mail: abhigupta78@gmail.com

Background and Aims: The mammalian liver has unique property to regenerate upon tissue loss, which induces quiescent hepatocytes to enter the cell cycle and undergo limited replication under the control of multiple hormones, growth factors, and cytokines. Cannabinoid receptors are well known characterized with distinct physiological properties. Recent studies have shown that cannabinoid receptors are critical for the release of various cytokines like TNF-α and IL-6 and play an important role in liver regeneration. The present study aims to evaluate the liver regeneration in subjects undergoing right lobe donor hepatectomy for LDLT (human regenerative model) and to investigate the role of peripheral blood cannabinoid receptor expression on immune cells and its effect in stimulating circulating TNF-α and IL-6.

Methods: 25 consecutive healthy and asymptomatic donors undergoing right lobe donor hepatectomy for Living donor liver transplant were included in the study. The study was approved by Institute Review Board and Ethical Committee. Venous blood samples were taken before surgery (Day 0) and on Post Operative days (POD) 1, 3, 7, 14 and 42. PBMCs were isolated by ficoll gradient method and RNA was extracted. The cannabinoid receptors expression profile was evaluated by RT-PCR at days 0, 3 and 7, whereas TNF-α and IL-6 were measured in plasma at different time points by ELISA.

Results: Very low or faint expression of CB1 and CB2 were seen on PBMCs at day 0. Significant increased expression of CB1 was observed at POD 3 (15 fold) and 7 (30 fold) compared to Day 0. However, CB2 expression was first increased at day 3 (8 fold) and decreased at Day 7 (Figure 1). Significant rise in the TNF-α and IL-6 levels was observed only on POD 1 ($p = 0.03$; $p < 0.0001$) but not subsequently for TNF-α. The increased IL-6 levels on POD 3 ($p = 0.01$), 7 ($p = 0.003$), 14 ($p = 0.002$) and 42 ($p = 0.03$) remained higher than Day 0. This may indicate the presence of an active CB1 receptor on PBMCs and plasma secretion of IL-6 during regeneration.

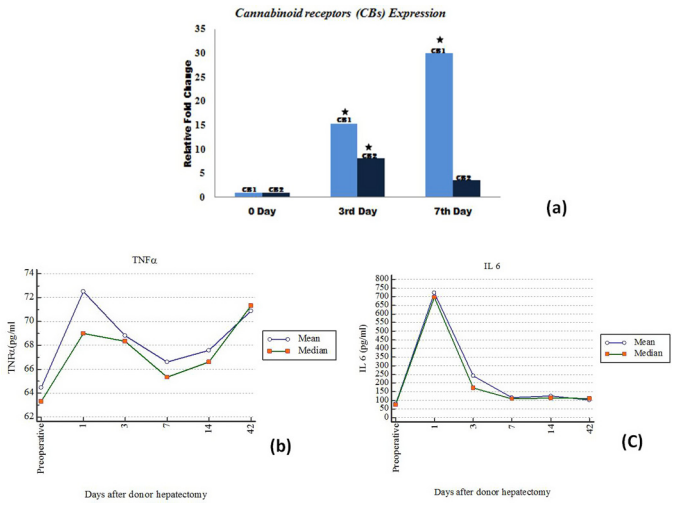

Figure 1.

Conclusions: The present study confirms the sequential expression of CB1 receptor which suggests its major role in liver regeneration in

donors undergoing partial hepatectomy. The novel findings reveal the release of cytokines TNF-α and IL-6 (regenerative markers) which might be influenced by CB1 receptor. This could pave way an insight to understand the role of cannabinoid receptors in liver regeneration.

P0004

THE TRANSPORTABLE MACHINE PERFUSION AIRDRIVE®, A NOVEL APPROACH TO SAFELY EXPAND THE DONOR POOL FOR LIVER TRANSPLANTATION

P. Compagnon[1], I. Ben Mosbah[2], E. Levesque[3], H. Hentati[1], M. Disabato[4], M. Costa[5], J. Cohen[2], D. Azoulay[4]. *[1]Service de Chirurgie Hépatobiliaire et Transplantation, [2]INSERM U955, [3]Service de réanimation digestive, [4]Service de Chirurgie Hepatobiliaire et Transplantation, [5]Service de Chirurgie Hepatobilaire et Transplantation, Hôpital Henri Mondor, Créteil, France*
E-mail: philippe.compagnon@hmn.aphp.fr

Background and Aims: Livers derived from donation after circulatory death (DCD) suffer warm ischemia (WI) and are infrequently used for transplantation; they have the potential, however, to considerably expand the donor pool. The Airdrive® is the first transportable oxygenated machine perfusion (MP) unit suitable for liver preservation. We aimed to determine whether the Airdrive® MP would improve the quality of these livers using a DCD large animal model.
Methods: Female large white pigs were used as organ donors and recipients. Liver allografts procured from heart beating donors and preserved by simple cold storage (SCS) served as controls (n = 6). In experimental groups, cardiac arrest was induced by IV injection of KCL. After 60min WI, livers were perfused in situ with KTK and subsequently preserved either by SCS (SCS group, n = 3) or hypothermic MP (Airdrive® group, n = 4) using MPS-Belzer solution. After 4 hr of preservation, all livers were transplanted into recipient pigs. The main judgment criterion was animal survival at day 5
Results: All animals that received a simple cold stored liver allograft after 60min WI experienced PNF and died within 6 hours after transplantion (5-day survival = 0%). In contrast, 5-day survival in animals that received a MP liver was 100% (4/4, Airdrive® group) as well as in controls (6/6). A post-reperfusion syndrome was observed in all animals (3/3) of the SCS group but none of the control or Airdrive® groups. These phenomena caused a significant increase in fluid challenge and catecholamine needs in SCS group relative to control and Airdrive® groups. At the end of cold preservation, ATP content was significantly higher in the Airdrive® group vs. SCS group. After reperfusion, MP livers functionned better (albumin production, prothrombin time rates) and showed less hepatocellular and endothelial cell injury, in agreement with better preserved liver integrity (histology) vs. SCS group. MP livers also exhibited higher ATP reccovery than SCS livers. The protective effect of the Airdrive® device was associated with a significant attenuation of oxidative stress (lower lipid peroxidation, higher catalase and superoxyde dismutase activity), and a better endoplasmic reticulum adaptation leading to limit mitochondrial damage (cytochrome c, caspase 9, GLDH), and apoptosis (caspase 3 and TUNEL)
Conclusions: This study demonstrates for the first time the efficacy of the transportable MP Airdrive® device to enhance donor liver viability for transplantation in a clinically relevant DCD model.

P0005

THE NEW STRATEGY OF AUTOLOGOUS LIVER CELL TRANSPLANTATION FOR ACUTE LIVER FAILURE AFTER MASSIVE HEPATECTOMY: ROLE OF HEPATOCYTES AND LIVER NON PARENCHYMAL CELLS

S. Kita[1], K. Yasuchika[1], T. Ishii[2], H. Katayama[1], E.Y. Yoshitoshi[1], S. Ogiso[1], T. Kawai[1], K. Yasuda[1], K. Fukumitsu[1], M. Mizumoto[1], S. Uemoto[1]. *[1]Surgery, Graduate School of Medicine Kyoto University, Kyoto, [2]Surgery, Nishikobe Medical Center, Kobe, Japan*
E-mail: yulala@kuhp.kyoto-u.ac.jp

Background and Aims: Post-operative liver failure is one of the most critical complications of extensive hepatectomy. Allo-hepatocyte transplantation has been considered as an attractive therapy for lethal post-hepatectomy liver failure. On the other hand, resected livers of patients with hepato-biliary cancers contain not only cancer cells but also large amounts of normal hepatocytes. In this study, we aimed to utilize normal liver cells in resected livers, and evaluate the effect of autologous liver cell transplantation in rat models of post-hepatectomy liver failure.
Methods: Post-hepatectomy liver failure was induced by 90% partial hepatectomy (PH). The isolated graft liver cells which consisted of hepatocytes and non-parenchymal cells (NPCs) were transplanted into mesenteries of hepatectomized rats. We evaluated the effect of autologous liver cell transplantation on hepatectomized rats, the function of remnant livers and transplanted hepatocytes. Furthermore, in order to investigate which the hepatocytes or NPCs played an effective role in the autologous transplantation, the liver cells were separately divided into hepatocytes and NPCs, and transplanted, respectively.
Results: The survival rate of the liver cell transplantation group (69.2%) was significantly improved ($p = 0.00043$) in comparison to the control group (7.7%) 7 days after PH. The transplanted liver cells produced albumin in the NARs during 24 hours after transplantation. Although the viable transplanted cells deteriorated in the transplanted site, histological findings and adenosine-5′-triphosphate assay revealed the protective effect of transplanted cells on the remnant livers. The dual roles of the transplanted cells, one of them was the compensation of the proper hepatic function and the other was protection of the native liver would affect the rescue of fatal liver failure. And, hepatocytes could protect remnant livers and that NPCs could not protect remnant livers. This protective effect for remnant liver could lead to improve the survivorship in this liver failure model.
Conclusions: This study demonstrates the autologous liver cell transplantation could lead to the improvement of the survivorship. Our results indicated that we would get over donor shortage and rejection in the future.

P0006

HEPATIC ISCHEMIA/REPERFUSION INDUCES CHANGES IN TISSUE AND BILIARY LEVELS OF ARGININE AND ITS METHYLATED DERIVATIVES

L.G. Di Pasqua[1], V. Rizzo[2], C. Berardo[1], P. Richelmi[1], M. Vairetti[1], A. Ferrigno[1]. *[1]Internal Medicine and Therapeutics, University of Pavia, [2]Molecular Medicine, University of Pavia and IRCCS S. Matteo, Pavia, Italy*
E-mail: mariapia.vairetti@unipv.it

Background and Aims: Arginine (Arg), the substrate for nitric oxide synthase (NOS), can be methylated to form symmetrical dimethylarginine (SDMA) and asymmetrical dimethylarginine (ADMA), the last an endogenous inhibitor of NOS. SDMA is mostly excreted in the urine, while ADMA is mainly subjected to degradation in the liver. We recently reported that ADMA is also secreted in bile (Ferrigno et al., 2014). Arg competes with ADMA and SDMA for cellular transport across cationic amino-acid transporters (CATs) (Closs et al., 1997). Here we evaluate the changes in serum, tissue and biliary levels of Arg, citrulline (Cit), ADMA and SDMA as well as the modifications in CATs after ischemia-reperfusion (I/R) injury.
Methods: Male Wistar rats were subjected to 30-min partial hepatic ischemia by clamping the hepatic artery and the portal vein (n = 8) or sham-operated (n = 7). After 60-min reperfusion, serum, tissue and bile samples were collected and the concentrations of ADMA, SDMA, Arg and Cit were measured. AST, ALT and Alkaline Phosphatase (AP) levels in serum and bile were also determined. Using RT-PCR analysis, mRNA of cationic transporters, 2A (CAT-2A) and 2B (CAT-2B), for Arg and its methylated derivatives were also quantified.
Results: A decrease in serum Arg and an increase of Cit were detected after I/R; no changes in ADMA and SDMA were found. Both forms of methylarginenes, Arg and Cit were also detected in bile: a significant increase in ADMA and Cit and a decrease in SDMA and Arg were observed in bile at the end of reperfusion. On the contrary, lower ADMA levels and higher SDMA levels were quantified in liver biopsy after I/R when compared with sham-operated rats. A marked increase in AST, ALT and AP levels in serum and bile confirmed both hepatocyte and cholangiocyte damage. A decrease in mRNA transporter CAT-2A but not in CAT-2B was detected.
Conclusions: This study supported our previous results on the biliary ADMA clearance and demonstrated, for the first time, that the liver is also responsible for the biliary excretion of SDMA: the clearing of SDMA is not only confined to the kidney, but the liver could also take up SDMA from the portal and systemic circulation. These data also suggested that tissue and biliary changes in ADMA and SDMA should be CAT-2B transporter-dependent representing a step forward in the understanding of the mechanisms involved in the control of Arg and its methylated derivatives during hepatic I/R.

P0007

HEPATIC T CELLS DERIVED FROM NORMOTHEMIC MACHINE PERFUSED GRAFTS CONTAINED MORE REGULATORY T CELLS AND FEWER PROINFLAMMATORY CYTOKINES PRODUCING T CELLS THAN THOSE FROM COLD STORAGE GRAFTS

X. Huang[1], R. Ravikumar[2], C. Coussios[2], P. Srinivasan[1], N. Heaton[1], P. Friend[2], W. Jassem[1], Y. Ma[1]. *[1]Liver Institute, King's College, London, [2]Surgical Sciences, Oxford University, Oxford, United Kingdom*
E-mail: wayel.jassem@kcl.ac.uk

Background and Aims: In liver transplantation, ischemia reperfusion (I/R) injury is associated with an inflammatory response that has an impact on graft and patient outcomes. Ex-vivo normothermic machine perfusion (NMP) of donor allografts prior to transplantation has the potential to attenuate I/R injury, leading to improved liver function following implantation and increased utilization of grafts from marginal donors. Livers contain a significant amount of mononuclear cells that are involved in hepatic inflammatory processes. To assess the influence of NMP on hepatic inflammation, the phenotype and function of intra-hepatic lymphocytes derived from NMP- versus cold storage (CS)-preserved livers were compared.
Methods: All samples were obtained from liver allografts used for the phase I clinical trial of the Organanox NMP device. Second passage perfusates were collected from 12 grafts donated after brain death (DBD) immediately after NMP and compared to that of 21 CS grafts. Hepatic mononuclear cells (HMC) contained in the perfusate were isolated by density gradient centrifugation. Flow cytometry was used to define the phenotypes and the proportions of activated cytokine producing HMC by utilizing staining with various leukocyte lineage and activation markers.
Results: The mean preservation time was 11.5 hours for NMP and 9.5 hours for CS. Although the frequency of CD4+ T cells, NK and NKT cells were comparable between NMP and CS grafts, the frequency of CD8+ T cells ($p = 0.01$) and CD4+ CD25+ FOXP3+ regulatory T cells (Tregs) ($p = 0.03$) was significantly higher in NMP than in CS liver grafts. The proportions of both CD4+ and CD8+ T cells producing the pro-inflammatory cytokines IFNg ($p = 0.008$ and $p = 0.006$, respectively) and IL-17 ($p < 0.001$ and $p < 0.001$, respectively) was significantly lower in NMP than in CS grafts. Additionally, there were fewer CD4+ T cells producing the T cell trophic factor IL-2 in NMP versus CS allografts. There were no significant differences in T cell expression of immunosuppressive cytokines IL-10 or TGF-b.
Conclusions: These data demonstrate more Tregs and less pro-inflammatory T cells in NMP allografts, as compared to their CS counterparts. Brain death has been previously characterized as a pro-inflammatory state and the utilization of NMP rather than standard cold storage techniques modulates the allograft inflammatory response. Further studies are warranted to determine if these findings are associated with the improved clinical outcomes.

P0008

A MULTIDRUG STRATEGY TO ATTENUATE ISCHEMIA REPERFUSION INJURY IN EXPERIMENTAL LIVER TRANSPLANTATION

K. Yamanaka[1], P. Houben[1], H. Bruns[1], D. Schultze[1], E. Hatano[2], P. Schemmer[1]. *[1]Dept. of General, Visceral and Transplant Surgery, University Hospital Heidelberg, Heidelberg, Germany; [2]Dept. of Surgery, Graduate School of Medicine, Kyoto University, Kyoto, Japan*
E-mail: peter.schemmer@med.uni-heidelberg.de

Background and Aims: To develop a multidrug strategy designed to target various pathophysiological ischemia reperfusion injury (IRI) mechanisms in liver transplantation (LT), focusing on high-mobility group box 1 (HMGB1) release as a molecular marker.
Methods: Orthotropic liver transplantation with arterialization was performed in rats after 8 hours cold storage in HTK solution. Donors underwent i.v. multidrug preconditioning with glycine, taurine, alanine, arginine and prednisolone. Controls received the same volume normal saline i.v. prior to organ donation.
Results: Trypan blue staining and transmission electron microscopy revealed that necrotic cell death of sinusoidal endothelial cells and ischemic changing of hepatocytes were attenuated significantly after multidrug preconditioning. Further HMGB1 was decreased in rinsed solution compared to controls, preconditioning with glycine alone and after preconditioning with a combination of glycine and taurine ($P = 0.0308$). The examination at 1, 3 and 5 hours after reperfusion showed that multidrug preconditioning significantly decreased time-dependent necrotic changing and inflammatory response, and decreased the risk of early death after transplantation

(p = 0.0289) depicted by H&E histology, serum liver enzymes immunohistochemisty for HMGB1, IL1, IL6, TNFα and CD3 and CD68 positive cells.
Conclusions: Multidrug donor preconditioning protects liver grafts from injury during the process of transplantation. HMGB1 might be a molecular maker that predicts early graft survival.

P0009
THE EFFECT OF GLUTAMINE IN THE LIVER INJURY RESULTING FROM INTESTINAL ISCHEMIA AND REPERFUSION IN RATS
N.P. Marroni[1], R. Hartmann[2], F. Licks[2], E. Schemitt[2], J. Colares[1], M. Soares[1], G. Zabot[3], H. Fillmann[3]. *[1]Universidade Luterana do Brasil, Canoas, [2]Universidade Federal do Rio Grande do Sul, [3]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil*
E-mail: norma.marroni@ulbra.edu.br

Background and Aims: The intestinal ischemia-reperfusion (I/R-i) can cause cellular damage to the tissue and in distant organs such as the liver. Some aggressor agents are involved in these processes, such as: the generation of free radicals, the nitric oxide and the release of pro-inflammatory cytokines. Due to the involvement of free radicals in the lesions of I/R-i, some therapeutic antioxidants options are being studied and tested in I/R-i lesions. The aim of the study was to evaluate effects of glutamine (Gln) in an animal model of I/R-i.
Methods: Twenty male Wistar rats were divided into four groups: Sham operated **(SO)**, Glutamine + Sham operated **(G+SO)**, ischemia–reperfusion **(I/R)**, Glutamine + ischemia–reperfusion-i **(G+I/R)**. The rats were subjected to occlusion of the superior mesenteric artery for 30 min followed by 15 min of reperfusion. The glutamine (25 mg/kg/day) was administered 24 and 48 h before I/R. Systemic injuries were determined by evaluating liver segments for oxidative stress using lipid peroxidation (LPO), levels of nitric oxide metabolites (NO) and the expression of the enzyme inducible nitric oxide synthase (iNOS) by western blot analysis. The statistical analysis used was ANOVA followed by Student–Newman–Keuls (mean±SEM) significant at $p < 0.05$.
Results: The animals treated with glutamine showed a significant reduced the expression of iNOS compared to animals of I/R group – Liver (**SO:** 1.17±0.33; **G+SO:** 0.86±0.30; **I/R:** 2.51±0.10; **G+I/R:** 1.86±0.13). The LPO levels showed a significant reduced the animals treated with glutamine compared to animals of I/R group – Liver (**SO:** 0.16±0.01, **G+SO:** 0.20±0.02, **I/R:** 0.45±0.03; **G+I/R:** 0.24±0.02). The NO levels also showed a reduction in the treated animals compared to animals of I/R group – Liver (**SO:** 5.4±0.8; **G+SO:** 6.9±0.8; **I/R:** 15.6±2.7**;** 1.8±0.2; **G+I/R**: 6.1±1.1).
Conclusions: In conclusion, we suggest that pretreatment with Gln reduced oxidative damage and decreased levels of NO and iNOS expression in liver tissue of animals subjected to intestinal ischemia and reperfusion model.

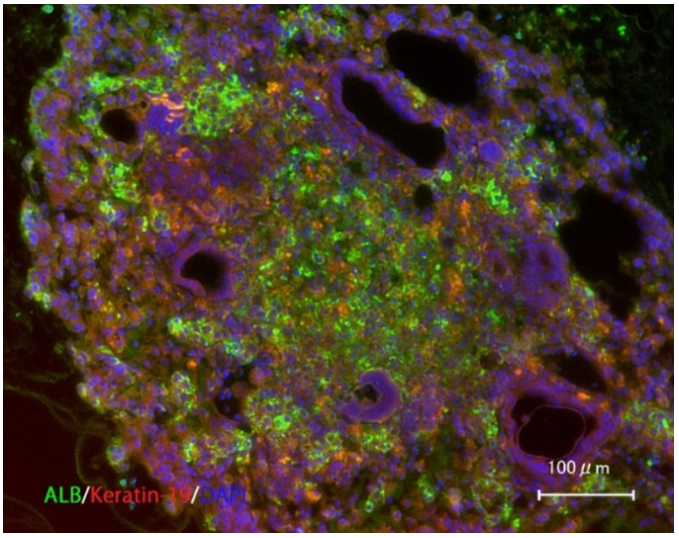
FETAL HEPATOCYTE AS A CELL SOURCE OF LIVER TISSUE ENGINEERING USING A DECELLULARIZED MATRIX
S. Ogiso[1], K. Fukumitsu[1], K. Yasuchika[1], J. Komori[1], T. Ishii[1], H. Katayama[1], T. Kawai[1], S. Kita[1], K. Yasuda[1], E.Y. Yoshitoshi[1], M. Mizumoto[1], S. Uemoto[1]. *[1]Division of Hepato-Pancreato-Biliary and Transplant Surgery, Department of Surgery, Kyoto University, Kyoto, Japan*
E-mail: oggy_so@ybb.ne.jp

Background and Aims: The therapy of choice for end-stage liver disease is whole-organ liver transplantation, but this chance is limited by a shortage of donor organs. Cell-based therapies and hepatic tissue engineering have been studied as alternatives to liver transplantation, but neither has proven effective to date. A regenerative medicine approach for liver replacement has recently been described that includes the use of a three-dimensional organ scaffold prepared by decellularization of xenogeneic liver. Although the decellularized liver matrix has considered as an ideal scaffold of artificial liver, the strategy has not yet achieved a sufficient function up to expectation. The present study investigated the efficacy and potential of fetal hepatocyte as a cell source of liver tissue engineering using a decellularized matrix.
Methods: Mice fetal (E14.5) or adult hepatocytes were seeded in a decellularized rat liver and cultured for one week in a customized organ chamber with perfusion of the whole-liver through the portal vein. Differentiation and liver-specific function of repopulated cells were examined by comparing the two groups of the livers assembled with the different cell sources.



Results: Immunofluorescence staining at two days showed that fetal hepatocytes differentiated into hepatic marker (albumin and cytochrome P450 subtype [CYP3A4])-expressing cells and biliary marker (cytokeratin 19)-expressing cells with the formation of bile duct-like tubular structures, while there remained α-fetoprotein-positive immature cells. Normalized gene expression levels of albumin and cytochrome P450 subtypes (CYP2E1 and CYP3A11) via quantitative RT-PCR at one week were lower in fetal hepatocyte than those in adult hepatocyte. On the other hand, functional assessment showed significantly higher albumin concentration in the culture medium of the fetal hepatocyte-recellularized liver than the adult hepatocyte-recellularized liver ($p < 0.01$), although urea synthesis was similar.
Conclusions: Fetal hepatocyte engrafted and differentiated into hepatic as well as biliary lineage to construct the three-dimensional architecture in the assembled liver, mimicking the native liver tissue. Furthermore, the fetal hepatocyte-recellularized liver had the non-inferior hepatic function to the adult hepatocyte-recellularized liver, suggesting that fetal hepatocyte is a good candidate for a cell source of liver tissue engineering using a decellularized matrix.

DIFFERENTIATION OF BONE MARROW-DERIVED MESENCHYMAL STEM CELLS INTO HEPATOCYTE-LIKE CELLS AND THEIR REGULATORY EFFECTS ON ACTIVATED LYMPHOCYTES AND LIVER GRAFT REGENERATION AND REJECTION

H.-L. Song[1], Z.-Y. Shen[1], W.-P. Zheng[1], B. Wu[1], C. Dong[1].
[1]*Department of Organ Transplantation, Tianjin First Center Hospital, Tianjin, China*
E-mail: hlsong26@163.com

Background and Aims: Cell-based tolerogenic therapy is a relatively new approach for the treatment of autoimmune diseases. Bone marrow derived mesenchymal stem cells (BM MSCs) are thought to be an attractive cell source for cell therapy because of their immaturity and low immunogenicity. BM-MSCs are able to differentiate into functional hepatocyte-like cells (HLCs) both *in vitro* and *in vivo*. However, the immunogenic and immunoregulatory effects of differentiated HLCs on lymphocytes and liver grafts *in vivo* have not been reported. To investigate the biological function of HLCs and their effects on activated lymphocytes and liver graft regeneration and rejection.
Methods: HLCs were induced from BM-MSCs and their immunoregulatory effects on activated lymphocytes were investigated. The effects of HLCs transplantation on liver graft regeneration and rejection were investigated in a rat model (BN-Lewis) with 50% reduced-size liver transplantation.
Results: The differentiation of BM-MSCs into HLCs was demonstrated as they exhibited hepatocyte-like morphology and expressed several liver-specific markers. HLCs inhibited lymphocyte proliferation induced by concanavalin A (ConA). Following HLCs transplantation into the rat model with 50% reduced-size liver transplantation, liver function markers and the proportion of hepatocytes in the S-phase of the cell cycle were significantly higher in the experimental group compared to controls ($P < 0.01$). Pathological changes in the HLC-treated groups were less severe than in the control animals.
Conclusions: HLCs inhibited lymphocyte proliferation and exhibited *in vitro* immunosuppressive functions that may be mediated by TGF-β1 and IL-6. HLCs were associated with improved rat liver regeneration and may be beneficial in cell therapies for liver transplant rejection and other liver diseases.

BILE-LIGATED RATS ARE SUSCEPTIBLE TO HYPOTENSION-INDUCED NEURONAL CELL LOSS: IMPLICATIONS FOR PERSISTING NEUROLOGICAL COMPLICATIONS FOLLOWING LIVER TRANSPLANTATION

M.-A. Clément[1], C. Bosoi[2,3], M. Tremblay[2], C. Bémeur[2,4], C. Rose[1,2,3,4].
[1]*Department of Pharmacology,* [2]*CRCHUM,* [3]*Medecine,* [4]*Nutrition, Université de Montréal, Montréal, Canada*
E-mail: clement.marcandre2@gmail.com

Background and Aims: Hepatic encephalopathy (HE) is a major neuropsychiatric complication caused by liver disease characterized by cognitive and motor dysfunction. The only curative treatment to date remains liver transplantation (LT). Historically, HE has always been considered to be a reversible metabolic disorder and has therefore been expected to completely resolve following LT. However, even following the implantation of a new liver, persisting neurological complications remain a common problem affecting as many as 47% (8–47%) of liver transplant recipients. LT is a major surgical procedure accompanied by intraoperative stress and confounding factors, including blood loss (hypovolumia) and hypotension. We hypothesize, in the setting of MHE, that the compromised brain becomes predisposed to what would normally be an innocuous hypotensive insult, resulting in cell injury and death.
Methods: Six-week bile-duct ligated (BDL) rats with MHE and respective controls will be used. Blood is withdrawn from the femoral artery (inducing hypovolemia) until an arterial pressure of 30 mmHg (hypotension) and maintained for 150 minutes. Upon sacrifice, brains are perfused and extracted for apoptotic analysis (western blot) and neuronal cell count (immunohistochemistry).
Results: Both BDL rats and SHAM-operated controls without hypotension do not display any neuronal loss. However, BDL rats following hypotension demonstrated a significant decrease in neuronal cell count in the frontal cortex using NeuN+DAPI and Cresyl Violet compared to hypotensive SHAM-operated controls. In addition, neuronal loss was associated with an increased in cellular stress protein, hsp32, hsp70 and caspase-3, suggesting apoptotic cell death.
Conclusions: These findings suggest that patients with MHE are more susceptible to hypotension-induced neuronal cell loss. Moreover, these results suggest a patient with HE (even MHE), with a "frail brain", will fare worse during LT and consequently result in poor neurological outcome. The combination of MHE and hypotension may justify for the persisting neurological complications observed in a number of cirrhotic patients following LT. This implies the impact of MHE on outcome is undervalued. MHE should not to be ignored and patients with MHE merit to be treated pre-LT.

P0013

RESOLVIN D1 PROTECTS LIVERS FROM ISCHEMIA/REPERFUSION INJURY BY ENHANCING M2 MACROPHAGE POLARIZATION AND EFFEROCYTOSIS

J.-W. Kang[1], J.-K. Shin[1], J.-W. Choi[1], H.-I. Cho[1], S.-M. Lee[1]. [1]*School of Pharmacy, Sungkyunkwan University, Suwon, Korea, South*
E-mail: jwkang86@gmail.com

Background and Aims: Complete resolution of an acute inflammatory response and its return to homeostasis are essential for tissue integrity and function. Resolution of inflammation is known to be an active process involving a new genus of lipid mediators called specialized pro-resolving lipid mediators such as Resolvin D1 (RvD1). While accumulating evidences suggest RvD1 counteracts proinflammatory signaling and promotes resolution, the specific cellular targets and mechanisms of action for RvD1 remains largely unknown. In the present study, we investigated the roles of RvD1 and its molecular mechanisms in ischemia/reperfusion (IR)-induced sterile inflammation.

Methods: Male C57BL/6 mice were subjected to 70% hepatic ischemia for 60 min followed by reperfusion. RvD1 was administered (5, 10 and 15 μg/kg, i.p.) 1 h prior to ischemia and directly before reperfusion. To deplete Kupffer cells (KCs), mice were pretreated with liposome clodronate (100 μL/mice, i.v.) at 24 h before ischemia. BOC-2, an antagonist for lipoxin A receptor/formyl-peptide receptor (ALX/FPR2), was pretreated (50 μg/kg, i.p.) 30 min before initial RvD1 treatment. The siRNA for ALX/FPR2 (90 μg/kg, i.v.) or control siRNA were pretreated at 72 and 48 h before ischemia.
Results: RvD1 attenuated the IR-induced hepatocellular damage as indicated by serum ALT activity and histopathological score. RvD1 attenuated the increases in the levels of TLR4, TNF-α, IL-6 and IL-1β mRNA expression. In purified KCs of mice exposed to IR, while the levels of M1 marker genes (NOS2a and CD40) increased, M2 marker genes (Arg1, MRC1 and MST1R) decreased demonstrating proinflammatory shift in KCs. RvD1 markedly attenuated these changes. Depletion of KCs by liposome clodronate abrogated the effects of RvD1 on proinflammatory mediators and macrophage polarization. In addition, RvD1 attenuated the increases in the levels of myeloperoxidase activity and CXCL1 and CXCL2 mRNA expression. RvD1 markedly augmented the efferocytic activity (apoptotic neutrophil clearance) of KCs as indicated by increases in $F4/80^{+}Gr\text{-}1^{+}$ cells in liver. However, BOC-2 pretreatment or gene silencing of the RvD1 receptor, ALX/FPR2, abrogated the anti-inflammatory and proresolving action of RvD1.
Conclusions: These results suggest that RvD1 ameliorates IR-induced hepatic injury and this protection is associated with enhancement of M2 polarization and efferocytosis via ALX/FPR2 activation.

THE EFFECT OF DIFFERENT NUTRITIONAL SUPPORT IN LIVER SURGERY

M.M. Braz[1], B. Kleuser[2], S. Fayyaz[2], M.B. Jiménez Castro[1], J.G. Sancho[3], F.S. Ramalho[4], M.E.P. Cornide[1], L. Torrens[1], J. Rodes[5], C. Peralta[1]. *[1]Protective strategies against hepatic ischemia-reperfusion injury, Institut d'Investigacions Biomediques August Pi i Sunyer, Barcelona, Spain, Barcelona, Spain; [2]Institute of Nutritional Science, University of Postdam, Postdam, Germany; [3]Hepatic Hemodynamic Laboratory, Institut d'Investigacions Biomediques August Pi i Sunyer, Barcelona, Spain, Barcelona, Spain; [4]Faculdade de Medicina de Ribeirao Preto/USP, Ribeirao Preto, Brazil; [5]Institut d'Investigacions Biomediques August Pi i Sunyer, Barcelona, Spain, Barcelona, Spain*
E-mail: mariana.pato@hotmail.com

Background and Aims: Temporary occlusion of liver blood supply for complex liver operation is common in liver surgery. Steatosis is a risk factor in partial hepatectomy (PH) under ischaemia-reperfusion (I/R), once impairs regenerative response and reduces tolerance to hepatic injury. Nutritional support strategies, as energy source for liver regeneration, remain poorly investigated. We aimed to investigate the effect of different nutritional support on damage and hepatocyte proliferation in liver surgery.
Methods: Male Wistar rats fed with a choline-deficient or standard chow diet for 10 days for nutritional obesity experimental model were used. Steatotic and non-steatotic rat livers were subjected to surgery and the effects of either glucose solution (28%, energy content 4.6 MJ/1000 ml) or lipid emulsion (10%, energy content 4.6 MJ/1000 ml. The emulsion comprised 52% linoleic acid, 22% oleic acid, 13% palmitic acid, 8% linolenic acid, 4% stearic acid, 1% other fatty acids, 8.184 g/l egg phospholipids and 15 g/l glycerine) treatment on damage and regeneration, and part of the underlying mechanisms, were investigated.
Results: In nutritional obesity model, our results revealed an improvement in damage and regenerative process of PH+I/R+28% Glucose and PH+I/R+10% Lipid emulsion in non-steatotic livers when compared with the PH+I/R group and not differences were observed when comparing both treatments. In steatotic livers, glucose (PH+I/R+28% Glucose group) did not protect against damage whereas lipid treatment (PH+I/R+10% Lipid emulsion group) conferred protection. The benefits of these treatments on regenerative failure in steatotic livers were more evident when lipid infusion was administered.
Conclusions: Both nutritional supplements offered the equivalent protection to the non-steatotic liver submitted to PH under I/R. The opposite was seen in fatty liver, since the treatment with lipid emulsion decreased the injurious effects of the hepatic surgical procedure in the presence of steatosis.

P0015
ESTABLISHMENT OF PORTAL VEIN LIGATION + IN SITU SPLITTING MODEL ON RAT

W. Wei[1], T. Zhang[1], S. Zafarnia[2], M. Schwier[3], C. Xie[1], C. Kan[1], O. Dirsch[4], U. Settmacher[1], U. Dahmen[1]. *[1]Department of General, Visceral and Vascular Surgery, Jena University Hospital, Jena, [2]Department of Experimental Molecular Imaging, RWTH Aachen University, Aachen, [3]MEVIS, Fraunhofer Institute for Medical Image Computing MEVIS, Bremen, [4]Institute of Pathology, Jena University Hospital, Jena, Germany*
E-mail: wei.weiwei@med.uni-jena.de

Background and Aims: Associating Liver Partition with Portal Vein Ligation for Staged Hepatectomy (ALPPS) is an emerging surgical strategy. It induces more and faster liver regeneration of portal non-deprived lobe than that in PVE and PVL, which can induce the rapid growth of future liver remnant (FLR) and reduce post-hepatectomy liver failure (PHLF). However, the underlying mechanism is uncertain. To study the underlying mechanism of liver regeneration and alteration of biochemistry, it is important to establish a reliable ALPPS model on rats.
Methods: Portal vein ligation was achieved by occlusion of portal branches feeding left liver lobe and right lobe (approximate 70%PVL). In situ splitting was performed according to the portal fissure. A sterile plastic film was placed on the transection surface of left median lobe. The caudate lobes were resected (10%PHx), simulating the clinical situation of atypical resection during first stage. The liver regeneration of right median lobe was evaluated. The model was tested by imaging techniques (CT scan and 3D reconstruction) after harvest on day 7.
Results: Rats can survive 100% after performing the procedure correctly. The future remnant liver (right median lobe) grew significantly (200% of initial size). 3D reconstruction showed the right median portal vein was well reserved, while the rest portal veins were properly ligated. All hepatic veins were well reserved. No obvious revascularization was found between left and right median lobe.
Conclusions: Based on the anatomy of rodent liver, the ALPPS model can be performed reliably and well-tolerated. The whole procedures included the ligation of left portal vein, transection of median lobe along the portal fissure and resection of caudate lobe.

P0016
VISUALIZATION OF LIVER REGENERATION AFTER 70% PARTIAL HEPATECTOMY IN MICE

C. Xie[1], W. Wei[1], U. Dahmen[1]. *[1]Department of General, Visceral and Vascular Surgery, Jena University Hospital, Jena, Germany*
E-mail: Chichi.xie@med.uni-jena.de

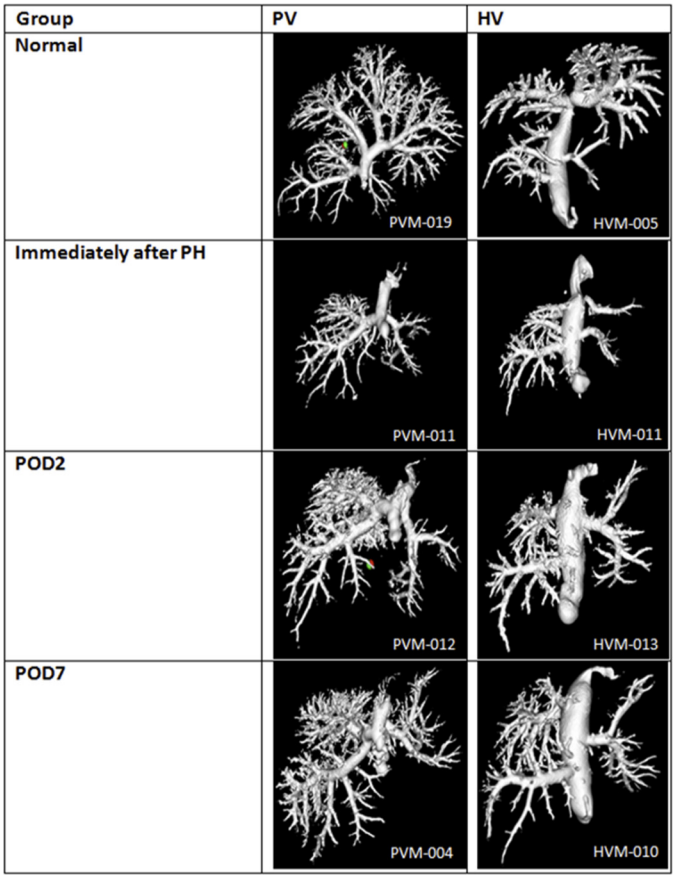
Background and Aims: Mouse partial hepatectomy model is the most common used model to investigate liver regeneration. However, little is known about the kinetics of vascular regeneration after liver resection in mice. The aim of this study was to
1. Establish a method to visualize vascular regeneration by injecting a contrast agent (Microfil) and subsequent CT-imaging of the explanted regenerating mouse liver.

2. Observe kinetics of vascular regeneration of portal and hepatic vein after 70% PH in mice.

Methods: *Specimen preparation:* Laparotomy was performed on anesthetized mice before, immediately after and on POD2 and POD7 after 70%PH (n = 6/time point). After systemic heparinization, portal veinwas cannulated with 26G heparinized catheter and flushed with heparinized saline to remove the blood in liver and to prevent blood clotting using a speed-controlled perfusion device (0.4 ml/min). The mice were euthanized thereafter. Next, two specimen preparation methods were utilized: (1) portal vein vascular system: microfil reagent was perfused into portal vein after heparin perfusion via existing catheter (0.2 ml/min). (2) Hepatic venous system: infrahepatic inferior vena cava (IVC) was cannulated with another 26G catheter. Microfil component was perfused into IVC to hepatic vein through this catheter after the branches of IVC were ligated and suprahepatic inferior vena cava was clamped.
Micro-CT scanning: The microfil samples were subjected to CT scanning using SkyScan 1172 (Tomoscope Duo, CT-Imaging, Erlangen, Germany) μCT system (SkyScan, Kontich, Belgium) as described by Josef Ehling.

Results: *Micro-CT images:* Using the method described above, we could obtain micro-CT images suitable for 3D-reconstruction. Comparing the Micro-CT images obtained on POD2 with those obtained immediately after PH group, the vessel diameter doubled by POD2. In contrast, the number of third order branches from both portal and hepatic venous tree did increase by POD2, but even more by POD7, leading to an increased vascular density.

Conclusions: CT imaging of explanted livers after microfill contrasting the vascular tree represents a useful tool for visualizing vascular regeneration after partial hepatectomy. Vascular growth consists of enlarging the diameter of the vascular stem with its main branches and outgrowth of additional terminal branches in both the portal venous and hepatic venous tree.



P0017

DEVELOPMENT OF TISSUE-ENGINEERED VASCULARIZED PORCINE LIVER SCAFFOLDS FOR HUMAN TRANSPLANTATION

K.H. Hussein[1,2], K.-M. Park[1,2], G.-J. Hoon[1], S.-R. Yang[1,3], S.-M. Park[1,3], H.M. Woo[1,2,4]. *[1]Stem Cell Institute, [2]College of Veterinary Medicine, [3]Department of Thoracic and Cardiovascular Surgery, School of Medicine, Kangwon National University, Chuncheon, Korea, South; [4]Harvard Stem Cell Institute, Renal Division, Brigham and Women's Hospital, Harvard Medical School, MA, United States*
E-mail: Kamalhussein1986@gmail.com

Background and Aims: There is an ever-rising demand for transplantable livers in end-stage liver failure patients for replacement of damaged livers. The field of regenerative medicine could provide a solution through engineering of bioartificial livers. Our aims are to establish an optimized protocol for constructing a bioartificial hepatic lobe, investigate its immunocompatibility and create a humanized recellularized hepatic scaffold using porcine livers.

Methods: Decellularization of the right lateral lobe was performed by perfusing sodium dodecyl sulfate through the right branch of portal vein. Decellularized lobes were evaluated by morphologic and biochemical techniques. DNA content was quantified to validate the decellularization protocol. Presence of α 1,3-galactosyltransferase, major histocompatibility complex, porcine vonWillebrand Factor and sialoadhesin was checked to exclude the potential rejection and thrombosis after transplantation. Additionally, porcine endogenous retrovirus, a well-known zoonotic risk, was analyzed. Xeno-reactivity of decellularized tissue against human PBMCs was also examined. We recellularized this lobe by HepG2 cells and human endothelial cells via portal vein, then cultured inside a bioreactor for 10 days. Perfusion of recellularized scaffolds with human blood was performed to check the patency of vessels. Distribution of seeded cells within scaffolds was analysed by histology. Immunohistochemistry and PCR were performed for evaluating the functions and proliferating abilities of cells grown within scaffolds.

Results: A translucent lobe with an intact vascular network was successfully developed. H&E staining showed complete removal of the cellular materials and preserving the intact architecture. Although resulting matrices maintained the complex composition of ECM, approximately 99% of DNA was eliminated. The scaffolds were depleted from immunogenic and viral antigens. Human immune response against scaffolds was non-significant. After recellularization, HepG2 cells were almost evenly distributed within scaffolds. No thrombosis was observed after human blood perfusion, indicating a fully endothelialized vascular tree. Immunohistochemistry and PCR confirmed that seeded cells retain their functions and proliferating abilities.

Conclusions: Decellularized porcine liver provides a tissue engineering platform that can be used potentially after recellularization and endothelization as a liver support system or direct transplantation in human.

P0018

ADENOSINE PROTECTS LIVER AGAINST OXIDATIVE STRESS DAMAGE IN LIVER ISCHEMIA/REPERFUSION (I/R) INJURY

A. Veljkovic[1], G. Kocic[1], T. Cvetkovic[1], D. Sokolovic[1], M. Radojkovic[2], T. Jevtovic[1], B. Djordjevic[1], M. Despotovic[1]. *[1]Medical faculty Nis, Republic of Serbia, [2]Clinical center Nis, Nis, Republic of Serbia*
E-mail: veljkovicandrej@yahoo.com

Background and Aims: Ischemia/reperfusion (I/R) injury is a multifarious process detrimental to liver graft function. Mechanisms involved in I/R injury are essential for the design of therapeutic strategies to improve the outcome of liver transplantation. The inflicts tissue damage and initiates. There are many reports on generation of reactive oxygen species

subsequent to re-oxygenation and they initiate a cellular cascade leading to inflammation, cell death, and possible organ failure. Complex manifestations such as rapid depletion in cellular ATP, increase in cytosolic calcium, activation of phospholipases and proteases, infiltration of neutrophils as well as arachidonic acid metabolism may reflect changes in the steady-state concentration of pro/antioxidants resulting in oxidative stress. The aim of this study was to examine the effect of adenosine preconditioning in protecting against a hepatic I/R injury

Methods: We have studied the lipid peroxidation levels (as MDA), glutathione (GSH) levels, catalase (CAT) and glutathione peroxidase (GPx) activity by appropriate spectrophotometric methods, in liver homogenate of male rabbits, one month old, who were allocated into two groups. The first group I/R animals were subjected to 45 min of right-lobe hepatic ischemia, followed by 48 hours of reperfusion. The second group intraportally received infusion of adenosine in physiological solution in dose of 1 mg/kg 20 min before I/R damage. The animals were sacrificed 48 h afterwards, livers were quickly removed, frozen and homogenised on ice.

Results: Obtained results demonstrated that MDA level was significantly decreased in second group compared to I/R group ($p < 0.001$). The levels of GSH as well as CAT activities were increased in adenosine treated group ($p < 0.001$ vs. I/R group). The results also showed statistically significant decrease activity of GPx ($p < 0.001$ vs. I/R group).

Conclusions: These results suggest that intraportally infused adenosine attenuates reperfusion injury of the liver, presumably by suppressing the activation of neutrophils and oxidative stress, so adenosine preconditioning can have protective effect during liver transplantation.

P0019

ADIPONECTIN AND RELATED ADIPOCYTOKINES IN STEATOTIC AND NON-STEATOTIC LIVER TRANSPLANTATION

M.B. Jiménez Castro[1], A. Casillas Ramírez[2], M.E. Cornide Petronio[1], M. Mendes Braz[1], J. Gracia Sancho[3], L. Torrens[1], J. Rodés[1], C. Peralta[1]. *[1]Protective strategies against hepatic ischemia-reperfusion injury, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [2]Hospital Regional de Alta Especialidad de Ciudad Victoria, Ciudad Victoria, Mexico; [3]Hepatic Hemodynamic Laboratory, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain*
E-mail: monicabjimenez@hotmail.com

Background and Aims: Controversial roles for adiponectin and related adipocytokines have been described in different liver pathologies, nevertheless it is unknown their possible implication in ischemia-reperfusion injury associated with liver transplantation. Our study aimed at characterizing the role of the adiponectin-derived molecular pathway in transplantation with steatotic and non-steatotic liver grafts

Methods: Steatotic and non-steatotic liver transplantationwas carried out and the hepatic levels of adiponectin, visfatin and resistin were measured and modulated either pharmacologically

Results: Pharmacological strategies aimed at modulating adiponectin or resistin were irrelevant for non-steatotic liver grafts submitted to 6 h of cold ischemia. However steatotic livers are more predisposed to downregulate both adiponectin and resistin when subjected to transplantation. Visfatin is not involved in either the vulnerability of steatotic and non-steatotic livers to damage associated with transplantation or in the benefits of adiponectin in steatotic liver transplantation. Adiponectin pre-treatment only protected steatotic grafts and did it so through a resistin-dependent mechanism. Adiponectin-derived resistin accumulation activated the PI3K/Akt pathway. Strategies aimed at increasing adiponectin prevented the downregulation of PI3K/Akt pathway and protected steatotic liver grafts. Conversely, PI3K/Akt pathway upregulation and hepatic protection induced by adiponectin were abolished when resistin action was inhibited

Conclusions: Our findings reveal a protective pathway in steatotic liver transplantation, which may help develop new strategies aimed at increasing either adiponectin or resistin in the steatotic liver undergoing transplant to ultimately increase organ donor-pool for transplantation since they may improve the outcomes of steatotic liver grafts that otherwise would not be transplanted

P0020

ROLE OF ENDOTHELIAL AUTOPHAGY IN LIVER ISCHEMIA AND REPERFUSION INJURY

S. Guixé-Muntet[1], S. Vila[1], C. Peralta[2], J.C. Garcia-Pagan[1], J. Bosch[1], J. Gracia-Sancho[1]. *[1]Barcelona Hepatic Hemodynamic Lab, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS) – Hospital Clínic de Barcelona – CIBEREHD – University of Barcelona Medical School, [2]IDIBAPS & CIBEREHD, Barcelona, Spain*
E-mail: sguixemuntet@gmail.com

Background and Aims: The liver endothelium is highly susceptible to Ischemia/Reperfusion (I/R) injury, thus its preservation determines the success of transplantation. It is unknown wether Autophagy, an intracellular process that controls cellular homeostasis and survival, plays a role in liver endothelial I/R injury. Simvastatin, a vasoprotective compound that preserves liver microcirculation through a KLF2-dependent and cholesterol-independent manner, has recently been shown to activate autophagy.

Aims: (1) Characterize autophagy in liver sinusoidal endothelial cells (LSEC) cultured under I/R conditions, and its effects on cell viability, and (2) evaluate the role of autophagy in the protection of the liver microcirculation conferred by simvastatin, and its underlying molecular pathways, using *in vitro* and *ex vivo* models of hepatic I/R injury.

Methods: *in vitro*: primary LSEC where pretreated with simvastatin (KLF2 inducer; 5μM), GGPP (KLF2 inhibitor; 1μM) and/or chloroquine (autophagy inhibitor; 20μM) and cultured mimicking I/R [6 h, 12 h or 24 h in University of Wisconsin solution (UWS) or Celsior at 4°C + 2 h of warm reperfusion; n = 3 per condition]. Determinations: Autophagic flux as LC3 levels in presence or absence of chloroquine, cell death by acridine orange and propidium iodide staining, KLF2 levels by western blot.

Ex vivo: Wistar rats were treated with simvastatin (1 mg/kg i.v.), chloroquine (60 mg/kg i.p.) + simvastatin, or vehicle (n = 8 per group). 30min later livers were explanted, cold stored in UWS for 16 h and, and after 2 h of reperfusion hepatic microvascular function was characterized.

Results: *In vitro*: LSEC cold stored in Celsior solution exhibited a time-dependent activation of autophagic flux. However, no changes in autophagic flux were observed in UWS-stored LSEC due to an inhibited formation of autolysosomes. Simvastatin re-activated autophagy in UWS-stored cells, which in turn increased KLF2 expression, and ultimately improved cell viability. The beneficial effects of simvastatin were blunted when autophagy or KLF2 expression were previously inhibited.

Ex vivo: simvastatin ameliorated the microvascular function of UWS-stored liver grafts. This effect was markedly diminished when hepatic autophagy was inhibited.

Conclusions: The present study describes for the first time two concepts: (1) activation of endothelial autophagy as a protective strategy during organ cold storage for transplantation, and (2) induction of the transcription factor KLF2 through the activation of autophagy.

P0021

ALTERING TRANSPLANTED CELL ENGRAFTMENT AND PROLIFERATION IN THE LIVER THROUGH PARACRINE SIGNALING WITH COTRANSPLANTATION OF LIVER SINUSOIDAL ENDOTHELIAL CELLS AND HEPATOCYTES IN MICE

S. Merlin[1], K. Bellofatto[1], E. Berishvili[2], B. Joseph[2], R. Badhe[2], S. Gupta[2], A. Follenzi[1,2]. *[1]Department of Health Sciences of University of Piemonte Orientale, Novara, Italy; [2]Albert Einstein College of Medicine, Bronx (NY), United States*
E-mail: simone.merlin@med.unipmn.it

Background and Aims: Liver is maintained in a healthy state by tightly regulated interactions among liver cell types. For instance, liver sinusoidal endothelial cells (LSECs) are able to initiate and sustain liver regeneration process. After cell transplantation, multiple cell compartments are activated and cell-cell interactions regulate transplanted cell engraftment and proliferation. Activation or disruption of LSEC facilitates engraftment of transplanted hepatocytes (HEP), as well as LSEC. To develop strategies for liver-directed cell and gene therapy, insights into such cell-cell interactions will be helpful, particularly for improving transplanted cell engraftment, survival and proliferation. Recently, we demonstrated that under suitable conditions transplanted LSEC can engraft, function and reconstitute the hepatic endothelium. We studied potential roles of LSEC in engraftment and liver repopulation of transplanted HEP.
Methods: We used C57Bl/6, GFP^+ and $DPPIV^-$ mice as HEP and LSEC donors and $DPPIV^-$ mice as recipients treated with monocrotaline alone or in combination with riphampicin and phenytoin, which improves transplanted cell engraftment and proliferation. In some experiments LSEC were transduced withlentiviral vectors expressing VEGF or HGF. We compared the gene expression profile of genes specific for ECs biology in the transplanted livermice.
Results: After 1w cotransplantation improved the overall cell engraftment. After 6w the liver endothelium of recipient mice was replaced by transplanted LSEC and the overall HEP proliferation was not improved compared to mice transplanted with HEP alone. After LSEC genetic manipulation, in vitro experiments showed that LSEC-released factors promoted HEP proliferation or viability, while in vivo improvedHEP engraftment, demonstrating thatnative LSEC were not providing enough paracrine factors and so additional manipulations are needed to improve HEP engraftment. Gene expression profile analysis of EC specific genes 6, 24, 48 h and 1w post-transplant showed that LSEC transplantation does not perturb the liver microenvironment at any time point, while changes were detected after HEP infusion or cotransplantation, meaning that major changes can be attributed to HEP.
Conclusions: The ability to reconstitute the liver with LSEC and HEPco-transplantationwill offer potent ways to investigate biological mechanisms of cell-cell interactions to develop protocols for cell therapy of suitable disorders.

WHOLE ORGAN ENGINEERING USING DECELLULARIZED SCAFFOLD FOR LIVER TRANSPLANTATION IN LARGE ANIMAL MODEL

K. Inomata[1], H. Yagi[1], K. Tazima[1], K. Sugiyama[1], M. Hieda[1], Y. Abe[1], T. Hibi[1], M. Kitago[1], M. Shinoda[1], T. Akaike[2], O. Itano[1], Y. Kitagawa[1]. *[1]Department of Surgery, Keio University, [2]Department of Biomolecular Engineering, Graduate School of Bioscience and Biotechnology, Tokyo Institute of technology, Tokyo, Japan*
E-mail: inomaru_6480@hotmail.com

Background and Aims: Fulminant hepatic failure remains a serious clinical condition that is associated with a high mortality rate. The only effective treatment is liver transplantation, however, there is currently a severe shortage of donor livers. Therefore a novel methodology to replace organ transplant and shift to regenerative approaches is strongly required. The organ decellularization can produce the native organ scaffold which can carrier any type of cell source include iPS derived cells. These scaffolds are generated by removing viable cells from organ and the vascular structure was preserved, which can be connected to native vascular system by surgical anastomoses. It is important to find the feasibility of this technology to be applied into human scale and to see biological alterations of the scaffold after implantation.
Methods: We demonstrated that the decellularization methodology could be applied in large animal model and it could be sufficiently recellularized with endothelial cells and hepatocytes. The decellularized scaffold was generated by procedure using Trypsin, SDS, TrytonX-100 and CHAPS. To prevent coagulation after blood perfusion, endothelial cells and hepatocytes were infused into the scaffold with monitoring intravascular pressure and perfusion flow rate. In addition we also infused the amphipathic polymer having an anti-coagulant activity into the scaffold. Blood flow was evaluated by angiography after vascular anastomoses after transplantation. Histological study was performed after transplantation to evaluate cell infiltration, degree of coagulation and adhesion around the scaffold.
Results: The endothelial cells could cover most of the vessel lumen of the scaffold and the hepatocytes were well distributed into the parenchymal space. We could successfully transplant the recellularized graft in porcine body by vessel anastomosis of portal vein and IVC without any leakage. Although histological study showed that the coagulation was not completely avoided of the vascular system in the graft, the coagulation was less in the area sufficiently covered with the endothelial cells and the hepatocytes. The graft was well perfused and preserved in the porcine abdominal cavity without bleeding or absorption.
Conclusions: Although it requires improvement and customization in point of anti-coagulation, we could scale-up and optimize the system to apply this unique technology for clinical applications.

P0023

COMPARISON OF THE C3A AND HepaRG LIVER CELL LINES IN MONOLAYER AND 3D FOR BIOARTIFICIAL LIVER APPLICATION

M. Van Wenum[1,2,2], R.A.F.M. Chamuleau[1], E.J. Hendriks[2], T.M. van Gulik[2], A.A.A. Adam[1], R. Hoekstra[1,2]. *[1]Tytgat Institute for Liver and Intestinal Research, [2]Surgical laboratory, Academic Medical Center of the University of Amsterdam, Amsterdam, Netherlands*
E-mail: m.vanwenum@amc.uva.nl

Background and Aims: Recently, the first clinical trials of Bioartificial livers (BAL) loaded with a proliferative hepatocyte source have started. C3A cells are among the most commonly deployed cell lines in BAL devices. However, we and others have suggested that the hepatic progenitor cell line HepaRG exhibits a phenotype that reflects the phenotype of primary hepatocytes to a significantly higher extent compared to C3A cells, which would render this cell line more suitable for BAL application. No head-to head comparison between C3A and HepaRG is available yet. Therefore, we directly compared parameters relevant for BAL therapy of both cell lines, in monolayers and laboratory sized BAL devices.
Methods: First we defined the optimal culture and differentiation conditions for C3A cells (acquired from ATCC) in monolayers and in laboratory sized AMC miniBALs. Next, we compared the C3A cells with HepaRG cells both differentiated in optimal conditions in the same culture medium in monolayer and miniBALs.
For comparison, the cells were assessed at biochemical level for ammonia elimination, urea cycle activity, albumin production, AST and LDH leakage, amino acid metabolism, glucose and lactate metabolism. The results were normalized to total protein content. In addition the cells were assessed for transcript levels of hepatic genes.

Results: Both cell lines reached a higher differentiation grade in BALs compared to monolayer. HepaRG cells outperformed C3A cells for most tested parameters. Most notably, C3A cells produced lactate and ammonia whereas HepaRG consumed both compounds when cultured in a BAL. In addition C3A cells consumed glutamine while HepaRG cells showed pronounced production, suggesting high activity of glutaminase in C3A cells and more active glutamine synthase in HepaRG cells. Gene expression levels for xenobiotic metabolism and membrane transporters were 15–200 fold higher in HepaRG. Expression of the fetal marker AFP was up to 10^4 fold higher in C3A cells. Cell leakage was significantly higher in C3A and albumin synthesis was comparable between the cell lines.
Conclusions: Both cell lines perform better in the environment of a BAL as compared to monolayers. HepaRG cells significantly outperform C3A cells on a multitude of parameters relevant for BAL application. These results thus suggest that HepaRG may be the more suitable biocomponent for BAL application.

E-mail: totoali1@hotmail.com

Background and Aims: Several studies have demonstrated the role of mesenchymal stem cells in the hepatic regenerative process. The aim of the study was to investigate the feasibility of liver damage repair using Wharton's jelly-derived mesenchymal stem cells (WJMSCs; the major umbilical cord stem cell population) combined with praziquantel (PZQ) to treat Schistosoma (S.) mansoni-induced liver fibrosis.
Methods: Mice received early (8th week post infection) and late (16th week post infection) intra-hepatic injection of WJMSCs, alone or combined with oral PZQ, to investigate the treatment efficacy on both acute and chronic stages of liver fibrosis, respectively. Histopathological, morphometric, and immunohistochemical analysis for alpha fetoprotein, alpha smooth muscle actin, Hep par-1, cytokeratin-18, vimentin, and β2-globulin, were performed. Relative mRNA expression of albumin, alpha fetoprotein, alpha smooth muscle actin, collagen I, and interleukin 13 was measured by real time reverse transcription polymerase chain reaction (RT-PCR). Gelatin zymographic analysis for matrix metalloproteinase (MMP)-2 and 9 was also performed. The previously mentioned studies were used to monitor transplanted stem cell differentiation into hepatocyte-like cells and to assess S. mansoni-induced liver fibrosis.
Results: Histopathological and morphometric findings showed a regression in fibrosis in WJMSCs-treated groups and better results were obtained when PZQ was combined to stem cell therapy. Immunohistochemical and RT-PCR findings showed positive expression for hepatocyte-specific markers in transplanted groups and an amelioration of fibrosis-related markers. Gelatin zymography results showed an elevation of the enzymatic activity of MMP-2 and -9 in WJMSCs-treated groups. Meanwhile, PZQ caused a reduction in the activity of both enzymes. Combined treatment, however, caused no or little change
Conclusions: The differentiation of transplanted WJMSCs into functioning hepatocyte-like cells in the livers of S. mansoni-infected mice may have contributed to partial repair of liver fibrosis, especially when PZQ is administered concomitantly

Liver transplantation/Surgery: b. Clinical

THE PUBLIC HEALTH VALUE OF SPARING LIVERS FOR TRANSPLANTATION THROUGH SYSTEMATIC TREATMENT OF HEPATITIS C
W. Stevens[1], Y. Sanchez[2], R. Brookmeyer[3], D. Lakdawalla[4], S. Marx[2], T. Juday[2]. *[1]Precision Health Economics, Santa Monica, CA, [2]AbbVie Incorporated, North Chicago, IL, [3]University of California Los Angeles, [4]University of Southern California, Los Angeles, CA, United States*
E-mail: warren.stevens@precisionhealtheconomics.com

Background and Aims: The increasing availability of highly efficacious new treatments for hepatitis C virus (HCV) is expected to significantly reduce the number of people progressing to end stage liver disease (ESLD) and becoming candidates for liver transplantation in the future. Our study aims to quantify the potential benefits for ESLD patients waiting for liver transplants (LTs) in the US beyond those who have HCV. Several studies have modeled the potential changes in screening and treatment pathways likely to result from new HCV treatment introductions, but these models have been developed primarily to assess health outcomes in HCV patients such as decompensated cirrhosis, hepatocellular carcinoma, and liver related death. Moreover, the effect of new treatments on the availability of future transplants depends on the complex interaction of HCV epidemiology, the prevalence of other diseases – most notably alcoholic liver disease, and nonalcoholic fatty liver disease (NAFLD) – and on the future supply of healthy livers for transplantation.
Methods: To ensure robustness, we used multiple methods to estimate future demand for livers between 2015 and 2035. We used a Markov model to study a scenario of widespread screening and treatment for HCV implemented from 2015 to 2020. The Markov model results were validated against those of an attributable risk model based on both Organ Procurement and Transplantation Network and National Health and Nutrition Examination Survey data. We also considered a number of scenarios for future disease trends, ranging from stable prevalence of non HCV liver disease

to projected growth in prevalence based on empirical evidence of trends in risk factors such as obesity and diabetes, the primary drivers of NAFLD incidence.
Results: The projected cumulative number of LTs averted for ESLD patients due to highly effective HCV treatment is estimated to be 10,490 over the period 2015–2035 (see Figure). Of this total, 7,320 livers would accrue to patients without HCV, accounting for 9% of livers used for all non-HCV liver transplants over this time period and approximately 123,700 life-years gained by non-HCV patients.
Conclusions: More systematic use of highly effective treatments for HCV in the US may have substantial public health benefits for patients suffering from ESLD due to decreased liver transplantation in the HCV population. Most of these benefits accrue to patients without HCV.

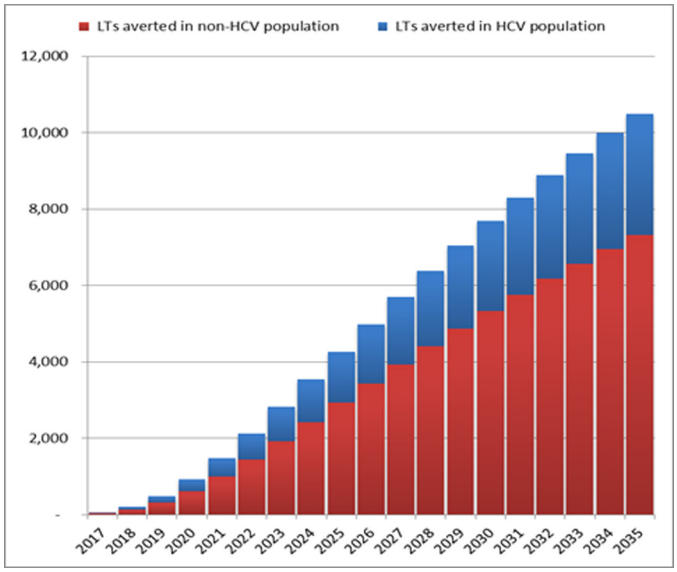

Figure: Cumulative estimation of liver transplants (LTs) averted from years 2015–2035 in the US from a scenario of introducing widespread screening and treatment of HCV in 2015–2020.

Internal Medicine Department, Hospital Vall d'Hebrón, [10]Liver Unit, Hospital Clínic, Barcelona, Spain*
E-mail: aforner@clinic.ub.es

Background and Aims: Previous studies including a limited number of patients and/or short follow-up offer conflicting data regarding the impact of HIV on survival in patients with hepatocellular carcinoma (HCC) after liver transplantation (LT). The aim of this prospective multicenter study was to evaluate the influence of HIV infection in tumor recurrence and post-LT survival in HCC patients treated by LT.
Methods: Prospective cohort study including HIV infected patients undergoing LT for HCC in 22 Spanish hospitals (cohort FIPSE) and transplanted HIV (−) patients matched for age, gender, year of LT, HCV, HBV and HCC in a ratio 1: 3. Incidental HCC patients were excluded. Enrollment began in January 2002 and the end of follow-up was in July 2014.
Results: 74 patients HIV (+) patients and 222 HIV (−) underwent LT for HCC during the study period. Most were men (86%) and had HCV co-infection (92%). HIV (+) patients were younger (47 vs. 51 years, $p < 0.001$) and had genotype non-1 with higher frequency (55 vs. 25%) and less frequent HCV replication at the time of LT (80% vs 90%) compared to HIV (−) patients. At the time of LT, median [interquartile range] CD4/mm3 were 347 [238–523] and the majority of HIV (+) patients (96%) were on antiretroviral therapy. The HIV viral load was <50 copies/ml in 93%. There were no differences in waiting time until the LT (4.5 vs. 5.4 months, $p = 0.35$), in baseline HCC characteristics at the moment of waiting list inclusion and on explant histological parameters between both groups. After a median follow-up of 46 [25–72] months, 12 (16%) HIV (+) patients and 32 (14%) HIV (−) patients had tumor recurrence. The probability of recurrence at 1, 3, and 5 years in HIV (+) and HIV (−) was 7%, 17% and 20% vs. 5%, 11% and 19%, respectively ($p = 0.876$). Analyzing jointly HIV patients (+) and HIV (−), microscopic vascular invasion (HR, 3.79; 95% CI, 1.67 to 8.57) was the only factor independently associated with HCC recurrence. Survival at 1, 3 and 5 years for HIV (+) patients compared to HIV patients (−) was 87%, 78% and 69% vs. 89%, 78% and 73% ($p = 0.905$). HCV infection (HR, 8.85 95% CI, 1.23 to 63.64) and the presence of satellite nodules (HR, 1.92; 95% CI, 1.13 to 3.24) were the only variables independently associated with mortality.
Conclusions: HIV infection has no impact on HCC recurrence or survival after LT. These results support the indication of LT in HIV-infected patients with HCC.

P0027
COST-EFFECTIVENESS OF PRE-TRANSPLANT SOFOSBUVIR TO PREVENT RECURRENCE OF HCV INFECTION AFTER LIVER TRANSPLANTATION

A. Vitale[1], G. Spolverato[1], P. Burra[2], U. Cillo[1], S. Fagiuoli[3], Liver Transplantation NITp working group. *[1]Dipartimento di Chirurgia Generale e Trapianto d'Organo, Unità di Chirurgia Epatobiliare e Trapianti Epatici, Università di Padova, Padova, [2]Unità di Trapianto Multiviscerale, Università di Padova, Padova, [3]Gastroenterology and Transplant Hepatology, Ospedale Papa Giovanni XXIII, Bergamo, Italy*
E-mail: alessandro.vitale@unipd.it

Background and Aims: The strong efficacy of pre-transplant Sofosbuvir (SOF) plus Ribavirin in preventing recurrence of hepatitis C virus (HCV) infection after liver transplantation (LT) has been reported. The aim of this study was to evaluate the cost-effectiveness of this strategy in the North Italy Transplant program (NITp) area.
Methods: We first evaluated the impact of HCV infection on post-LT survival in 2376 consecutive adult patients (MELD ≤25, period 2004–2009, NITp area) and prevalence-costs of conventional standard of care (SOC) antiviral therapy (Peginterferon plus ribavirin) after LT. A Markov model was developed to compared two strategies: SOF + Ribavirin (RBV) as pre-LT anti-HCV treatment (strategy A), versus on-demand post-LT SOC antiviral therapy (strategy B). The endpoint was incremental cost-effectiveness ratio (ICER) as costs ($)/quality-adjusted life year (QALY).
Results: Among the 1794 patients undergoing LT and meeting the inclusion criteria, 860 (48%) were HCV+ and 50% of them received SOC therapy post-LT (drugs and adverse effects management mean costs = 16,440$ for patient). HCV etiology had a strong impact on post-LT survival (hazard ratio 1.59, 95% CI 1.22–2.09, $p = 0.0007$). After Monte Carlo simulation, pre-LT SOF therapy showed a median

survival benefit of 2.0 QALYs, and an ICER of 33,600$/QALY. Costs of SOF therapy, sustained viral response rate 12 weeks after LT, and recipient age were the main ICER predictors at multivariate analysis.

Conclusions: Pre-transplant SOF in HCV patients proved to be a cost-effective treatment compared to post-LT SOC therapy.

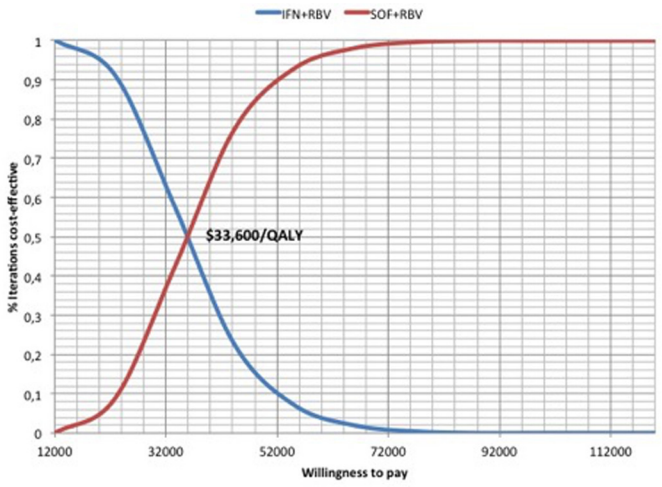

Figure: Cost effectiveness acceptability curve.

P0029

ACTIVE IMMUNIZATION IN PREVENTION OF DE NOVO HEPATITIS B IN ADULT LIVING DONOR LIVER TRANSPLANTATION WITH CORE ANTIBODY POSITIVE GRAFT

P.Y. Loh[1], C.C. Lin[2], C.L. Chen[2]. *[1]Department of Gastroenterology and Hepatology, Changi General Hospital, Singapore, Singapore; [2]Liver Transplantation program and Department of Surgery, Kaohsiung Chang Gung Memorial hospital, Kaohsiung, Taiwan*
E-mail: lohpohyen@yahoo.com

Background and Aims: De novo hepatitis B infection (DNHB) can occur in transplant recipients who receive organs from anti-HBc(+) donors. Post transplant prophylaxis can reduce the risk of DNHB. However, the issues of development of antiviral drug resistance and high cost of HBIG make it to be impractical for long term use. Studies on active immunization in paediatric population have shown promising results. However, its effect in adults is still uncertain. Our aim is to investigate the use of HBV vaccination as an alternative to prevent DNHB in adult living donor living transplantation.

Methods: Patients (with age ≥18 years) who received anti-HBc(+) liver grafts in a single center were enrolled. The cohort was stratified into 3 groups according to the response to HBV vaccination (flow chart). Group 1: responder to pre transplant vaccination with anti-HBs titer >1000 IU/L at the time of transplantation and for post transplant surveillance only; Group 2: no response to pre transplant vaccinations but responded to post transplant vaccination with anti-HBs titer >100 IU/L after transplantation, lamivudine was stopped after a minimum period of 2 years; Group 3: no response to pre and post transplant vaccination, lamivudine was continued indefinitely.

Results: A total of 71 patients were enrolled (group 1: 24, group 2: 32 and group 3: 15). All recipients with high pre transplant anti-HBs titers (group 1) achieved post transplant anti-HBs level >100 IU/L. Groups 1 and 2 had significant higher DNHB-free survival rates than group 3 (gp 1 vs 3: $p = 0.016$, and gp 2 vs 3: $p = 0.004$ respectively). All 3 cases of DNHB were from group 3, none was detected in groups 1 and 2 after a median follow-up of 61 months.
Higher recipient and donor pre transplant anti-HBs titer, post transplant achievement of anti-HBs >100 IU/L, and higher post transplant peak anti-HBs titer were associated with reduced risk of DNHB on univariate analysis ($p < 0.05$). However, multivariate analysis using cox regression analysis failed to find significant association.

Conclusions: Active immunization is effective in preventing DNHB in adult living donor liver transplantation, by keeping pre transplant anti-HBs level of >1000 IU/L and post transplant anti-HBs of >100 IU/L. With vaccination, lamivudine can be stopped in patients who achieve post transplant anti-HBs level of >100 IU/L. Hence, active immunization provides a cheaper and safe alternative to existing regimens.

UTILITY BASED CRITERIA TO SELECT PATIENTS WITH HEPATOCELLULAR CARCINOMA FOR LIVER TRANSPLANTATION: A MULTICENTRE COHORT STUDY

A. Vitale[1], F. Farinati[2], F. Trevisani[3], P. Burra[4], E.G. Giannini[5], G. Spolverato[1], U. Cillo[1], ITA.LI.CA. study group. *[1]Dipartimento di Chirurgia Generale e Trapianto d'Organo, Unità di Chirurgia Epatobiliare e Trapianti Epatici, Università di Padova, Padova, [2]Divisione di Gastroenterologia, Università di Padova, [3]Department of Medical and Surgical Sciences, Division of Semeiotics, Alma Mater Studiorum – University of Bologna, Bologna, [4]Divisione di Gastroenterologia, Università di Padova, Padova, [5]Unità di Gastroenterologia, Università di Genova, Genova, Italy*
E-mail: alessandro.vitale@unipd.it

Background and Aims: The lifetime utility of liver transplantation (LT) in patients with hepatocellular carcinoma is still controversial. The aim of this study was to understand when LT is cost-effective for HCC patients in order to suggest new potential transplant selection criteria.

Methods: The overall design of this study involved a real cohort of transplantable Italian HCC patients (n = 2419 selected from the ITA.LI.CA database) undergoing non-transplant therapies for whom a survival analysis and calculation of direct costs of therapies were performed, and then a Markov model to calculate the survival benefit and cost-utility of LT over non-LT therapies. Post LT survival was calculated using the α-fetoprotein (AFP) model based on AFP values and radiological size and number of nodules. Primary endpoint was Net Health Benefit (NHB), defined as LT survival benefit in quality adjusted life years (QALYs) minus incremental costs (#)/willingness to pay ($32,946, corresponding to the Italian Gross Domestic Product).

Results: We developed a prognostically accurate survival model predicting non-LT survival, based on AFP model variables, Child Pugh classes, and type of alternative therapy (resection, loco-regional, or best supportive care). The calculated median cost of non-LT therapies per patient was $21,670. The Monte Carlo

simulation showed that in patients with resectable child A HCC, the NHB of LT was always negative, independently from the AFP model values, while in unresectable HCC patients, the NHB of LT was positive for AFP model values ≤4, and negative for values >4.
Conclusions: LT proved to be cost-effective in HCC patients with unresectable tumor and AFP model values ≤4.

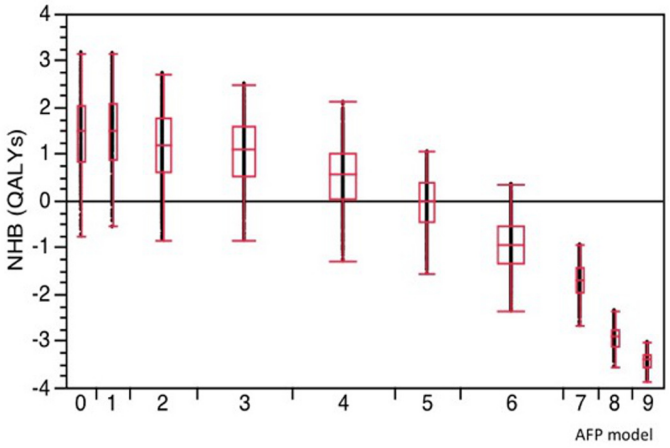

Figure: NHB of liver transplantation in unresectable HCC patients.

P0031
FREQUENCY AND OUTCOMES OF SIMULTANEOUS LIVER KIDNEY TRANSPLANTATION IN NASH

A.K. Singal[1], M. Hasanin[1], M. Kaif[1], Y.-F. Kuo[2], R. Wiesner[3].
[1]Gastroenterology and Hepatology, UAB, Birmingham, [2]Biostatistics, UTMB, Galveston, [3]Gastroenterology and Hepatology, Mayo Clinic, Rochester, United States
E-mail: ashwanisingal.com@gmail.com

Background and Aims: Frequency of liver transplants (LT) is increasing in non-alcoholic steatohepatitis (NASH) with better outcomes compared to other etiologies. Similar data on simultaneous liver kidney (SLK) transplants are limited.
Methods: UNOS database (2002–2011) queried for deceased donor first LT for primary biliary cirrhosis (PBC), primary sclerosing cholangitis (PSC), hepatitis C virus (HCV), alcoholic liver disease (ALD), combined ALD and HCV, NASH, cryptogenic cirrhosis (CC), hepatitis B virus (HBV), and hepatocellular carcinoma (HCC) and stratified to LT alone (LTA) and SLK. LT indication was stratified to PBC+PSC+ALD (group I), NASH+CC (group II), and HCV±ALD+HBV+HCC (group III).
Results: Of 40,326 analyzed LT (9495, 5448, and 25,383 in groups I–III respectively), about 5.8% (N = 2319) received SLK (6%, 9%, and 5% in groups I–III respectively). Of LTA, 22%, 14%, and 64% were performed for group I–III respectively. Similar respective figures of all SLK were 23%, 20%, and 57% respectively (Figure). Frequency of SLK increased from about 4% in 2002 to about 7% in 2011. Trends for group I–III were 4% to 5.8%, 4% to 10%, and 4% to 8% respectively. SLK for NASH+CC (group II, n = 477) compared to 1842 non-NASH SLK (group II+III) were older, more likely to be females, diabetics, and Caucasians, and have higher body mass index. Five year respective outcomes after SLK comparing group I–III were 78% vs. 76% vs. 66% for liver graft, 79% vs. 72% vs. 65% for kidney graft, and 81% vs. 77% vs. 69% for patient survival, Log Rank P < 0.0001 for all. Comparing groups I and II, outcomes were similar for liver graft (P = 0.29) and patient survival (p = 0.14) but worse for group II on kidney graft (P = 0.01). Diabetics compared to non-diabetics had worse five year kidney survival for non-NASH SLK (67% vs. 71%, P = 0.044). Similar respective figures among group II were 69% vs. 78%, P = 0.017. Patients receiving SLK for NASH or CC (group II) were 29% more likely to lose kidney graft [1.29 (1.002–1.67)] compared to non-NASH transplants after controlling for recipient characteristics and kidney donor risk index. Other strong predictors were black race [1.32 (1.06–1.63)] and dialysis [1.26 (1.07–1.49)].
Conclusions: Frequency of SLK transplants is increasing among NASH patients requiring liver transplantation. SLK recipients for NASH have worse renal outcomes independent of associated diabetes. Studies are needed to examine mechanisms of renal pathology in NASH and to develop strategies to improve renal outcomes in NASH patients receiving SLK.

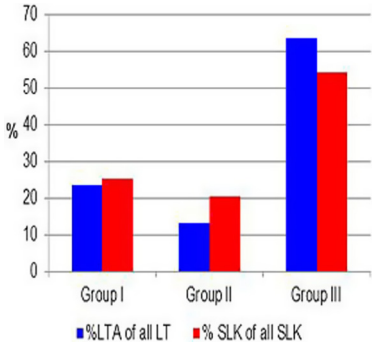

Figure: LTA (blue bars) and SLK (red bars) for specific etiology as proportion of all LTA and SLK respectively.

P0032
THE IMPACT OF ISCHEMIA/REPERFUSION INJURY ON LIVER ALLOGRAFTS FROM DECEASED AFTER CARDIAC DEATH VERSUS DECEASED AFTER BRAIN DEATH DONORS

B. Amir Sayed[1,2], J. Xu[3], A.M. Casas-Ferreira[4], P. Srinivasan[1], N. Heaton[1], Y. Ma[1], C. Legido-Quigley[3], S. Fuggle[5], W. Jassem[1]. *[1]Liver Transplant Unit, Institute of Liver Studies, King's College Hospital, London, United Kingdom; [2]Department of Transplant Surgery, Emory University, Atlanta, United States; [3]Institute of Pharmaceutical Science, King's College London, London, United Kingdom; [4]Department of Analytical Chemistry, University of Salamanca, Salamanca, Spain; [5]Nuffield Department of Surgery, University of Oxford, John Radcliffe Hospital, Oxford, United Kingdom*
E-mail: b.a.sayed@emory.edu

Background and Aims: The continuing shortage of appropriate organs for transplantation has led to the reevaluation and use of organs procured from donors after cardiac death. The pathophysiologic processes associated with cardiac as compared to brain death are poorly understood. The aim of this study was to determine how the ischemia/reperfusion (I/R) event associated with transplantation affects allografts obtained from donors after cardiac death (DCD) versus donors after brain death (DBD).
Methods: Allograft leukocyte infiltration and expression of inflammatory and cell death markers were compared between DCD (n = 22) and DBD (n = 13) livers by immunohistochemical (IHC) analysis using pre- and post-reperfusion liver biopsies. TUNEL staining was performed to evaluate cell death. Hepatocyte inflammation was assessed by liquid chromatography-mass spectrometry (LC-MS) measurement of various ceramides in an independent cohort consisting of DCD (n = 13) and DBD (n = 10) allografts. The means of IHC findings were compared with a Student's *t*-test, and Spearman's test was used to determine significant correlations with respect to donor and recipient clinical parameters. For ceramide analysis, univariate non-parametric Wilcoxon sign-rank test was performed.
Results: Prior to transplantation, DBD livers have higher levels of leukocyte infiltration and increased expression of pro-apoptotic factor FasL and high levels of intracellular adhesion molecule-1 (ICAM-1), as compared to DCD allografts. Following reperfusion, the neutrophil infiltration and platelet deposition associated with

I/R injury remained more prominent in DBD grafts as compared to their DCD counterparts. Further, there was greater upregulation of pro-inflammatory ceramides in post-transfusion biopsies in DBD as compared to DCD allografts. Despite decreased inflammation, DCD allografts had significantly higher levels of cell death than DBD grafts, which correlated with the duration of warm ischemia time as well as significantly higher levels of aspartate aminotransferase (AST) in the serum of recipients of DCD livers in the acute post-transplant period.
Conclusions: These data suggest that ischemia/reperfusion injury causes a non-inflammatory necrosis in DCD allografts with an appreciable effect on early graft function. The long-term consequences of increased inflammation in DBD allografts and cell death in DCD allografts are unknown and warrant further investigation.

P0033
PROSPECTIVE EVALUATION OF INTRAOPERATIVE PORTO-CAVAL GRADIENT AFTER MAJOR HEPATECTOMY

M.-A. Allard[1], O. Ciacio[1], G. Pittau[1], M. Gelli[1], R. Memeo[1], A. Sa-Cunha[1], D. Castaing[1], D. Cherqui[1], R. Adam[1], E. Vibert[1,2,3].
[1]Centre Hepato-Biliaire, AP-HP Hôpital Paul Brousse, [2]Unit 785, INSERM, [3]UMR-S 785, Univ Paris-Sud, Villejuif, France
E-mail: eric.vibert.pbr@gmail.com

Background and Aims: It has been shown that portal pressure may be a predictor of posthepatectomy liver failure. The aim of this study was to prospectively assess the relationship between porto-caval gradient (PCG) and portal vein pressure (PVP) with respect to postoperative morbidity and mortality.
Methods: From January 2013 to June 2014, measurements of caval and portal pressure at the end of a major liver resection have been performed in a single institution. Preoperative, intraoperative and postoperative data have been prospectively collected in the e-Hpbchir database. The main endpoint was the severe morbidity (Dindo Clavien score grade III-V). Secondary endpoints were the comprehensive complication index, postoperative ascitis and jaundice.
Results: A total of 119 patients have been included. Median value (range) of PCG and PVP were 6 mmHg (0–22) and 13 mmHg (3–29), respectively. The optimal cutoff value that best predicts severe morbidity was 12 mmHg for PCG (AUC=0.657) and 18 mmHg for PVP (AUC=0.664). Severe morbidity occurred more often in patients with PCG ≥12 mmHg (70% vs 25%; $P = 0.0001$) and in those with PVP ≥18 mmHg (69% vs 23%; $P < 0.0001$). The PCG correlates the PVP ($r = 0.79$; $P < 0.001$). Mean comprehensive complication index was significantly higher in patients with elevated PCG [43 (±29) vs 22 (±20); $P = 0.005$] and elevated PVP [42 (±26) vs 21 (±20); $P = 0.0004$]. Patients with PCG ≥12 mmHg developed more often postoperative ascitis and jaundice compared to those with PCG <12 mmHg (35% vs 3%; $P < 0.0001$). Similar differences were observed in patients with a PP ≥18 mmHg (27% vs 3%; $P = 0.0006$).
Conclusions: This study prospectively validates the predictive value of porto-caval gradient for severe morbidity after major hepatectomy, similar to that we observed with portal vein pressure retrospectively. This confirms that portal flow modulation must be explored to improve post-operative results of major hepatectomy.

P0034
GOOD OUTCOME OF PATIENTS TRANSPLANTED WITH MELD SCORE GREATER THAN 30: PAUL-BROUSSE HOSPITAL EXPERIENCE

F. Artru[1,2], A. Louvet[2], P. Ichaï[1], J. Berthaux[1], A. Coilly[1], M. Boudon[1], T. Antonini[1], E. De Martin[1], E. Vibert[3], D. Samuel[1], F. Saliba[1].
[1]Réanimation hépatique, Centre hépato-biliaire, hôpital Paul Brousse, Villejuif, [2]Service des maladies de l'appareil digestif, CHRU, Lille, [3]Service de chirurgie hépato-biliaire et de transplantation hépatique, Centre hépato-biliaire, hôpital Paul Brousse, Villejuif, France
E-mail: flo_artru@hotmail.com

Background and Aims: Several studies observed that patients transplanted with MELD score ≥30 have a lower survival after liver transplantation (LT) as compared to patients with less severe disease but this issue remains controversial. Such information is crucial to evaluate sickest candidates for LT. To compare survival rates between patients with MELD ≥30 and MELD <30 at time of LT.
Methods: This is a single centre, retrospective study, performed from 2008 to 2014. Patients with fulminant hepatitis and combined liver-kidney transplantation were excluded. We compared survival of patients with MELD score ≥30 to that of patients with MELD score <30, transplanted in the same period in the same centre.
Results: We included 106 patients with MELD ≥30 at time of LT, who had the following characteristics (medians): age 53.2 years (95% CI 50.8–55.2), INR 4.22 (3.8–4.8), bilirubin 22.4 mg/dl (17.8–26.2), creatinine 0.99 mg/dl (0.85–1.3), albumin 30 g/l (29–31), MELD 36 (34–37). Median hospital stay before LT was 22 days. 8.5% were HIV-positive, 25.5% were hospitalised in ICU on the day of LT, 4.7% had renal replacement therapy, 8.5% required mechanical ventilation and 7.5% vasopressors. Indication of LT was cirrhosis in 86.75%, HCC 5.7% and retransplantation for 7.55% of patients. Patients with MELD score ≥30 had a median hospital stay after LT of 33 days. Three-year survival did not differ significantly between patients with MELD <30 ($n = 561$) and ≥30 (78.7±2.1% vs. 83.8±4.2% $p = 0.45$). Similar 3-year survival was also observed if the population is divided according to a MELD cut-off of 35: 80.7% (MELD ≥35) vs. 79.4% (MELD <35), $p = 0.9$. In the MELD ≥30 group, survival at 3 years of HIV-positive patients was 0% versus 92.1±3.3% in non-HIV patients ($p < 0.001$). Patients hospitalized in ICU had the same survival at 3 years than those who were not in ICU: 77.8 vs. 85.3%, $p = 0.4$. In patients with MELD ≥30, patients who died within 3 years had a more prolonged hospital stay before LT than survivors (43 vs. 21 days, $p = 0.001$), longer hospital stay after LT (61 vs. 30 days, $p < 0.001$) and were younger (48 vs. 54 years, $p = 0.04$; probably related to the HIV indication). All other tested parameters did not differ between patients who died and survivors. Prognostic scores such as SOFA, CLIF-SOFA and IGS2 were not helpful in predicting survival.
Conclusions: Liver transplantation in patients with MELD ≥35 is safe with excellent survival at 3 years. HIV infection is a major pejorative predictor of death after liver transplantation in our cohort

P0035
ARE THERE DEMOGRAPHIC, BEHAVIOURAL AND PSYCHOSOCIAL FACTORS THAT PREDICT ALCOHOL CONSUMPTION BEFORE OR AFTER LIVER TRANSPLANTATION?

H.C. Aldersley[1], A.S. Rinomhota[2], S. Farid[1], K.L. Rothwell[1], E.A. Shepherd[3], M.A. Aldersley[1]. *[1]Leeds Teaching Hospitals NHS Trust, [2]University of Leeds, Leeds, [3]Royal Free Hospital, London, United Kingdom*
E-mail: haldersley@hotmail.co.uk

Background and Aims: Alcohol related liver disease (ALD) is the second commonest indication for liver transplant in the UK. Selection of these patients is controversial due to the perceived

self-inflicted nature of the disease and due to the risk of relapse to alcohol post-transplantation. It is important to be able to identify those patients who are at risk of relapse in order to provide support.
To determine whether the Relative Risk Factors for Relapse (RRFR) score and/or High Risk Alcohol Relapse scale (HRAR) can predict alcohol consumption in pre and/or post-liver transplant patients.
Methods: Retrospective analysis of patients' medical records. Univariate analysis was conducted to compare categorical variables between the relapse versus the non-relapse group.
Results: Between September 2008 and March 2013, 197 patients were listed for a liver transplant with a diagnosis of ALD. At the time of analysis 114 of the 197 patients (57.9%) had received a liver transplant. Thirty-two (16.3%) had been removed due to deterioration or death, twenty-four (12.2%) had improved and no longer required a transplant and sixteen patients (8.1%) were removed for consuming alcohol. Five of the patients were excluded from post-transplant analysis due to death before 90 days. Fourteen patients were reported as relapsing to alcohol post-transplant. The HRAR scale failed to predict alcohol consumption in patients pre-transplant ($P = 0.454$) or post-transplant ($P = 0.218$). None of the three variables that make up the HRAR scale were predictive of relapse. A high RRFR score was highly predictive of relapse in pre-transplant patients ($P = 0.004$) but not post-transplant ($P = 0.6$). Of the seven variables that make up the RRFR score illicit drug misuse was the only predictor of pre-transplant alcohol consumption ($P = 0.005$). Poor social support and lack of replacement strategies were found to be predictive of relapse in post-transplant patients ($P = 0.016$ and 0.044 respectively).
Conclusions: The HRAR and RRFR are currently used in four of the seven UK liver transplant centres. As the HRAR is not predictive of alcohol consumption its use to assist in decision making regarding transplant suitability should be discontinued. The RRFR is a predictor to alcohol consumption pre-transplant however further investigation is required to validate its use in the transplant setting.

P0037
PROGRESSIVE PORTAL AND LOBULAR FIBROSIS IN LONG TERM SURVIVING PEDIATRIC LIVER GRAFTS: DIFFERENT COMPARTMENTS WITH DIFFERENT BACKGROUNDS

M. Baas[1], A.S. Gouw[1], M.C. van den Heuvel[1], H.J. Verkade[1], B.G. Hepkema[1], P.M. Peeters[1], R. Scheenstra[1]. *[1]University Medical Center Groningen, Groningen, Netherlands*
E-mail: baas.marjolein@gmail.com

Background and Aims: Long-term survival after pediatric liver transplantation (LTx) has improved. However, multiple studies have shown that long-term graft survival is associated with increasing histological abnormalities, predominantly fibrosis and hepatitis. We previously reported the presence of graft fibrosis in 2 studies of CSA treated patients at 1 and 10 years after LTx. The aim of this study was to evaluate graft fibrosis according to the acinar distribution and establish a correlation with clinical characteristics of patients who all received tacrolimus as the main immunosuppressive therapy. We hypothesize that the portal, perisinusoidal and centrilobular distribution of graft fibrosis results from different underlying conditions.
Methods: We reviewed the histological features in protocol liver biopsies taken at 1 and 5 years after transplantation of 47 children. Fibrosis was assessed according to the Liver Allograft Fibrosis Scoring system (LAFSc).
Results: Fibrosis was present in 84% of the 1-year biopsies and 86% of the 5-year biopsies. An increased incidence of all 3 types of fibrosis was observed between 1 and 5 years. At 5 years centrilobular fibrosis was present in 85% of cases, sinusoidal fibrosis in 79% and portal fibrosis in 62%. The number of biopsies that showed histological hepatitis or minimal reactive changes decreased between 1 and 5 years after transplantation and were not related to fibrosis. There was a trend toward an association between biliary complications and portal fibrosis at 5 years ($p = 0.06$) while total bilirubin and γGT were clearly associated with portal fibrosis ($p = 0.02$ for both). Other liver function tests were not related to fibrosis. Centrilobular fibrosis was related to HLA mismatches ($p = 0.05$), primarily at the HLA class I level. Rejection was related to the development of sinusoidal fibrosis ($p = 0.02$). Previously described relation between fibrosis and (pre)transplant related factors, e.g. CMV status, cold ischemia time, donor age and graft type could not be confirmed in this study.
Conclusions: Using the LAFS scoring system, we found in this new cohort of tacrolimus treated patients a high incidence of progressive fibrosis in the 1 year and 5 year protocol biopsies after LTx. Progression of fibrosis was observed in all acinar compartments and each of the 3 locations is associated with different clinical conditions. Portal fibrosis with biliary complications, centrilobular fibrosis with HLA class I mismatch and sinusoidal fibrosis with previous rejection episodes.

P0038
CHARACTERIZATION OF HUMORAL REJECTION IN LIVER PEDIATRIC TRANSPLANTATION

M. Dao[1], D. Habès[2], C. Mussini[1], E. Gonzales[2], C. Suberbielle[3], E. Jacquemin[2], D. Charron[3], C. Guettier[1]. *[1]Anatomie et Cytologie pathologiques, [2]Hépatologie pédiatrique, CHU Bicêtre, Le Kremlin Bicêtre, [3]Laboratoire d'Histocompatibilité, CHU Saint-Louis, Paris, France*
E-mail: dao.myriam@gmail.com

Background and Aims: The aim of the study is to correlate C4d immunostaining, pathological features of liver grafts and the presence of donor specific antibodies (DSA) in pediatric transplant recipients.
Methods: 31 graft biopsies (27 ten-year biopsies and 5 biopsies on indication) performed in 31 pediatric transplant recipients were reviewed for histological features according to Banff recommandations. Immunostaining for C4d was performed on deparaffinized tissue sections and analyzed semiquantitatively. DSA were quantified by Luminex Single Antigen.
Results: C4d immunostaining was positive in 28/31 biopsies with the following pattern: portal stroma (diffuse 7/31, focal 13/31), portal vein endothelial cells (7/31, 23%), peribiliary capillar plexus (18/31, 58%), centrilobular vein endothelial cells (10/31, 32%) and sinusoidal cells (19/31, 69%). 11/31 biopsies were classified as chronic rejection, defined by centrilobular fibrosis with hepatocellular loss. Diffuse portal stroma and endothelial (at least one endothelial type) C4d immunostaining were significantly associated with histological features of chronic rejection ($p = 0.0036$ and 0.013). DSA results were available in 20 patients: 20% had DSA class 1, 75% DSA class 2. 30% were negative. C4d immunostaining of sinusoidal cells ($p = 0.0018$) and of at least one type of endothelium ($p = 0.024$) was significantly associated with DSA. There was no significant association but only a trend for chronic rejection and DSA ($p = 0.069$).
Conclusions: The C4d immunostaining of portal stroma and endothelial cells is correlated on the one hand with the pathological features of chronic rejection, on the other hand with the presence of DSA. These results strongly suggest the participation of humoral mechanisms in liver graft chronic rejection in pediatric population.

P0039

PREDICTION OF HCC RECURRENCE AFTER LIVER TRANSPLANTATION BASED ON EXPLANTS PATHOLOGY: COMPARISON OF PREDICTION ACCURACY OF 4 PROGNOSTIC MODELS IN A PROSPECTIVE EXTERNAL COHORT

C.E. Costentin[1], F. Roudot-Thoroval[2], T. Decaens[1], J. Calderaro[3], A. Luciani[4], G. Amaddeo[1], A. Laurent[5], C. Duvoux[1], for the French study group for LT and HCC. *[1]Hépatologie, [2]Santé Publique, [3]Anatomo-pathologie, [4]Radiologie, [5]Chirurgie digestive, Hôpital Henri Mondor, Créteil, France*
E-mail: Charlotte.costentin@hmn.aphp.fr

Background and Aims: After liver transplantation for HCC, histological features of the explant liver are of great importance to identify patients at high risk of recurrence. This is a crucial step to adapt screening strategies, and to select best candidates to changes in immunosuppression and potential adjuvant therapies. The aim of this study was to test the performances of published models of prediction of HCC recurrence based on histo-pathological findings in an external cohort of liver transplant patients.
Methods: Among the 5 published models, one included the presence of giant/bizarre cells, a variable which is not available in usual pathological reports of liver explants and was therefore excluded (Parfitt et al. 2007). The 4 other models (Iwatsuki et al. 2000, Chan et al. 2008, Mazzafero et al. 2009, Decaens et al. 2011) used a mix of usual variables (number of nodules, size of the largest, tumor differentiation, existence of micro/macrovascular invasion, tumor burden uni or bilobar) and were tested in a cohort of 318 patients transplanted in 20 French centers for HCC between 2003 and 2005 and followed prospectively for 5 yrs.
Results: Predicting performances of the different models are reported in table 1. All 4 explanted models were able to identify patients with tumours features associated with a 5-yr rate of recurrence >50% ($p < 0.001$), compared to low risk pts in all models (see table). However, predictive accuracy of US models was lower than expected in this European cohort compared to European models. In particular, low risk score in the Chan model was associated with a 24% risk of recurrence in the current validation cohort and very high risk score in the Iwatsuki model was associated with a lower risk of recurrence of 50% in the French cohort. By contrast, expected predictive values of both French and up to seven models were found reproducible.
Conclusions: Both French (Decaens et al.) and Up to seven models may serve as a tool for identification of explant-based prediction of patients at high risk of recurrence in a European population and therefore guide change in immunosuppression and identification of best candidates for adjuvant therapies.

Table (abstract P0039).

Study	Participants	Model components	Performance of models in original reports	5Y recurrence rate in the current French cohort

E-mail: ddavola@unav.es

Background and Aims: Cardiovascular (CV) diseases are a major cause of death after liver transplantation (LT) at long term. The objective of this study was to analyse the main causes of mortality and the risk factors for death and for cardiovascular death 5 years after LT.
Methods: Data from 1819 liver receptors followed-up in 15 Spanish centres were collected prospectively. The main causes of death 5 years after LT have been analysed. Multivariate COX regression model analysis was used to identify baseline variables related to 5-years mortality and CV mortality.
Results: Among the 1819 patients the overall 5-year mortality was 26.3% (n = 479). The main causes of death were liver diseases (27.1%), cancer (20.1%), infectious diseases (16.3%) and cardiovascular diseases (12.1%). The multivariate analysis identified the following baseline predictive factors for 5-year mortality: age (HR 1.01, 95% CI 1.00–1.02; p 0.025), hepatocellular carcinoma (HR 1.26, 95% CI 1.02–1.5; p 0.027), hepatitis C virus infection (HR 1.52, 95% CI

1.23–1.87; p 0.000), hyperlipidaemia (HR 0.5, 95% CI 0.38–0.87; p 0.021), insulin-dependent diabetes (HR 1.62, 95% CI 1.26–2.07; p 0.000), hyperuricemia (HR 1.35, 95% CI 1.06–1.73; p 0.015), chronic renal failure (HR 1.45, 95% CI 1.12–1.88; p 0.004) and previous CV events before LT (HR 1.58, 95% CI 1.17–2.14; p 0.003). The age at the time of transplantation (HR 1.033, 95% CI 1.0–1.06; p 0.033), chronic renal failure (HR 2.31, 95% CI 1.25–4.27), previous CV events (HR 2.3, 95% CI 1.123–4.71; p 0.023), hypercholesterolemia (HR 0.13; 95% CI 0.019–0.9; p 0.048) and the use of mycophenolate mofetil (MMF)-free immunosuppressive regimen (HR 2.36; 95% CI 1.23–4.51; p 0.009) were identified as the main predictors for CV mortality at 5 years.

Conclusions: CV diseases are the fourth cause of death among LT recipients after 5 years of follow-up. The age at the time of transplantation, the presence of previous CV disease, patients with hypercholesterolemia, chronic renal failure and patients treated with MMF-free regimen showed an increased risk of CV death.

P0041

THE IMPACT OF DONOR AND RECIPIENTS SINGLE NUCLEOTIDE POLYMORPHISMS OF LIVING FIBROSIS PROGRESSION IN LIVING LIVER TRANSPLANTATION FOR HEPATITIS C

H. Miyaaki[1], T. Ichikawa[1], N. Taura[1], S. Miuma[1], H. Shibata[1], T. Honda[1], K. Nakaoa[1]. [1]*Department of Gastroenterology and Hepatology, Nagasaki University, Nagasaki, Japan*
E-mail: miyaaki-hi@umin.ac.jp

Background and Aims: Recently, some previous reports showed that some of single nucleotide polymorphism (SNPs) affect liver fibrosis progression in patients with hepatitis C virus (HCV). In this study, we examined the impact of donor and recipient SNPs on the progression of fibrois after liver transplantation for HCV.

Methods: This cohort study enrolled 42 patients with HCV who underwent liver transplantation in our hospital. We genotyped 3 genotypes (rs4374383, rs2629751, rs9380516) that emerged in GWA study of liver fibrosis progression related to HCV infection (Gastroenterology 2012; 143:1244–1252 e1241–1212), rs8099917 in IL28B that were associated interferon treatment response in Japanese (Nat Genet 2009; 41: 1105–1109), and rs738409 in PNPLA3 that were identified as a genetic predictor for hepatic stetosis (Hepatology 2010; 52: 1274–1280) and recently were reported as significant predictor of fibrosis with HCV, using a Taqman assay. One year progress of liver fibrosis was defined as the development of fibrosis (≥F1) at liver biopsies 1 year after liver transplantation. The association with one year progress was examined. The time to ≥shininuyma F2 (portoportal septa) or HCV-related mortality was also analyzed.

Results: Results; Patients with fibrosis (≥F1) of liver at one year after liver transplantation were detected in 30 cases (70%). The rs2629751 genotype have showed significantly association with fibrosis progression at one year after liver transplantation (AA: GG or GA = 57%: 88%, P < 0.05). A total of 21 patients developed the primary outcome of ≥F2 (portoportal septa) or HCV-related mortality. The time to ≥stage 2 fibrosis or HCV related mortality have showed significantly difference in only donor's rs2629751 genotype (AA: GG or GA = 5.5±0.6 years: 3.6±0.7 years, p = 0.025).

Conclusions: The rs2629751 genotype is an important predictor of posttranspant outcome in HCV. This result might be useful in donor selection for liver transplantation with HCV, and may guide decisions regarding early antiviral treatments.

P0042

SAFETY AND EFFICACY OF SOFOSBUVIR AND SIMEPREVIR TREATMENT IN HEPATITIS C GENOTYPE 1 LIVER TRANSPLANT RECIPIENTS WITH ADVANCED FIBROSIS/RECURRENT CIRRHOSIS

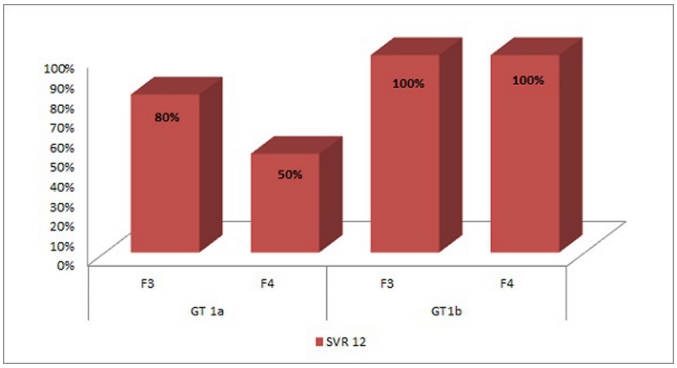
A.F. Carrion[1], A. Peyton[1], D. Avalos[1], E. Martin[1], J. Gutierrez[1], C. O'Brien[1], P. Martin[1], K.R. Bhamidimarri[1]. [1]*Hepatology, University of Miami-Miller School of Medicine, Miami, United States*
E-mail: dr_ram7@yahoo.com

Background and Aims: Recurrent hepatitis c (HCV) is invariable in liver transplant recipients (LTR) which can result in accelerated fibrosis and graft failure. There is limited data with sofosbuvir and simeprevir treatment (COSMOS regimen) in HCV positive LTR with advanced fibrosis. We aim to submit our safety and efficacy data of COSMOS regimen in HCV genotype 1 LTR with advanced fibrosis or cirrhosis.

Methods: Retrospective analysis of 19 LTR with recurrent HCV genotype 1 with 53% METAVIR F4 were treated with sofosbuvir 400 mg orally daily and simeprevir 150 mg orally daily for 12 weeks at the Miami Transplant Institute. There were 9 LT recipients with HCV genotype 1a (4 cases with F4) and 10 with HCV genotype 1b (6 cases with F4). The median time from LT to start of treatment was 65 months (range 2–194). The majority of individuals (84%) had failed previous treatment with interferon-based regimens and 21% were treated with regimens containing a protease inhibitor. This study was an IRB approved study.

Results: All 19 individuals completed 12 weeks of antiviral therapy with sofosbuvir and simeprevir and only one interrupted therapy for 1 week due to hospitalization for problems unrelated to hepatic decompensation or drug-related adverse events (AEs). No severe AEs occurred; the most common AEs were fatigue (21%), headache (16%), nausea (16%), skin rash and photosensitivity (11%). All individuals had undetectable HCV-RNA at EOT. SVR12 was achieved in 84% of individuals: 100% in HCV genotype 1b and 67% in HCV genotype 1a (P = 0.046).

Conclusions: COSMOS treatment for 12 weeks with sofosbuvir and simeprevir was well tolerated in LTR with advanced fibrosis and cirrhosis. Overall SVR12 rate was 84% with distinct difference among genotype 1a and 1b, 67% and 100% respectively. The effect of longer duration of therapy or addition of ribavirin in LTR with advanced fibrosis/cirrhosis and HCV genotype 1a infection needs to be further evaluated.



P0043

RATE OF EMPLOYMENT AFTER LIVER TRANSPLANTATION IN FRANCE: A SINGLE CENTRE STUDY

M. Rudler[1], G. Rousseau[2], P. Lebray[3], J.-C. Vaillant[4], E. Savier[4], D. Eyraud[4], T. Poynard[4], D. Thabut[4]. [1]*Hepatology,* [2]*Hepato-bibliary surgery, Pitié-Salpêtrière Hospital,* [3]*Assistance Publique Hôpitaux de Paris, UPMC,* [4]*Pitié-Salpêtrière Hospital, PARIS, France*
E-mail: marika_rudler@yahoo.fr

Background and Aims: A return to gainful employment is an important outcome parameter after liver transplantation (LT). A

recent study in the United States (US) has shown a very high rate of unemployment after LT (75%). To date, no data is available in France, where the public health insurance program guaranties financial protection for everyone.
Aims: To assess employment rate after LT in a French LT centre and to determine factors associated with employment after LT.
Methods: All patients transplanted in our centre between January 2000 and April 2011 were subjected to a questionnaire, provided they met the following criteria: (1) aged 18–65 at time of LT; (2) being alive 1 year after LT, (3) being alive, not retired and discharged from hospital at time of survey, (4) being French resident and affiliated to French national health insurance.
Results: 345 LT were performed in 314 patients during the study period. 109 patients were not considered for the study: 23 patients died within the first year after LT, 28 patients were dead at the time of the survey, 3 were still hospitalized, 7 patients were living in a foreign country, 11 were retired and 37 had an age >65 after LT. 205 patients were included in the study. The response rate was 76.6% (157/205): mean delay after LT: 6.1±0.9 years, French nationality 77.7%, male gender 73.2%, mean age at LT 48.8±9.9 yr. Aetiologies of liver disease were the following: alcohol 32.5%, hepatitis C 26.1%, alcohol and hepatitis C 3.8%, hepatitis B 15.3 %, biliary cirrhosis 5.1%, auto-immune 2.5%, other causes 14.7%. At 2-year, 43.3% of patients were employed. The demographic variables associated with post LT employment included male gender ($p < 10^{-3}$), aged under 40 at time of LT ($p = 0.02$), sedentary work occupation ($p = 0.007$), raising children younger than 18 years old at time of LT ($p = 0.01$), high level of education ($p = 0.001$), not being affiliated to the French universal health coverage so called 'CMU' ($p = 0.001$). Among patients who did not return to work after LT, only 53.3% stated they felt physical disabilities.
Conclusions: The rate of going back to work after LT in France was 43.1%, which was higher than the one reported the US study. However this rate remains low and encouraging policies are needed in order to help liver recipients who wish to work after LT.

P0044
MRCP TAKEN ONE MONTH AFTER LDLT MAY PREDICT BILIARY COMPLICATION
S. Lee[1], J.Y. Choi[1]. [1]*Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, South*
E-mail: jychoi@catholic.ac.kr

Background and Aims: Biliary complications are common and important complications after living donor liver transplantation (LDLT). There are several diagnostic tools for detection of biliary complications. Magnetic resonance cholangiopancreatography (MRCP) is known to be an accurate method in evaluation of the biliary system. However, the value of MRCP findings to predict biliary complication after liver transplantation have not been studied. Therefore, we have studied the value MRCP imaging taken one month after LDLT for prediction of biliary complications.
Methods: We included 201 patients who took LDLT from 2006 to 2010. Patients took MRCP 1 months after LDLT. MRCP images were analyzed for angle of anastomosis in 3D image, presence of filling defect, length of filling defect in 3D image and MIP image, presence of intrahepatic bile duct dilatation, biliary stricture and leakage. Angle of anastomosis was defined as angle between donor site bile duct and recipient's common bile duct. Patients who received biliary intervention during the follow up period were considered to have biliary complication.
Results: During a follow up until December 31, 2012, 94 patients developed biliary complication. In multivariate analysis using Cox-regression method, decreased angle of anastomosis (hazard ratio, 0.986; 95% CI, 0.979 to 0.993; P = 0.000), filling defect in MIP image (hazard ratio, 1.838; 95% CI, 1.178 to 2.868; P = 0.007) and leakage (hazard ratio, 3.457; 95% CI, 1.215 to 9.835; P = 0.020) were significant risk factors for development of biliary complication. Cut-off value for angle of anastomosis was 109.85° with 68.1% sensitivity and 79.2% specificity.
Conclusions: In MRCP images taken 1months after LDLT, decreased angle of anastomosis as well as filling defect in MIP image and biliary leakage, is associated with increased risk of biliary complications.

P0045
LONG TERM LOW DOSE STEROID TRIPLE IMMUNOSUPPRESSIVE REGIMENS IN POST TRANSPLANT AUTOIMMUNE HEPATITIS (AIH) PATIENTS REDUCES THE INCIDENCE OF RECURRENT DISEASE AND IS NOT ASSOCIATED WITH INCREASED MORTALITY
T.L. Krishnamoorthy[1,2], J. Miezynska-Kurtycz[3], J. Hodson[4], B.K. Gunson[1], J. Neuberger[1], P. Milkiewicz[5], Y.H. Oo[1]. [1]*Liver and Hepatobiliary Unit, Birmingham NIHR Liver Biomedical Research Unit, Queen Elizabeth Hospital, Birmingham, United Kingdom;* [2]*Department of Gastroenterology & Hepatology, Singapore General Hospital, Singapore, Singapore;* [3]*Department of Gastroenterology & Internal Medicine, MSW Hospital, Szczecin, Poland;* [4]*Wolfson Computer Laboratory, University Hospitals Birmingham, Birmingham, United Kingdom;* [5]*Liver & Internal Medicine Unit, Department of General, Transplant & Liver Surgery, Medical University of Warsaw, Warsaw, Poland*
E-mail: thineshlk@gmail.com

Background and Aims: Optimal immunosuppression for post transplant AIH patients reduces the risk of AIH recurrence (AIHR) while minimizing the complications associated with long term use. Our practice is to maintain long-term low dose steroids in addition to at least one other immunosuppression. We describe our experience with a focus on factors associated with AIHR as well as graft and patient survival over a 15 year period.
Methods: We collected data on patients transplanted between Dec 1999 – Sep 2014 in a single transplant unit. AIHR was diagnosed by the presence of elevated IgG, consistent histology and exclusion of other causes. Outcomes of AIHR, regraft-free and overall survival were assessed using Kaplan–Meier survival analysis methods and log-rank tests. All analyses were performed using IBM SPSS Statistics 22 with $p < 0.05$ deemed to be statistically significant.
Results: 78 patients were transplanted with a median follow-up of 101 months. The cohort was mainly Caucasian (78%), female (77%), with type 1 AIH (91%) and a mean age of 42.7 years (SD=14.3). Patients were transplanted for acute liver failure in 14% of the cohort and cirrhosis in 86%. Only 5 patients developed AIHR, giving estimated rates of 0%, 5% and 11% at 1, 5 at 10 years respectively. Overall survival was 92%, 86% and 72%, and re-graft free survival was 85%, 74% and 64% at 1, 5 at 10 years respectively.
Maintenance immunosuppression data were available for 67/78 patients. 11 patients were censored as they had either died or had follow up <1 year post transplant. Table 1 documents the different regimens and outcomes. 12 patients were not on prednisolone (PR) for reasons of PTLD (1), steroid related side effects (4), patient choice (1) and records were unavailable for the remainder (6). 63% of patients continued on triple immunosuppression with PR without any significant deleterious effects on mortality, graft survival or AIHR.
Regraft-free survival was significantly shorter in AIH type 2 than in type 1, with rates at 5 years of 38% and 78% respectively ($p = 0.02$), mainly due to incidences of early post transplant hepatic artery thrombosis. Overall survival was similar in the two groups ($p = 0.24$).
Conclusions: This is the largest single centre cohort of post transplant AIH patients. Type 1 AIH patients have better early outcomes than type 2 patients but similar overall survival. Triple

immunosuppression with low dose PR seems to be generally safe and leads to lower incidences of AIHR than in the published literature.

Table 1. Different immunosuppression combinations and associated outcomes

Drug combination	%	Overall survival (%)		Re-graft free survival (%)		Freedom from AIHR (%)	
		1 year	5 year	1 year	5 year	3 year	5 year
T only	5	100	100	100	67	100	100
T + A/M	14	100	89	78	78	100	100
PR + T	18	100	100	82	82	100	100
PR + T + A/M/S	63	100	91	100	83	94	91
		p value 0.626		p value 0.959		p value 0.311	

Survival rates are based on Kaplan–Meier estimates, and include only those patients who have survived past 1 year from transplant.
A, azathioprine; M, mycophenolate mofetil; PR, prednisolone; S, sirolimus; T, tacrolimus.

P0046
RESPONSE TO LOCO-ABLATIVE TREATMENT OF HCC PRIOR TO LIVER TRANSPLANTATION IS ASSOCIATED WITH LOW RECURRENCE RATES IN PATIENTS EXCEEDING THE MILAN CRITERIA

A. Finkenstedt[1], A. Vikoler[2], K. Mülleder[3], M. Portenkircher[3], J. Peterson[3], A. Luger[3], R. Bale[3], W. Vogel[1], S. Schneeberger[4], I. Graziadei[5], B. Glodny[3], H. Zoller[1]. *[1]Internal Medicine II, Medical University of Innsbruck, [2]Internal Medicine II, Medical University Innsbruck, [3]Department of Radiology, [4]Department of Transplantation Surgery, Medical University of Innsbruck, Innsbruck, [5]Department of Internal Medicine, Academic Teaching Hospital Hall in Tirol, Hall, Austria*
E-mail: armin.finkenstedt@uki.at

Background and Aims: The Milan criteria are the most widely accepted selection criteria for liver transplantation (LT) in cirrhotic patients with hepatocellular carcinoma (HCC). Several groups have challenged these criteria and shown that tumors exceeding MC can be transplanted. However, these attempts have been associated with an increased rate of HCC recurrence. The aim of this study was to investigate if response to loco-ablative bridging therapy before LT can be used to identify patients exceeding the MC who can undergo LT without an increased HCC recurrence risk.
Methods: Patients who underwent LT for HCC at our institution between 2002 and 2013 were included. Baseline CT scans and scans prior to LT were independently reviewed by two radiologists to assess MC and response to loco-ablative therapies (TACE, RFA) according to mRECIST. A multivariate regression model was used to assess risk factors for HCC recurrence.
Results: One hundred seventy-four HCC patients (89% male, mean age 60 years) underwent LT. Fatty liver cirrhosis (55%) and chronic hepatitis C (30%) were the most common underlying liver diseases. Seventy-one patients (41%) exceeded MC (up to 9 lesions) and ablative treatment was performed in the vast majority of patients (94%). Response to loco-ablative bridging therapy was not associated with HCC recurrence in patients within the MC. Patients exceeding MC but achieving complete remission after loco-ablative bridging therapy had a comparable 5-year recurrence rate to all patients within MC (16.7% vs. 8.5%; $p = 0.588$). In contrast, 5-year recurrence rate was significantly higher in patients outside the criteria and stable disease/partial response (21.9%; $p = 0.024$) and in those with progressive disease (48.1%; $p < 0.001$). Tumor grading, histologic and radiologic evidence of vascular invasion were independent risk factors for HCC recurrence in a multivariate regression analysis. Overall survival was independently associated with radiologic evidence of vascular invasion and response to ablative treatment with a five-year post LT survival of 75% in the overall cohort.
Conclusions: Response to neoadjuvant loco-ablative treatment identifies a subgroup of patients exceeding the MC that can undergo LT without an increased risk of HCC recurrence. From our findings we conclude that LT can be offered to selected patients with HCC tumor stage beyond the MC.

P0047
RECIPIENT (BUT NOT DONOR) ADIPONECTIN POLYMORPHISMS ARE ASSOCIATED WITH POST TRANSPLANT HEPATIC STEATOSIS

B. John[1], A. Garber[2], T. Aiken[3], D. Thomas[4], R. Konjeti[5], D. Chen[6], R. Lopez[4,7], J.J. Fung[8], M. Askar[4,6]. *[1]Gastroenterology and Hepatology, [2]Medicine, Cleveland Clinic, [3]Cleveland Clinic Lerner College of Medicine, [4]Cleveland Clinic, Cleveland, [5]Medicine, Brown University, Rhode Island, [6]Pathology and Laboratory Institute, [7]Quantitative Health Sciences, [8]Transplant Surgery, Cleveland Clinic, Cleveland, United States*
E-mail: johnb@ccf.org

Background and Aims: Metabolic syndrome and hepatitis C genotype 3 infection are known predictors of post-transplant steatosis but the role of genetic factors are less well established. Adiponectin is an adipokine with anti-inflammatory and anti-atherogeneic properties. Hypoadiponectinemia is well described in pre-transplant NAFLD independent of insulin resistance and is implicated in the loss of hepatic fat in 'burnt out' NASH cirrhosis. The role of Adiponectin in the liver transplant recipient is unclear. We explored the association between donors and recipients Adiponectin genetic polymorphisms and biopsy proven post-transplant hepatic steatosis.
Methods: We identified consecutive patients transplanted for HCV cirrhosis between 2006–2011 at a tertiary care center in the United States. This was a case-control study with cases defined as subjects with steatosis (5% or greater) and controls with minimal or no steatosis (<5%) on post transplant biopsy. Donors and recipients were tested for the rs1501299, rs2241766, rs266729 and rs2241766 Adiponectin polymorphisms using the QLAamp DNA Mini Kit assay testing by TaqMan SNP genotyping assay.

Table: Recipient and donor adiponectin polymorphisms and post-transplant steatosis

Factor	Overall (N = 111)		No steatosis (N = 72)		Steatosis (N = 39)		p-value [a]
	N	Summary	n	Summary	n	Summary	
Recipient rs1501299	110		71		39		**0.028**
GG		55 (50.0)		30 (42.3)		25 (64.1)	
non-GG		55 (50.0)		41 (57.7)		14 (35.9)	
Donor rs1501299	111		72		39		0.19
GG		59 (53.2)		35 (48.6)		24 (61.5)	
non-GG		52 (46.8)		37 (51.4)		15 (38.5)	
Recipient rs2241766	111		72		39		0.83
TT		87 (78.4)		56 (77.8)		31 (79.5)	
non-TT		24 (21.6)		16 (22.2)		8 (20.5)	
Donor rs2241766	106		69		37		0.61
TT		80 (75.5)		51 (73.9)		29 (78.4)	
non-TT		26 (24.5)		18 (26.1)		8 (21.6)	
Recipient rs266729	109		71		38		**0.008**
CC		75 (68.8)		55 (77.5)		20 (52.6)	
non-CC		34 (31.2)		16 (22.5)		18 (47.4)	
Donor rs266729	111		72		39		0.22
CC		71 (64.0)		49 (68.1)		22 (56.4)	
non-CC		40 (36.0)		23 (31.9)		17 (43.6)	
Recipient rs17300539	108		72		36		**0.026**
GG		94 (87.0)		59 (81.9)		35 (97.2)	
non-GG		14 (13.0)		13 (18.1)		1 (2.8)	
Donor rs17300539	109		71		38		0.55
GG		92 (84.4)		61 (85.9)		31 (81.6)	
non-GG		17 (15.6)		10 (14.1)		7 (18.4)	

Values are presented as Mean±SD, Median [P25, P75] or N (column %).
[a] From Pearson's chi-square test.

Results: Clinical data were collected for a total of 302 patients who were transplanted for HCV during the study period. 111 patients who had available donor DNA, recipient DNA, and a post-transplant liver biopsy were included in the analysis. Of these,

35% developed significant steatosis (cases). Cases and controls were well matched in terms of age, gender, donor risk index, cold ischemia time as well as pre and post transplant metabolic syndrome. Cases were more likely to be white and to have genotype 2. Univariable analysis showed that recipient rs1501299, rs266729 and rs17300539 polymorphisms were found to be associated with post-LT steatosis. After adjusting for race and hepatitis C genotype, recipients with GG rs1501299 were 2.5 times more likely to develop steatosis after LT than those with non-GG genotypes. Similarly, recipients with GG rs17300539 genotype were more likely to develop steatosis after LT than those with non-GG genotypes ($p = 0.049$). None of the donor Adiponectin polymorphisms were associated with post transplant steatosis.

Conclusions: Recipient but not donor Adiponectin gene polymorphisms are associated with post-transplant hepatic steatosis. Further studies are needed to explore the potential role for Adiponectin in the pathogenesis of post transplant steatosis and NASH.

P0048

RISK FACTORS FOR EARLY KIDNEY DYSFUNCTION AFTER LIVER TRANSPLANTATION AND THEIR IMPACT ON GRAFT LOSS: INSIGHTS FROM THE LIVER MATCH COHORT STUDY

M. Angelico[1], A.P. Mitterhofer[2], A. Nardi[3], T. Marianelli[4], L. Parlati[5], F. Tinti[2], S. Ginanni Corradini[5], the Liver Match Study Group.
[1]Hepatology and Transplant, Tor Vergata University, [2]Nephrology, La Sapienza University, [3]Biostatistics, [4]Hepatology and Transplant, Tor Vergata University, [5]Gastroenterology, La Sapienza University, Rome, Italy
E-mail: angelico@med.uniroma2.it

Background and Aims: Early Kidney Dysfunction (EKD) is a frequent event during the first six months after liver transplantation (LT) and can be a determinant of long-term outcome. On the other hand, the introduction of MELD to prioritize candidates for LT has resulted in a greater propensity to transplant those with poor kidney function. The impact of this policy on the risk of EKD and its effect on 5-year graft loss were the objectives of this study.

Methods: We evaluated 1302 patients undergoing LT in Italy from June 1, 2007 to May 31, 2009 belonging to the Liver Match cohort (median donor and recipient age: 56 and 55 years, respectively, males: 79%; HCV+ patients: 45.5%). EKD was staged based on the lowest estimated glomerular filtration rate (eGFR, MDRD-4 formula) at 3 and 6 months after LT, as follows: eGFR >60 ml/min (EKD stage 1–2); 45 ≤ eGFR < 60 ml/min (EKD stage 3a); 30 ≤ eGFR < 45 ml/min (EKD stage 3b); and eGFR <30 ml/min (EKD stage 4–5).

Results: We identified 812 patients as EKD stage 1–2 (62.4%), 404 as EKD stage 3a/b (31.0%) and 86 as EKD stage 4–5 (6.6%). Multinomial logistic analysis identified four recipient risk factors for EKD: old age, female gender, and low eGFR and sodium levels at LT. Odds ratios and 95% CI for EKD stage 3a/b vs stage 1–2 were as follows: age (×10 years): 1.63, 1.40–1.89; female vs male gender: 2.29, 1.68–3.12; *e*GFR at LT (30–60 vs >60 ml/min): 2.55, 1.79–3.64; *e*GFR at LT (<30 vs >60 ml/min): 2.82, 1.35–5.89; serum sodium at LT (per 5 meq/L): 0.86, 075–098. Odds ratios and 95% CI for EKD stage 4–5 *vs* stage 1–2 were as follows: age (×10 years): 1.70, 1.28–2.27; female *vs* male gender: 2.0, 1.58–3.46; *e*GFR at LT (30–60 vs >60 ml/min): 2.72, 1.50–4.94; *e*GFR at LT (<30 vs >60 ml/min): 9.74, 4.08–23.28; serum sodium at LT (per 5 meq/L): 0.73, 0.58–0.92.

Cox regression identified EKD stage as a significant risk factor for 5-year graft loss, after adjusting for the other significant predictors (donor age, recipient HBcAb and HCV positivity). Assuming EKD stage 1–2 as reference level, the hazard ratios of graft loss for EKD stages 3a, 3b, and 4–5 were 0.89 ($p = 0.4729$), 1.68 ($p = 0.0059$) and 3.38 ($p < 0.0001$), respectively.

Conclusions: The development of EKD stage ≥2b entails a high risk of graft loss after LT and that the probability of EKD can be estimated before LT. This suggests that high risk patients can be identified and should be considered for alternative treatment strategies, including combined liver-kidney transplantation.

P0049

EVALUATION OF ACOUSTIC RADIATION FORCE IMPULSE IMAGING (ARFI) ELASTOGRAPHY FOR NON-INVASIVE LIVER FIBROSIS ASSESSMENT IN PATIENTS AFTER LIVER TRANSPLANTATION

D. Attia[1,2], C. Meyer-Heithuis[1], E. Jaeckel[1], J. Klempnauer[3], M. Manns[1], M. Gebel[1], A. Potthoff[1]. *[1]Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany; [2]Gastroenterology, Hepatology and Endemic Medicine, Beni Suef University, Beni Suef, Egypt; [3]Department of Visceral and Transplantation Surgery, Hannover Medical School, Hannover, Germany*
E-mail: dinaismail76@yahoo.com

Background and Aims: Transient elastography proved to accurately diagnose graft fibrosis and liver cirrhosis in patients with recurrent HCV after liver transplantation. The aim of this prospective study was to evaluate the diagnostic accuracy of liver stiffness measurement (LSM) by ARFI elastography staging graft fibrosis in liver transplant recipients undergoing protocol liver biopsy.

Methods: 108 liver transplant recipients (59% males; mean age 52±12 y) were enrolled in the study. Main etiologies that led to liver transplantation were viral hepatitis (n = 37), alcoholic liver disease (n = 18) acute liver failure (n = 10) and genetic liver diseases (n = 9). All patients received ARFI elastography of the liver at the same day of the protocol biopsy. Biopsy results with rejection activity index (RAI) ≥5 were excluded from the study (n = 7). Liver histology was used as reference. All laboratory and clinical data were recorded.

Results: The area under the curve (AUC) of LSM detecting ≥F2, ≥F3 and F4 were 0.75, 0.86 and 0.98, respectively, in comparison to liver biopsy. Cut off values of LS were 1.48 m/s, 1.62 m/s and 1.99 m/s, respectively. The sensitivity and specificity were 82% and 70%, 100% and 81%, 100% and 97%, respectively. Although there was a significant correlation between LS and histologic liver fibrosis ($r = 0.759$, $p < 0.001$) and hepatic activity index (HAI) ($r = 0.342$, $p < 0.001$), there was no correlation detected with RAI ($r = -0.118$, $p = 0.239$).

Conclusions: ARFI elastography is able to diagnose liver cirrhosis with an excellent diagnostic accuracy in liver transplant patients. Interestingly, cut off values were higher than the previously described LS values staging liver fibrosis in non-transplanted patients with chronic liver diseases.

P0050

NEUROLOGICAL SYNDROME 'DE NOVO' IN FAMILIAL AMYLOIDOTIC POLYNEUROPATHY AFTER LIVER TRANSPLANT

E.M.D.S. Mateus[1], I. Mega[2], A. Morbey[3], J. Veloso[3], R. Perdigoto[3], H. Glória[3], J. Machado[3], A. Martins[1], E. Barroso[1], Centro Hepato-Bilio-Pancreático e de Transplantação do Hospital Curry Cabral – Centro Hospitalar Lisboa Central. *[1]Surgery – Transplant, [2]Psychology – Transplant, [3]Hepatology – Transplant, Hospital Curry Cabral, Lisboa, Portugal*
E-mail: eliamateus@yahoo.com

Background and Aims: Transthyretin familial amyloid polyneuropathy (TTR-FAP) is a progressive neurodegenerative, disabling and life-threatening polyneuropathy affecting the peripheral and autonomic nerves, first identified in Portugal, with a wide variation in age of onset and symptoms. TTR is synthesized mainly in the liver, and liver transplant (LT) seems to have a favorable effect on the course of neuropathy, being a potential treatment currently available for TTR-FAP. Some patients developed transitory "de novo" neurological symptoms (unilateral paresthesias, aphasia, dysarthria, dizziness and vertigo syndrome), all of them 8 or more years after LT.

Methods: Medical records from TTR-FAP adult patients submitted to liver transplant in a single center more than eight years ago were reviewed (until December 2006, 681 LT were performed, 179 by FAP; 125 patients are still alive, 28 of them with neurological syndrome *de novo*). All the patients were submitted to a thorough neurological workup, and almost all had normal exams. MRIs were not performed due to protocol cardiac pacemaker insertion prior to liver transplant.
Results: 28 patients (22%) developed the same transitory, sporadic "de novo" neurological symptoms such as generalized absence, drowsiness, headache, unilateral paresthesias, hemiparesis, aphasia, dysarthria, slurred speech, double vision, blurred vision, partial seizures and myoclonic, dizziness and vertigo syndrome, behavior changes and mental confusion. All patients are treated or have been in the past with calcineurin inhibitors (CNI), 26 with cyclosporine and 2 with tacrolimus; those in which CNI were suspended improved or remained without these symptoms.
Antiepileptic drugs were prescribed with partial remission of the symptoms.
Conclusions: Neurological syndrome *de novo* have a significant impact on quality of life of these patients. These symptoms may be due to the natural progression of the disease apparently due to the increased survival of these patients with the LT.
We must review the immunosuppression of these patients.
Further studies are needed to improve treatment and quality of life of the transplanted TTR-FAP.

P0051
PERIOPERATIVE WHITE BLOOD CELL COUNT AS A MARKER FOR PATIENT AND GRAFT SURVIVAL AFTER ORTHOTOPIC LIVER TRANSPLANTATION

F.A. Helfritz[1], F. Lehner[1], M.P. Manns[2], J. Klempnauer[3], S. Ciesek[2].
[1]General-, Visceral- and Transplant Surgery, Hannover Medical School, [2]Gastroenterology, Hepatology and Endocrinology, [3]General-, Visceral- and Transplant Surgery, Medical School Hannover, Hannover, Germany
E-mail: sandra_ciesek@hotmail.com

Background and Aims: Orthotopic liver transplantation (OLT) is a standard procedure in endstage liver disease. However, recipients of OLT have an 10–15% risk to die within one year after transplantation. We evaluated whether different parameters of infection including cytokines and blood cells predict post-OLT mortality, graft survival and rate of acute rejection.
Methods: We collected clinical and laboratory data of 104 patients undergoing liver transplantation between 2011 and 2012 from Hannover Medical School. Patients were stratified by (i) patient survival, (ii) graft survival and (iii) episode of rejection(s) and were followed from OLT for one year. Laboratory data of peritransplant period (0–4 days after OLT) were analysed.
Results: Inflammatory markers like CRP and procalcitonin had no significant effect on one-year patient or graft survival after OLT ($p = 0.3$ or $p = 0.8$ respectively). Interestingly, white blood cell count (WBC) early after OLT was a prognostic marker for patients ($p = 0.019$) and graft survivial ($p = 0.03$). Importantly, white blood cell count early after OLT was independent from rate of acute rejection episodes. White blood cell count >20,000/μl within the first four days after OLT was associated with a higher patient and graft mortality. Patient mortality was 30% (WBC >20,000/μl) in comparison to 13% (WBC <20,000/μl). These results were independent from the underlying liver disease or type of immunosuppressive regimen.
Conclusions: These data demonstrate that white blood cell count >20,000/μl early after OLT is a cheap prognostic marker for patient and graft survival, while perioperative procalcitonin and CRP have no influence.

P0052
INFUSION OF THIRD-PARTY MESENCHYMAL STROMAL CELLS AFTER LIVER TRANSPLANTATION: A PHASE I, OPEN-LABEL, CLINICAL STUDY

O. Detry[1], M. Vandermeulen[1], M.-H. Delbouille[1], A. Deroover[1], J. Somja[2], N. Bletard[2], A. Briquet[3], C. Lechanteur[3], Y. Beguin[3]. *[1]Dpt of Abdominal Surgery & Transplantation, [2]Dpt of Pathology, [3]Dpt of Hematology, University of Liege, CHU Liege, Liege, Belgium*
E-mail: olivier.detry@transplantation.be

Background and Aims: Mesenchymal stromal cells (MSC) are multipotent bone marrow progenitors that have demonstrated significant immunosuppressive effects in various *in vivo* and *in vitro* studies. This study aimed to be the first evaluation of the safety and tolerability of MSC infusion after liver transplantation in a prospective, controlled phase-1 study.
Methods: Clinical grade MSCs were locally collected from the bone marrow of unrelated healthy donors. They were cultured in a GMP-compliant lab, underwent extensive quality controls and were frozen for storage in a MSC bank. When needed for patient treatment, MSC were thawed and intravenously injected into patients. 10 liver transplant recipients under standard immunosuppression (TAC-MMF-low dose steroids until day 30) received $1.5–3 \times 10^6$/kg MSC on post-operative day 3 ± 2. These patients were prospectively compared to a group of 10 control (MSC-) liver recipients. Primary endpoints were MSC infusion toxicity, and incidence of cancer and opportunistic infections at month 6. Secondary endpoints were patient and graft survivals and rejection at month 6, as well as the effects of MSC on recipients' immune function and on immunohistology of at month 6 graft biopsies.
Results: No MSC infusional toxicity was observed. Both groups were comparable in terms of donor and recipient characteristics. There was no difference in primary end-points between control and MSC groups. No patient developed *de novo* cancer. There was no statistical difference in patient and graft survivals or in rejection rates. There was no graft rejection in the MSC group. Month-6 graft biopsies were not different according to Banff and fibrosis scores.
Conclusions: This phase 1 study showed excellent tolerability and safety of a single infusion of third-party MSC after liver transplantation. There were no graft safety issues and no excess of immunosuppression after MSC injection. Further analyses of consequences of MSC injection on the immune profile are needed. The possibility of avoiding calcineurin-inhibitors with repeated MSC injections as main immunosuppressive therapy and/of tolerance induction by MSC infusion should be investigated by further studies.

P0053
DINSTICT INTRAHEPATIC CYTOKINE PROFILES FOR THE DIFFERENTIATON OF ACUTE CELLULAR REJECTION VS RECURRENT HEPATITIS C IN LIVER TRANSPLANTED PATIENTS

P. Fytili[1], T. Krech[2,3], A. Gonnermann[4], A. Großhennig[4], D. Jonigk[2], F. Lehner[5], M.P. Manns[1], A. Koch[4], J.U. Becker[2,6], H. Wedemeyer[1].
[1]Department of Gastroenterology, Hepatology and Endocrinology, [2]Institute of Pathology, Medical School of Hannover, Hannover, [3]Department of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, [4]Institute for Biometry, [5]Clinic for General, Abdominal and Transplant Surgery, Medical School of Hannover, Hannover, [6]Department of Pathology, University of Cologne, Cologne, Germany
E-mail: pfytili@hotmail.com

Background and Aims: Graft reinfection in liver transplanted patients with hepatitis C virus (HCV) infection is universal and triggers rejection episodes as well as liver damage and fibrosis. Reliable differentiation between HCV infection early after liver transplantation and acute cellular rejection (ACR) is of great importance for clinicians and poses a challenge for pathologists.

The aim of this study was a comprehensive analysis of intrahepatic cytokine and chemokine profiles and identification of inflammatory signatures that could be used to differentiate ACR from recurrent HCV in liver transplant recipients.
Methods: 60 HCV liver transplanted patients that underwent liver biopsy because of elevated transaminases in the first year after liver transplantation were included in this study. RNA was extracted from embedded biopsies and the expression of 47 chemokines and cytokines (mRNA), involved in inflammatory response, was determined by quantitative real time PCR.
Receiver operating (ROC) analysis was performed for all measured parameters and correlations in in the expression of cytokines and chemokines were analysed with SAS 9.3 and R 3.1.0.
Results: Blinded pathological reading revealed a definite diagnosis in 20 biopsies (10 ACR and 10 graft HCV, "training cohort"), a probable diagnosis in 21 patients (8 recurrent HCV and 13 ACR) and no conclusive result in 19 biopsies. Expression levels of five cytokines had an AUC >0.7 regarding diagnosis of an ACR in the training cohort. Their cut off values were estimated using Youden-Index and the calculation of odds ratio with 95% CI, revealed 3 parameters (CCL2, CXCL9, CCL11) that were differently expressed in the two patient groups (ACR vs graft hepatitis C). Distinct expression pattern revealed an up regulation of CCL2 together with CCL4, CCL5, HGF, IL18, TGFb1 and PDGF in patients with ACR that was not observed in those with HCV recurrence. Similarly, CXCL9 correlated with IFNg expression in patients with ACR but with CCL4 in HCV graft hepatitis.
Importantly, the identified parameters and expression patterns did not differentiate ACR and recurrent HCV hepatitis in the group with probable pathological diagnosis.
Conclusions: ACR and HCV-induced graft hepatitis in liver transplant recipients show distinct intrahepatic cytokine and chemokine patterns. This work shows that the histopathological analysis is equivocal and that further analysis of intahepatic cytokines and chemokines signatures could complement und facilitate the histopathological diagnostics.

P0054
SAFETY AND EFFICACY OF SUBCUTANEOUS HEPATITIS B IMMUNOPROPHYLAXIS USING "ON DEMAND" APPROACH AND COST ANALYSIS: A SINGLE CENTER EXPERIENCE

S. Pecere[1], A. Baldan[1], M.G. Lucà[1], L. Pasulo[1], A. Tortora[1], M. Rota[2], S. Fagiuoli[1]. *[1]Gastroenterology and Transplant Hepatology, liver transplant, Bergamo, [2]Department of Epidemiology, Pharmacological Research, Milano, Italy*
E-mail: silvia.pecere@gmail.com

Background and Aims: Hepatitis B immunoglobulin (HBIG) administration is the backbone for prophylaxis of HBV re-infection after liver transplantation (LT). Long term effects and efficacy of HBIG are well known only for intravenous (IV) and intramuscular (IM) formulations. Aim is to investigate efficacy, safety and feasibility of "on demand" subcutaneous (SC) administration of the new formulation of HBIG BT088 (Zutectra®) in LT patients.
Methods: A total of 47 pts (11F, 36M, mean age 60±9 years) were switched from IV (13 pts – 32%) or IM (28 pts – 68%) to SC HBIG administration during a period of 3 years from January 2011. The conversion to SC administration occurred at a mean time of 36 (±38) months from the LT. They were prospectively enrolled and followed up for at least 38(±12) months. The dose of HBIG was initially standardized to 1000 IU/week SC. After a period of stabilization, patients were offered a "on demand" approach, aiming at a targeted level of serum antiHBs ranging between 100 and 150 UI/L.
Results: All patients were HBV-DNA negative at the time of transplantation (9 spontaneously – 19%, 38 under NUCs – 81%) and were on a combination prophylaxis with HBIG and NUCs. All patients became rapidly independent for the weekly SC self-injection. The treatment was effective in maintaining trough anti-HBs levels greater than 100 UI/l in all patients. 90% of patients showed a mean HBsAb titer greater than 136 UI/l. Overall, mean values of HBsAb were 239 UI/l (±115). The mean HBsAb titer prior to switching to SC formulation was 384±125, with a mean monthly injection of 5000 U/L. In 60% of the patients the administration of SC HBIg were at least on a Q2-weeks administration (Table 1). No drug-related side effects or injection site problems were observed. As anticipated, the anti HBs titers progressively decreased with time from OLT but remaining above the "safe" level of 100 U/L.
Conclusions: SC HBIG for long term prophylaxis of post LT HBV re-infection has proven to be safe, well-accepted and effective in maintaining the targeted protective anti-HBs levels. Moreover, individualization of immunoprophylaxis according to the lowest protective anti-HBs titers is easily applicable with the SC formulation, allowing the exploration of new schedules in order to improve costs per patient/year while maintaining efficacy.

P0055
SAFETY AND EFFICACY OF ANTICOAGULATION THERAPY FOR PORTAL/SPLANCHNIC VEIN THROMBOSIS IN PATIENTS WITH LIVER CIRRHOSIS ON THE WAITING LIST FOR LIVER TRANSPLANTATION

L. Gheorghe[1], S. Iacob[1], C. Ester[1], R. Iacob[1], C. Gheorghe[1], I. Popescu[1]. *[1]Fundeni Cinical Institute, Bucharest, Romania*
E-mail: msiacob@gmail.com

Background and Aims: In patients with advanced cirrhosis, the presence of portal vein thrombosis (PVT) represents a cause of increased morbidity and mortality. Despite the high frequency of PVT in patients with end stage liver disease on the waiting list (WL) for liver transplantation (LT), there are few data on the efficacy and safety of anticoagulation therapy in this setting. Therefore neither clear recommendations, nor consensus regarding the optimal regimen and duration of anticoagulation therapy have been addressed in recent consensus publications on this specific issue.
Aim: To investigate the safety and efficacy of anticoagulation therapy for portal/splanchnic vein thrombosis in patients with liver cirrhosis on the WL for LT.
Methods: We included 121 patients with liver cirrhosis included on the waiting list for LT.
Results: The prevalence of PVT on the National WL for LT is 19.1%. Out of 121 patients, 44.6% received anticoagulant therapy. 35.1% received low weight heparine and 64.9% received acenocumarol for a mean time of 9.4±1.4 months. 39.6% of them had recanalization of the PVT, while 31.4% remained stable after 3 months of anticoagulant therapy. Complete and partial repermeabilization was acheived in 14.5% (7/48) and 85.5% (41/48) respectively. 13.2% of patients were transplanted. Overall death was encountered in 28.1% (34/121) of patients while on the WL and 4.9% (6/121) died after LT. Severe hemmorhagic events (variceal bleeding/hemoperitoneum/ hemorrhagic stroke) occured in 9.2% of patients receiving anticoagulant therapy.
Conclusions: PVT prevalence on WL for LT is high. Anticoagulant therapy is administred in 44.6% of patients, is safe and rather efficacious in recanalization of PVT before LT.

P0056

THE IMPACT OF METABOLIC SYNDROME AND PREVALENT LIVER DISEASE ON LIVING DONOR LIVER TRANSPLANTATION: A PRESSING NEED TO EXPAND THE POOL

W. Al-Hamoudi[1,2], F. Abaalkhail[2], A. Bendahmash[1], N. Allam[3], N. Almasri[2], H. Al-bahili[2], M. Al-Sebayel[2], D. Broering[2], H. Elsiesy[2].
[1]Gastroenterology and Hepatology department, King Saud University, [2]Department of Liver Transplantation and Hepatobiliary Surgery, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia; [3]Hepatology department, National Liver Institute, Menoufeya University, Menoufeya, Egypt
E-mail: walhamoudi@gmail.com

Background and Aims: Organ shortage has been the ongoing obstacle to expand liver transplantation world-wide. Living donor liver transplantation (LDLT) was hoped to improve this shortage. The aim of the present study was to analyse the impact of metabolic syndrome and prevalent liver disease on living donations. of new strategies.
Methods: From July 2007 to December 2012, a total of 171 deceased donor liver transplants and 190 living donor liver transplants (LDLT) were performed at our institution. In total, 265 patient were excluded because of either diabetes or a mody mass index (BMI) >28. Eight hundred potential living donors were assessed according to a step-wise evaluation protocol. The age of the donors receiving work-up ranged from 18 to 60 years. The majority were first and second degree relatives of the patients.
Results: Only 190 (24%) were accepted for donation and 610 (76%) were rejected. Some potential donors were excluded at initial screening due to incompatible blood groups (115; 14.3%), social reasons (40; 5%), or elevated liver enzymes (9; 1%). A total of 85 (10.5%) donors were excluded due to positive hepatitis serology. Steatosis resulted in the exclusion of 84 (10.5%) donors. In addition, 80 (10%) potential donors were rejected due to variations in biliary anatomy, and 20 (2%) were rejected due to aberrant vascular anatomy. Rejection due to biliary-related aberrancy decreased significantly in the second half of our program (14.5% vs. 5%, p = 0.0001). In total, 110 (13.7%) potential donors were rejected due to insufficient remnant volume (<30%) as determined by CT volumetry, whereas 24 (3%) were rejected due to a graft-to-recipient body weight ratio less than 0.8%.
Conclusions: Metabolic syndrome and viral hepatitis negatively impacted our living donor pool. Expanding the donor pool requires the implementation of new strategies.

P0057

BACTERIOBILIA IN LIVER TRANSPLANTED PATIENTS

M.J. Silva[1], J. Veloso[1], H. Peres[2], T. Pina[2], M. Pinto[2], V. Duarte[1], E. Barroso[1]. *[1]Hepato-Bilio-Pancreatic and Transplantation Centre, [2]Clinical Pathology Department, Central Lisbon Hospital Centre, Lisbon, Portugal*
E-mail: mariojorgesilva01@gmail.com

Background and Aims: Liver transplanted patients are at increased risk for bacteriobilia, as they undergo biliary tract handling, immunosupression and frequent antimicrobial therapy. Bile microbial patterns seem to differ from non-transplanted patients.
We aimed to characterize biliary microbial isolates retrieved during endoscopic retrograde cholangiopancreatography (ERCP) to liver transplanted patients.
Methods: Validated microbial isolates, and respective resistance testing, from cultures of bile and biliary prosthesis retrieved endoscopically from liver transplanted patients at our centre between June 2009 and December 2013 were retrospectively analyzed. Sensitivity to usual empirical antibiotics for cholangitis was assessed; as well as for vancomycin in *Enterococci* isolates. Extended spectrum beta-lactamase (ESBL) expressing bacteria were considered resistant to piperacillin/tazobactam, independently of *in vitro* sensitivity.
Results: A total of 328 different isolates were cultured from samples retrieved during 229 ERCP performed to 86 patients, 69.8% males, median age 54 years [19;71].
The majority of isolates (57.3%, n = 188) were gram negative bacteria, 40.5% (n = 133) gram positive bacteria and 2.1% (n = 7) fungi.
Considering only bacterial isolates, gram positive predominated in inaugural *vs* subsequent ERCP (63.0% *vs* 39.4%, p = 0.18). Differences were not significant among other subgroups, where gram negative isolates were more common (patient gender, biliary stenosis, lithiasis, prosthesis, and time since liver transplant).
Among gram negatives, 86.7% were *Enterobacteriaceae* (47.2% of them *Escherichia coli*), 7.4% *Pseudomonas aeruginosa* and 6.7% *Acinetobacter baumanii*. Among gram positives, 65.6% were *Enterococci* (43.0% of them *E. faecium*), 12.0% *Streptococci* and 5.3% *Staphylococci*. All isolated fungi were *Candida* species.
Resistance rates in *Enterobacteriaceae* were 45.3% to ciprofloxacin, 25.8% to cefotaxime, 23.3% to piperacillin/tazobactam and 1.8% to meropenem; 57.7% were multi-drug resistant. All *Acinetobacter* and 41.7% of *Pseudomonas aeruginosa* isolates were resistant to ciprofloxacin. Among *Enterococci*, 17.8% were resistant to vancomycin, and 36.4% resistant to ampicillin (10 confirmed *E. faecium* were sensible to ampicillin).
5.6% and 1.6% of bile and prosthesis cultures, respectively, were sterile.
Conclusions: Considerable levels of antimicrobial resistance were found. Empiric antibiotic therapy may be adjusted to inaugural vs subsequent ERCP.

P0058

SOFOSBUVIR-BASED ANTIVIRAL THERAPY IS HIGHLY EFFECTIVE IN RECURRENT HEPATITIS C IN LIVER TRANSPLANT RECIPIENTS: A "REAL-LIFE" CANADIAN MULTICENTER EXPERIENCE

N. Faisal[1], M. Bilodeau[2], B. Aljudaibi[3], K. Peltekian[4], E.M. Yoshida[5], T. Hussaini[6], P. Ghali[7], S.E. Congly[8], M. Ma[9], C. Cooper[10], N. Selzner[1], E.L. Renner[1], L.B. Lilly[1]. *[1]Multiorgan Transplant, Toronto General Hospital, University Health Network, Toronto, [2]Transplant Hepatology and Gastroenterology, University of Montreal, Montreal, [3]Transplant Hepatology and Gastroenterology, University of Western Ontario, London, [4]Transplant Hepatology, Dalhousie University / Queen Elizabeth II Health Science Centre, Halifax, [5]Transplant Hepatology and Gastroenterology, [6]University of British Columbia and Vancouver General Hospital, Vancouver, [7]Transplant Hepatology and Gastroenterology, University of McGill, Montreal, [8]University of Calgary, Calgary, [9]Transplant Hepatology and Gastroenterology, University of Alberta, Edmonton, [10]Division of Infectious Diseases, University of Ottawa, Ottawa, Canada*
E-mail: nabiha.faisal@uhn.ca

Background and Aims: Hepatitis C (HCV) recurrence is universal in patients who are viremic at the time of liver transplant (LT), and adversely affects outcomes with compromised patient and graft survival. This study aims to evaluate the efficacy, safety and tolerability of regimens containing sofosbuvir (SOF) in the treatment of HCV recurrence in all genotypes (GT) in patients outside of clinical trials in all seven Canadian transplant centers.
Methods: 120 LT recipients from across Canada with HCV recurrence were started on SOF based regimens [SOF + simeprevir (SIM) +/− ribavirin (RBV) n = 53; SOF + pegylated interferon + RBV n = 25; SOF + RBV n = 36; and SOF + Ledipasvir n = 6] between January and November 2014. Patient mean age was 58±6.85 years, and the majority (83%) were GT1, male (81%), Caucasian (85%) and treatment experienced (82%). 30% had fibrosing cholestasic (FCH)/aggressive HCV in the graft, 50% had F3/4 fibrosis. 58% were on tacrolimus, 36% on cyclosporine, and 6% on rapamycin. Median time from LT to treatment was 27 (1–

309) months. Two patients were HIV co-infected. The primary outcomes include patient and graft survival, on- and end-of-treatment response and sustained virological response at 12 weeks after treatment end (SVR12), and adverse events (AEs), including rejection, need for blood transfusions or growth factors, and other complications.

Results: 54/57 (95%) patients were HCV RNA undetectable at end of treatment (EOT), and SVR12 was achieved in 24/27 (89%) patients, with 3 relapsers. Week 4 of treatment data was available in 2/3 of patients and 58% had HCV RNA levels below the lower limit of quantification (LLQ). Creatinine levels (umol/L) were unchanged [median pre-treatment: 112 (54–257) vs. on-treatment: 109 (57–400), p = NS]. Severe anemia (Hb <85 g/l) requiring erythropoietin and/or blood transfusion occurred in 13% of patients, more frequently in RBV based regimens. Generalized AEs included fatigue, headache and nausea (seen in 20%), and photosensitivity skin rash (3%). 7 patients died (n = 1 intracranial bleed, n = 4 sepsis and n = 2 decompensated). No episodes of rejection occurred on treatment and no interactions with any concomitant immunosuppressive agents were reported.

Conclusions: Sofosbuvir based antiviral therapy for HCV recurrence after LT is well tolerated, and preliminary results suggest high efficacy overall, including in aggressive HCV and cirrhotic patients. No immunosuppression changes were needed when using these regimens.

P0059

META-ANALYSIS: SVR12 WITH SIMEPREVIR AND SOFOSBUVIR (SMV+SOF) FOR 12 WEEKS IN 225 LIVER TRANSPLANT (LT) RECIPIENTS WITH HCV GENOTYPE 1 (HCV-1)

N.H. Nguyen[1], B.E. Yee[1], G.A. Lutchman[2], J.K. Lim[3], M. Nguyen[2].
[1]*School of Medicine, University of California, San Diego, La Jolla,* [2]*Department of Gastroenterology and Hepatology, Stanford University Medical Center, Palo Alto,* [3]*Yale Liver Center, Yale University School of Medicine, New Haven, United States*
E-mail: mindiehn@stanford.edu

Background and Aims: Recently, the all-oral combination of SIM+SOF became available for the treatment of HCV-1 patients; however, safety, efficacy, and effectiveness data with SIM+SOF in post-LT patients is limited due heterogeneous study designs and small sample sizes. Our goal was to perform a meta-analysis of the available literature for SIM+SOF with and without ribavirin (RBV) in post-LT patients.

Methods: In November 2014, we conducted a systematic literature search for 'simeprevir' in MEDLINE, AASLD, APASL, DDW, EASL, and World Transplant Congress for the year of 2014. Literature search review and data extraction were performed independently by two authors (NN and BY) using a case report form and checked by a third author (MN) with discrepancies resolved by consensus. Inclusion criteria were: original studies of ≥5 post-LT HCV-1 patients treated with SIM+SOF±RBV that had SVR12 data. Exclusion criteria were HIV or HBV co-infection. We used random-effects models to estimate effect sizes, and Cochrane Q-test (*p*-value <0.10) with I^2 statistic (>50%) to assess study heterogeneity.

Results: Our analysis included eight studies and a total of 225 post-LT patients with SVR12 data. The majority of studies were conducted in a university setting (n = 6). Most patients were male (range 59–81%). Proportion with advanced fibrosis ranged from 6 to 41%. Pooled rates were as follows: end of treatment response was 98% (CI: 95.1–99.1%); SVR4 was 90% (CI: 82–94.6%); and SVR12 was 85% (CI: 79.4–89.3%). SVR 12 data was available in 2 studies to compare patients with mild fibrosis (n = 69) to those with advanced fibrosis (n = 24). SVR12 in patients with mild fibrosis was 90.1% (CI: 61.8–98.1%), which was significantly higher than SVR12 in advanced fibrosis at 55% (CI: 13.9–90.6%), OR 8.4 (CI: 2.2–31.74, p = 0.002). The most common pooled side effects were: fatigue 22% (47/216), headache 7% (n = 17/208), and pruritus 7% (n = 17/171). No treatment withdrawals were reported in these studies. Data was insufficient to examine SVR12 in subsets of patients treated with RBV vs. without and in patients with prior treatment failure vs. treatment-naïve patients.

Table 1. Characteristics of studies included in meta-analysis

First author, year	Setting	Collaboration	ITT analysis	Sample size with SVR12 data	Age (years)	Male, N (%)	Advanced fibrosis, N (%)
Aquel B, 2014	University	Multi-center	Yes	66	61.6±6	77 (76)	28 (28)
Gordon FD, 2014	University	Single center	No	15	–	–	1 (6)
Gutierrez JA, 2014	University	Single center	No	37	60.2±9.3	22 (59)	14 (38)
Suliman I, 2014	Community	Single center	Yes	8	62.5	6 (60)	–
Lutchman GA, 2014	University	Single center	Yes	31	62.3±5	43 (81)	11 (33)
Nair S, 2014	University	Single center	Yes	27	56±5	28 (61)	19 (41)
Ripper SJ, 2014	Community	Single center	No	23	60.9	21 (84)	7 (28)
Crittenden N, 2014	University	Single center	No	18	–	–	–

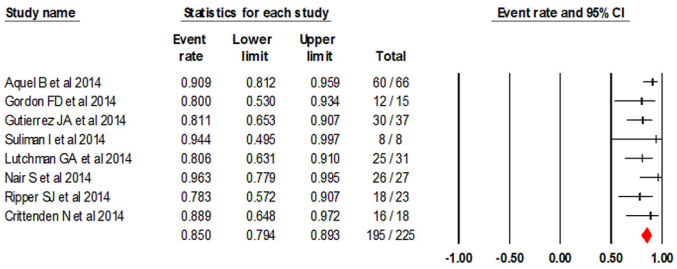


Figure 1. Pooled estimate of SVR12 in post-liver transplant patients.

Conclusions: SVR12 rates with SIM+SOF±RBV for 12 weeks in post-LT patients was approximately 85% suggesting high effectiveness even in this special population. This combination also appeared well-tolerated in the post-transplant setting. Patients with mild fibrosis are more likely to achieve SVR12.

P0060

ANTIVIRAL THERAPY WITH SOFOSBUVIR PLUS RIBAVIRIN IN HCV-INFECTED CIRRHOTIC PATIENTS AWAITING LIVER TRANSPLANTATION: PRELIMINARY DATA FROM A SINGLE-CENTRE EXPERIENCE

S. Strona[1], S. Martini[1], D. Arese[1], M. Sacco[1], R. Romagnoli[2], F. Tandoi[2], A. Ottobrelli[1], M.R. Torrani Cerenzia[1], F. Balzola[1], M. Salizzoni[2], M. Rizzetto[1]. [1]*Gastrohepatology Unit,* [2]*Liver Transplant Centre, General Surgery Unit, A.O.U. Città della Salute e della Scienza di Torino, Turin, Italy*
E-mail: silvia.strona@gmail.com

Background and Aims: Clearance of HCV infection before liver transplantation (LT) prevents recurrence after LT and could improve graft survival. We evaluated safety and efficacy of all oral antiviral therapy (Tx) with sofosbuvir (SOF) plus ribavirin (RBV) in HCV-infected cirrhotic patients (pts) before LT.

Methods: Among pts awaiting LT in our Centre, since June 2014 to date we enrolled 24 HCV cirrhotic pts with HCC within Milan criteria (15 pts) and/or decompensated liver disease. Median MELD 13 (range 7–19); Child-Turcotte-Pugh score B 71% and C 17%; 83% male, mean age 55.4 years, mean BMI 25.8. Mean baseline HCV RNA 6.17 $\log_{10}$ IU/mL (4.91–7.11 $\log_{10}$ IU/mL); GT1b 55%, GT1a 4%, GT2 4%, GT3 29%, GT4 8%; IL28 CC 20%; 63% had previous HCV Tx. Planned treatment is SOF 400 mg/die (compassionate use) and RBV (weight-based: 1000 mg daily if <75 kg; 1200 mg daily if ≥75 kg) for 48 weeks or until LT.

Results: To date, 10/24 pts received 12 weeks of Tx. Antiviral treatment resulted in rapid suppression of circulating virus with a median decrease in HCV RNA of 3.27 $\log_{10}$ IU/mL after 1 week of Tx; 10/20 pts (50%) at week 4 and 14/14 (100%) at week 8 were HCV RNA negative. Other results available until now are

depicted in the Table. No serious adverse events were observed. RBV reduction and/or epoetin administration was required in 25% of pts; 3 pts underwent blood transfusion and 3 were hospitalized due to complications of liver disease. Of the 7 pts transplanted until now, 4 had HCV RNA <15 IU/mL for a median of 62 days (31–91) and discontinued antiviral Tx at the time of LT. All those 4 pts are currently HCV RNA negative after a median follow-up post-LT of 45 days (16–69). Two pts underwent LT while still being HCV RNA positive after less than 4 weeks of Tx, and the last one was transplanted 3 days ago having HCV RNA <15 IU/mL since 5 days.

Time point (No. of patients)	HCV RNA negative	HCV RNA <15 IU/mL	MELD score, median (range)	Child–Pugh score	
				B (%)	C (%)
Basal (N = 24)	0%	0%	13 (7–19)	71%	17%
Week 4 (N = 20)	50%	75%	14 (6–23)	33%	39%
Week 8 (N = 14)	100%	100%	13 (7–18)	64%	21%
Week 12 (N = 10)	100%	100%	14 (7–21)	40%	30%
Week 16 (N = 7)	100%	100%	15 (9–21)	29%	20%
Week 4 after LT (N = 3)	100%	100%			

Conclusions: An all oral Tx with SOF plus RBV induces rapid HCV clearance and is well tolerated in cirrhotic pts awaiting LT. Preliminary post-LT SVR4 rate is promising in pts undergoing LT after at least 1 month from viral clearance. Further data will be presented as they become available.

P0061

TREATMENT WITH NEW ALL-ORAL DIRECT ACTING ANTIVIRALS IN HCV-RECURRENCE IN LIVER TRANSPLANT-SETTING INDUCES A REDUCTION OF IMMUNOSUPPRESSIVE DRUG LEVELS

J. Cabezas[1,2], M. Berenguer[3], J.M. Pascasio[4], M.-C. Londoño[5], J.M. Sousa Martín[4], C. Navascués[6], C. Vinaixa[3], I. Baños[7], J.L. Calleja[7], M. Rodríguez[6], X. Forns[5], J. Crespo[1,2]. *[1]Hepatology Unit, Digestive Service, University Hospital Marqués de Valdecilla, [2]Research Institute Valdecilla, IDIVAL, Santander, [3]Hepatology Unit and CIBERehd, University Hospital La Fe, Valencia, [4]Hepatology Unit, University Hospital Virgen del Rocío, Sevilla, [5]Liver Unit, IDIBAPS and CIBERehd, Hospital Clinic, Barcelona, [6]Hepatology Unit, Hospital Universitario Central de Asturias, Oviedo, [7]Hepatology Unit, University Hospital Puerta de Hierro, Madrid, Spain*
E-mail: joweycabezas@gmail.com

Background and Aims: *Introduction:* New direct acting antiviral agents (DAA) are an important advance in HCV treatment. DAA combinations have shown high efficacy in difficult-to-treat patients. They are not supposed to have significant pharmacological interaction with immunosuppressants (IS), so they are good candidates to treat liver transplant (LT) patients.
Aim: To describe efficacy and safety of DAA-treatments in patients with HCV-recurrence after LT. We focused our study in the potential immunosuppressant level reduction during DAA-treatment.
Methods: We evaluated 71 LT patients under IFN-free DAA treatment, including 18 patients with fibrosis cholestatic hepatitis. We monitored them weekly the first month and then every 2 weeks.
Results: 53 males. Patients' mean age was 56 years old (range 41–74); Range time from LT 1–198 months. Genotype distribution: 1a, 8 patients; 1b, 55, and 5 genotype 3 and 3 patients genotype 4. Fibrosis evaluation of HCV recurrence (METAVIR): F <2, 23 patients; F3, 10; F4, 31. 52 treatment experienced. All patients were on a stable IS regimen: 50 tacrolimus, 12 cyclosporine and 9 with mTOR.
Efficacy: 46/71 achieved RVR; and 58/70 achieved RNA undetectable at week 8, and 60/60 at week 12. Patients did not developed any significant adverse events. 2 deaths were reported, not related to antiviral treatment.
Mean IS level reduction was 30% (range 3–82%) between week 1 and 26 (mean 6). IS doses were adjusted in 42/65; 6/68 had an acute rejection.
The majority of patients improved AST levels. 13/71 improved albumin level; 35/71 improved bilirubin level; and 21/71 improved INR. Almost all patients improved non-invasive fibrosis scores by week 4: APRI decreased a mean 3.5 (range 0.2–10.2), FORNS mean 1.8 (range 1.2–10.2), Fibroindex mean 0.9 (range 0.1–5.6) and Fib-4 mean 4.4 (range 0.7–19.5). IS level reduction correlates significantly with non-invasive scores improvement: Pearson values for APRI 0.41 ($p = 0.005$); FORNS 0.55 ($p < 0.0001$); Fibroindex 0.45 ($p = 0.05$) and Fib-4 0.32 ($p = 0.038$). 37/71 patients improved MELD score between 1 and 17 points.
Conclusions: All-oral DAA combinations have a high viral efficacy with an excellent safety profile in LT patients. Despite the absence of a pharmacological interaction we have observed a decrease in immunosuppression levels, this could be related to a quick liver function recovery that improves IS clearance. In these patients, it would be recommended to closely monitor immunosuppression levels.

P0062

CHANGES IN CEREBRAL HEMODYNAMICS IN CIRRHOTIC PATIENTS AFTER LIVER TRANSPLANTATION

R.U. Macias-Rodriguez[1], O. García Flores[1], A. Ruiz-Margain[1], C. Cantú-Brito[2], A. Torre[1]. *[1]Department of Gastroenterology, [2]Department of Neurology, Instituto Nacional de Ciencias Médicas y Nutrición "Salvador Zubirán", Mexico City, Mexico*
E-mail: ricardomacro@yahoo.com.mx

Background and Aims: Changes in cerebral hemodynamics before and during liver transplantation (LT) have been related to poor neurological outcomes after LT. Improvement in cognitive function after LT has been related to decreased cerebral white matter lesions induced by microvascular lesions (leukoaraiosis) secondary to low-grade cerebral edema. However most of studies have addressed these changes in the acute setting during and immediately after LT in cirrhosis as well as in acute liver failure and few have evaluated the long-term changes in cerebral hemodynamics in this population, therefore we aimed to investigate the long-term changes on cerebral hemodynamics in cirrhotic patients after LT.
Methods: This was a prospective cohort study. Patients were evaluated by Transcranial Doppler Ultrasonography (TCD) obtaining Pulsatility index (PI) a marker of cerebrovascular structural integrity and breath-holding index (BHI) a marker of cerebrovascular reactivity which were measured in the middle cerebral artery pre and post-LT. Critical flicker frequency (CFF), psychometric hepatic encephalopathy score (PHES) and West-Haven criteria were used for HE characterization. Mean follow up after LT was 6 months.
Results: We included 17 patients (11 males); median age pre-LT was 45 (40–53) years, major etiology was hepatitis C virus (8/17), most of patients were Child–Pugh B (12/17), MELD score was 15.5 (12–17.5), MELD-Na 18, PHES −3 and CFF 38.5 Hz. Previous to the LT 11/17 patients had HE (6/4/1; covert, grade I and grade II HE, respectively), 5/17 ascites and 5/17 hepatocellular carcinoma. A decrease in PI was observed in all patients after LT and an increase in BHI in 9/17 (PI 1.01 and BHI 0.77 pre-LT vs PI 0.78 and BHI 0.72 post-LT, $P < 0.001$ and 0.740, respectively). The change on PI corresponds to a decrease of 22% and an increase on BHI of 55% after LT. Clinical improvement in cognition was observed in all patients with overt HE after LT.
Conclusions: These results show an improvement in cerebral hemodynamics at long-term after LT in cirrhosis, indicating less arterial cerebral vasoconstriction (decrease in PI) and an improvement in cerebrovascular autoregulation in 9/17 patients (increase in BHI). This could explain the improvement in cognitive function after LT and the decrease in cerebral white matter lesions induced by microvascular lesions described in some studies. TCD

could be considered as a useful tool for the assessment of the changes in cerebral hemodynamics pre and post-LT in cirrhosis.

P0063

SOFOSBUVIR PLUS RIBAVIRIN FOR THE TREATMENT OF SEVERE HCV RECURRENCE AFTER LIVER TRANSPLANTATION: PRELIMINARY DATA FROM A SINGLE-CENTRE EXPERIENCE

S. Marco[1], S. Martini[1], S. Strona[1], D. Arese[1], D. Cocchis[2], S. Mirabella[2], G. Rizza[2], F. Tandoi[2], R. Romagnoli[2], A. Ottobrelli[1], M.R. Torrani Cerenzia[1], F. Balzola[1], M. Salizzoni[2], M. Rizzetto[1]. *[1]Gastrohepatology Unit, [2]Liver Transplant Centre, General Surgery, A.O.U. Città della Salute e della Scienza di Torino, Torino, Italy*
E-mail: marco.sacco10@gmail.com

Background and Aims: Recurrent hepatitis occurs in the vast majority of HCV-positive recipients who are viremic at the time of liver transplantation (LT). We evaluated safety and efficacy of all oral antiviral therapy (Tx) with sofosbuvir (SOF) plus ribavirin (RBV) in a population of HCV-infected patients (pts) having severe recurrent hepatitis after LT.
Methods: Among HCV viremic pts transplanted in our Centre since 2000, we enrolled to date 107 pts affected by HCV RNA-positive recurrent hepatitis with fibrosis score F3 (21 pts) or F4 (86 pts) according to Metavir. 78% male, mean age 60.5 years, mean BMI 24.7; 49% are receiving cyclosporine, 43% mycophenolate, 38% tacrolimus and 3% m-TOR inhibitors. GT1 75% (GT1a 13%), GT2 5%, GT3 15%, GT4 5%; IL28 CC 24%; 65% had prior HCV Tx. According to compassionate use, pts receive SOF 400 mg/die plus RBV (weight-based: 1000 mg daily if <75 kg; 1200 mg daily if ≥75 kg) for 24 weeks. Median time from LT to Tx 4.96 years (0.25–14.25); mean baseline HCV RNA 6.62 $\log_{10}$ IU/mL (3.4–7.9 $\log_{10}$ IU/mL); mean GFR 76 mL/min.

Time point (No. of patients)	HCV RNA negative	HCV RNA <15 IU/mL	Mean Hb (g/dL)	Mean GFR (mL/min)	MELD score, median (range)	Child score	
						B (%)	C (%)
Basal (N = 107)	0%	0%	12.8	76	12 (6–22)	26%	5%
Week 4 (N = 98)	51%	88%	11.1	75	12 (6–26)	22%	6%
Week 8 (N = 77)	99%	100%	10.2	75	12 (6–22)	23%	6%
Week 12 (N = 31)	100%	100%	10.8	75	13 (6–28)	29%	13%
Week 16 (N = 9)	100%	100%	10.5	87	8 (6–18)	44%	11%
Week 24 (N = 2)	100%	100%	11.4	101	12 and 14	A6 and B7	
Week 4 after end of Tx (N = 2)	50%	50%	12.6	102	11 and 16	A5 and B9	

Hb, haemoglobin.

Results: Until now, 31/107 pts completed 12 weeks of Tx. After 1 week of Tx, median decrease in HCV RNA was 3.61 $\log_{10}$ IU/mL; 50/98 (51%) at week 4 and 76/77 (99%) at week 8 were HCV RNA negative. Other results available until now are shown in the Table. Of the 2 pts who completed the planned therapy and reached 4 weeks post-Tx, one relapsed; he is IL28 TT, GT1a and the only one who tested HCV RNA <15 IU/mL at week 8 on Tx. The most common adverse events were fatigue, headache and nausea. During Tx, 1 patient had variceal bleeding (day 78) and 1 died due to multiorgan failure (day 86); 25% received blood transfusion or epoetin; 1 patient temporally discontinued RBV because of skin rash. Minimal immunosuppression dose adjustments were required on Tx and no rejection episodes were recorded.
Conclusions: In pts with severe HCV recurrence post-LT, an all oral antiviral regimen using SOF plus RBV is very well tolerated and easy to manage, while allowing rapid HCV clearance. Data on sustained virologic response will be presented as they become available.

P0064

RIBAVIRIN PRE-TREATMENT IN LIVER TRANSPLANT PATIENTS WITH HCV RECURRENCE: RESULTS FROM PEARL MULTICENTRE RANDOMIZED TRIAL

V. Giannelli[1], A. Zanetto[2], P. Burra[3], P.R. Francesca[4], A. Gasbarrini[4], U.V. Comandini[5], G.M. Ettorre[5], M. Giusto[1], E. Biliotti[1], M. Merli[1], G. Taliani[1]. *[1]Sapienza University of Rome, Rome, [2]University of Padova, Padova, [3]University of Padova, [4]Catholic University, [5]POIT, Rome, Italy*
E-mail: mr_valegiann84@hotmail.it

Background and Aims: The treatment of liver transplanted patients with HCV recurrence is still a critical issue as the antiviral treatment regime based on the new DAA is not universally available and, due to high cost, restricted to patients with moderate/severe fibrosis (F≥3). In a previous pilot uncontrolled study we showed that 8-week ribavirin (RBV) pre-treatment before standard antiviral therapy with RBV and PEG-IFN, exhibits a better safety profile and therapy outcome in liver transplant patients with HCV recurrence. We aimed at further verify our hypothesis through a multicenter randomized controlled study (clinicaltrial.gov: NCT00993122).
Methods: The study is a multicentre prospective randomized controlled trial comparing 8-weeks RBV treatment followed by 48 weeks of PegIFN-Riba (PR) therapy vs. 48 weeks of PR. Riba and PEG-IFN2b and were given according to the EASL guidelines. Randomization was stratified for HCV genotype. 4 Italian centers participate in patients enrollment according to the inclusion and exclusion criteria starting from 2011 for a consecutive period. Inclusion criteria were: post-transplant HCV recurrence observed at least 6 months after liver transplant. Patients were excluded if they failed to meet the standard eligibility criteria for PEG-IFN/RBV treatment. IL28B polymorphism was also examined.
Results: Forty-nine patients were randomized 1:1 to RBV pre-treatment (pre-treatment group) or PEG-IFN2b (standard group). Liver biopsy prior to therapy showed moderate fibrosis (F <2) in 54% of patients and severe fibrosis (F >3) in 46%. HCV genotype were 1b 78% and non-1 22%. During RBV pre-treatment, HCV RNA showed a decline of 0.64 log10 IU/mL compared to pre-treatment level ($P < 0.003$) that was unrelated to the IL28B rs12979860 genotype (CC vs CT/TT, $P = 0.320$). The rate of rapid virological response (RVR) was significantly higher in the RBV pre-treatment arm compared to the standard treatment arm ($P = 0.040$) while the SVR rate was similar (48% and 43%, respectively; $p > 0.300$). However, the risk to develop severe therapy-related side effects and the need for supportive therapy was higher in the standard compared to the pre-treatment arm (32 vs 18%, respectively; $P = 0.042$).
Conclusions: In conclusion, RBV pre-treatment showed a significant antiviral activity independent to fibrosis at baseline or IL28 genotype. Although RBV pre-treatment failed to achieve a better outcome (SVR), the reduced incidence of serious adverse events might favor this option.

P0065

EFFECT OF PORTAL VEIN THROMBOSIS (PVT) ON SURVIVAL AFTER LIVER TRANSPLANTATION (LT): A METANALYSIS

A. Zanetto[1], K.-I. Rodriguez-Castro[1], E. Nadal[1], A. Ferrarese[1], G. Germani[1], F.P. Russo[1], P. Burra[1], M. Senzolo[1]. *[1]Multivisceral Transplant Unit, Gastroenterology, Department of Surgery, Oncology and Gastroenterology, Padua University Hospital, Padua, Italy*
E-mail: alberto.zanetto@yahoo.it

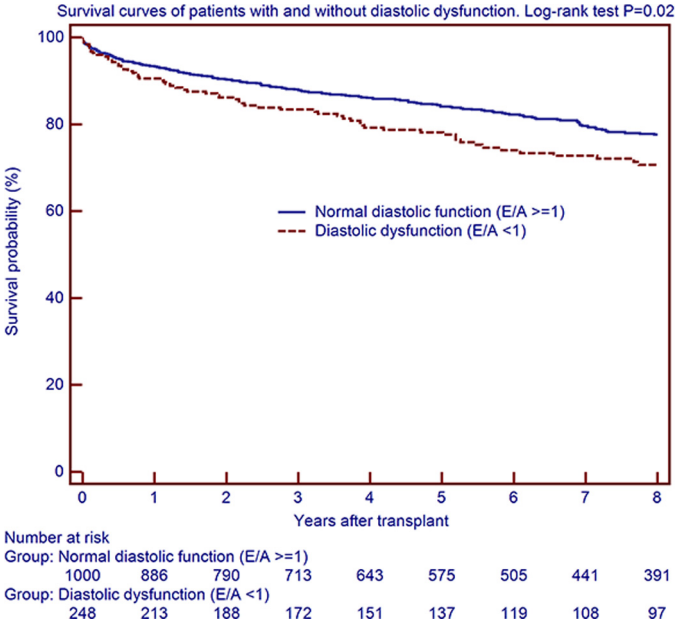
Background and Aims: Portal vein thrombosis (PVT) is a common complication in patients with liver cirrhosis undergoing liver transplant (LT). Although PVT is no longer considered an absolute controindication to LT, published data of its effect on mortality after the surgery are heterogeneous and discordant. The aim of the present study was to systematically review the current literature on the role of PVT in LT recipients in term of outcome.

Methods: A systematic review of the English and non English literature was performed by analyzing studies that report on PVT in LT recipients and were published between January 1986 and January 2013. We performed a meta-analysis using the 30-day and 1-year mortality as endpoints in all the studies, using random effect model.
Results: Twenty-six studies among the total of 426 articles initially retrieved were considered. Of 25,753 LT, 2004 were performed in patients with PVT (7.78%), and approximately half had complete thrombosis (according to Yerdel's classification) at the time of LT. Seven studies report on 30-day mortality in both patients with PVT and without PVT, for a pooled mortality rate of 10.5% vs 7.7% (P = 0.01) respectively with OR equal to 2.29 (95%, CI 1.43–3.68). Nineteen studies report on 1-year mortality after LT in both patients with and without PVT, for a pooled mortality rate of 18.8% vs 15.3% (P = 0.001). The OR for 1 year mortality in patient with PVT was 1.39 (95%, CI 1.18–1.64). Four studies report on 30-day mortality in both patients with partial and complete PVT, for a pooled mortality rate of 5.9% vs 17.5% (P = 0.001) respectively, with OR equal to 5.65 (95%, CI 2.00–15.96). There wasn't heterogeneity between studies both for the 30-day and 1-year mortality.
Conclusions: Presence of PVT in liver transplant recipients increases 30-day and 1-year mortality, therefore screening and treatment of this complication in patient awaiting LT seems essential.

P0066
DIASTOLIC DYSFUNCTION IS PROGNOSTIC FOR MORTALITY IN LIVER TRANSPLANTED PATIENTS WITH NORMAL EJECTION FRACTION

T. Peeraphatdit[1], N. Naksuk[2], C. Thongprayoon[3], P. Phatharacharukul[1], C. Krittanawong[2], P. Ricci[4], R. Chaiteerakij[5,6], K. Klarich[2], L.R. Roberts[5]. *[1]Internal Medicine, University of Minnesota, Minneapolis, [2]Cardiology, [3]Anesthesiology, Mayo Clinic, Rochester, [4]Gastroenterology, Minneapolis Veterans Affairs Health Care System, Minneapolis, [5]Gastroenterology and Hepatology, Mayo Clinic, Rochester, United States; [6]Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand*
E-mail: peera004@umn.edu

Background and Aims: Coronary artery disease and left ventricular ejection fraction (EF) are the main means of cardiovascular risk assessment of liver transplant (LT) candidates. The prognostic value of diastolic dysfunction, which is recognized as an early marker of cardiac risk in the general population, has not been studied in patients with cirrhosis. We aimed to evaluate the association between diastolic dysfunction in cirrhotic patients with normal EF and long-term mortality after LT.
Methods: Consecutive cirrhotic patients undergoing LT at a tertiary medical center between 2003 and 2013 were identified. Patients with combined heart and liver transplant, amyloidosis, hemochromatosis, sarcoidosis or carcinoid liver disease were excluded. 1,248 LT recipients with normal EF (>55%) were included. Diastolic dysfunction in cirrhosis was defined as a ratio of the early to late ventricular filling velocities (E/A ratio) value <1, according to the 2005 World Congress of Gastroenterology consensus. The association between baseline characteristics and estimated mortality was calculated using Cox Regression analysis.
Results: The prevalence of diastolic dysfunction was 20% in cirrhotic patients with EF ≥55%. Patients with diastolic dysfunction were older (59±7 vs. 51±11 years; p < 0.0001) and had greater preexisting cardiovascular comorbidities, diabetes, hypertension and hyperlipidemia compared to those with normal diastolic function (p < 0.05 for all). During median follow-up of 5.9 years after LT, the mortality of patients with diastolic dysfunction was 5.0% compared to 3.6% per person-year in those without diastolic dysfunction (p = 0.02) (Figure 1). Diastolic dysfunction was independently associated with an increase in all-cause mortality (adjusted hazard ratio 1.4, 95% confidence interval: 1.1–1.8; p = 0.02). Preexisting cardiovascular comorbidities, hypertension, hyperlipidemia and obesity were also independently associated with mortality.
Conclusions: Left ventricular diastolic dysfunction independently predicts post-LT mortality. This finding suggests that pre-transplant assessment of diastolic function adds an incremental value in predicting post-transplant mortality among cirrhotic patients with normal ejection fraction.



P0067
HEPATITIS C VIRUS INFECTION IS ASSOCIATED WITH LOWER SURVIVAL FOLLOWING LIVING DONOR LIVER TRANSPLANTATION IN THE U.S.

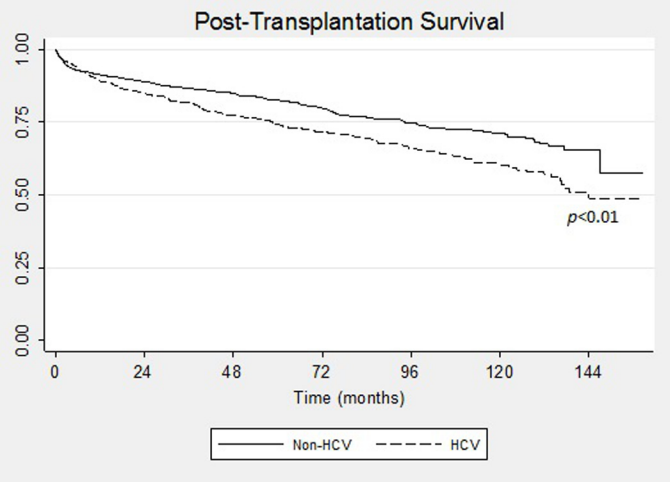
R.B. Perumpail[1], A. Liu[2], R. Liang[3], D.T. Chao[1], S. Saab[4], Z.M. Younossi[5,6], R.J. Wong[7], A. Ahmed[1], W. Concepcion[8], C.O. Esquivel[8], C.A. Bonham[8]. *[1]Medicine, Stanford University School of Medicine, Stanford, CA, [2]Medicine, Albert Einstein School of Medicine, Bronx, NY, [3]Medicine, Santa Clara Valley Medical Center, San Jose, CA, [4]Medicine and Surgery, David Geffen School of Medicine at the University of California at Los Angeles, Los Angeles, CA, [5]Medicine, Center for Liver Diseases, Inova Fairfax Hospital, [6]Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church, VA, [7]Medicine, Alameda Health System – Highland Hospital Campus, Oakland, CA, [8]Surgery, Stanford University School of Medicine, Stanford, CA, United States*
E-mail: perumpai@stanford.edu

Background and Aims: Living donor liver transplantation (LDLT), well studied in Asia, may address the gap between the limited availability of deceased donor livers and the growing waiting list for liver transplantation. However, concern exists regarding potential increased long-term mortality following LDLT due to recurrent hepatitis C virus (HCV), which remains the leading cause of end-stage liver disease resulting in liver transplantation in the U.S. Nevertheless, large studies examining the association of HCV on long-term survival post-LDLT in the U.S. are lacking.
Methods: We conducted a retrospective cohort study using population-based national data from the United Network for Organ Sharing registry to evaluate the impact of HCV on long-term survival among adult patients undergoing LDLT in the U.S. from 1995 to 2012. Survival outcomes among patients

undergoing LDLT were stratified by HCV status. Post-LDLT survival was evaluated with multivariate Cox proportional hazards model adjusted for age, gender, race/ethnicity, obesity, hepatocellular carcinoma (HCC), Model for End-Stage Liver Disease score, ascites, hepatic encephalopathy, diabetes mellitus (DM), and year of liver transplantation.

Results: Overall, 2,258 adult patients underwent LDLT from 1995–2012, including 882 with HCV (39.1%) and 1,376 without HCV (60.9%). On multivariate Cox proportional hazards modeling, patients with HCV had significantly lower post-LDLT survival compared with non-HCV patients (HR 1.42, 95% CI, 1.10–1.83, $p < 0.01$) (Figure). HCC (HR 1.81, 95% CI, 1.25–2.63, $p < 0.01$), older age (HR 1.03, 95% CI, 1.02–1.04, $p < 0.001$), and DM (HR 1.52, 95% CI, 1.09–2.11, $p = 0.02$) were similarly associated with a significantly lower survival following LDLT. Patients with HE (HR 1.27, 95% CI, 0.97–1.65, $p = 0.08$) had a non-significant trend toward lower survival, whereas obesity (HR 1.08, 95% CI, 0.82–1.43, $p = 0.58$) was not associated with survival following LDLT.

Conclusions: Among U.S. adult patients undergoing LDLT for chronic liver disease, HCV infection is associated with significantly lower post-LDLT survival compared to non-HCV patients. HCC, older age, and DM are also associated with lower survival following LDLT. These findings may enable optimization of patient selection for LDLT and identification of a population that may benefit greatly from HCV eradication with recent availability of highly efficacious interferon-free antiviral therapy.



P0068

ALCOHOLIC ETIOLOGY AND INSULIN DEPENDENT DIABETES ARE ASSOCIATED TO THE PRESENCE OF CORONARY DISEASE IN CIRRHOTIC PATIENTS WITH BASAL CORONARY RISK

M. Romero[1], M.M. Salcedo[1], D. Rincón[1], A. Fernández-Yunquera[1], M.D. Pérez-Valderas[1], C. Carbonell[1], C. Marta[1], G. Clemente[1], R. Yotti[2], R. Bañares[1]. *[1]Hepatology, [2]Cardiology, HGU Gregorio Marañón, Madrid, Spain*
E-mail: mario_romero_cristobal@hotmail.es

Background and Aims: The prevalence of coronary artery disease (CAD) in patients who are been evaluated for liver transplantation (LT) seems to be higher than in the general population and related to a higher morbimortality after LT. However, there is no consensus for its diagnosis and treatment. Data about the potential risk factors are also scarce. Our objectives were (1) to analyze the prevalence of CAD diagnosed by angiography in a population of patients who were been evaluated for LT and had a high basal risk and (2) to determine the risk factors associated.

Methods: 203 patients were evaluated for LT in our centre (June 2012 to February 2014). The indications for the coronary evaluation (by direct angiography or CT-coronariography) were (1) symptoms or previous history of CAD; (2) imaging data of atherosclerosis in other localizations; (3) ≥3 cardiovascular risk factors (CVRF): male, >50 years, smoking, dyslipidemia and hypertension; (4) diabetes; (5) LVEF <50%. Stenosis >50% was defined as significant and revascularization was considered.

Results: The coronary study was indicated in 129 cases and it was eventually performed in 74 of them who did not have any other contraindication for LT (61 direct angiographies and 13 CT-coronariographies). The indications were: 43 cases (58.1%) with ≥3 CVRF, 26 (35.1%) for diabetes, 1 (1.4%) for atherosclerosis in other localizations and 1 (1.4%) for previous history of CAD. Three additional explorations were performed for other reasons. CAD of any severity was detected in 34 cases (45.9%). Eight of them (10.8%) had significant stenosis and 6 were treated. No adverse events were reported. After a median follow up period of 10.2 months, there were no coronary events in the 44 patients who received LT. Into the subpopulation of patients selected for the coronary evaluation, the group with CAD had more frequently alcoholic disease (70.6% vs 45.0%; p = 0.04), insulin dependent diabetes (IDDM) (29.4% vs 12.5%; p = 0.08), consumed a higher number of cigarettes per day (21.9 vs 13.3, p = 0.05) and had a higher MELD score (16.8 vs 12.8, p = 0.08). In the multivariate analysis, the alcoholism (OR 3.5 [95% CI 1.2–9.9]; p = 0.02) and IDDM (OR 3.8 [95% CI: 1.1–13.9]) were independent risk factors.

Conclusions: The prevalence of CAD detected by angiography in cirrhotic patients who are been evaluated for LT and have high basal risk is close to 50%. In this population, the alcoholism and IDDM are associated to a higher risk of CAD. The diagnosis and treatment of CAD in this population is safe.

P0069

RISK FACTORS FOR METABOLIC SYNDROME AFTER LIVER TRANSPLANTATION: WHAT HAS CHANGED OVER TIME

E. Vanni[1], R. Ibrahim Kamal Jouness [1], S. Mirabella[2], A. Marengo[1], A. Milan[3], C. Rosso[1], V. Boano[1], E. Mosso[1], C. Di Stefano[3], E. Nada[2], L. Mezzabotta[1], M. Rizzetto[1], M. Salizzoni[2], R. Romagnoli[2], E. Bugianesi[1]. *[1]University of Turin, Department of Medical Sciences, Division of Gastroenterology, [2]Liver Transplant Center, [3]University of Turin, Department of Medical Sciences, Division of Internal Medicine, Turin, Italy*
E-mail: ester.vanni@unito.it

Background and Aims: Post-Transplant Metabolic Syndrome (PTMS) is common among liver transplantation (OLT) recipients and may contribute to non-graft-related morbidity/mortality. The aim of this study is the definition of the factors contributing to PTMS development with particular regard to changes in the immunosuppressive regimens.

Methods: Three hundred and ninety-three patients who underwent OLT at Turin Liver Transplant Center were prospectively enrolled (group A: pre-mTOR inhibitors – OLT between 1998–2003, n = 167; group B: m-TOR inhibitors – OLT between 2008–2012, n = 226). Overall the median follow-up was 60 months (1–204), 144 (83–204) in group A and 48 months (1–60) in group B. Clinical, laboratory parameters, prescribed medications, clinical events/deaths were recorded every 6–12 months. Clinical features of the donors and histological data of the allograft were collected. Univariate and multivariate analysis were performed to identify risk factors associated with PTMS development.

Results: Clinical features and OLT indications were comparable between the two groups except for HBV and alcoholic cirrhosis as underlying liver disease (29.9% group A vs 20.9% group B, p = 0.033; 13.8% group A vs 18.2% group B, p = 0.004). In the whole cohort, cryptogenic cirrhosis was an OLT indication in 2.8% (11/393) without temporal changes. Overall pre-OLT MS was found in 1.8% (7/393) subjects, without temporal changes, while PTMS

in 24.9% (98/393; group A 37.9%, group B 22.6%, p = 0.003). Overall multivariate analysis identified pre-OLT hyperglycemia and post-OLT weight gain as predictive risk factors for PTMS. However, independent risk factors were different in the two groups: post-OLT weight gain (OR 1.53, 95% CI 1.26–1.85, p = 0.0001) and post-OLT US liver steatosis (OR 4.12, 95% CI 1.48–11.4, p = 0.006) in group A; post-OLT weight gain (OR 1.36, 95% CI 1.17–1.57, p = 0.0001), pre-OLT hyperglycemia (OR 3.57, 95% CI 1.28–9.88, p = 0.014), macrovacuolar steatosis ≥20% in the allograft (OR 4.74, 95% CI 1.23–18.27, p = 0.024) and treatment with m-TOR inhibitors (OR 17.43, 95% CI 3.36–90.39, p = 0.001) in group B. Cardiovascular (CVD) events were reported in 2.7% (10/393; group A 4.2%, group B 1.8%, p = ns). Overall 18.5% (73/393) died, 6.8% (5/73) for CVD (group A 2.1%, group B 0.9%, p = ns).
Conclusions: Overall, host-related factors contribute to PTMS development, but the introduction of mTOR inhibitors is an additional risk factor particularly when suboptimal livers are transplanted.

P0070
EFFICACY OF THERAPEUTIC ERCP IN BILIARY COMPLICATIONS FOLLOWING LIVER TRANSPLANT: 10-YEARS EXPERIENCE
A.R. Alves[1], D. Gomes[1], S. Mendes[1], N. Almeida[1], R. Mesquita[1], E. Camacho[1], E. Furtado[2], C. Sofia[1]. *[1]Gastrenterology Department, [2]Pediatric and Adult Liver Transplantation Unit, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*
E-mail: alvess.anarita@gmail.com

Background and Aims: Biliary tract complications following liver transplant remain an important source of morbidity and mortality. Endoscopic retrograde cholangiopancreatography (ERCP) has become a common therapeutic option before other invasive procedures. The aim of this study was to evaluate ERCP efficacy in managing these complications.
Methods: It was performed a retrospective study of all patients submitted to therapeutic ERCP due to post-liver transplant biliary complications, between September 2004 and September 2014, in a predominantly deceased donor liver transplantation center.
Results: Therapeutic ERCP was performed in 120 patients (64.2% men; mean age at first ERCP of 46.3±14.3years). Mean time between liver transplant and first ERCP was 19.8±38.8 months. Biliary complications were anastomotic strictures (AS) in 59.3%, non anastomotic strictures (NAS) in 14.1%, bile leaks in 5.9% and biliary filling defects (like stones or sludge) in 7.4%. Stents were placed in 61.7% patients, balloon dilation was performed in 62.5% and filling defects were removed in 29.5%. Each patient needed a mean of 3.27±2.40 ERCPs, performed during a period of 18.7±19.3 months. Mean follow-up was 32.9±30.5 months. Globally, biliary complications were successfully managed by ERCP in 43.3% of patients. Per complication, ERCP was successful in 41.2% of AS, 15.8% of NAS, 87.5% of leaks and 90.0% of lithiasis. One quarter of patients required a percutaneous or surgical intervention due to ERCP inefficacy. Diagnose of a bile leak (p = 0.001) or lithiasis (p = 0.003) was associated with higher chance of successful ERCP treatment, while the presence of a NAS was associated with unsuccessful ERCP (p = 0.001). No statistical difference was found for AS.
Conclusions: ERCP allowed resolution of a biliary complication in 43.3% of patients, avoiding a more invasive procedure. Endoscopic treatment is particularly efficient in patients with bile leaks, lithiasis and AS.

P0071
REAL-TIME MEASUREMENTS OF TISSUE OXYGEN MICROTENSION AS A MARKER OF BILE DUCT VIABILITY IN LIVER TRANSPLANTATION
E. Navarro-Rodríguez[1], R. Ciria-Bru[1], M. Sanchez-Frias[2], J. Medina-Fernández[1], A.B. Gallardo-Herrera[1], M.D. Ayllon-Teran[1], S. Rufián-Peña[1], P. López-Cillero[1], J. Briceño-Delgado[1]. *[1]General Surgery, [2]Anatomic Pathology, HU Reina Sofía (Córdoba), Córdoba, Spain*
E-mail: helenanr1@hotmail.com

Background and Aims: The main aim was to evaluate bile duct viability by assessing its microvascular quality using an innovative real-time oxygen tension device by testing different areas in both donor and recipient's side. The findings were subsequently correlated with immunohistochemical and histopathological results. As a secondary aim, differences in bile duct micro-oxygenation status were analysed according to several donor, recipient and technical factors.
Methods: Observational prospective cohort study with 18 patients included from November 2013 to September 2014. Tissue oxygen microtension measurements were made using Oxylite® device in different areas of recipient and donor's bile duct intraoperatively after biliary anastomosis was made. Bile duct and hepatic artery biopsies were taken from donor and recipient.
Results: A total of 18 patients underwent liver transplantation with a median age of 53 years old (44–60) and MELD of 18 (17–26). Mean oxygen microtension value in the graft bile duct at anastomosis level was 106 (92–118) mmHg, being 125 (108–134) mmHg 1.5 cm proximal to the hilar plate. Mean micro-oxygenation value in the bile duct recipient was 117 (100–150) mmHg, whilst a value of 138 (119–183) mmHg was observed 1.5 cms distal to the anastomosis. Tissue oxygen microtension was statistically higher in distal areas to section border of the biliary anastomosis, with an overall pO2 increase distal to the anastomosis of 17.94 mmHg (p < 0.001) and 21.61 mmHg (p < 0.001) in the graft and recipient, respectively. Biliary anastomosis was performed above the cystic duct insertion in the donor bile duct in 10 patients, with significant higher values of pO2 microtension (p = 0.017). Histological injury grade 2–3 in biliary mural stroma and grade 1–3 in peribiliary vascular plexus of graft's bile duct graft were associated with lower tissue oxygen pressure, as well as injury grade 2 in biliary epithelium and grade 1–3 in peribiliary vascular plexus of recipient's bile duct were associated with lower micro-oxygenation (p < 0.05).
Conclusions: Biliary anastomosis is a critical point in liver transplantation. Our results demonstrates that terminal border of donor and recipient bile duct are low-vascularized areas. Tissue microoxygenation improves significantly in areas close to the hilar plate and to the duodenum in the donor and recipient's sides, respectively. Histopathological findings of bile duct injury are associated to worst tissue microoxigenation.

P0072
MICROINVASIVE INTRAOPERATIVE ULTRASOUND PATTERN IN PREDICTING OUTCOMES FOR SINGLE SMALL (<3 cm) HEPATOCELLULAR CARCINOMA
M. Costa[1,2], R. Santambrogio[1], M. Barabino[1], M. Zuin[3], E. Bertolini[3], E. Opocher[1]. *[1]Chirurgia Epato-bilio-pancreatica e Digestiva, Ospedale San Paolo, Milano, Italy; [2]Hepato-bilio-pancreatique et Transplantation Hepatique, Hôpital Henri Mondor, Créteil, France; [3]Medicina VI, Ospedale San Paolo, Milano, Italy*
E-mail: mara.costa@unimi.it

Background and Aims: The significance of tumor microinvasion (portal venous, hepatic vein, or bile duct infiltration and/or intra-hepatic metastasis, MI) in patients with single, small (<3 cm) hepatocellular carcinoma (HCC) remains unclear. Aim of the study was to evaluate MI impact (MI^+ vs MI^-) on HCC recurrence and

long-term survival in patients treated by hepatic resection (HR) or surgical radiofrequency ablation (RFA).
Methods: All patients with single, small HCC who underwent HR or RFA between 1997 and 2013 were included in this study. In agreement with the histological criteria described by Yamashita, the intraoperative ultrasound (IOUS) definition of MI has been defined according to our previous report on IOUS HCC classification.
Results: 370 patients (141 HR) were included: 144 (39%) patients had MI^+: 33% in VE-HCC (<2 cm) and 49% in the others (2–3 cm) ($p = 0.002$). In the HR subgroup, IOUS findings were associated with histopathologic features ($p = 0.0001$), sensitivity to detect MI^+ being 84% and positive predictive value being 86%. MI+ patients had significantly worse survival than MI^- (5-year survival: 33% vs. 49%, respectively; $p = 0.0358$) and higher intra-hepatic recurrences (5-year HCC recurrences: 86% vs. 64%, respectively; $p = 0.0001$). No difference was found among MI^+ patients submitted to HR or RFA for long-term survival or intra-hepatic recurrence, while a higher rate of local recurrence was found after RFA (5-year local recurrences: 48% vs 9%, respectively; $p = 0.0001$).
Conclusions: In patients with single, small HCC, the prevalence of MI^+ is high, even in cases of HCC <2 cm. IOUS findings strongly correlated with histopathologic criteria in detecting MI^+. MI^+ HCC patients had a worse prognosis, irrespective to treatment. IOUS MI pattern (during a bridging treatment) may represent a valid tool in the selection of HCC patients for transplantation.

P0073
INDIVIDUALIZING HBIg REINFECTION PROPHYLAXIS AFTER HBV-INDUCED LIVER TRANSPLANTATION: RESULTS FROM A MATHEMATICAL MODELING APPROACH BASED ON CLINICAL DATA

N. Filmann[1], J. Rosenau[2], M.P. Manns[3], H. Wedemeyer[4], E. Herrmann[1]. *[1]Institute of Biostatistics and Mathematical Modeling, Goethe University Frankfurt, Frankfurt, Germany; [2]Department of Internal Medicine, University of Kentucky, Lexington, United States; [3]Department of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, [4]Department of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany*
E-mail: filmann@med.uni-frankfurt.de

Background and Aims: Although hepatitis B immune globuline (HBIg) administration in combination with hepatitis B virus (HBV) polymerase inhibitors is the standard of care for prophylaxis of reinfection after liver transplantation (LTX) for HBV-related liver disease in many transplant centers worldwide, no rational basis for HBIg doses schedules exists until today. Individualized treatment regimens are of particular interest for high risk patients, HDV-coinfected patients (virtually no treatment options in case of reinfection), and because of the high costs and limited availability of HBIg.
The objective of the present study is the mathematical analysis of the virus kinetics after HBV-induced LTX and pharmacokinetics of HBIg after LTX.
Methods: Serial quantifications of anti-HBs and HBsAg for 67 patients were available for this retrospective analysis. All patients were transplanted at Hannover Medical School between 1994 and 2012. For part of these patients, clinical data was already published (Rosenau et al., 2007, Mederacke et al, 2012). We developed and evaluated new virus kinetics models basing on existing approaches (Nowak et al., 1996, Mager and Jusko, 2001, and Gourley et al., 2008). A potential reinfection of the graft was considered as well as HDV-coinfection during the modeling process. Model parameters were estimated by non-linear fitting of individual patient data.
Furthermore, a simulation study was performed to evaluate potential therapeutic regimes based on individual parameters. The defined goal of treatment in this simulation study was to decrease HBsAg under the detection limit within 11 days after LTX. Secondary criterion was the cost-effectiveness of the analyzed therapeutic regimes.
Results: In our simulations, we estimated that patients with a serum HBsAg level over 5,000 IU at the time of LTX benefited most likely from a therapy regime with a single dose of 20,000 IU during the anhepatic phase and subsequently 10,000 IU daily, while patients with a HBsAg-level below 5,000 IU profited from a therapy regime with a single dose of 10,000 IU and 4,000 IU subsequently. Patients with serum-HBsAg below 100 IU needed a single dose of 10,000 IU only. Overall, simulation results suggest treatment individualization according to baseline HBsAg-levels as a reasonable and feasible approach.
Conclusions: We propose an approach to model pharmacokinetics and pharmacodynamics of HBIg after HBV-induced LTX. The modeling results reveal potential risk factors and form a basis for treatment individualization.

PREVALENCE AND RISK FACTORS OF METABOLIC SYNDROME AFTER LIVER TRANSPLANTATION: A SINGLE CENTRE EXPERIENCE

V. Pepe[1], G. Germani[1], A. Ferrarese[1], A. Zanetto[1], I. Bortoluzzi[1], E. Nadal[1], F.P. Russo[1], M. Senzolo[1], U. Cillo[2], P. Burra[1].
[1]Multivisceral Transplant Unit, Department of Surgery, Oncology and Gastroenterology, [2]Hepatobiliary Surgery and Liver Transplant Unit, Department of Surgery, Oncology and Gastroenterology, Padova University Hospital, Padova, Italy
E-mail: veronica.pepe19@gmail.com

Background and Aims: Metabolic syndrome (MS) affects more than half of liver transplant (LT) recipients, increasing long term mortality and morbidity. However, few studies have evaluated the short and long-term prevalence of the MS post-LT and its potential risk factors. The aim of this study was to evaluate the short and long-term prevalence and the potential risk factors of MS after LT.
Methods: Patients who underwent LT at the Padova Liver Transplant Center between January 2000 and March 2013 (retrospective cohort) and between April 2013 and April 2014 (prospective cohort) and who were followed-up at Multivisceral Transplant Unit were included. Patients <18 years, who underwent multiorgan transplantation or re-LT and with MS diagnosed at the time of LT were excluded. For each patient general and metabolic variables, donor characteristics, transplant variables were recorded.
Results: In the retrospective cohort 161 patients (120 M, 41 F) were included. Mean±SD age at transplant was 52.5±9.5 years. The most common indication to LT was HCV-related cirrhosis (49.1%). A post-LT significant increase in BMI values, in diabetes and hypertension prevalence and in total cholesterol and triglyceride levels was found compared to pre-LT values. At a mean post-LT follow-up of 6.9±4.2 years 81/161 (50.3%) patients developed MS. Recipient male sex (OR 2.36, $p = 0.045$), a higher pre-LT BMI (OR per unit 1.14, $p = 0.03$), and the presence of pre-LT diabetes (OR 5.98, $p = 0.04$) were associated with the development of post-LT MS. In the prospective cohort 15 patients were included (10 M), mean±SD age at LT of 52.2±5.8 years. HCV-related cirrhosis was the most common indication to LT (33%). At 3, 6 and 12 months after LT a significant increase in BMI values, diabetes and hypertension prevalence and in cholesterol and triglyceride levels was found compared to pre-transplant values and 5/15 (33.3%), 3/11 (27.3%) e 4/10 (40%) patients developed MS.
Conclusions: Post-LT MS affects nearly half of LT recipients, starting early after LT. Recipient male gender, pre-LT diabetes and increased BMI are risk factors for MS after LT. Lifestyle modifications, should be recommended to transplanted recipients, especially in the overweight/obese ones, starting in the early post-LT period. This would facilitate prevention of body weight gain and the associated abnormalities, thus reducing incidence of post-LT MS and the related cardio-vascular events.

P0075

HEALTH-RELATED QUALITY OF LIFE IS IMPROVED AFTER LIVER TRANSPLANTATION AND IS RELATED TO DISEASE ACCEPTANCE, HELPLESSNESS AND PERCEIVED DISEASE BENEFITS

W. Develtere[1], L. Onghena[1], X. Rogiers[2], R.I. Troisi[2], F. Berrevoet[2], A. Vanlander[2], A. Geerts[1], H. Van Vlierberghe[1], X. Verhelst[1], C. Poppe[3]. [1]*Department of Gastroenterology and Hepatology,* [2]*Department of Hepatobiliary Surgery and Transplantation Medecine,* [3]*Transplantation Center, Ghent University Hospital, Ghent, Belgium*
E-mail: xavier.verhelst@uzgent.be

Background and Aims: Liver transplantation (LT) is the only curative treatment for end-stage liver disease (ESLD) with excellent long-term outcomes, regarding morbidity and mortality rates. However, an important outcome parameter is health-related quality of life (QoL). Improvement of QoL has been described after liver transplantation. We wanted to confirm these findings with specific attention for psychological parameters such as acceptance, helplessness and perceived disease benefits.
Methods: We performed a cross-sectional study (pre-post design) in a liver transplant unit. Self-report questionnaires were conducted in 120 patients with ESLD: 60 patients pre-transplantation and 60 post-transplantation. A control group of 57 patients with ESLD without the perspective of a transplantation also completed the same questionnaires on QoL (SF-36), acceptance (ICQ), helplessness (ICQ) and disease benefits (ICQ). Clinical and socio-demographical data were collected from the medical files. Data were analysed using the Mann–Whitney U test and Spearman's rank correlation coefficient.
Results: The studied groups of patients were comparable regarding age and MELD score, but the control group was significantly older ($p = 0.09$). We observed a significant increase in QoL as soon as 3 months after LT ($p = 0.046$) as well regarding the mental component summary scale ($p = 0.029$) as the physical component summary scale ($p = 0.033$). After liver transplantation, patients report more acceptance ($p < 0.01$) and disease benefits ($p < 0.0001$) and a decrease in helplessness ($p < 0.05$). General QoL is positively significant correlated ($p < 0.001$) with acceptance ($r_s = 0.737$) and disease benefits ($r_s = 0.494$), and negatively with helplessness ($r_s = -0.828$).
Conclusions: These data confirm an increase of QoL starting from 3 months after liver transplantation. We observed a better acceptance of their illness and more benefits of the illness after transplantation. Patients also report to feel less helpless, but the decrease is less distinct. We also found a high association between the QoL and helplessness. We assume that these findings indicate that patients receive a lot of attention and support for their illness after transplantation but still feel slightly uncertain and helpless about the future, regarding coping with it (medication, diet, …). These aspects deserve more attention and could give new directions in the approach of liver patients after transplantation. Further research on this matter is necessary.

P0076

ALCOHOL RELAPSE AND CARBOHYDRATE DEFICIENT TRANSFERRIN MEASUREMENT AFTER LIVER TRANSPLANTATION FOR ALCOHOLIC LIVER CIRRHOSIS

D. Kollmann[1], S. Rasoul-Rockenschaub[1], E. Freundorfer[1], G. Györi[1], G. Silberhumer[1], T. Soliman[1], G.A. Berlakovich[1]. [1]*Department of Surgery, Division of Transplantation, Medical University of Vienna, Vienna, Austria*
E-mail: dagmar.kollmann@meduniwien.ac.at

Background and Aims: End-stage alcoholic liver disease (ALD) is the second most-common indication for LT in Europe. However, it induces more debate than any other indication, mainly due to apprehensions about the abstinence period before listing to LT. Long-term observation after LT is challenging and biomarkers e.g. carbohydrate deficient transferrin (CDT) may help identifying a possible alcohol relapse. We intended to analyse the outcome of patients with LT due to ALD at the Medical University of Vienna.
Methods: A retrospective analysis of prospectively collected data from patients listed for LT with ALD as main or secondary indication between 1996 and 2012 was performed. Primary endpoints were long-term patient and graft survival as well as incidence of alcohol relapse. The latter was strictly defined as any post-LT alcohol consumption, evaluated by a specialist psychologist. A defined period of sobriety before LT was not required at our institution. CDT-levels were measured regularly after LT and were correlated with clinical outcome.
Results: From 1996 to 2012, 458 patients were listed for LT due to ALD as main or secondary indication. Out of these, 382 (83%) were transplanted, 36 (8%) died on the waiting list and 40 (9%) were removed from the waiting list. From patients who received LT, ALD was the main indication in 290 and the secondary indication in 90 patients. The median follow-up amounted 73 months (0–213). One-, and 5-year patient and graft survival was 82%, 69% and 82%, 75%, respectively. The alcohol relapse rate at 1- and 3-years showed 4.8% and 12.9%, respectively. Patients with ALD as main indication experienced significantly more often an alcohol relapse (log rank; $p = 0.037$). CDT levels were measured regularly post-LT and showed a sensitivity of 94% and a specificity of 87%. 186 of 382 patients died during the observation period, 32 with an alcohol relapse and 154 without. In patients who died with alcohol relapse, death was significantly more often liver-related than in patients without alcohol relapse (Chi-squared test; $p < 0.0001$). Alcohol relapse and ALD as main or secondary indication for LT did not significantly affect long-term patient and graft survival.
Conclusions: This large single centre analysis presents excellent long-term outcome in patients with LT for ALD. Our alcohol relapse rate was low compared to published data, although a strict definition was applied. Furthermore, post-LT CDT-measurement proofed to have high sensitivity for diagnosing alcohol relapse.

P0077

IMPROVEMENT OF LIVER ELASTICITY IN HCV-PATIENTS UNDER SOFOSBUVIR-BASED THERAPY AFTER LIVER TRANSPLANTATION

L.L. Seifert[1], E. Vorona[1], C. Bester[1], S. Beckebaum[1], I. Kabar[1], P. Baier[1], A. Hüsing[1], M. Stahl[1], V. Cicinnati[1], H.H.-J. Schmidt[1]. [1]*Klinik für Transplantationsmedizin, Universitätsklinikum Münster, Münster, Germany*
E-mail: l_seif03@uni-muenster.de

Background and Aims: Recurrence of HCV and its related progression of fibrosis after liver transplantation (OLT) are well documented. So far, interferon (IFN) based antiviral therapy represents the hallmark in treating HCV patients also after OLT. Neither sustained virologic response (SVR) nor safety profiles of the INF-based therapies are satisfactory for transplant recipients. In January 2014 the direct-acting antiviral (DAA) drug sofosbuvir (SOF) was introduced in Germany followed by simeprevir in May 2014 and daclatasvir in August 2014. Efficacy and safety of these newly introduced drugs are promising, experience in interactions are limited. The purpose of this ongoing analysis is to circumvent the progression of fibrosis in HCV liver transplant recipients.
Methods: Patients post OLT presenting with biopsy proven HCV inflammation were/are treated with SOF and Ribavirin (RBV) for 24 weeks ($n = 13$) or SOF in combination with another DAA ($n = 3$) for 12 weeks. Laboratory parameters and Fibroscan® were/are assessed constantly every fourth week during the treatment and 12 weeks after the end of the regimen. As control group HCV liver transplant recipients who received originally antiviral therapy with pegylated INF and/or RBV and/or Telaprevir (TLV) were retrospectively evaluated.

Results: Nine out 13 subjects with SOF/RBV had a rapid virologic response (RVR) and additional 4 patients developed an early virologic response (EVR). Comparing the two studied groups the rate of RVRs is significantly higher in the SOF-based therapies (p = 0.025, Fisher's exact test, 2-sided). All patients whose treatment ended at least 12 weeks ago show a SVR (n = 5). The three patients treated with two DAAs developed a RVR. Four patients who experienced a failure of an INF-based antiviral response responded to SOF/RBV. Preliminary data on Fibroscan® analysis revealed 12 patients with regression of fibrosis during the treatment with SOF in combination with RBV or another DAA. There were no side effects observed, which resulted in premature termination of SOF.
Conclusions: SOF seems to be a safe and effective therapeutic option in OLT patients infected with HCV. Preliminary results show that regression of fibrosis after OLT is feasible within 24 or 12 weeks of therapy at least in a subgroup of patients. This new interferon-free era of treating HCV will likely result in improved outcome of both patient and transplant survival in transplant recipients being infected with HCV.

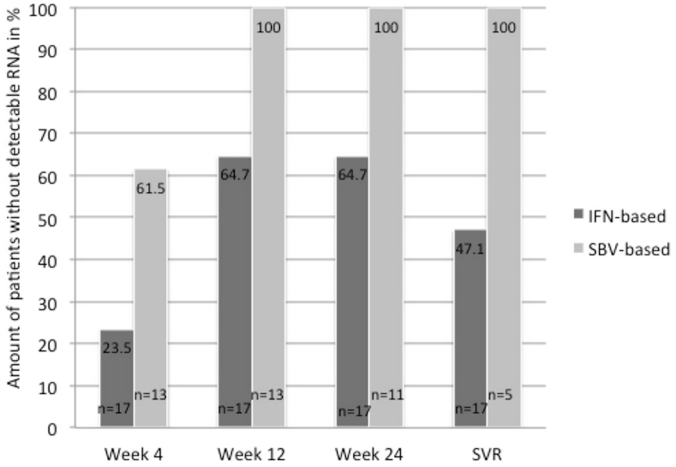

Figure: Progress of virologic response. The percentages of patients with no detectable HCV-RNA at different stages of the therapy with SOF and RBV are illustrated. The absence of detectable RNA in week 4 is defined as a rapid virologic response (RVR), in week 12 as an early response (EVR) and 24 weeks after the end of the therapy as a sustained response (SVR). The higher rate of RVRs under SBV is significant (p = 0.025, Fisher's exact test, 2-sided) and very promising, as a fast response was an important factor indicating a future success of the therapy in several other studies concerning HCV.

P0078
LAPAROSCOPIC RADIOFREQUENCY ABLATION VERSUS HEPATIC RESECTION IN THE TREATMENT OF VERY EARLY HEPATOCELLULAR CARCINOMA IN CIRRHOTIC CARCINOMA: A COHORT STUDY

M. Costa[1,2], R. Santambrogio[1], S. Bruno[3], M. Kluger[2,4], J. Salceda[2], A. Belli[2,5], A. Laurent[2], M. Barabino[1], E. Opocher[1], D. Azoulay[2], D. Cherqui[2,6]. *[1]Chirurgia Epato-bilio-pancreatica e Digestiva, Ospedale San Paolo, Milano, Italy; [2]Service de Chirurgie Digestive, Hepato-bilio-pancreatique et Transplantation Hepatique, Hôpital Henri Mondor, Créteil, France; [3]Medicina Interna ed Epatologia, AO Fatebenefratelli e Oftalmico, Milano, Italy; [4]Section of Hepatobiliary Surgery and Liver Transplantation Department of Surgery, New York Presbyterian Hospital – Weill-Cornell Medical Center, New York, United States; [5]Dipartimento di Chirurgia Oncologica Addominale, Istituto Nazionale Tumori "G. Pascale", Napoli, Italy; [6]Centre Hépato-Biliaire, Hôpital Paul Brousse, Villejuif, France*
E-mail: mara.costa@unimi.it

Background and Aims: Available studies showed conflicting results concerning survival rates for patients with cirrhosis and concurrent very early (VE) hepatocellular carcinoma (HCC) (stage 0 according BCLC classification: single <2 cm or carcinoma in situ, Child A) treated by laparoscopic radiofrequency ablation (LRFA) or hepatic resection (HR). Even if very few comparative studies between HR and RFA have been reported for VE-HCC, some experts have recommended modification of BCLC therapeutic algorithm in this subgroup of patients: RFA should be the first-line therapy and HR should be considered only in patients with failure of or contraindications to RFA. We compared HR versus LRFA as initial treatment for VE-HCC on survival, disease free survival (DFS) and HCC recurrences in a large cohort of patients followed in clinical practice
Methods: Two independent cohort series (Milan, Creteil), which include 855 patients with HCC who underwent HR (n = 529) or LRFA (n = 326), were retrospectively analysed. 176 patients had a VE HCC. Patients not suitable to HR (requiring a very large parenchymal loss at HR, due to the position of the lesion) were treated by LRFA (n = 92), the others underwent HR (n = 84). At the time of surgical procedure no relevant differences were seen between the 2 groups in term of liver disease status. In any case, Kaplan–Meier method was used to assess overall survival (OS), tumour recurrence rate and disease-free survival (DFS) before and after propensity score matching
Results: The 1-, 3- and 5-year OS rates for the LRFA group and the HR group were 92%, 66%, 46% and 94%, 89%, 75% respectively. The corresponding DFS rates for the 2 groups were 64%, 30%, 14%, and 82%, 58%, 39%, respectively. OS and DFS were significantly lower in the RFA group than in the HR group (p = 0.0029 and p = 0.0002, respectively). The 5-year HCC recurrence rate was higher in the LRFA group than in the HR group (82% vs. 56%; p = 0.0008). After propensity score matching, only survival rates become not significantly different. Multivariate analysis confirmed that treatment and BCLC stage are the only predictive factors for survival and intra-hepatic recurrences
Conclusions: HR yielded better disease-free survival rates than LRFA with not significant difference in survival. HR should be preferred in patients with peripheral tumours or with tumours located near gallbladder, main biliary ducts, bowel loops or big vessels, in which RFA may be less effective, if not dangerous. HR is the first-line option treatment for patients with VE-HCC

P0079
NUCLEOS(T)IDE ANALOGUE PROPHYLAXIS AFTER HEPATITIS B IMMUNOGLOBULIN WITHDRAWAL IS SAFE AND EFFECTIVE AGAINST HEPATITIS B AND D RECURRENCE AFTER LIVER TRANSPLANTATION

E. Cholongitas[1], T. Vasiliadis[2], I. Goulis[1], N. Antoniadis[3], P. Chalevas[1], I. Fouzas[3], D. Giakoustidis[3], G. Imvrios[3], O. Giouleme[4], V. Papanikolaou[3], E. Akriviadis[1]. *[1]4th Department of Internal Medicine, Aristotle University of Thessaloniki, [2]3rd Internal Medicine Department, Aristotle University of Thessaloniki, Papageorgiou Hospital, [3]Department of Transplant Surgery, Aristotle University of Thessaloniki, [4]2nd Propaedeutic Department of Internal Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece*
E-mail: cholongitas@yahoo.gr

Background and Aims: nucleos(t)ide agents (NAs) have made hepatitis B immunoglobulin (HBIG)-sparing protocol an attractive approach against hepatitis B virus (HBV) recurrence after liver transplantation (LT). However, this approach is considered controversial in patients transplanted for HBV and hepatitis D (HDV) coinfection.
Methods: all patients transplanted for HDV/HBV cirrhosis (7/1997 to 3/2013) were prospectively evaluated. After LT, each patient received HBIG (1,000–10,000 IU IV/IM in anhepatic phase and daily for 7 days and then monthly 1,000–2,000 IU IM) for a median time of 18 (range: 6–144) months plus NA and then continued with

NA mono- or dual prophylaxis. All patients were followed up with HBV serum markers and HBV-DNA, while anti-HDV/HDV-RNA was performed in those with HBV recurrence

Results: 34 recipients (all but 1 with undetectable HBV-DNA at LT; all with detectable HDV-RNA at LT) were included (11 men, mean age: 46.7±16 years). After HBIG discontinuation, NA(s) was received as monoprophylaxis (lamivudine: 2, adefovir: 1, entecavir: 9, TDF: 12) or as dual NA prophylaxis [lamivudine+adefovir (or tenofovir) in 10 patients]. None of the patients had HBV/HDV recurrence during combination of HBIG/NA(s) administration. However, two (5.8%) of the 34 patients had HBV/HDV recurrence after HBIG withdrawal [median follow up period: 28 (range 12–58) months]. These 2 patients had undetectable HBV-DNA but positive HDV-RNA at LT and they were under combination of lamivudine+adefovir prophylaxis at the time of recurrence. Statistical analysis revealed no factor significantly associated with HBV/HDV recurrence (pre-LT characteristics, antiviral protocol and immunosuppressive regimen post-LT), but those with recurrence had received HBIG for shorter period, compared to those without recurrence (median: 9 vs 20 months, p = 0.008). Glomerular filtration rate was not different between nucleoside and nucleotide (±nucleoside) analogue groups and similar regarding their serum calcium and serum phosphorus.

Conclusions: we showed for the first time that maintenance therapy with NA(s) prophylaxis after HBIG discontinuation was effective against HBV/HDV recurrence, but it seems that longer period of HBIG administration is needed before its withdrawal after LT.

P0080

HIGHER SURVIVAL IN BABY BOOMERS FOLLOWING LIVER TRANSPLANTATION: AN ANALYSIS OF THE UNOS DATABASE

R.B. Perumpail[1], J. Marcus[2], R. Liang[3], A. Liu[4], A. Laurain[1], S. Saab[5], M. Stepanova[6,7], Z.M. Younossi[6,7], R.J. Wong[8], A. Ahmed[1]. *[1]Medicine, Stanford University School of Medicine, Stanford, CA, [2]Jewish Hospital of Cincinnati, Cincinnati, OH, [3]Medicine, Santa Clara Valley Medical Center, San Jose, CA, [4]Medicine, Albert Einstein College of Medicine, Bronx, NY, [5]Medicine and Surgery, David Geffen School of Medicine at the University of California at Los Angeles, Los Angeles, CA, [6]Medicine, Center for Liver Diseases, Inova Fairfax Hospital, [7]Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church, VA, [8]Medicine, Alameda Health System – Highland Hospital Campus, Oakland, CA, United States*
E-mail: perumpai@stanford.edu

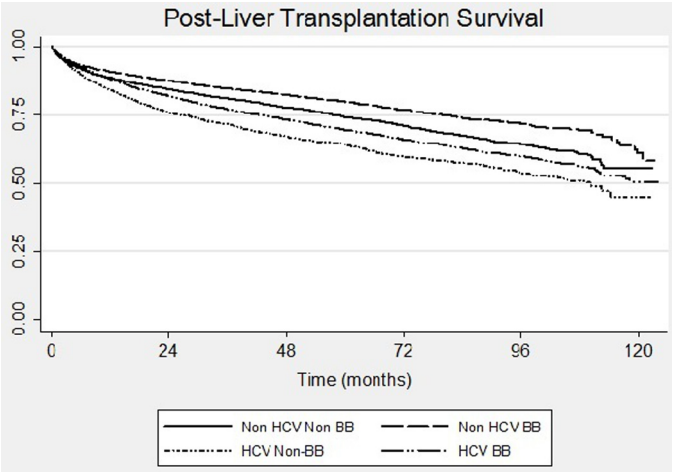
Background and Aims: According to the Centers for Disease Control and Prevention, individuals born between 1945 and 1965, the "baby boomer (BB) cohort", accounted for 81% of all chronic hepatitis C virus (HCV)-infected patients in the U.S. A significant proportion of HCV-infected BB have already developed complications of HCV-related cirrhosis, including hepatocellular carcinoma (HCC) and hepatic decompensation requiring liver transplantation (LT). The impact of the emerging BB generation on survival following LT in the U.S. remains unclear.

Aim: To evaluate the impact of birth cohort and HCV status on survival following LT among U.S. adult LT recipients.

Methods: Utilizing population-based national data from the United Network for Organ Sharing (UNOS) registry from 2003 to 2012, we evaluated birth cohort-specific (BB vs. non-BB) and etiology-specific (HCV vs. non-HCV) patient survival following LT among U.S. adults. Overall survival following LT, stratified by birth cohort and HCV status, was analyzed with Kaplan–Meier methods and multivariate Cox proportional hazards models adjusted for age, sex, HCC, body mass index, race/ethnicity, year of LT, diabetes mellitus, Model for End-Stage Liver Disease (MELD) score, albumin, ascites, hepatic encephalopathy, and cardiac disease.

Results: From 1995 to 2012, there were 89,479 LT performed in the U.S.: 68.0% (n = 60,842) among BB and 32.0% (n = 28,637) among non-BB. During the MELD era, from 2003 to 2012, overall patient survival following LT was the highest among the non-HCV BB cohort and the lowest among the HCV non-BB cohort. Among patients with HCV, BB patients had significantly higher 5-year survival following LT compared to non-BB patients (69.5% vs. 64.2%, p < 0.001) [Figure]. Among patients with non-HCV-related liver disease, similar trends were seen, with significantly higher 5-year survival following LT among the BB cohort compared with the non-BB cohort (79.8% vs. 74.2%, p < 0.001) [Figure]. Based on multivariate Cox proportional hazards models, compared to non-BB patients, patients in the BB cohort had significant higher post-LT survival (HR, 0.87; 95% CI, 0.81–0.93, p < 0.001).

Conclusions: BB patients demonstrated a significantly higher survival following LT compared to non-BB cohort patients. While survival following LT among HCV patients in our current study confirms previously reported outcomes, we also report a novel and significant birth cohort effect on post-LT survival. Further studies are needed to understand the survival advantage in the BB cohort.



P0081

REDUCED CALCINEURIN INHIBITOR EXPOSURE EARLY AFTER LIVER TRANSPLANTATION PROTECTS AGAINST RENAL DYSFUNCTION INDEPENDENTLY OF THE USE OF BASILIXIMAB INDUCTION THERAPY

S. Onali[1], A. Mansell[1], S. Aspite[1], L. De Luca[1], E. Tsochatzis[1], J. O'Beirne[1], D. Patch[1], D. Thorburn[1], M. Pinzani[1], P. Manousou[1]. *[1]The Royal Free Sheila Sherlock Liver Centre, Royal Free London NHS Foundation Trust and UCL Institute for Liver and Digestive Health, London, UK, London, United Kingdom*
E-mail: simona.onali@yahoo.it

Background and Aims: Basiliximab use with delayed entry of tacrolimus (TAC) as renal sparing agent may help reduce renal impairment in liver transplant (LT) recipients. We aimed to evaluate factors affecting renal dysfunction and the effect of basiliximab post-LT.

Methods: All consecutive LT patients (1/2006–1/2014) with a follow up >3 months and eGFR <90 ml/min/1.73m^2 at day 1 post-LT were analyzed for factors known to affect renal dysfunction: biochemical/clinical data, donor age, cold/warm ischemia time, mean trough TAC levels up to days 7, 15, 30 post-LT, basiliximab use, initial/maintenance immunosuppression, acute cellular rejection (ACR), diabetes mellitus (DM) pre and post-LT, systemic hypertension, days on filtration post-LT. Renal impairment was defined as mild: eGFR 60–89and moderate/severe: eGFR <60. Endpoints were eGFR at 3 months and at last follow up post-LT.

Results: 126 patients given basiliximab were compared with 189 consecutive patients with eGFR <90 at day 1 post-LT (control group). Basiliximab group had mean TAC trough levels 3.4 ng/ml vs 5.9 ng/ml of controls at the first week and 4.2 ng/ml vs

6.6 ng/ml respectively at 15 days post-LT. 20 (16%) on basiliximab had ACR vs 72/188 (38%) controls (p = 0.001). Of those not on basiliximab, 35% (35/97) with TAC levels >5 ng/ml vs 41% (38/92) with TAC <5 ng/ml at week 1 post-LT experienced ACR episodes (p = NS).
Logistic regression analysis showed that factors associated with moderate–severe renal impairment (eGFR <60) at 3 months post-LT were: recipient age >50 years (p < 0.001, OR = 1.06, 95% CI 1.03–1.1), mean CNI levels >5 ng/ml at week 1 post-LT (p = 0.003, OR = 0.4, 95% CI 0.3–0.7) and mean CNI levels >7 ng/ml up to 15 days post-LT (p = 0.019, OR = 0.85, 95% CI 0.75–0.97). The same factors were associated with mild renal impairment (eGFR <90).
Factors associated with moderate/severe renal impairment at last follow up (median 48 mo) in the Cox regression analysis were: mean TAC levels >7 ng/ml at day 15 post-LT (p = 0.003, OR = 1.9, 95% CI 1.2–2.9) and use of steroids >3 months post-LT (p = 0.006, OR = 0.7, 95% CI 0.5–0.9).
Conclusions: Basiliximab use allows reduced TAC trough levels with less episodes of ACR compared with the control group. However, TAC trough levels <7 ng/ml at 15 days post-LT regardless of basiliximab use, were protective of renal function without predisposing to ACR in patients with renal impairment at baseline.

PROOF-OF-PRINCIPLE EVALUATION OF IMMUNOMODULATORY DRUGS IN PROMOTING PHAGOCYTOSIS CAPACITY IN PATIENTS WITH LIVER FAILURE

C. Bernsmeier[1], R. Tidswell[1], L. Ghataore[2], V.C. Patel[1], A. Singanayagam[1], E. Triantafyllou[1], W. Khamri[3], M. Heneghan[1], C. Willars[1], W. Bernal[1], G. Auzinger[1], D.R. Taylor[2], R.P. Vincent[2], Y. Ma[1], M.R. Thursz[3], J.A. Wendon[1], C.G. Antoniades[1,3]. [1]*Institute of Liver Studies, King's College Hospital, King's College London,* [2]*Department of Clinical Biochemistry, King's College Hospital,* [3]*Hepatology Department, St. Mary's Hospital, Imperial College London, London, United Kingdom*
E-mail: christine.bernsmeier@kcl.ac.uk

Background and Aims: Secondary infections are the main cause of death in patients with acute- (ALF) and acute-on-chronic liver failure (ACLF) and have been attributed to monocyte dysfunction. The use of steroids in these patients is common but controversial. Beneficial effects on haemodynamics do not confer survival benefit. Their immunomodulatory effect in liver failure syndromes is poorly understood. Steroid clearance was found decreased in critically ill patients. We determined monocyte phagocytosis in patients with liver failure and developed an ex-vivo proof-of-principle evaluation of drugs aimed at boosting innate immune responses.
Methods: Phagocytosis of *E. coli* and oxidative burst by monocytes was studied ex-vivo on monocytes from patients with ALF (n = 24), ACLF (n = 26), cirrhosis (n = 5) and compared to healthy controls (HC, n = 16) using pHrodo assay (Invitrogen) and Phagoburst (Glycotope). Immunophenotype (CD14, CD16, HLA-DR, CD163, MERTK, Fcy-receptors CD32, CD64) was assessed by flow cytometry. PBMCs from ALF/ACLF patients were treated ex-vivo with Interferon-γ (IFN-γ, 50 ng/ml), N-acetylcysteine (NAC, 250 mg/l) and hydrocortisone (500–10,000 nmol/l) for 48 h. Baseline plasma cortisol levels were assessed by liquid chromatography-mass spectrometry.
Results: Phagocytosis of *E. coli* was impaired in patients with ALF compared to HC (p < 0.0001) and ACLF compared to cirrhosis and HC (p = 0.004/p = 0.0028); and correlated negatively with activation marker CD163 (r = −0.365, p = 0.043). Oxidative burst was impaired in ALF (p = 0.0369) but not ACLF (p = 0.1275/p = 0.9897). Expression of Fcy-receptors was preserved. Ex-vivo treatment with IFN-γ (p = 0.0133) and NAC (p = 0.0156) decreased, and hydrocortisone at doses up to 2000 nmol/l increased phagocytosis (500 nmol/l, p = 0.0039; 1000 nmol/l, p = 0.0137; 2000 nmol/l, p = 0.371). Plasma cortisol levels >2000 nmol/l in patients on hydrocortisone treatment were associated with impaired phagocytosis (p = 0.0401) and high 28-day mortality (83.3%).
Conclusions: Defective phagocytosis occurs in patients with ALF and ACLF and may impair host defence. IFN-γ and NAC inhibited, while hydrocortisone enhanced monocyte phagocytosis capacity ex-vivo. High plasma cortisol levels in patients on hydrocortisone treatment conferred phagocytic defect and poor outcome. Decisions to use approved agents with immunomodulatory effects in patients with liver failure syndromes need careful consideration, hydrocortisone dosing and drug-monitoring require evaluation in clinical studies.

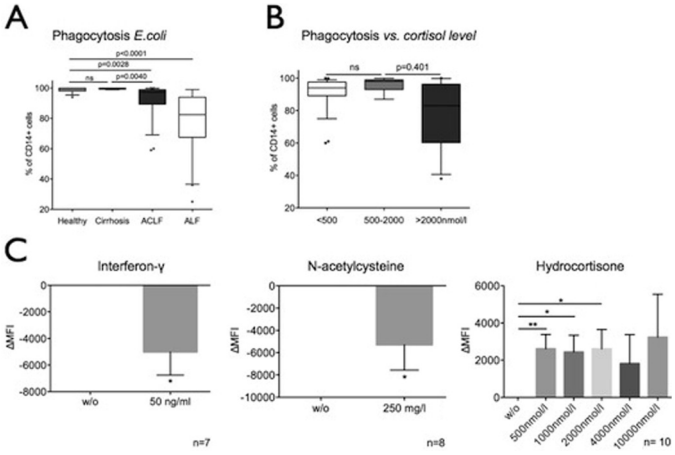

Figure: (A) Ex-vivo phagocytosis of *E. coli* in patients with ACLF and ALF compared to healthy controls and stable cirrhotic patents. (B) Ex-vivo phagocytosis in ACLF in relation to the baseline plasma cortisol level. (C) Phagocytosis after ex-vivo treatment of rnonocytes from patients with liver failure with interferon-γ, N-acetylcysteine and hydrocortisone for 48 h.

P1295
ROLE OF CK 18 (M30) IN PREDICTING MORTALITY IN PATIENTS WITH ACUTE LIVER FAILURE

P. Kar[1], C. Malik[1], R.K. Hazam[1], A. Bagchi[1], A. Chakravarti[2]. [1]*Medicine,* [2]*Microbiology, Maulana Azad Medical College, New Delhi, India*
E-mail: premashishkar@gmail.com

Background and Aims: Poor prognosis of acute liver failure (ALF) is well known. Although numerous prognostic criteria's have been established, they lag in their predictive accuracy when applied to Asian population. Also with the recent interest in cell death markers, the study was undertaken to assess the role of Cytokeratin 18 (M30) in ascertaining the prognosis of patients with ALF and thus identify who all will benefit from a liver transplant.
Methods: Forty-five adult patients with ALF were evaluated and managed in ICU in the Department of Medicine, of Lok Nayak hospital, New Delhi, India. Besides the liver function test and serological markers for HbsAg, IgM anti HCV, IgM anti-HAV, IgM anti-HEV and CK 18 (M30) levels were done by ELISA at base line and on follow up course in the hospital.
Results: The mean cleaved CK18 [M30] levels in ALF patients who survived were 767.37±247.97mIU/ml and in those who expired

were 1094.67±239.37 mIU/ml. The difference in values between these groups was statistically significant (p = 0.004).
There was a statistically significant difference in total leucocyte count, serum creatinine, INR and cleaved CK18 M30 levels among those that survived vs expired. Multivariate analysis found that all these independently predict mortality. A receiver operating characteristic curve was drawn for the new score. The score found was compared with the King's College criteria and the MELD score, the new scoring system was found to have higher sensitivity and specificity for mortality compared with other standard prognostic markers in ALF, and has a better diagnostic accuracy (Table 1).

Table 1. Sensitivity and specificity for mortality

	King's College Hospital Criteria	MELD score (≥20.96)	New score (≥0.15)
Sensitivity	69.4%	91.7%	94.4%
Specificity	88.8%	88.9%	89.9%
Positive predictive value	96.1%	96.9%	94.4%
Negative predictive value	42.10%	66.7%	77.7%
Diagnostic accuracy	73.3%	88.9%	91.1%
AUROC	–	0.944	0.978

The predicted probability of mortality can be found from the equation:
COMPUTED SCORE = −0.404 + (0.074·INR) + (0.00004513·TLC) + (0.0001·M30).
Conclusions: The results of our study suggest that initial serum CK 18 (M30) levels predict outcome in ALF patients. The ALF patients with serum Cleaved CK 18[M30] levels at admission more than 988.07 mIU/ml are candidates for liver transplantation, which can be life saving for these patients.

P1296
BLOCKING NMDA RECEPTORS PROLONGS SURVIVAL IN RATS WITH ACUTE LIVER FAILURE BY DUAL PROTECTIVE MECHANISMS IN KIDNEY AND BRAIN

O. Cauli[1], A. Gonzalez-Usano[2], A. Cabrera-Pastor[2], C. Gimemez-Garzo[2], A. Ruiz-Sauri[3], V. Hernandez-Rabaza[2], A. Agusti[4], A. Urios[2], A. Miguel[5], I. Torregrosa[5], C. Carda[3], C. Montoliu[4], V. Felipo[2]. *[1]Centro De Investigacion Principe Felipe, Valencia, Spain; [2]Laboratory of Neurobiology, Centro De Investigacion Principe Felipe, [3]Departamento de Patologia, Universidad de Valencia, [4]INCLIVA, [5]Servicio de Nefrologia, Hospital Clinico, Valencia, Spain*
E-mail: vfelipo@cipf.es

Background and Aims: Treatment of patients with acute liver failure (ALF) is unsatisfactory and mortality remains unacceptably high. Blocking NMDA receptors delays or prevents death of rats with ALF. The underlying mechanisms remain unclear. Clarifying these mechanisms will help to design more efficient treatments to increase patient's survival. The aim of this work was to shed light on the mechanisms by which blocking NMDA receptors delays rat's death in ALF.
Methods: ALF was induced by galactosamine injection. NMDA receptors were blocked by continuous MK-801administration. Edema and cerebral blood flow were assessed by magnetic resonance. The time course of ammonia levels in brain, muscle, blood and urine; of glutamine, lactate and water content in brain, glomerular filtration rate and kidney damage and of hepatic encephalopathy (HE) and intracranial pressure were assessed.
Results: ALF reduces kidney glomerular filtration rate (GFR) as reflected by reduced inuline clearance. GFR reduction is due to both reduced renal perfusion and kidney tubular damage as reflected by increased Kim-1 in urine and histological analysis. Blocking NMDA receptors delays kidney damage, allowing transient increased GFR and ammonia elimination which delays hyperammonemia and associated changes in brian. Blocking NMDA receptors does not prevent cerebral edema or blood–brain barrier permeability but reduces or prevents changes in cerebral blood flow and brain lactate.
Conclusions: Dual protective effects of MK-801 in kidney and brain delay cerebral alterations, hepatic encephalopathy, intracranial pressure increase and death. NMDA receptors antagonists may increase survival of patients with ALF by providing additional time for liver transplantation or regeneration.

P1297
DO MOLECULAR ALTERATIONS IN THE HEV GENOME PLAY A KEY ROLE IN ACUTE LIVER FAILURE?

J. Borkakoti[1], G. Ahmed[2], S. Kumar[1], P C. Ray[3], P. Kar[1]. *[1]Medicine, Maulana Azad Medical College, New Delhi, [2]Biotechnology, Gauhati University, Gauhati, [3]Biochemistry, Maulana Azad Medical College, New Delhi, India*
E-mail: borkakoti.jayanta@gmail.com

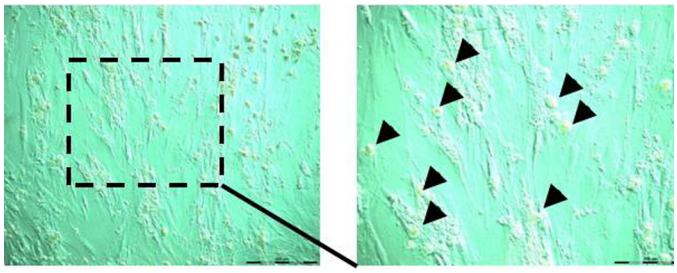
Background and Aims: Hepatitis E virus is a key public health disease in many developing countries and is also endemic in some industrialized countries. Very few studies have reported about the nucleotide substitutions in HEV and its association with acute liver failure (ALF). The present study was designed to assess the substitutional profile in the HEV isolates with acute liver failure and acute viral hepatitis from North Indian population. Besides, it was also aimed to associate the substitutions with the poor outcome of the disease.
Methods: A total of 42 patients with acute liver failure and 205 patients with acute viral hepatitis were screened for the study during the years 2011–2014. HEV IgM was detected by anti HEV IgM ELISA. HEV RNA was detected using Viral RNA extraction kit. The RNA Dependent RNA polymersase (RdRp) region of the Open Reading Frame 1 (ORF 1) protein of the HEV genome was amplified using Reverse Transcriptase PCR. HEV viral load was detected using Real time PCR. Representative samples were directly sequenced. Full length nucleotide sequences of HEV isolates were retrieved from the Gen Bank /EMBL/DDBJ databases and compared with the reference strains. Sequences were aligned by CLUSTAL W software.
Results: The mean age of the AVH and ALF patients were 23.82±2.88 years and 24.7±3.42 years respectively. HEV RNA was detected in 105 (51.21%) AVH and 31 (73.8%) ALF patients respectively. The substitutions 4476C>G and 4616A>C were present in 45.45% (25/55) of all the sequences amplified for the ORF 1 region while they were present in 100% (25/25) of the patients with acute liver failure. The substitutions were also found to be significantly different (p < 0.0001) when compared to patients with AVH. At the amino acid level, the Cysteine1483Tryptophan and Asparagine 1530 Threonine mutations were the most significant mutations (p < 0.0001) obtained in 100% (25/25) of the patients with acute liver failure compared to none (0/30) of the patients with AVH and the viral load corresponding to these 25 samples was significantly higher 58627.56±47029.83 copies/ml than 5682.16±4982.74 copies/ml (p < 0.0001) of the other isolates lacking these mutations.
Conclusions: The nucleotide substitutions in the RdRp region may play a crucial role in enhancing HEV replication thus leading to disease severity. The amino acid substitutions had a significant association with the poor outcome in ALF patients.

P1298

HYPOXIC PRECONDITIONING POTENTIATES TROPHIC EFFECTS OF MESENCHYMAL STEM CELLS ON CO-CULTURED HUMAN PRIMARY HEPATOCYTES

H. Qin[1,2], C. Filippi[1], R.R. Mitry[1], A. Dhawan[1], R.D. Hughes[1].
[1]*Institute of Liver Studies, King's College Hospital NHS Foundation Trust,* [2]*Division of Transplantation Immunology & Mucosal Biology, King's College London School of Medicine, London, United Kingdom*
E-mail: hong.qin@outlook.com

Background and Aims: Hepatocyte transplantation has been emerging as a promising alternative treatment modality for acute liver failure; however, marginal quality of cellular transplants is a major limitation. Mesenchymal stem cells (MSCs) could improve liver-specific metabolism of co-cultured hepatocytes. The present work aimed to potentiate hepatotrophic effects of MSCs co-culture using hypoxic preconditioning (HPc).
Methods: Human adipose-derived MSCs were subjected to 20%> (normoxia-preconditioned, NPc) or 2%> O_2 (HPc) for 24 h and co-cultured with primary human hepatocytes in a 3-dimensional architecture (Figure 1, the arrowheads indicating hepatocytes), with mono-cultured hepatocytes as control. Albumin secretion and CCK18 release were assayed to investigate trophic and antiapoptotic effects of co-culture on hepatocytes. Indirect co-culture was established to investigate the role of paracrine factors in hepatotrophic effects of co-culture. Reactive oxygen species (ROS) activity was antagonised by adding N-acetylcysteine to investigate whether HPc potentiated MSCs by intracellular ROS-dependent mechanisms, including TNF-α, TGF-β1, extracellular collagen, and apoptosis-associated caspase and BAX/BCL-2 signalling pathways.
Results: HPc significantly potentiated albumin secretion (day 7, HPc *vs.* NPc, 3.9±0.2 *vs.* 3.3±0.3 folds of control, $P < 0.01$) but further inhibited CCK18 release (day 5, 0.44±0.06 *vs.* 0.63±0.08 fold of control, $P < 0.01$) from co-cultured hepatocytes. Indirect co-culture showed no significant hepatotrophic effects. HPc-induced potentiative effects were eliminated by ROS antagonisation (albumin, 0.83±0.06 fold of HPc co-culture, $P < 0.01$; CCK18, 1.4±0.2 folds of HPc co-culture, $P < 0.01$). Decreased hepatocyte autocrine TNF-α, increased MSCs autocrine TGF-β1 and enhanced MSCs deposition of extracellular collagen mediated potentiative effect of HPc on MSCs co-culture. Enhanced inhibitive effect of HPc on apoptosis of hepatocytes co-cultured with MSCs resulted from downregulated expression of *CASP9*, *BAX*, *BID* and *BLK* and upregulated expression of *BCL-2*.
Conclusions: HPc potentiated MSCs and improved co-culture hepatotrophic and antiapoptotic effects by nonparacrine, intracellular ROS-dependent mechanisms, including autocrine TGF-β, extracellular collagen and caspases and BAX/BCL-2 signalling pathways.



P1299

PLATELET ALPHA-GRANULE RELEASE IN LIVER REGENERATION AFTER HEPATECTOMY

P. Starlinger[1], S. Haegele[1], D. Wanek[1], S. Zikeli[1], F. Offensperger[1], D. Schauer[1], E. Fleischmann[2], B. Gruenberger[3], C. Brostjan[1], T. Gruenberger[1], A. Assinger[4]. [1]*Surgery,* [2]*Anesthesiology, Medical University of Vienna,* [3]*Internal Medicine, Brothers of Charity Hospital,* [4]*Physiology and Pharmacology, Medical University of Vienna, Vienna, Austria*
E-mail: stefanie.haegele@meduniwien.ac.at

Background and Aims: Platelet activation results in α-granule exocytosis and release of mediators crucial for various (patho) physiological processes like angiogenesis and liver regeneration. As α-granules contain pro- and anti-proliferative factors, it has been speculated, that platelets are capable of selective α-granule release.
Methods: We investigated if this selective release also occurs *in vivo* and correlates with clinical outcome by monitoring 130 patients undergoing partial hepatectomy.
Results: Liver resection resulted in elevated plasma levels of α-granule factors in all patients. Low plasma levels on the first postoperative day of vascular endothelial growth factor (VEGF) and fibrinogen but high thrombospondin-1 (TSP-1), platelet factor-4 (PF4) and transforming growth factor-β (TGF-β) levels predicted liver dysfunction. Furthermore, platelets of patients with liver dysfunction failed to secrete intra platelet VEGF after liver resection. Based on these results, patients within a high risk group (high TSP-1 and low VEGF) suffered from a significantly increased incidence of postoperative liver dysfunction as well as severe morbidity.
Conclusions: This indicates that the postoperative profile of circulating platelet-derived factors correlates with the ability of the remnant liver to regenerate. Accordingly, the modulation of platelet α-granule release in patients may represent an attractive target for therapeutic interventions to modify liver regeneration or angiogenesis.

P1300

SPHEROID RESERVOIR BIOARTIFICIAL LIVER TREATMENT INHIBITS ALPHA-AMANITIN INDUCED FULMINANT HEPATIC FAILURE IN RHESUS MONKEY MODEL

J. Bao[1,2], H. Bu[1,2], S.L. Nyberg[3]. [1]*Laboratory of Pathology,* [2]*Key Laboratory of Transplant Engineering and Immunology, Ministry of Health, West China Hospital, Sichuan University, Chengdu, China;* [3]*Division of Transplantation Surgery, Department of Surgery, Mayo Clinic, Rochester, United States*
E-mail: baoji@scu.edu.cn

Background and Aims: High mortality rate in amanita phalloides intoxications is principally a result of the fulminant hepatic failure (FHF) following massive death of liver cells due to hepatocellular uptake of α-amanitin (α-AMA), the major amatoxin, with limited therapeutic options. Recovery would be more frequent if a supportive therapy were available to correct the toxic milieu of FHF to prevent its extrahepatic manifestations and to assist in liver regeneration. Therefore, a novel supportive therapy, the Spheroid Reservoir Bioartificial Liver (SRBAL) composed of over 100 gram porcine primary hepatocyte aggregates ("spheroids"), was developed. The spheroids were engineered by a novel rocked high-density suspension culture technique. Once formed, spheroids are placed in a continuous perfusion bioreactor, which provides functionality to the device.
Methods: The SRBAL was recently evaluated in an ambulatory primate model of α-AMA and LPS combine-induced FHF. Rhesus monkeys were randomized into three treatment groups: no therapy (n = 3), no cell device therapy (n = 3), and SRBAL therapy (n = 3). SRBAL treatment was 6 hours in duration after toxin administration

12 hours. There was no difference in the level of liver failure between groups prior to the initiation of treatment.
Results: All treatment procedures were completed successfully without any adverse reaction. All samples presented negative PERV DNA and RT activity. The levels of antibodies were similar before and after treatment. A significant survival benefit was observed with SRBAL compared to the two control groups (100% vs. 0% vs. 0% at 60 hours after toxin administration, $p < 0.001$). Animals treated with the SRBAL maintained stable plasma ammonia levels during treatment compared to control animals. Relatively low plasma concentrations of S-100 beta protein, as a marker of astrocytic damage, from monkeys with hepatic failure during SRBAL therapy were noted. SRBAL therapy can prevent irreversible brain damage from hepatic encephalopathy via reduce the ICP peak in FHF. The clinical symptoms such as acratia, anorexia and abdominal distension were improved and recovered at 5 days after SRBAL treatment.
Conclusions: Results of this pivotal preclinical study demonstrate that the SRBAL improved survival in a xenogeneic model of amatoxin and endotoxin induced FHF.

P1301
A NOVEL ROLE FOR KRÜPPEL-LIKE-FACTOR 6 IN HEPATIC REGENERATION AND ACUTE LIVER FAILURE
S. Sydor[1], J. Best[1], P. Manka[1], F.J. Cubero[2], M. Schlattjan[1], T. Schreiter[1], D. Vetter[3], A. Paul[4], S.L. Friedman[5], G. Gerken[1], A. Canbay[1], L.P. Bechmann[1]. *[1]Department of Gastroenterology and Hepatology, University Hospital Essen, Essen, [2]Department of Medicine III (Gastroenterology, Metabolic Diseases and Intensive Care), University Hospital RWTH Aachen, Aachen, Germany; [3]Department of Surgery, University Hospital Zurich, Zurich, Switzerland; [4]Department of General- and Transplant-Surgery, University Hospital Essen, Essen, Germany; [5]Division of Liver Diseases, Mount Sinai School of Medicine, New York, NY, United States*
E-mail: svenja.sydor@uni-due.de

Background and Aims: The zinc finger protein Krüppel-like factor 6 (KLF6) is a multifunctional transcription factor and tumor suppressor. Previous studies identified KLF6 as a mediator of hepatocyte glucose and lipid homeostasis and downregulation of KLF6 was associated with accelerated tumor-growth of hepatocellular cancer. So far, no data is available on the role of KLF6 in regeneration after acute liver injury. Here, we investigated the expression of hepatocyte KLF6 in patients with acute liver failure (ALF), in a human ex-vivo perfusion model of acetaminophen (APAP) induced liver injury and in mice undergoing partial hepatectomy (PHx).
Methods: KLF6 expression was assessed by immunohistochemistry (IHC) in liver samples from patients with drug-induced ALF (n = 10) compared to controls (n = 10). In an established ex-vivo perfusion model non-cirrhotic liver tissue from patients who received partial liver resections for metastatic surgery (n = 6) was treated with APAP for up to 30 hours. KLF6 expression was quantified before and after APAP treatment by qRT-PCR and IHC. In a murine model of hepatocyte specific KLF6 knockout (KO) compared to wildtype (wt) mice we performed PHx (n = 6 mice/group). Utilizing Affymetrix Array (HT-MG430) Genearray and qRT-PCR, we assessed mRNA expression of different targets following PHx. Hepatocyte proliferation after PHx was determined by PCNA and Ki67 staining.
Results: IHC in ALF patients revealed significant upregulation of KLF6 within hepatocytes compared to controls. APAP perfusion of liver tissue significantly induced KLF6 mRNA- and protein-expression. In mice PHx led to significant induction of KLF6 expression at different timepoints. In hepatocyte specific KLF6-KO mice cell proliferation was significantly induced at early timepoints following PHx. The mRNA expression of autophagy-related molecules atg7 and beclin1 was significantly reduced in KLF6-KO before and after PHx compared to wt-animals.
Conclusions: Our findings suggest an important role for KLF6 in liver regeneration, as KLF6 expression is upregulated in different models of acute liver injury and ALF patients. Hepatocyte proliferation following PHx was induced in KLF6-KO, suggesting a role for KLF6 in hepatic regeneration. Reduced atg5 and beclin1 expression suggests a novel link between KLF6 and autophagy.

P1302
EVIDENCE FOR THE ICG-CLEARANCE-TEST AS A RELEVANT PREDICTOR OF POST HEPATECTOMY LIVER FAILURE
S. Haegele[1], F. Offensperger[1], E. Lahner[1], A. Assinger[2], E. Fleischmann[3], B. Gruenberger[4], T. Gruenberger[1,5], C. Brostjan[1], P. Starlinger[1]. *[1]Surgery, [2]Physiology and Pharmacology, [3]Anesthesiology, Medical University of Vienna, [4]Internal Medicine, Brothers of Charity Hospital, [5]Surgery I, Rudolf Foundation Clinic, Vienna, Austria*
E-mail: stefanie.haegele@meduniwien.ac.at

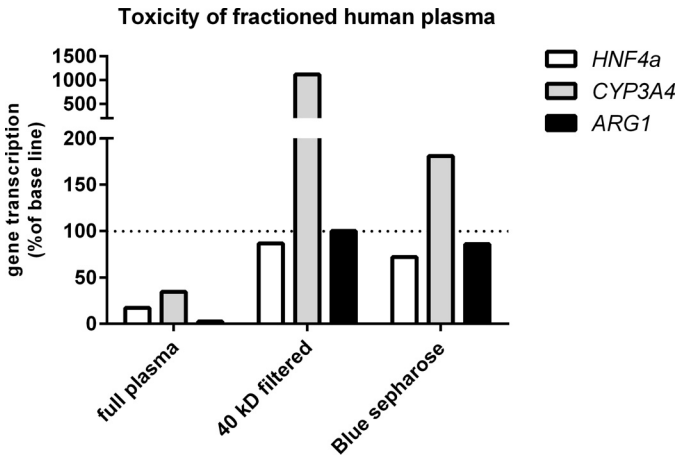
Background and Aims: Liver resection has gained importance in the treatment of liver tumors. In this context, the most significant factor determining postoperative outcome of these patients is the ability of the remnant liver to regenerate. To pursue liver function in an adequate manner, sufficient and clinically viable tests are required. Given the controversially discussed data about the dynamic liver function tests, no consensus about the quantity of the ICG-Test has yet formed. Accordingly, we investigated if the ICG-Clearance test eligible determines post hepatectomy liver failure and clinical outcome.
Methods: Therefore, 130 patients undergoing liver resection surgery were included in this study and ICG-values were recorded one day prior to surgery, as well as on the first and fifth postoperative day. Serum markers of liver function were used to evaluate liver regeneration (LR) and liver dysfunction (LD).
Results: Plasma diffusion rate (PDR), as well as the retention rate after 15 minutes (R15), significantly deteriorated after liver resection ($p < 0.05$) and remained worsened up to the fifth postoperative day. Accordingly, preoperative reduced ICG-levels were able to predict postoperative liver dysfunction (LD) in a sufficient way (AUC [area under the curve] = PDR: 0.72, R15: 0.73; $p \geq 0.05$). Furthermore, we validated that a PDR of <17% and

a R15 of <8% were associated with an increased incidence of postoperative LD (specificity: 82%, sensitivity: 50.5%) and were able to identify high-risk patients prior to surgery.
Conclusions: These findings indicate that the ICG-Clearance Test is a valuable tool for the prediction of LD and poor clinical outcome after liver resection. Additionally, PDR and R15 may represent useful parameters to identify high-risk patients prior to surgery that require consideration and close monitoring for potential complications.

P1303
HUMAN PLASMA TOXICITY IN DIFFERENTIATED HepaRG PROGENITOR CELLS IN THE CONTEXT OF THE BIOARTIFICIAL LIVER

M. Van Wenum[1,2], R.A.F.M. Chamuleau[2], E.J. Hendriks[1], T.M. van Gulik[1], R. Hoekstra[1,2]. [1]*Surgical laboratory,* [2]*Tytgat Institute for Liver and Intestinal Research, Academic Medical Center of the University of Amsterdam, Amsterdam, Netherlands*
E-mail: m.vanwenum@amc.uva.nl

Background and Aims: The AMC-Bioartificial Liver (BAL) is based on the human liver progenitor cell line HepaRG, cultured in 3D under 40% O_2, and is intended to treat patients suffering from Acute Liver Failure. During therapy, cells are in contact with the patients plasma. We previously found that plasma of both healthy and ischaemic-liver rats reduced hepatic transcript levels and hepatic functionality. However, no data on human plasma are available.
We aimed to assess human plasma toxicity on HepaRG cells in monolayer and in the AMC-BAL and to identify the underlying mechanism.
Methods: Cells were cultured in lab scale BALs, culture plates (2D in 20 and 40% O2) and non-woven polyester matrices (3D in 20% O_2). Cultures were exposed to pooled full human plasma from healthy donors or to standard culture medium for 16 hours unless stated otherwise. Transcript levels of hepatic genes Cyp3A4, HNF4A and ARG1 were analysed by qRT-PCR. This panel of genes was previously found to reflect detrimental plasma effects in a consistent and sensitive way. Ammonia elimination and urea production were quantified by biochemical assays as a measure of hepatic functionality. Plasma fractionation was performed with commercial molecular weight-exclusion filters, Bligh & Dyer (B&D) lipid extraction and Blue Sepharose affinity chromatography.



Results: Human plasma had a dose-dependent toxic effect on HepaRG cells. In monolayers we observed an 80% reduction of hepatic gene transcription within 8 hours of plasma exposure. Hepatic functions decreased within 16 hours. The toxic effect was ameliorated when plasma was passed through filters >40 kDa, or run over Blue Sepharose. After B&D extraction, the hydrophobic phase had a toxic effect similar to full plasma.
In BALs, the 16 h plasma exposure effects on transcript levels were less pronounced and functions were unaffected. Cells were also less affected by plasma when cultured under 3D conditions; increased oxygenation had no significant effect.
Conclusions: Plasma toxicity is due to one or more toxic components. The causative agent(s) is/are likely hydrophobic and protein bound, or, if not protein bound, the agent(s) is/are sized >40 kDa.
HepaRG cells are partly protected from toxicity when cultured in the AMC-BAL, 3D configuration contributes to this effect but is not the single explanatory factor. Practically, these findings suggest that it may be beneficial to combine BAL support with artificial liver support, such as albumin dialysis, to maintain high hepatic functionality during therapy.

P1304
PREDICTION OF INTRACRANIAL HYPERTENSION IN PATIENTS WITH ACUTE LIVER FAILURE

P. Nissen Bjerring[1], F.S. Larsen[2]. [1]*Gastro Unit, Medical Section, Hvidovre Hospital, Hvidovre,* [2]*Department of Hepatology, Rigshospitalet, Copenhagen, Denmark*
E-mail: peterbjerring@gmail.com

Background and Aims: Acute liver failure (ALF) is a life threatening condition that in combination with persistent hyperammonaemia carries a high risk of intracranial hypertension (ICH). The pathophysiology involved is believed to be brain oedema and hyperaemia due to cerebral metabolic disturbances. In this study we aimed to construct a predictive model identifying patients who develop ICH from a set of clinically available baseline variables in a cohort of patients from our liver intensive care unit.
Methods: 45 patients with ALF and persistent hyperammonaemia *or* clinical signs of ICH were included. Cerebral microdialysis and continuous measurement of intracranial pressure (ICP) was performed. Baseline values of ICP, arterial lactate and ammonia were registered. The concentration of lactate, pyruvate and glutamine was measured in the microdialysate. The need for renal replacement therapy (RRT) and vasopressors at inclusion was registered. ICH was defined as ICP >20 mmHg for more than one hour. As predictive functions, we used logistic regression and support vector machines and evaluated the prediction error rate of ICH/non-ICH with five-fold cross validation.
Results: 21 patients (47%) developed ICH 39 (0–108) hours [median (range)] after inclusion and was the cause of death in ten of those patients. The baseline arterial ammonia was 186 (60–340) μM, the cerebral lactate to pyruvate ratio 29 (9.1–173) and glutamine 3.2 (0.2–7.3) mM. Only glutamine was significantly different between subjects with and without ICH (3.7 vs. 2.7 mM, respectively, $p < 0.05$). A support vector machine model based on baseline ICP and microdialysate analysis gave the lowest prediction error rate (30%).
Conclusions: ICH is a frequent complication in this subgroup of ALF patients and is associated with elevated extracellular glutamine in the brain as previously reported. The median lactate to pyruvate ratio was close to normal levels. Our predictive model based on neuroinvasive observations at baseline allowed us classify patients as ICH/non-ICH correctly in 70% of the cases.

P1305
MITOCHONDRIAL FUNCTION IS PRESERVED IN CEREBRAL CORTEX IN A RAT MODEL OF ACUTE HYPERAMMONAEMIA AND SYSTEMIC INFLAMMATION

P. Nissen Bjerring[1], A.M. Witt[2], F.S. Larsen[2]. [1]*Gastro Unit, Medical Section, Hvidovre Hospital, Hvidovre,* [2]*Department of Hepatology, Rigshospitalet, Copenhagen, Denmark*
E-mail: peterbjerring@gmail.com

Background and Aims: In acute liver failure (ALF) cerebral oedema and high intracranial pressure (ICP) are potentially

deadly complications. Astrocytes cultured in ammonia have shown mitochondrial dysfunction and in rat models of liver failure lactate production in the brain has been observed. These findings support the hypothesis of a compromised brain metabolism during ALF. In contrast, normal lactate levels are found in cerebral microdialysate of ALF patients and the oxygen to glucose ratio of cerebral metabolic rates remains normal. To investigate this inconsistency we studied the mitochondrial function in brain tissue with respirometry in an animal model of acute hyperammonaemia and systemic inflammation as well as in a dose-response study.

Methods: Wistar rats were given ammonia+lipopolysaccharide (LPS) or saline+saline. Ammonia or saline was infused for 120 minutes before the animals were sacrificed. Cerebral cortex was analysed with respirometry (Oroboros Instruments). Cortex homogenate was studied in a chamber measuring the oxygen consumption rate. Substrates of the citric acid cycle, uncouplers and inhibitors of the mitochondrial complexes were successively added to the chamber to investigate the mitochondrial function in detail. In a separate dose-response experiment cortex from healthy rats was incubated for 120 minutes in sodium or ammonium acetate in concentrations up to 80 mM prior to respirometry.

Results: Infusion of ammonia resulted in hyperammonaemia (1550±147 μM vs. control 48±5 μM, $p < 0.01$). This was associated with an elevated ICP (6.8±2.1 mmHg vs. control 2.0±0.4 mmHg, $p < 0.05$) and tissue lactate concentration (23±5 mM vs. 16±0.4 mM, $p < 0.05$). No differencesbetween the groups was found in the total respiratory capacity or the function of the individual mitochondrial complexes. We did not observe increased proton leak across the inner mitochondrial membrane. Ammonia in concentrations of 40 and 80 mM reduced the respiratory capacity but not compared to corresponding sodium acetate controls. We found a linear relationship between the inner membrane proton leak and the ammonia/sodium acetate concentration.

Conclusions: Hyperammonaemia and systemic inflammation lead to increased ICP and cerebral lactate accumulation. We found no indications of impaired oxidative metabolism. In the dose-response study, extreme concentrations of ammonia lead to reduced oxidative capacity which however also was found after exposure to sodium acetate suggesting an effect of osmolality rather than ammonia itself.

P1306
SYPHILITIC HEPATITIS IN HUMAN IMMUNODEFICIENCY VIRUS (HIV)-INFECTED PATIENTS

L. Rabinowich[1], E. Katchman[2], L. Mlynarsky[1], O. Shibolet[1], D. Turner[2]. *[1]Liver Unit, Department of Gastroenterology, [2]Krusaid Cobler AIDS Center, Infectious Diseases Unit, Tel-Aviv Sourasky Medical Center, Tel Aviv, Israel*
E-mail: liane.rabinowich@gmail.com

Background and Aims: Hepatitis secondary to *Treponema pallidum* infection was reported as an uncommon presentation of early syphilis. Resurgence of syphilis has been observed among men having sex with men (MSM) infected with HIV. Data regarding the prevalence and pattern of syphilitic hepatitis among HIV-infected patients is limited.

Methods: Retrospective analysis of epidemiological, clinical and laboratory data of HIV-infected patients diagnosed with early syphilis in the TASMC from January 2000 to March 2014.

Results: 125 cases of primary or secondary syphilis were diagnosed in 116 HIV-infected patients. All the subjects were male with a median age of 37 years. 96% were MSM. Syphilis and HIV were diagnosed simultaneously in 21.6%, and 52% were receiving ART at the time of diagnosis. Liver involvement was observed in 59 cases (47.2%). Comparing patients with syphilis to those with syphilitic hepatitis there was no difference regarding mean age, risk factors, duration of HIV prior to syphilis diagnosis, ART treatment or HIV viral load. A significant decrease was observed in mean CD4 and CD8 cell count in the syphilitic hepatitis group (for CD4: 610.9±248.7 cells/mm^3 vs. 471.3±195.9 cells/mm^3, $p = 0.001$; for CD8: 1112.8±537.8 cells/mm^3 vs. 874.8±442.9 cells/mm^3, $p = 0.01$) as well as a tendency towordes higher VDRL titers ($p = 0.06$). The pattern of liver enzymes elevation was mixed in 51% of cases, predominantly cholestatic in 37%, and predominantly hepatocellular in 13%. Elevation of cholestatic enzymes was mild (<2.5 times of ULN) in 47.5%, however 15.3% of the cases presented with a marked increase (10 x ULN). Most patients had either no or only mild elevation of hepatocellular enzymes (37.3% and 32.2% of the cases respectively). However 11.9%, presented with at least moderate hepatocellular enzyme elevation (>5 times of ULN). Symptomatic and biochemical resolution of the hepatitis ensued following antibiotic therapy in all patients.

Conclusions: Hepatitis is common in HIV infected patients with syphilis and may be the presenting sign of *Treponema pallidum* infection. Liver impairment was predominantly cholestatic, but transaminases elevations were not uncommon. Syphilis must be considered in the diagnosis of HIV patients presenting with hepatitis.

E-mail: michael.mc.maes@vub.ac.be

Background and Aims: Pannexins (Panx) constitute a relatively new family of transmembrane proteins that form channels linking the cytoplasmic compartment with the extracellular environment. The pannexin family consists of 3 members of which Panx1 is expressed in the liver. It is well-known that Panx1 plays a key role in innate immunity by facilitating activation of the inflammasome. Recently, Panx1-mediated inflammation was found to be involved in non-alcoholic steatohepatitis in mouse. In the present study, it is investigated whether this also holds true for acute liver failure *in casu* triggered by acetaminophen.

Methods: Mice were overdosed with acetaminophen followed by treatment with the Panx1 channel inhibitor ^{10}Panx1 after 1.5 hours. Sampling was performed 24 hours after acetaminophen administration. Evaluation of the effect of Panx1 channel inhibition was based on a number of clinically relevant read-outs, including assessment of alanine and aspartate aminotransferase serum levels as well as histopathological examination of liver tissue with quantification of cell death. Inflammation was studied by measurement of cytokine levels in liver and serum.

Results: All parameters measured indicate a significant reduction of liver damage, including cell death and inflammation, upon treatment of acetaminophen-intoxicated mice with ^{10}Panx1.

Conclusions: The results of this study demonstrate the clinical potential of Panx1 channel inhibition as a therapeutic strategy in the treatment of acetaminophen-induced acute liver failure.

ROTATIONAL THROMBOELASTOMETRY CAN AVOID UNNECESSARY SUBSTITUTION OF COAGULATION FACTORS IN ACUTE AND CHRONIC LIVER DISEASES

S. Bedreli[1], J.-P. Sowa[1], S. Blomeyer[1], G. Gerken[1], F.H. Saner[2], A. Canbay[1]. [1]*Department of Gastroenterology and Hepatology,* [2]*Department of General, Visceral and Transplantation Surgery, University Hospital, University Duisburg-Essen, Essen, Germany*
E-mail: ali.canbay@uni-due.de

Background and Aims: Acute liver failure (ALF) and liver cirrhosis (LC) are associated with complex hemostatic disorders. Conventional tests for blood clotting (International Normalized Ratio, INR; partial thromboplastin time, PTT; number of thrombocytes; fibrinogen) would suggest increased bleeding tendency. Though, many patients exhibit increasing incidence of thrombosis with liver disease progression. We aimed to elucidate, if rotational thromboelastometry (ROTEM®) can reduce substitution of coagulation factors to patients with ALF or LC prior intervention.
Methods: Patients with ALF with (n = 10) or without ROTEM® (n = 9) and patients with LC with (n = 25) or without ROTEM® (n = 16) analysis prior an intervention were analysed retrospectively. All recruited patients exhibited compromised coagulation according to conventional coagulation tests. Substitution of coagulation factors was assessed and for patients not receiving substitution, theoretical substitution according to conventional standards was calculated.
Results: Both groups of ALF patients (with and without ROTEM®) had impaired coagulation according to conventional parameters. Quick, INR, PTT, platelet count, and fibrinogen concentration did not differ between the groups. 4 patients without ROTEM® measurement received 2000 IU PCC (prothrombin complex concentrate) and 1 patient received 6000 IU PPC. In patients with ROTEM® analysis no substitution of coagulation factors was performed, as this was not indicated. Based on conventional coagulation parameters, these patients would have received a mean amount of 1150 IU PPC, corresponding to approx. 9200€. All LC patients exhibited impaired coagulation and both groups had roughly equal coagulation parameters. Patients in the group without ROTEM® received a total of 20500 IU PCC, 12U fresh frozen plasma (FFP) and 1g fibrinogen. In contrast patients with ROTEM® were given 8500 IU PCC, no FFP, and 18g fibrinogen. Based on conventional parameters only these patients would have received 37000 IU PCC and only 8.5g fibrinogen. In total the reduction of substitution would amount to approx. 20,600 €. In none of the patient groups adverse events or complications were observed.
Conclusions: By ROTEM® analysis hemostasis can be evaluated in more detail for ALF and in patients with chronic liver diseases. Substitution of coagulation factors can be significantly reduced without increasing the risk for the patients.

CD34 PATTERNS IN BONE MARROW INDICATE THE STATUS OF FUNCTIONAL RESERVE OF BONE MARROW IN CIRRHOSIS

C. Bihari[1], A. Rastogi[1], P. Saxena[2], M. Hasan[3], N. Trehanpati[3], L. Anand[4], A. Kumar[3], S.K. Sarin[4]. [1]*Pathology,* [2]*Hematolgy,* [3]*Research,* [4]*Hepatology, Institute of Liver and Biliary Sciences, Delhi, Delhi, India*
E-mail: drcbsharma@gmail.com

Background and Aims: Cirrhosis can cause various systemic manifestations. Bone marrow microenvironment alterations in the cirrhosis are not clearly known. Present study was aimed to assess the bone marrow profile in cirrhosis cases.
Methods: Bone marrow (BM) biopsies and aspirate of cirrhosis cases were analyzed. Bone marrows were performed to evaluate cytopenias and pyrexia of unknown origin. These were assessed for cellularity, myeloid: erythroid ratio, myelogram, iron and reticulin. Hematological, clinical parameters and liver severity indices were correlated. Immunohistochemical staining for CD34, Thy-1, S-100, beta catenin, notch-1 and p53 were done for the assessment of in bone marrow cellular microenvironment. Two pathologists independently evaluated the sections. Positive stained cells were counted minimum in five high power fields and average was calculated.
Results: A total of 96 cases of bone marrows were studied. Mean age was 49±11.8 years and male:female ratio was 2:1. On examination of BM biopsy sections two patterns of CD34 staining were noted: (1) Cellular CD34 (*cCD34*: cells >10/20×, with occasional vessels <2 capillaries/20×); in 43 and (2) Vascular CD34 (*vCD34*: vessels >10/20× with <5/20× cells positivity); in 53 cases. Mean age in both groups were comparable (p = 0.146). Hemoglobin (p < 0.001), platelet counts (p = 0.004) and total albumin (p = 0.001) were significantly lower in the *vCD34* group than in the *cCD34* group. Spleen size was comparable in both groups (p = 0.961). Modified end stage liver disease score [MELD] (p < 0.001), total bilirubin (p < 0.001), international normalized ratio [INR] (p = 0.001), myeloid:lymphoid ratio (p = 0.05) and TNF-α (p = 0.013) were significantly higher in the *vCD34* group. In the *vCD34* group 27/53 showed reticulin lying down, whereas in the *cCD34* group only 5/43 had reticulinization of the marrow. Immunohistochemical staining showed Thy-1 positive hematopoietic stem cells were more evident in *cCD34* (21.4±4.1) than in *vCD34* (3.8±1.6) (p < 0.001). Similarly S-100 positive Schwann cells were much higher in *cCD34* (15.2±5) as compared to *vCD34* (4.7±1.8) (p = 0.03). Results are summarized in Table 1.
Conclusions: Bone marrow in cirrhosis has two distinct patterns. *cCD34* pattern in bone marrow indicates adequate reserve for hematopoietic activity and seen with favorable liver functions. *vCD34* points towards the depletion of the bone marrow reserves. Elevated myeloid:lymphoid ratio and increased reticulin in the *vCD34* group denote ageing of BM.

Table 1. Comparison of parameters in Cellular CD34 (*cCD34*) and Vascular CD34 (*vCD34*) groups

Parameter	Cellular CD34 (n = 43)	Vascular CD34 (n = 53)	P value
Age (years)*	48±12.5	50.5±11.2	0.176
Male:Female	1.8:1	2.1:1	0.328
Spleen size (cm)*	14.2±2.7	14.8±3.7	0.961
Hemoglobin*	9.9±2	8.4±1.9	0.001
Total leukocyte count $\times 10^3$/cu.mm**	4 (3–7)	5 (3.5–9)	0.148
Platelet count $\times 10^3$/cu.mm**	89 (59–180)	64 (42–90)	0.004
Myeloid:Erythroid ratio*	1.2±0.7	1.2±0.8	0.981
Cellularity (%)*	53.1±11.3	48.2±14.1	0.084
Bone marrow fibrosis; reticulin positive (%)	11.6 (5/43)	51 (27/53)	0.01
Bilirubin (mg/dl)**	1 (1–3)	4 (3–5.7)	<0.001
Creatinine (mg/dl)	1.2±0.8	1.5±0.7	0.310
Albumin (g/dl)	3±0.7	2.4±0.6	0.001
International Normalized Ratio**	1 (1–2)	2 (1–2)	0.001
Modified End stage Liver Disease score*	13.8±6.7	21.1±8.2	<0.001

SODIUM BENZOATE AND RIFAXIMIN ARE ABLE TO RESTORE BLOOD–BRAIN BARRIER INTEGRITY IN CIRRHOTIC RATS WITH HEPATIC ENCEPHALOPATHY

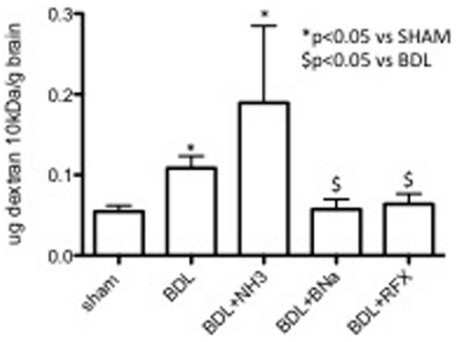
S. Mouri[1], H. El Mourabit[1], C. Rey[1], R. Morichon[2], D. Wendum[3], E. Lasnier[3], C. Housset[1], N. Weiss[1], D. Thabut[4], on behalf of BLIPS: Brain–Liver Pitié-Salpêtrière Study Group. *[1]Sorbonne Universités, UPMC Univ Paris 06, CDR Saint-Antoine & Institute of Cardiometabolism and Nutrition (ICAN), INSERM, UMR_S 938, [2]Institut Fédératif de Recherche en Santé, Saint-Antoine IFR-65, [3]APHP, UPMC, hôpital St Antoine, [4]Sorbonne Universités, UPMC Univ Paris 06, CDR Saint-Antoine & Institute of Cardiometabolism and Nutrition (ICAN), INSERM, UMR_S 938 and APHP, Groupement Hospitalier Pitié-Salpêtrière-Charles Foix, Paris, France*
E-mail: dominique.thabut@psl.aphp.fr

Background and Aims: Hepatic encephalopathy (HE) is a severe complication of cirrhosis which independently influences prognosis. We previously showed an increase in blood–brain barrier (BBB) permeability in cirrhotic rats with HE. The aim of the present work was to assess the effects of sodium benzoate (Bna), a drug removing ammonia through non-urea cycle pathway, and Rifaximin (RFX), a non adsorbable antibiotic, on BBB permeability in cirrhotic rats with HE.

Methods: Three groups of rats were considered: SHAM, Bile Duct Ligation (BDL), BDL + hyperammonic dietary (BDL-NH3). In each group, rats were treated by BNa or RFX. HE was assessed using neurocomportemental testing (6 minutes tail suspension test assessing the time of immobility). NH3 levels were assessed before sacrifice. BBB permeability was assessed by IV injection of a fluorochrome (Texas Red 10kDa) before transcardial washing. Brain fluorescence was estimated by fluorimetry after right hemisphere squeezing.

Results: Mean time of immobility was longer in BDL-NH3 and BDL rats than in SHAM ($p = 0.0004$). Ammonemia was significantly higher in the BDL-NH3 than in BDL rats, and higher in the BDL than in SHAM rats ($p < 0.0001$). Intra-cerebral fluorescence was significantly higher in BDL-NH3 than in BDL group, and higher in BDL than in SHAM group ($p = 0.029$) confirming the passage of the fluorochrome through the BBB. BNa treatment significantly decreased ammonemia levels and intra-cerebral fluorescence in the BDL and BDL-NH3 rats ($p < 0.04$ for all) but did not modify the mean time of immobility. On the contrary, RFX treatment did not modify ammonemia levels but significantly decreased intra-cerebral fluorescence ($p < 0.05$) and the mean time of immobility ($p = 0.0004$) (see Figure).

Conclusions: In cirrhotic rats displaying HE, BBB permeability is increased, through different mechanisms dependent and independent of hyperammonemia. BNa and RFX are effective in restoring BBB integrity in HE cirrhotic rats but only RFX is able to decrease HE in this model



P0084

OXIDATIVE STRESS REDUCTION BY NANOPARTICLES OF CERIUM OXIDE (CeO_2NPS) PARTIALLY REVERTS THE ACTIVATION OF PORTAL ENDOTHELIAL CELLS FROM CIRRHOTIC RATS

J. Rodríguez Vita[1,2,3], J. Ribera[1,2,3], G. Casals[1,2,3], D. Oró[2,3,4], S. Marfà[1,2,3], B. Morales[1,2,3], T. Yudina[5], V. Puntes[5], W. Jiménez[1,2,3,6], M. Morales-Ruiz[1,2,3]. *[1]Deparment of Biochemistry and Molecular Genetics, Hospital Clinic of Barcelona, [2]CIBERehd, [3]IDIBAPS, [4]Deparment of Biochemistry and Molecular Genetics, Hospital Clinic de Barcelona, [5]Catalan Institute of Nanotechnology, [6]Departament of Physiological Sciences I, University of Barcelona, Barcelona, Spain*
E-mail: rodriguez@clinic.ub.es

Background and Aims: Hepatic and splanchnic endothelial cells undergoes phenotypic transformation process during the progression of liver fibrosis. However, it is unknown whether this endothelial dysfunction occurs in other vascular areas such as the portal vein. The aim of this study was, therefore, to characterize the degree of activation of endothelial cell lines isolated from the portal vein of control (PVEC-CT) and cirrhotic (PVEC-CH) rats and evaluate new strategies to block the activation of PVECs.

Methods: Cirrhosis was induced in male Wistar rats by inhalation of CCl_4. The PVECs were isolated from the portal vein using anti-CD31 antibodies. The phenotypic differences between PVEC-CT and PVEC-CH were evaluated by RT-PCR. CeO_2NPs were synthesized by precipitation of cerium salt and tetramethylammonium hydroxide.

Results: Primary cultures of PVEC-CT and PVEC-CH (purity >95%, two clones per condition) were immortalized by retroviral transduction of the SV40 virus T antigen. The PVEC-CH showed an overexpression of collagen-I, endothelin-1, TIMP1, TIMP2, IL-6 and PLGF ($n = 10$), compared with PVEC-CT. The same panel of genes was overexpressed in isolated portal veins of CH rats ($P < 0.01$, $n = 10$ per condition). In order to find common causes for this phenotypic alteration, we studied the degree of oxidative stress present in these cell lines. The PVEC-CH showed a significant increase of oxidative stress (dichlorofluorescein, $n = 10$) compared with PVEC-CT. Several pre-clinical studies have demonstrated the antioxidant properties of CeO_2NPs. Consistent with these studies, the treatment of PVEC-CH with 1 μg/mL CeO_2NPs for 24 hours significantly reduced the levels of oxidative stress and the expression of TIMP2 and IL-6 genes ($n = 10$). In addition, we studied the therapeutic potential of CeO_2NPs in vivo. Cirrhotic rats were treated i.v. with vehicle ($n = 5$) or 0.1 mg/kg CeO_2NPs ($n = 5$) twice a week for 2 weeks. The portal veins of CH rats treated with CeO_2NPs showed a significant decrease of IL-6, compared to the vehicle treatment.

Conclusions: We generated immortalized cell lines of PVECs from CT and CH rats that maintain their phenotypic differences. Intracellular oxidative stress reduction, mediated by CeO_2NPs treatment, partially reverted the pathological phenotype of PVECs from cirrhotic rats *in vivo* and *in vitro*.

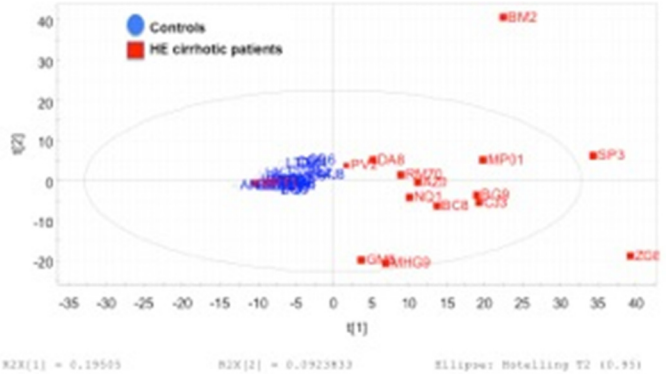
These results may open new perspectives for the applicability of nanomedicine in the treatment of endothelial dysfunction.

P0085

HEPATIC ENCEPHALOPATHY: CEREBROSPINAL FLUID METABOLOMICS HIGHLIGHTS ALTERATION OF MULTIPLE METABOLIC PATHWAYS REPRESENTING NEW POTENTIAL THERAPEUTIC TARGETS

N. Weiss[1], F. Isnard[2], S. Attala[2], B. Colsch[2], M. del Mar Amador[3], F. Lamari[3], M. Rudler[4], F. Sedel[5], C. Junot[2], D. Thabut[4], on behalf of BLIPS: Brain–Liver Pitié-Salpêtrière Study Group. *[1]Neurological ICU, APHP, UPMC, IHU-A, Groupement Hospitalier Pitié-Salpêtrière-Charles Foix, Paris, [2]Service de Pharmacologie et d'Immunoanalyse, Laboratoire d'Etude du Métabolisme des Médicaments, MetaboHUB-Paris, CEA, iBiTec-S, Gif sur Yvette, [3]Metabolic biochemistry, Assistance Publique – Hôpitaux de Paris, UPMC, [4]Hepatology ICU, APHP, UPMC, Groupement Hospitalier Pitié-Salpêtrière-Charles Foix, [5]Neurology, APHP, UPMC, IHU-A, Groupement Hospitalier Pitié-Salpêtrière-Charles Foix, Paris, France*
E-mail: dominique.thabut@psl.aphp.fr

Background and Aims: Hepatic encephalopathy (HE) is a neurological complication of cirrhosis, impairing survival and quality of life. Its incidence is growing because of the improved prognosis of other complications of cirrhosis, and of the widespread use of TIPS. However, besides hyperammonemia which is often pointed out as a cause of HE, the pathophysiological mechanisms of HE remains poorly understood, which prevents the development of therapeutic strategies. To address this issue, metabolomics was used to identify dysfunction of metabolic pathways in cerebrospinal fluid (CSF) samples of cirrhotic patients suffering from HE. The aim of this study was to detect new therapeutic targets for HE associated with cirrhosis.
Methods: Cerebrospinal Fluid (CSF) samples were collected on 14 cirrhotic patients admitted in ICU for HE, in whom infection of central nervous system has to be ruled out, and were compared to CSF of 27 control patients without any proven neurological disease. Metabolomic analysis was performed using 3 liquid chromatographies coupled to high resolution mass spectrometry methods (LC-HRMS). Informatic data processing tools were used.
Results: LC-HRMS methods led to the characterization of 150 metabolites in CSF samples of HE patients, which were mainly aminoacids and organic acids. Interestingly, according to human metabolome database, 40% of those metabolites were not reported as present in CSF before. HE patients could be easily discriminated from controls on the basis of metabolomic information (Figure). Concentrations of 102 metabolites were found to be significantly altered in HE patients: metabolotypes displayed alterations in several major metabolite classes such as ammoniac, bile acids, but also amino-acids, acylcarnitines, and nucleosides. Accumulations of acetylated compounds, which could be due to a defect of the Krebs cycle, were reported for the first time in HE patients, and could constitute interesting therapeutic targets.



Conclusions: By enabling the simultaneous monitoring of a large set of metabolites in cirrhotic patients with HE, CSF metabolomics highlighted several altered metabolite pathways linked to ammonia metabolism, neurotransmission and energy metabolism. The pharmacological relevance of our findings has to be explored on animal models, as they could constitute interesting new therapeutic targets.

P0086

HYPERAMMONEMIA ALTERS AQP4 AND MIR-196A EXPRESSION IN PRIMARY ASTROCYTES: IMPLICATIONS FOR BRAIN EDEMA

C. Pérez-Monter[1], A. Estanes-Hernández[1], A. Torre-Delgadillo[1].
[1]Gastroenterology, INCMNSZ, Mexico City, Mexico
E-mail: carlos.perezm@incmnsz.mx

Background and Aims: A key feature accounting for hepatic encephalopathy (HE) symptoms is brain oedema. During HE, NH_4^+ significantly increases in the general circulation leading to a higher astrocyte glutamine synthesis, increasing the intracellular osmotic pressure. To counteract it, astrocytes promote water inwards movement through aquaporin channels (AQPs). In mammals, AQP expression is regulated at the transcriptional and post-transcriptional level by different signals, including ammonia and small nucleic acids. Here, we aim to characterize the role of miR-196a in AQP4 gene expression control during hiperammonemic conditions.
Methods: Astrocyte culture was prepared from post-natal CD1 pup mice using trypsin. Cells were grown in DMEM supplemented with FBS (10%) at 37°C under 5% CO_2 atmosphere, and were exposed to 5 or 10 mM NH_4Cl solution. RNA was extracted to synthetize cDNA to be used in qPCR for AQP4, GFAP, and other transcripts involved in the cellular volume response. Cytotoxic effects of NH4Cl were determined using the MTT assay. Cell volume was determined using Calcein-AM (4μM). The cell monolayer was optically sectioned along the vertical axis using confocal microscopy and the Zen-lite software. Images were using the 3-D counter tool of the Fiji version ofImageJ software v1.48. Volume is expressed as the mean volume in μm^3.
Results: To determine the viability of NH_4Cl treated cells, MTT assays were performed. Treatment of astrocytes with NH_4Cl does not modify viability (96±3.5% *vs* control cells). In accordance, NH_4Cl significantly increases the expression of AQP4 (1.4±0.1 fold change *vs* control) at 12 hr of treatment, while that of GFAP was increased just after 24 hr of treatment (1.8±0.3 fold change *vs* control), as determined by qPCR and Western blot assays. Moreover, when AQP5 and APQ9 transcripts were analysed, a significant increased was also observed. Cell volume status indicates that astrocytes incubated with NH_4Cl, increase its volume in a significant manner (301963±30056 μm3 *vs* control cells). We measured the miR-196a expression and found that miR-196a is strongly down-regulated in response to the NH_4Cl treatment, thus suggesting that might be of relevance for AQP4 gene expression modulation.
Conclusions: NH_4Cl treatment increases the expression of AQP4 and GFAP, in a dose-dependent manner. This increase is accompanied by a reduction in the miR-196a expression, strongly suggesting that this miRNA is involved in the control of cellular volume response.

P0087
LOW SERUM C24 CERAMIDE IS PREDICTIVE OF HEPATIC DECOMPENSATION AND POOR OVERALL SURVIVAL IN LIVER CIRRHOSIS

G. Grammatikos[1], N. Ferreiros[2], O. Waidmann[1], D. Bon[3], S. Schroeter[1], A. Koch[4], E. Herrmann[5], S. Zeuzem[1], B. Kronenberger[1], J. Pfeilschifter[4]. *[1]Medizinische Klinik 1, [2]Pharmazentrum Frankfurt, Institut für klinische Pharmakologie, [3], Institute of Biostatistics and Mathematical Modelling, [4]Pharmazentrum Frankfurt, Institut für Allgemeine Pharmakologie und Toxikologie, [5]Institute of Biostatistics and Mathematical Modelling, Johann Wolfgang Goethe University Frankfurt, Frankfurt am Main, Germany*
E-mail: georgios.grammatikos@kgu.de

Background and Aims: Very long chain ceramides constitute bioactive molecules with functional implications in liver homeostasis. Particularly, ablation of very long chain ceramides in a ceramide synthase 2 knockout mouse model has been shown to cause a severe hepatopathy.
Methods: We assessed via mass spectrometry serum concentrations of sphingolipid metabolites in a series of 244 patients with liver cirrhosis prospectively followed for a median period of 228±217 days.

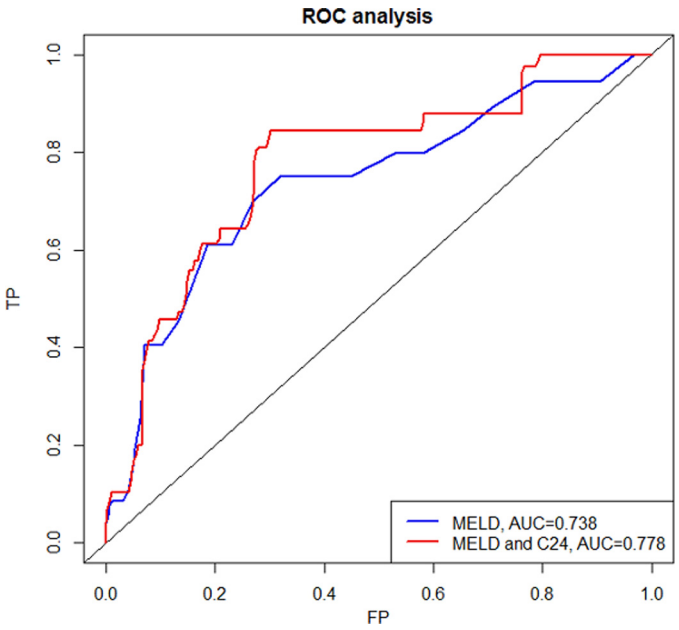


Figure 1.

Results: We observed a significant decrease of long and very long chain ceramides, particularly of C24ceramide, in patients with increasing severity of liver cirrhosis ($p < 0.001$). Additionally, hydropic decompensation, defined by clinical presentation of ascites formation, was significantly correlated to low C24ceramide levels ($p < 0.001$) while a significant association to hepatic decompensation and poor overall survival was observed for low serum concentrations of C24ceramide ($p < 0.001$) as well. Multivariable Cox regression in patients with decompensated liver cirrhosis further identified low serum C24ceramide as an independent predictor of overall survival [hazard ratio (HR) = 0.411, confidence interval (CI) 0.144–1.171, $p = 0.096$]. A novel updated prediction score combining Model of end stage liver disease (MELD) and C24ceramide showed a higher area under the curve (AUC) value as compared to the MELD score alone (0.778 versus 0.738, $p < 0.001$) in a time-dependent receiver operating characteristic (ROC) analysis regarding overall survival in these patients (Figure 1).
Conclusions: Serum levels of long and very long chain ceramides show a significant correlation to disease severity and hepatic decompensation and are independently associated with overall survival in a prospective series of patients with liver cirrhosis. Particularly C24ceramide may be considered as a novel non-invasive biomarker in patients with decompensated liver cirrhosis.

FERMENTED MILK CONTAINING *Lactobacillus paracasei* subsp. *paracasei* CNCM I −1518 REDUCES BACTERIAL TRANSLOCATION IN RATS TREATED WITH CCl_4

G. Soriano[1,2], E. Sánchez[1], J.C. Nieto[3,4], S. Vidal[3], F.J. Sancho[1], P. Sancho-Bru[2,5], B. Mirelis[1], H. Corominola[6], C. Juárez[1], C. Guarner[1,2,7]. *[1]Hospital de la Santa Creu i Sant Pau, Barcelona, [2]CIBERehd, Instituto de Salud Carlos III, Madrid, [3]IIB-Hospital de la Santa Creu i Sant Pau, Barcelona, [4]Universitat Autònoma de Barcelona, Cerdanyola del Vallès, [5]IDIBAPS, Hospital Clínic, [6]Danone & Nutricia Research, [7]Universitat Autònoma de Barcelona, Barcelona, Spain*
E-mail: gsoriano@santpau.cat

Background and Aims: Certain probiotics can prevent pathological bacterial translocation in liver diseases by modulating intestinal microbiota and improving gut barrier and immune disturbances. The aim was to evaluate the effect of a fermented milk containing *Lactobacillus paracasei* subsp. *paracasei* CNCM I −1518 on bacterial translocation, intestinal microbiota, gut barrier and inflammatory response in rats with experimental cirrhosis induced by CCl_4 administration.
Methods: Thirty-nine Sprague-Dawley rats treated with CCl_4 were randomized into two groups: a probiotic group ($n = 20$) that received fermented milk containing *L. paracasei* subsp. *paracasei* CNCM I −1518 in drinking water, and a water group ($n = 19$) that received water only. Treatment began at week 6 of CCl_4 administration and continued until laparotomy, performed one week after development of ascites. A control group included 10 healthy rats. At the end of the study we evaluated bacterial translocation, intestinal flora, intestinal barrier (ileal claudin-4, β-defensin-1, occludin and malondialdehyde as index of oxidative damage) and cytokines in mesenteric lymph nodes and serum.
Results: Mortality during the study was similar in the probiotic group (7/20, 35%) and the water group (6/19, 31%) ($p = 1$). The incidence of bacterial translocation was 1/13 (7.7%) in the probiotic group, 7/13 (54%) in the water group ($p = 0.03$ vs probiotic group) and 0/10 in the control group ($p = 0.007$ vs water group). The concentration of ileal and cecal enterobacteria and enterococci was similar in the probiotic and the water groups. The ileal β-defensin-1 concentration was higher and ileal malondialdehyde levels were lower in the probiotic group than in water group ($p = 0.01$). There were no differences in serum cytokines between groups but TNF-α levels in mesenteric lymph nodes were lower in the probiotic group than in the water group ($p = 0.02$).
Conclusions: Fermented milk containing *Lactobacillus paracasei* subsp. *paracasei* CNCM I −1518 decreases bacterial translocation and ileal oxidative damage and increases ileal β-defensin-1 expression in rats treated with CCl_4, suggesting an effect on the intestinal barrier integrity.

PLASMA BETATROPHIN LEVELS IN PATIENTS WITH LIVER CIRRHOSIS

M.T. Arias[1,2], M. García-Unzueta[2,3], S. Llerena[1,2], P. Iruzubieta[1,2], A. Puente[1,2], J. Cabezas[1,2], C. Alonso[1,2], A. Cuadrado[1,2], J.A. Amado[2,3], J. Crespo[1,2], E. Fabrega[1,2]. *[1]Gastroenterology an Hepatology Unit, University Hospital Marqués de Valdecilla, [2]IDIVAL, [3]Endocrinology Unit, University Hospital Marqués de Valdecilla, Santander, Spain*
E-mail: digfge@humv.es

Background and Aims: Insulin resistance (IR) is common in cirrhosis and with advancement of liver disease. In these patients there is a compensatory increase in pancreatic B-cell insulin

secretion to overcome the IR. Recently, Douglas A. Melton's group from Harvard University reported the identification of betatrophin as a circulating protein secreted from the liver under insulin resistant states which is sufficient to dramatically and specifically increase the replication of B-cells in mouse resulting in an increased functional B-cell mass over time. In addition, in human studies betatrophin levels are associated with indexes of IR. The role of betatrophin in cirrhosis is at present unknown. The aim of this study was to investigate plasma levels of betatrophin in cirrhosis

Methods: We measured plasma betatrophin concentrations in 40 patients with cirrhosis (27 in Child–Pugh's class B, and 13 in Child–Pugh's class C) and compared these values with those in 15 age-matched healthy subjects. According to MELD score, 20 patients showed a MELD score higher than 14. IR was assessed by the Homeostasis Model Assessment (HOMA).

Results: Plasma betatrophin levels were significantly increased in patients with cirrhosis compared with healthy subjects. In addition, we found a positive correlation between plasma betatrophin levels and severity of cirrhosis according Child–Pugh or MELD score. Moreover, IR in cirrhotic patients was seen in 82.5%. In these group of patients betatrophin levels were significantly higher than group of patients without IR.

Conclusions: Plasma betatrophin is increased in patients with cirrhosis compared with healthy subjects. The increase in plasma betatrophin levels is related to the severity of cirrhosis as well as with the emergence of IR. Thus, these preliminary results show that betatrophin may contribute to counteract at least in part IR in patients with cirrhosis but more studies are needed to confirm it.

MELATONIN PROTECTS THE LIVER IN AN EXPERIMENTAL MODEL OF CIRRHOSIS

N.P. Marroni[1], S. Bona[2], G. Rodrigues[3], A.J. Moreira[4], T.R. da Silveira[5], C.A. Marroni[6]. *[1]Postgraduate Program in Cell and Molecular Biology Applied to Health, Universidade Luterana do Brasil, Canoas, [2]Postgraduate Program in Medical Sciences: Medicine, Universidade Federal do Rio Grande do Sul, Porto Alegre, [3]Universidade Luterana do Brasil, Canoas, [4]Postgraduate Program in Biological Sciences: Physiology, Universidade Federal do Rio Grande do Sul, [5]Center of Experimental Research, Hospital de Clínicas de Porto Alegre, [6]Postgraduate Program in Liver Diseases, Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, Brazil*
E-mail: nmarroni@terra.com.br

Background and Aims: Liver diseases are a major public health problem, accounting for a significant number of hospital visits and admissions and an increasing mortality rate. Melatonin (MLT) is a powerful antioxidant molecule that has been shown to be beneficial in various conditions, including liver diseases. The objective of the present study was to evaluate the effect of MLT on experimental liver cirrhosis induced by carbon tetrachloride (CCl_4) in rats.

Methods: We used 20 male Wistar rats (230–250 g) divided into 4 groups: I: Control (CO); II: CO+MLT; III: CCl_4; and IV: CCl_4+MLT. CCl_4 was administered as follows: 10 doses every 5 days, 10 doses every 4 days, and 7 doses every 3 days. MLT was administered intraperitoneally at a dose of 20 mg/kg from the 10th week to the end of the experiment (16th week).

Results: The use of MLT decreased lipid peroxidation (F2-isoprostanes) and NAD(P)H:quinone oxidoreductase 1 (NQO1) expression in the CCl_4+MLT group compared with the CCl_4 group. Liver histological analysis with HE staining showed that the animals of the CCl_4 group had histological changes, such presence of inflammatory infiltrate. In the CCl_4+MLT groups; however, the incidence of presence of inflammatory infiltrate were lower than those of the CCI4 group. The animals of the CCl_4 group, also had significantly increased NF-κB p65 and iNOS expressions when compared with the control groups. The use of MLT caused a significant decrease in the expression of these proteins in the CCl_4+MLT group when compared with the CCl_4 group. CCl_4 significantly increased the expression of TGF-β1 and α-SMA. In contrast, the group receiving MLT significantly decreased the expression of these proteins when compared with the CCl_4 group, thus suggesting the inhibitory effect of MLT on the activation of hepatic stellate cells and ECM deposition. With it animals of the CCl_4+MLT group showed a significant reduction of fibrosis with incomplete fibrotic septa and nodules, observed in the histological staining picrosirius. Liver fibrosis changes liver vascular architecture creating a hypoxic environment, which is an important stimulus for the production of angiogenic factors such as vascular endothelial growth factor. In the CCl_4+MLT group, this expression was significantly reduced when compared with the CCl_4 group.

Conclusions: Our findings suggest that MLT has a potent antifibrogenic effect, modulating parameters of oxidative stress, angiogenesis, and inflammation.

N-ACETYLCYSTEINE MODULATES ANGIOGENESIS, VASODILATION AND DNA DAMAGE IN STOMACH OF PORTAL HYPERTENSIVE RATS

N.P. Marroni[1], F. Licks[2], R. Hartmann[2], C. Marques[2], E. Schemitt[2], M. Soares[1], J. Reys[1], C. Fisher[1], J. da Silva[1]. *[1]Universidade Luterana do Brasil, Canoas, [2]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil*
E-mail: norma.marroni@ulbra.edu.br

Background and Aims: Portal Hypertension is associated with the development of a collateral circulation due to a progressive increase on portal pressure. This hyperdinamic state leads to dilation in several segments of the digestive tract, including stomach. Our aim was evaluate the antioxidant effect of N-Acetylcysteine (NAC) on the stomach of on portal hypertensive rats.

Methods: The animals were divided in four experimental groups (n = 6): Sham-operated (SO), SO + NAC, Partial portal vein ligation (PPVL) and PPVL + NAC. N-acetylcysteine (10 mg/kg ip) was administered daily for 7 days and started 8 days after surgery. We performed evaluation of portal pressure, performed immunohistochemistry of eNOS, VEGF and nitrotyrosine (NTT) proteins in stomach. We also evaluated the expression of endothelial nitric oxide synthase (eNOS) and vascular endothelial growth factor (VEGF) by Western blot analysis and assessed DNA damage in blood sample by comet assay. Statistical significance was calculated using Graphpad Instat, version 3.0 for Windows. Variance analysis (ANOVA) and Student-Newman-Keuls were used for multiple analysis, and the level of significance was 5% ($P < 0.05$). For the comet assay, the normality of variables was evaluated using the Kolmogorov–Smirnov test.

Results: The portal hypertensive group showed an increase in portal pressure eNOS, VEGF and NTT expression when compared to SO group. NAC was able to decrease portal pressure values, and the expression of all the proteins evaluated: eNOS, VEGF and NTT when compared to the PPVL group. Furthermore, NAC was able to modulate DNA damage in PPVL + NAC animals.

Conclusions: In conclusion, NAC was able to minimize gastric vasodilation, evaluated by eNOS, angiogenisis, evaluated by VEGF, and oxidative stress evaluated by NTT. This antioxidant treatment protected gastric mucosa also from DNA damage. Due to this results, we believe NAC is able to protect stomach from the alterations developed by the PPVL procedure.

IL-17 A AND F ISOFORMS AND THEIR RECEPTORS MEDIATE LIVER DAMAGE IN EXPERIMENTAL CHOLESTASIS AND THE IL17 A/F HETERODIMER INDUCES A PROFIBROGENIC PROFILE IN HEPATIC STELLATE CELLS IN VITRO

S. Zepeda-Morales[1], S. Del Toro-Arreola[1], L. Sánchez-Orozco[2], M. Fafutis-Morris[3], L. García-Benavides[4], A.L. Pereira-Suárez[3], M.R. Bueno-Topete[1]. *[1]Instituto de Enfermedades Crónico Degenerativas, [2]Biología Molecular y Genómica, [3]Laboratorio de Inmunología, [4]Instituto de Terapéutica Experimental y Clínica, CUCS, U de G., Guadalajara, jal, Mexico*
E-mail: ruthmyriamtop@hotmail.com

Background and Aims: Significant decrease in liver fibrosis in IL-17RA knockout mice has been demonstrated. However, the expression of IL-17 isoforms and their receptors in cholestatic liver fibrosis has not been explored; also, no information are about IL-17 heterodimer on hepatic stellate cells (HSC) signaling in vitro. The aim of this study was to analyze the expression variability of IL-17A, IL-17F and their receptors IL-17RA and IL-17RC in the liver of rats with cholestasis; aditionally we investigate the participation of IL-17 A/F heteodimer on HSC signaling
Methods: Male Wistar rats were sacrificed at days 8 and 30 after Bile duct ligation (BDL). IL-17A, IL17-F, IL-17RA and IL-17RC expression was determined by qRT-PCR in the liver. IL-17 and RORgt, were analyzed in liver homogenates by Western blotting. Activated HSC cells were stimulated with IL-17A/F, then the transcriptional factors Stat-3p, NF-κB and Smad-2p and profibrogenic genes collagen I, III and TGF-b were evaluated by qRT-PCR.
Results: Hepatic gene expression of IL-17A, IL-17-F and IL-17RC dramatically increased at 8 and 30 days post BDL. IL-17RA significantly increased at 30 days post BDL. The overall IL-17RC level was positively correlated with both IL-17A and IL-17F ($r = 0.48$, $P = 0.005$; and $r = 0.39$, $P = 0.012$, respectively). At the protein level, IL-17 and RORgt significantly increased 8 and 30 days post BDL. In vitro, Stat-3p, NF-κB, Smad-2p and profibrogenic genes collagen I, III and TGF-b significantly increased in IL-17 heterodimer stimulated cultured HSC
Conclusions: Our results suggest that IL-17 (A and F) isoforms and their receptors are critical mediators of liver damage in the pathogenesis of early and advanced experimental cholestatic fibrosis. Th17 cells might represent an important source of IL-17. Heterodimeric IL-17 A/F potentially induces profibrogenic genes in HSC culture.

EFFECT OF MESENCHYMAL STEM CELL ON HEPATIC FIBROSIS IN THIOACETAMIDE-INDUCED CIRRHOTIC RAT MODEL

S.K. Baik[1], Y.L. Lim[1], Y.Z. Cho[1], M.Y. Kim[1], Y.O. Jang[2], K.T. Suk[3], G.J. Cheon[4], Y.D. Kim[4], D.H. Choi[5]. *[1]Internal Medicine, [2]Cell Therapy and Tissue Engineering, Wonju Christian Hospital, Wonju, [3]Internal Medicine, Chuncheon Sacred Heart Hospital, Chuncheon, [4]Internal Medicine, Kangneung Asan Hospital, Kangneung, [5]Internal Medicine, Kangwon University School of Medicine, Chuncheon, Korea, South*
E-mail: youn07190720@naver.com

Background and Aims: Cirrhosis is a long-term consequence of chronic hepatic injury with fibrosis and no effective therapy except liver transplantation is currently available for decompensated cirrhosis. However, some practical limitations in liver transplantation lead us to a need for new therapeutic paradigm in this field. Recent reports have shown that the mesenchymal stem cells (MSCs) have the plasticity to differentiate into some kinds of tissue cells and improve organ function. Hence, we investigated the effect of direct inoculation of human bone marrow derived MSCs (BM-MSCs) in thioacetamide (TAA)-induced cirrhosis in a rat model.
Methods: Adult Sprague-Dawley rats were allocated into three groups (each group, $n = 15$) as follows: G1, shame; G2, TAA-control; G3, TAA+BM-MSC. To induce cirrhosis, 200 mg/kg TAA injection was done twice a week for 12weeks in G2 and G3. 2×10^6 cells of amplified human BM-MSCs were injected directly into the right liver lobe twice, at weeks 6 and 8 in G3. At 12 weeks, the effect of BM-MSCs on cirrhosis was analyzed histomorphologically using Laennec scores. α-Smooth muscle actin (α-SMA) expression by immunohistochemical staining, relative expression of collagen type 1, and transforming growth factor β (TGF-β) were also evaluated by real-time reverse transcriptase-polymerase chain reaction.
Results: Laennec scores were 0, 5.4±0.7 and 3.7±1.06 in G1, G2 and G3, respectively. Histologically, BM-MSCs injected group (G3) showed significant suppression of hepatic fibrosis compared with TAA-control group (G2) ($P < 0.001$). Expressions of α-SMA (%) were significantly lower in G3 than in G2 (3.08±1.26 vs. 7.00±4.12, $P < 0.05$). Also, the relative expression of collagen type 1 and TGF-β1 in RT-PCR were 0.64±0.24, 2.06±0.51, 1.32±0.31 and 0.62±0.28, 5.89±3.05, 2.22±1.41 in G1, G2 and G3, respectively ($P < 0.005$).
Conclusions: Our results showed that BM-MSCs could attenuate liver fibrosis in rats with TAA-induced cirrhosis, raising the possibility for clinical use of BM-MSCs in the treatment of cirrhosis.

IMPAIRED 11β-HYDROXYSTEROID DEHYDROGENASE TYPE 2 ACTIVITY CONTRIBUTES TO RENAL SODIUM AVIDITY IN HUMAN CIRRHOSIS

A. Dam Fialla[1], H.C. Thiesson[2], P. Bie[3], P.H. Hovind[4], O.B. Schaffalitzky de Muckadell[1], A. Krag[1]. *[1]Department of Gastroenterology and Hepatology, [2]Department of Nephrology, Odense University Hospital, [3]Cardivascular and Renal Research, University of Southern Denmark, Odense, [4]Department of Clinical Physiology and Nuclear Medicine, Glostrup Hospital, Glostrup, Denmark*
E-mail: adam@health.sdu.dk

Background and Aims: The enzymes 11β-hydroxysteroid dehydrogenase type 1 (11βHSD1) mainly located in the liver and type 2 (11βHSD2) mainly located in the kidney and colon interconvert cortisol and cortisone. The balance of the enzyme activity decides the presence of the abundant cortisol with high affinity for the mineralocorticoid receptor (MR). The enzyme 11βHSD2 protects the MR in the kidneys from stimulation from cortisol, which has a higher affinity than aldosterone. Thus a down regulation of the 11βHSD2 in patients with cirrhosis is a potential pathophysiological mechanism in sodium retention in cirrhosis. We hypothesize that 11βHSD1/11βHSD2 balance is increased due to down regulation of 11βHSD2 activity in cirrhosis and related to renal sodium retention.
Methods: Thirteen patients with cirrhosis and 6 healthy controls were investigated. On sodium fixed diet analyses of cortisol/cortisone metabolites as well as the sodium excretion in the urine were performed. The metabolites of cortisol are 5β-tetrahydrocortisol (THF) and 5α-tetrahydrocortisol (a-THF) and the metabolite of cortisone is 5β-tetrahydrocortisone (THE). The balance of 11βHSD1 and 11βHSD2 activity is expressed as the ratio; THF + allo-THF/THE.
Results: The balance of 11βHSD1/11βHSD2 activity was found to be significantly increased in the patients compared with healthy controls; THF+allo-THF/THE (patients: 0.77±0.09; controls: 0.55±0.04, $p < 0.05$). The urinary sodium volume (UNaV) and the fractionated sodium excretion (FeNa) were significantly reduced in the patients; UNaV (patients: 15.7±5.5 mmol/day; controls 63.4±16.6 mmol/day, $p < 0.01$); FeNa (patients: 0.12±0.04; controls: 0.34±0.11, $p < 0.05$). Urine flow rate was at the same level in the two groups (patients: 1.05±0.11 ml/min; controls 1.33±0.09 ml/min, $p > 0.05$), whereas creatinine clearance was statistically significant reduced in the patients (patients: 76.6±5.6 ml/min; controls: 105.8±9.2 ml/min, $p < 0.05$).
Conclusions: The balance of 11βHSD1/11βHSD2 enzyme activity is increased in cirrhotic patients and it demonstrates a down

regulation of 11βHSD2 enzyme activity. This suggests that the protection of the mineralocorticoid receptor from cortisol activation by 11βHSD2 may be impaired. The sodium retaining mechanisms in the distal tubule in cirrhosis is not only mediated by aldosterone, but also by the activation of the mineralocorticoid receptor by cortisol.

P0095

ER STRESS ENHANCES LIVER FIBROSIS THROUGH MIR-150 DEGRADATION AND XBP-1 SPLICING

F. Heindryckx[1], F. Binet[1], J. Kreuger[1], P. Gerwins[1]. [1]*Medical Cell Biology, Uppsala University, Uppsala, Sweden*
E-mail: fempie@gmail.com

Background and Aims: The unfolded protein response (UPR) is activated in several liver diseases, including NASH, cholestasis, viral hepatitis, alcoholic-induced liver injury and hepatocellular carcinoma. IRE1α, PERK and ATF6 are three parallel signaling pathways that mediate the UPR. IRE1α acts through both unconventional splicing of XBP1 mRNA and regulated IRE1-dependent decay of mRNA (RIDD), and also directly cleaves a subset of pre-miRNAs. The aim of our study is to define the mechanism by which the UPR enhances fibrogenesis and whether inhibition of the UPR could hinder development of cirrhosis.
Methods: Mice were injected with CCl_4 for 15 weeks and one group treated with 4μ8c, which is an inhibitor of IRE1α endonuclease activity. Fibrosis was evaluated by staining of liver sections with Sirius red and αSMA-antibodies. Stellate cells were isolated from healthy mice and stimulated with TGFβ +/− 4μ8c. miR150 levels were measured with qPCR. To show the direct effect of IRE1α RIDD activity on miRNA, an *in vitro* cleavage assay using pre-miRNA 5′-end labelled with ^{32}P-ATP was performed with the XBP1 stem loop as a positive control.
Results: Treatment of mice with 4μ8c significantly reduced fibrosis as shown by a reduction in both aSMA positive cells and Metavir score. This effects was likely due to activation of the UPR since 4μ8c treatment reduced the levels CHOP, BIP and spliced XBP1, which are markers of the activated UPR pathway. In support, *in vitro* studies using hepatic stellate cells isolated from mice and humans showed that 4μ8c inhibited TGFβ-induced differentiation into activated myofibroblasts. miR-150 is known to be anti-fibrotic and inibition of IRE1α with 4μ8c increased miR-150. Indirect evidence using various mutated IRE1α constructs and direct demonstration by recombinant enzyme cleavage showed that the RIDD activity of IRE1α destabilized and led to a downregulation of pre-miR-150 expression in activated myofibroblasts.
Conclusions: These data suggest that inhibiting IRE1α endonuclease activity attenuates liver fibrosis, possibly by affecting hepatic stellate cell differentiation via miR150 degradation.

D-DIMER AND FIBRINOLYTIC ACTIVITY IN PATIENTS WITH DECOMPENSATED LIVER CIRRHOSIS

R.G. Romanelli[1], A. Cellai[2], D. Lami[2], C. Tosti-Guerra[1], R. Abbate[2], D. Prisco[2], G. Laffi[1]. [1]*Dipartimento Medicina Sperimentale e Clinica-Liver Unit, University of Florence School of Medicine,* [2]*Sezione Malattie Aterotrombotiche, Dipartimento Area Critica Medico-Chirurgica, Florence, Italy*
E-mail: robertogiulio.romanelli@unifi.it

Background and Aims: Cirrhotic plasma could generate similar or even greater amounts of thrombin; a procoagulant imbalance has been introduced. Hyperfibrinolysis may complicate cirrhosis; standard tests (INR) fail to reflect bleeding tendency. Aim was to assess fibrinolytic system, clot lysis time and fibrinolysis of ascites.
Methods: We studied 33 pts with cirrhosis and 21 HS without no history of venous thromboembolism. EuroCLOT consortium was employed to study clot formation, morphology and fibrinolysis as dynamic process, measuring CLT (clot lysis time), CLR (clot lysis ratio), TAFI, PAI-1, t-PA, plasminogen, α2-antiplasmin, fibrinogen and D-dimer. We studied 11 A, 9 B, and 13 C cirrhotic pts. CP/MELD scores were significantly different among the three groups of pts. ($p < 0.001$). Systolic and diastolic blood pressure, heart rate, platelet counts, bilirubin and albumin levels were also different ($p < 0.001$).
Results: EuroCLOT data resulted significantly different (LagC, MaxabsC, CRC, Lys50t0, LysT, and LR) (from $p < 0.05$ to $p < 0.001$ CPB and CPC versus CPA and HS). Generated curves (AUC) were progressively decreased (from 585, to 316, 257, 1nd 129) ($p < 0.001$), so as TAFI values (from 8.4, to 8.32, 4.09, and 3.6 ug/mL, $p < 0.001$); PAI-1 and t-PA increased progressively, while α2-antiplasmin, plasminogen, and fibrinogen decreased progressively ($p < 0.001$). D-dimer plasma levels increased progressively and parallel to the severity of the disease. Ascites revealed small amounts of TAFI and increased levels of D-dimer ($p < 0.001$).
Conclusions: Liver cirrhosis is characterized by enhanced plasma fibrinolysis associated with the severity of the disease and this could be explained by the different methods used, the classical ones and the new global turbidimetric ones. Increased plasma and ascitic levels of D-dimer and altered fibrinolytic parameters were found in pts versus HS. Generated curves exploring both clotting and fibrinolytic parameters from EuroCLOT clearly showed delayed clot formation, decreased clot strength/hyperfibrinolysis, in parallel with the severity of the disease (Kleinegris MC et al, 2014). These data, expecially D-dimer levels both in plasma and ascites, further suggest that ascitic fluid is in continuous exchange with plasma, possibly through lympathic flux; moreover, absence of fibrinogen and increased fibrinogen/fibrin degradation products in this space suggests a possible role of ascites in the pathogenesis of coagulopathy of liver disease.

P0097

PRECISELY QUANTITATING THE DYNAMICS OF LIVER CIRRHOSIS IN A RAT MODEL

Y. Wang[1], H. Liu[2], X. Huang[2], C. Lin[2]. [1]*Hepatology Unit, Southern Medical University Nanfang Hospital,* [2]*Medical School, Southern Medical University Zhujiang Hospital, Guangzhou, China*
E-mail: yanwang@smu.edu.cn

Background and Aims: Detailed histologic changes in dynamic cirrhosis are yet to be fully available. The present study aims to address this issue using a structural quantitation tool for understanding the process and the potential impact on hepatic pathogenesis.
Methods: We used a CCl_4-induced cirrhotic rat model. Liver specimens ($n = 3–5$ per time point) were collected at 0, 6, 8 and 12 wks with treatment, and 2, 4, 8 wks after treatment, respectively. Samples' processing, histologic staging, and quantitative imaging analysis were performed routinely or as reported [J Hepatol 2014;61:260].
Results: To understand the process of cirrhosis initiation and progression, we measured the speed of changes ($mean_{T1}/mean_{T2}$/wk) in all structural fibrotic parameters between serial time points (Figure 1). At initiating stage (0–6 wk), the most significant changes happened to septal bridge; top 3 parameters are: crosslink number of septa collagen fiber (SCF) (67.44-fold, $p = 0.01$), long SCF number (65.04-fold, $p = 0.03$), and SCF width (60.54-fold, $p = 0.02$). At progressing stage (6–12 wk), the most significant changes mainly located in sinusoidal space; top 3 are: number of sinusoidal CF (FCF) (6.12-fold, $p = 0.03$), FCF crosslink (3.90-fold, $p = 0.00$) and long portal CF (3.12-fold, $p = 0.00$); from Ishak F5 to F6, significant increase happened in CF crosslink number (2.74-fold, $p = 0.01$), CF perimeter (2.53-fold, $p = 0.01$), and CF area (2.34-fold, $p = 0.02$). In the whole pathogenesis process (0–12 wk), the most dramatic change of scarring occurred to sinusoid, e.g. change in FCF length reached to 845.88-fold ($p = 0.00$).

During cirrhotic regression, at early 2 and 4 wks, most decrease happened to portal location; then it changed to septal bridge; fibrotic dissolving were faster at 2 wk than the rest time points. Even at the same stage of Metavir F4, there were significantly lower values of almost all fibrotic parameters of regressing cirrhosis in comparison with the ones of progression phases ($p < 0.05$).

Conclusions: In the present cirrhotic model, fibrosis grew faster at the initial stage, but slower down as cirrhosis progressing; at the progressing stage, the most dramatic fibrotic changes occurred to septa and sinusoid with the presence of increased crosslinking and long thick CF. Without injury, cirrhosis regressed fast within 2 wks, presenting a dynamic distribution. Regressing cirrhotic stage generally had lower level of fibrosis content than its progressing counterpart.

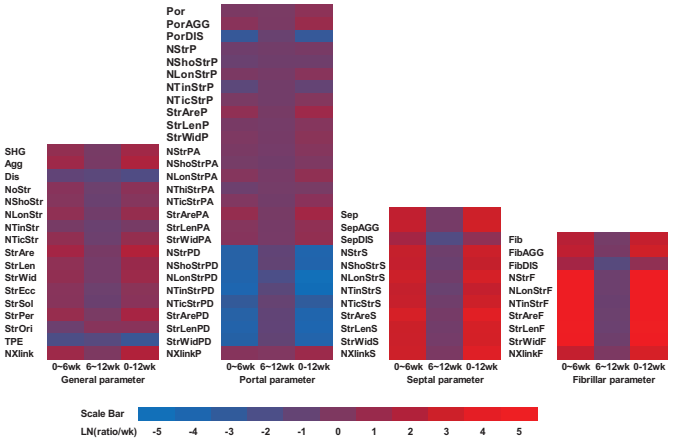

Figure 1. Velocity of changes in structural parameters in progressing cirrhosis.

MACROPHAGE INHIBITORY CYTOKINE-1 (MIC-1) IS ASSOCIATED WITH DEGREE OF LIVER FIBROSIS IN HCV-RELATED LIVER DISEASE – THE MILC STUDY

B. Watson[1], A. Baxter[2], V. Flood[3], L. Schofield[4], H.P. Zhang[5], M. Lee-Ng[5], D. How-Chow[6], S.N. Breit[5], D.A. Brown[5], M. Danta[1,6].
[1]Medicine, St Vincent's Clinical School, UNSW, [2]Dietetics, St Vincent's Hospital, [3]Faculty of Health Sciences, University of Sydney, [4]Clinical Research Unit, Garvan Institute, [5]St Vincent's Centre of Applied Medical Research, [6]Hepatology, St Vincent's Hospital, Sydney, Australia
E-mail: m.danta@unsw.edu.au

Background and Aims: Macrophage Inhibitory Cytokine-1 (MIC-1/GDF15) is a divergent member of the TGF-β superfamily that is overexpressed (10–100 fold) in cancer and some chronic diseases. At these levels it has emerged as a potential mediator of anorexia/cachexia. In severe liver disease, nutritional state predicts morbidity and mortality and we hypothesised that MIC-1/GDF15 may also mediate these nutritional changes. The aim of this study was to assess the relationship of serum MIC-1/GDF15 to disease severity and nutritional status in HCV-related liver disease.

Methods: A cohort of HCV infected patients from St Vincent's Hospital, Sydney, Australia were stratified by degree of liver fibrosis using Fibroscan into three groups: no fibrosis (F0/F1; <7 kPa); moderate liver fibrosis (F2/F3; 7.1–13 kPa) and cirrhosis (F4; >13 kPa). Each participant undertook a range of tests, including: anthropometric assessments (BMI, Triceps Skin Fold and Mid-Arm Muscle Circumference); nutritional assessments (subjective global assessment, a 72-hour food diary, handgrip strength, International Physical Activity Questionnaire); metabolic assessments (REE and RQ by indirect calorimetry); and serological investigations, including serum MIC-1/GDF15 levels. The statistical relationship between these parameters and serum MIC-1/GDF15 levels were then examined.

Results: To date, 58 patients (mean age 57 years; males 72%) have been enrolled into the study: n = 18 (F0/F1); n = 18 (F2/3); and n = 23 (F4), including 4 decompensated cirrhotics. Serum MIC-1/GDF15 levels strongly correlated with Fibroscan scores ($r = 0.74$; $p < 0.0001$). There was a significant difference in mean MIC-1/GDF15 levels between the three groups (F0/F1, 873 pg/ml; F2/F3, 1205 pg/ml; and F4, 2042 pg/ml; KW $p \leq 0.01$). MIC1/GDF15 also correlated with lower albumin and increased AST, GGT and bilirubin ($p < 0.01$). No patient in the cohort had objective malnutrition, nor was there any significant difference in nutritional status between the 3 study groups. MIC1/GDF15 was not associated with any measures of nutrition or metabolism.

Conclusions: The data suggests a direct relationship between elevated serum MIC-1/GDF15 levels and the degree of liver fibrosis. No meaningful interpretation of the relationship between MIC-1/GDF15 and nutritional or metabolic parameters could be made because serum MIC-1/GDF15 serum levels were below anorexogenic levels, malnutrition was absent and nutritional status was no different across the study groups. This may reflect the lack of decompensated cirrhotics to date.

P0099

CHOLESTATIC LIVER FIBROSIS CORRELATES WITH INCREASED IL-17 AND TGFβ-2 EXPRESSION

M. Bueno-Topete[1], S. Zepeda-Morales[1], L. García-Benavides[2], S. Del Toro-Arreola[1], E. Bastidas-Ramírez[1], M. Fafutis-Morris[3].
[1]Instituto de Enfermedades Crónico Degenerativas, [2]Instituto de Terapéutica Experimental y Clínica, [3]Laboratorio de Inmunología, CUCS, U de G., Guadalajara, jal, Mexico
E-mail: ruthmyriamtop@hotmail.com

Background and Aims: IL-17, TGF-β1/2 are citokines involved in the development of kidney, pulmonar and liver fibrosis. However, their expression kinetics in the pathogenesis of cholestatic liver fibrosis has yet to be been fully explored. The aim of the study was to analyze the expression of IL-17, RORgt, NKp46, TGF-b1, and TGF-b2 in the liver of rats with bile duct ligation (BDL).

Methods: Male Wistar rats were sacrificed at days 8 and 30 after BDL. IL-17A, TGF-b1 and TGF-b2 expression was determined by qRT-PCR. IL-17, TGF-b1, TGF-b2, RORgt, and NKp46 were detected in liver homogenates by Western blotting. Collagen deposition was confirmed with Masson's trichrome stain.

Results: Hepatic IL-17A expression dramatically increased 350 fold and 10 fold, at 8 and 30 days post BDL, respectively. TGFb1 and TGFb2 expression significantly increased as well. At the protein level, IL-17, TGF-b1, and RORgt significantly increased 8 and 30 days after BDL. Interestingly, a significant increase in TGF-b2 and decrease of NKp46 was observed only 30 days after BDL. Unexpectedly, TGF-b2 exhibited stronger signals than TGF-b1 at the gene expression and protein levels. Histological analysis showed bile duct proliferation and collagen deposition.

Conclusions: Our results suggest that pro-fibrogenic cytokines IL-17, TGF-b1 and, strikingly, TGF-b2 are critical mediators of liver damage in the pathogenesis of early and advanced experimental cholestatic fibrosis. Th17 cells might represent an important source of IL-17, while NK cell depletion may account for the perpetuation of liver damage in the BDL model.

QT ADAPTATION DURING EXERCISE IN LIVER CIRRHOSIS: ADJUNCTIVE SIGNS OF CIRRHOTIC CARDIOMYOPATHY

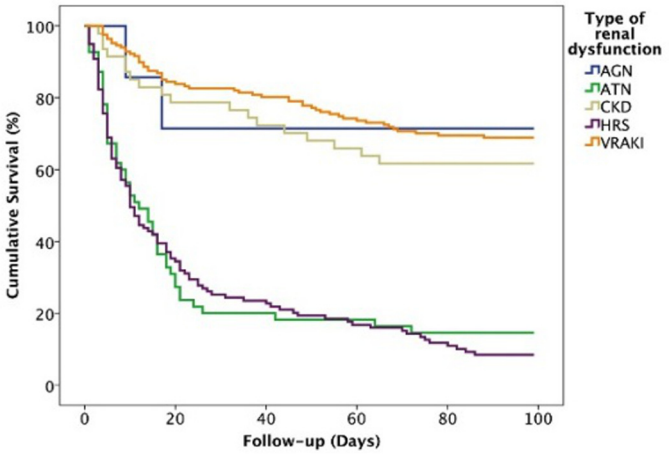
R.G. Romanelli[1], G. Barletta[2], R. Del Bene[2], F. Marra[1], F. Venditti[2], G. Laffi[1]. *[1]Dipartimento Medicina Sperimentale e Clinica-Liver Unit, University of Florence School of Medicine, [2]Heart and Vessels Department, Azienda Ospedaliero Universitaria Careggi, Florence, Italy*
E-mail: robertogiulio.romanelli@unifi.it

Background and Aims: QT-interval prolongation is frequently seen in liver cirrhosis. Whether it is simply a marker of disease severity is debated. Analysis of QT-interval behavior during physical exercise may disclose more specific abnormalities of cardiac repolarization of cirrhotic cardiomyopathy.
Methods: Thirty-eight outpatients with non-alcoholic liver cirrhosis and portal hypertension (32 males, aged 62±9 yrs) and 36 sex- and age-matched healthy subjects (32 males, aged 59±7 yrs) underwent bicycle exercise test with QT-interval measurement, echocardiographic and Doppler ultrasound analysis of systolic and diastolic left ventricular function, determinations of systemic hemodynamics and pro-brain natriuretic peptide concentration.
Results: Patients had longer Fridericia-corrected QT-interval than healthy subjects at baseline and peak-exercise and reduced chronotropic index, despite similar predicted workload. Corrected-QT shortening amount at peak-exercise was the same, however, in early-exercise corrected-QT increased in 6 healthy subjects and 25 patients, the increase being greater and significantly delayed in cirrhotic patients. QT hysteresis was greater in cirrhotic patients. Abnormal repolarization during exercise and recovery in patients with normal baseline corrected-QT did not correlate to Child–Pugh class score and hemodynamic alterations, whereas patients with >440 ms corrected-QT (n = 16) showed diastolic dysfunction and increased pro-brain natriuretic peptide plasma levels.
Conclusions: QT behavior during physical exercise supports the hypothesis of anomalous modulation of potassium currents in liver cirrhosis; only long rest corrected-QT correlates to clinical signs of cirrhotic cardiomyopathy.

P0101
SPECTRUM AND SHORT TERM OUTCOME OF RENAL IMPAIRMENT IN CIRRHOSIS

S. Vinit[1], A. Kumar[1], P. Sharma[1], R.K. Bansal[1], P. Tyagi[1], N. Bansal[1], V. Singla[1], M. Kumar[1], P. Ranjan[1], M.K. Sachdeva[1], A. Arora[1]. *[1]Gastroenterology and Hepatology, Sir Ganga Ram Hospital, New Delhi, India*
E-mail: drvinitshah@gmail.com

Background and Aims: Renal failure is the most powerful predictor of death in decompensated cirrhosis. We conducted this prospective, observational, cohort study to determine spectrum of acute kidney injury (AKI) as per IAC/ADQI, (International Ascites Club/Acute Dialysis Quality Initiative) definition in cirrhotics at admission or in hospital stay and study its outcome.
Methods: Cirrhotic patients diagnosed with AKI as per IAC/ADQI definition were enrolled and evaluated for the cause and type of AKI as per study definitions, investigated and treated as per study protocol. They were followed up to see reversibility of AKI and its effect on patients' in-hospital, 1 and 3 month outcome.
Results: 395 consecutive cirrhotics with renal impairment enrolled. In-hospital mortality 154 (39%). 226 (57.2%) survived at 1 month and 173 (43.8%) at 3 months. Median CTP 10 (5–14) and median MELD 25 (6–57). RRT (renal replacement therapy) required in 120 (30.4%). Infections were commonest precipitants with SBP, 84 (21.4%) the most common focus. VRAKI (volume responsive AKI) was commonest, 198 (50.1%). Among VNRAKI (volume non-responsive AKI), HRS (hepatorenal syndrome) seen in 85 (21.5%), ATN (acute tubular necrosis) in 55 (13.9%), and 9 (2.3%) had AGN (acute glomerulonephritis). Associated CKD (chronic kidney disease) seen in 48 (12.2%). VRAKI had best outcome followed by AGN and associated CKD. ATN/HRS had poor outcomes. Outcome was significantly poor in ACLF (acute on chronic liver failure), terlipressin non-responders and recurrent AKI. On multivariate analysis MELD score, serum albumin, presence of SBP and hypotension with inotropes requirement were significantly associated with HRS/ATN development. Presence of HE, low albumin and ATN/HRS were significantly associated with death.
Conclusions: AKI in cirrhotics was associated with significantly high in-hospital mortality, higher need for renal replacement therapy as well as progressively reduced 1 month and 3 month survival. VRAKI was the commonest with best outcome followed by HRS and ATN. Associated CKD had better 1 and 3 month survival than HRS/ATN. Presence of HRS/ATN, ACLF, recurrence of AKI in the same hospitalization were associated with poor 1 month and 3 month survival. MELD score, SBP, presence of hypotension with inotrope requirement were significant predictors of HRS/ATN development and presence of HRS/ATN, HE, low serum albumin were significant predictors of death. The survival in HRS/ATN did not correlate with infection-related parameters whereas that in VRAKI did.



P0102
DEGENERATION SIGNS OF PURKINJE NEURONS IN A NEW ANIMAL MODEL OF EPISODIC HEPATIC ENCEPHALOPATHY

T. García-Lezana[1,2,3], J. Romero-Giménez[1], M. Oria[1,2,3], J. Genescà[1,2,3], L. Chavarria[1,2,3], J. Córdoba[1,2,3]. *[1]Liver Unit, Hospital Vall Hebron, [2]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), [3]Departament Medicina, Universitat Autònoma de Barcelona, Barcelona, Spain*
E-mail: teresa.garcia.lezana@vhir.org

Background and Aims: Hepatic encephalopathy (HE) is a severe complication of cirrhosis. It has been classically considered as a reversible disease but several studies demonstrate that repeated episodes of HE may imply brain volume reduction and neuronal loss leading to persistent cognitive impairment. The aim of our study is the development of a new animal model of episodic HE, triggered by hyperammonemia and/or inflammation, which reproduces the features of HE patients and allows the identification of neurodegeneration evidences.
Methods: The animal model consists on the simulation of several episodes of HE in rats which previously underwent portacaval anastomosis surgery. The episodes were achieved trough the regular administration of ammonium acetate and/or lipopolisacharide (LPS). To confirm central nervous system damage, neurological status was assessed. After ten simulated episodes, brains were removed in order to quantify neuronal loss and to identify the signaling pathways involved in this process.

Results: Cognitive impairment was evaluated using a reflexes test, it revealed a lost of at least 50% of reflexes in 36% of the animals treated with ammonia; and an object recognition test, which evaluates memory and learning, shows a long-term mild decrease of those abilities in LPS-treated rats.
In cerebellum, neuronal counting proved a reduction in Purkinje cell population together with morphological changes attributed to degeneration process (shrinkage, dark cytoplasm and nucleus, and deformed nuclei) in all groups when compared with control.
Gene expression analysis evidenced a modulation of neuro-degeneration-related genes in cortex [adora2A Fold Change (FC): −2.45] and cerebellum (transtiretina FC: 17.45) but did not reveal any canonical pathway affected. The study of the pathways involved in neuronal death process in cerebellum shows an over-expression of senescence-related genes [IFN-γ FC = 2.15; cdkn1a (p21) FC: 1.88; cdkn2a ($p16^{INK4}$) FC = 1.68].
Conclusions: The neurological impairment found in patients is well reproduced by this new animal model of HE when ammonia is the precipitant factor of the episodes. Ammonia toxicity in central nervous system provokes gene expression changes in neurodegeneration-related genes, as well as Purkinje neurons death, probably through senescence pathways. The persistence of cognitive impairment after HE episodes resolution, observed in this animal model, could be caused by that premature senescence of Purkinje cells.

P0103
"PINRO" HYPOTHESIS FOR THE PATHOPHYSIOLOGICAL MECHANISM ABOUT HEPATITIS B VIRUS (HBV) RELATED ACUTE-ON-CHRONIC LIVER FAILURE (ACLF) PATIENTS – THE CRUCIAL ROLE OF SUBMASSIVE HEPATIC NECROSIS (SMHN)

B. Zeng[1,2], L.-Y. Chen[1,2], N.-N. Zhang[1,2], S. Yin[1,2], S.-T. Li[1,2], H.-L. Weng[3], Q. Xia[4], T.-L. Wang[5], H. Li[1,2]. *[1]Department of Gastroenterology, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, [2]Shanghai Institute of Digestive Disease, Shanghai, China; [3]Department of Medicine II, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany; [4]Department of Liver Surgery and Liver Transplantation, RenJi Hospital, School of Medicine, Shanghai Jiao Tong University, [5]Department of Pathology, Beijing China–Japan Friendship Hospital, Shanghai, China*
E-mail: jiazezengbo@126.com

Background and Aims: "PIRO" is the current hypothesis for the mechanism of ACLF. After our group finding SMHN was the major pathological feature of HBV related ACLF patients, we put forward "PIN(necrosis)RO" is the mechanism for HBV cirrhotic patients.
Methods: 174 liver transplanted HBV cirrhotic patients with acute decompensation were enrolled. 40% (69/174) had histological evidence of SMHN. Clinical features about inflammatory response and multiple organ failure (MOF) were compared between SMHN positive and negative group whenever acute insults exiting or not. Microarrays of 33 cirrhotic livers were used to investigate gene expression changes in hepatic metabolism (first response) after SMHN.
Results: Acute insults were identified in 58.6% (102/174) enrolled patients. There was no difference in either inflammatory (white blood cells count, WCC) or MOF parameter (CLIF-ACLF) between insults identified and unidentified group ($p > 0.05$ for all). However, in acute insults identified group, SMHN positive patients (n = 44) had a significantly higher WCC ($7.2\pm3.9\times10^9$/L vs $4.3\pm3.6\times10^9$/L), CLIF-SOFA [8 (6, 10) vs 4 (2, 6)] and MELD [32 (25.3, 36.5) vs 13.5 (10, 20.5)] than SMHN negative patients (n = 58) ($p < 0.001$ for all). In the meantime, SMHN positive patients (n = 25) also had both significantly more severe inflammation (WCC, $7.22\pm3.84\times10^9$/L vs $3.75\pm1.61\times10^9$/L) and MOF [CLIF-SOFA, 8 (7.5, 10) vs 4 (4, 6)] than SMHN negative patients (n = 47) in acute insults unidentified group. Comparing to the SMHN negative cirrhotic liver, microarray data showed that 12 of 15 most down-regulated pathways in SMHN positive liver were related to the hepatic biosynthesis, catabolism and metabolism of different amino acids, fatty acids and glucose. That reflected the more severe hepatic function damaging in SMHN patients. 11 of 15 most up-regulated pathway were related to inflammatory molecules and immune response markers in SMHN positive liver, which reflected the more deranged immune response after SMHN.
Conclusions: Our data showed the necrosis (SMHN), rather than acute insults, determined the progression of first (the damage of hepatic metabolism) and second (inflammatory response) response as well as further development of MOF. Thus the pathophysiological mechanism underling ACLF would be "PINRO": predisposition → injury → (submassive hepatic) necrosis → deterioration of liver function (first response)/deranged systemic inflammatory response (second response) → multiple organ failure.

P0104
THE LIVER SINUSOID WITHIN A MICROFLUIDIC CHAMBER: A NEW TOOL FOR VASCULAR BIOLOGY RESEARCH

R. Maeso-Díaz[1], X. Illa[2], S. Vila[1], J. Yeste[2], G. Marrone[1], M. Navarro-Zornoza[1,2], C. Peralta[3], R. Villa[2], J. Gracia-Sancho[1]. *[1]Barcelona Hepatic Hemodynamic Lab, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS) – Hospital Clínic de Barcelona – CIBEREHD, [2]Instituto de Microelectrónica de Barcelona (IMB-CNM) – CSIC – CIBERBBN, [3]IDIBAPS – CIBEREHD, Barcelona, Spain*
E-mail: raquelmaesodiaz@gmail.com

Background and Aims: The liver sinusoid plays a key role in the development of liver diseases, including cirrhosis and portal hypertension. In addition, therapies to improve liver function

should also target sinusoidal cells.
However, there are no *in vitro* research tools that correctly mimic the unique features of the sinusoid: adequate spatial distribution of cells, biomechanical stimulation of the endothelial lineage and free paracrine interactions.
Our aim was to design, fabricate and validate a three-dimensional co-culture chamber with microfluidics that mimics the hepatic sinusoid.
Methods: A transparent PMMA chamber composed by 3 growing areas of 9.7 cm^2 arranged at different heights and separated by 0.5 mm was manufactured. The higher level integrated a microfluidic system allowing the application of homogeneous shear stress on a reinforced porous membrane where the endothelium is grown. The middle level had a second culture membrane, and on the lower level, the growing area was the base of the camera.
Functional validation: Endothelial cells stimulated with shear stress (5 dyn/cm^2), HSC, and hepatocytes were cultured for 24 h in the chamber. Morphology, viability and endothelial nitric oxide production was analyzed.
Translational Validation: The applicability of the chamber in the field of cirrhosis was assessed co-culturing activated HSC and capillarized LSEC under shear stress, or in static conditions. Furthermore, the effects of adding the vasoprotective agent simvastatin were analyzed and compared with traditional culture methods.
Results: *Functional validation:* Cells grown in the chamber showed excellent viability. Endothelial cells were aligned in the direction of shear stress, and increased their production of nitric oxide.
Translational Validation: Dysfunctional LSEC cultured in the device showed a marked improvement in their phenotype (activation of the KLF2 pathway and decrease in endothelin-1) that was not observed using ordinary culture methods. The shear stress-derived improvement in LSEC led to a beneficial paracrine effect on HSC (reduced collagen I and alpha-SMA). Simvastatin addition produced a strong protective effect on both cell types, which was significantly higher than that obtained using traditional "transwell" methods.
Conclusions: We herein describe a novel, versatile, easy to operate and highly reproducible device that can be applied in different fields of vascular biomedical research, including hepatology.

P0105
CHANGES IN THE CNS CONNEXIN 43 EXPRESSION AND FUNCTION IN THE PATHOGENESIS OF HEPATIC ENCEPHALOPATHY

A. Hadjihambi[1], A. Gourine[2], R. Jalan[1]. [1]*Department of Liver and Digestive Health,* [2]*Neuroscience, Physiology & Pharmacology, UCL, London, United Kingdom*
E-mail: ucbthad@ucl.ac.uk

Background and Aims: Astrocytes, the most numerous glial cells, are hypothesized to play a role in the pathological mechanisms underlying hepatic encephalopathy (HE), although the clinical manifestations of HE are mainly neuronal. Astrocytes are extensively connected by gap junctions formed of connexins (Cxs), which may also exist as functional hemichannels allowing the exchange of molecules between the cytoplasm and the extracellular milieu. In pathological conditions, including HE, significant changes in astroglial anatomy and function may occur. In this study we investigated changes in the expression profile of Cx43 (predominant type of astroglial Cx) and hemichannel function in the cortex and cerebellum. The animal (rat) models of HE (bile duct ligation [BDL] and hyperammonemia) were used.
Methods: Cx43 mRNA and protein levels were quantified in the cortex and cerebellum of SHAM, BDL and hyperammonemic rats, using PCR and Western blots. Microelectrode biosensors were used for real time measurements of glutamate and lactate release by cortical and cerebellar slices prepared from the brains of SHAM, BDL and hyperammonemic animals.
Results: Cx43 mRNA expression was downregulated in the cortex and cerebellum of BDL and hyperammonemic rats. Western blots analysis revealed a reduction in Cx43 protein in the cortex. Biosensors showed a significant reduction in both tonic and stimulated lactate release in the cerebral cortex of hyperammonemic, but not BDL rats. Lactate release in the cerebellum of BDL and hyperammonemic rats was also decreased. Cortical slices obtained from BDL and hyperammonemic rats showed markedly higher glutamate release than that of SHAM animals under all conditions ($p < 0.05$). In the cerebellum, the tonic release of glutamate in hyperammonemic rats was higher than that of the SHAM animals. In both models a decrease in glutamate release due to hypoxia was observed.
Conclusions: The results of the present study suggest that HE is associated with significant changes in the connexin expression in the CNS. Altered Cx43 expression may play a role in a distinct neurochemical phenotype, as we report (lower lactate, higher glutamate) and is therefore hypothesised to play a significant role in the pathogenesis of the disease.

P0106
REDUCED EXPRESSION OF GLYOXALASE-I IN CIRRHOTIC LIVERS: A MECHANISM THAT COULD EXPLAIN HIGHER CONCENTRATION OF REACTIVE OXYGEN SPECIES (ROS) IN THE DEVELOPMENT OF CIRRHOSIS

M. Hollenbach[1], A. Thonig[1], S. Pohl[1], C. Ripoll[1], A. Zipprich[1].
[1]*Department of Internal Medicine I, Martin-Luther-University Halle-Wittenberg, Halle (Saale), Germany*
E-mail: marcus.hollenbach@medizin.uni-halle.de

Background and Aims: Formation of ROS is an important mechanism in the pathogenesis of cirrhosis leading to release of proinflammatory cytokines and activation of NF-kB. ROS result, amongst others, from high concentrations of methylglyoxal (MGO) causing cytotoxicity. MGO is metabolized by glyoxalase-I (Glo-I). However, the expression and activity of Glo-I as catalytic enzyme in reduction of MGO during development of cirrhosis has not been elucidated so far. The aim of this study was to analyze Glo-I during the development of cirrhosis in hepatocytes (HEP), hepatic stellate (HSC) and sinusoidal endothelial cells (SEC).
Methods: Specific activity, protein- and mRNA-levels of Glo-I were measured via kinetics, western-blot, RT-PCR, immunohistochemistry and ELISA in liver cell-lines and primary liver cells (HEP, HSC, SEC) from normal and cirrhotic rats with early and advanced cirrhosis (CCl_4 treatment for 8 [8w] and 12 [12w] weeks, respectively). HSC were stimulated by LPS (100 ng/ml) for 24 hours in presence and absence of higher dosis of ethyl pyruvate (EP; 20 mM), that decreases MGO. Fibrosis (collagen-I, α-SMA) as well as inflammatory (TNF-α, NF-kB, p-ERK, nrf2) markers were measured to identify the anti-fibrotic and anti-inflammatory effects of EP.
Results: Expression of Glo-I was reduced in early and advanced cirrhosis in whole liver (8w: 34.3±4.2%; 12w: 18.4±2.1%; $p < 0.001$) as well as HEP (8w: 39.1±13.6%; 12w: 41.4±12.0%; $p = 0.018$), HSC (8w: 58.1±9.4%; 12w: 15.9±4.2%; $p = 0.032$) and SEC (8w: 51.2±9.0%; 12w: 16.8±5.8%; $p < 0.001$) compared to normal (100%). 24 h-treatment of HSC with EP led to concentration-dependent reduction of LPS-induced production of TNF-α (−/+ 20mM EP: 397.1±71.3 / 121.0±28.2 pg/ml, $p = 0.06$) as well as collagen-I (−/+ 20mM EP: 9.9±0.9 / 1.16±0.5 ng/ml, $p < 0.001$) and alpha-α (−/+ 20mM EP: 76.7±2.0 / 52.9±2.0 ng/ml, $p < 0.001$). Effects were mediated via reduction of NF-kB (compared to normal: LPS: 137.5±4.4; LPS+20mM EP: 84.4±2.6%; $p < 0.001$), p-ERK (compared to normal: LPS: 217.3±25.1;% LPS+20mM EP: 103.9±13.4%; $p < 0.01$) and stimulation of nrf2 (compared to normal: LPS: 69.1±3.2%; LPS+20mM EP: 168.1±8.1%; $p < 0.001$).

Conclusions: Glo-I expression is reduced in cirrhosis, including hepatic stellate cells, sinusoidal endothelial cells and hepatocytes. EP regulates MGO-levels by Glo-I in activated HSC leading to reduction of fibrosis and inflammation. Therefore, MGO by leading to higher amounts of ROS could play an important role in the development of cirrhosis.

P0107

REDUCED ABUNDANCE OF MINERALOCORTICOID RECEPTOR IN CIRRHOSIS: A MECHANISM THAT IS LINKED TO HYPOXIA AND PROINFLAMMATORIC CYTOKINES

A. Wolf[1], B. Schreier[2], S. Mildenberger[2], S. Pohl[1], S. Rabe[2], A. Thonig[1], M. Gekle[2], A. Zipprich[1]. *[1]University Clinic for Internal Medicine I, Martin-Luther-University, [2]Julius-Bernstein-Institute of Physiology, Martin-Luther-University, Halle, Germany*
E-mail: anja.wolf@medizin.uni-halle.de

Background and Aims: Aldosterone induces fibrosis in liver through the mineralocorticoid receptor (MR). During development of cirrhosis the activation of renin-angiotensin-aldosterone-system results in higher levels of aldosterone. The aim of this study was to investigate the role of MR during the development of cirrhosis.
Methods: Male wistar rats were treated 5, 8 or 12 weeks (w) with CCl_4. Livers where excised and either conserved or treated for isolation of hepatocytes (pRH), hepatic stellate cell (pHSC) or endothelial cells (pLSEC). Gene expression was analyzed by realtime qRT-PCR. To gain more insight into the importance of MR in liver cirrhosis, HepG2 cells were treated with a combination of hypoxia and cytokines, mimicking conditions during development of cirrhosis, either with or without eplerenone (MR antagonist) or aldosterone (10 nM).
Results: In hepatocytes MR-mRNA was decreased after 12w CCl_4 treatment ($-\Delta\Delta$Ct: -1.46 ± 0.39 compared to control; $p<0.05$) compared to normal. In comparison, in pHSCs and pLSECs no alterations could be observed. Interestingly MR-mRNA content seemed to be higher in pRH (20-fold) compared to pHSC and pSEC in cirrhotic livers. To investigate if the alteration in MR expression leads to a change in MR dependent gene expression, serum and glycocorticoid regulated kinase (SGK-1) was analyzed. After 12w of CCl_4 treatment SGK-1 mRNA was reduced in whole liver lysate ($-\Delta\Delta$Ct: -3.88 ± 0.99 compared to control; $p<0.05$), pRH ($-\Delta\Delta$Ct: -1.26 ± 0.49 compared to control; $p<0.05$), but not in pHSCs ($-\Delta\Delta$Ct: 1.15 ± 1.07 compared to control; $p=0.40$) and pLSECs ($-\Delta\Delta$Ct: -0.77 ± 0.89 compared to control; $p=0.52$). To investigate the mechanism of MR regulation, HepG2 cells were incubated in mimicked cirrhotic milieu. While under normal conditions stimulation by aldosterone of the MR receptor was seen. MR protein expression decreases under combination of hypoxia and cytokine conditions regardless of presence of aldosterone or eplerenone.
Conclusions: In the liver the MR is mainly localized in hepatocytes. During cirrhosis the MR abundance is reduced. We propose that this is mediated by hypoxia and cytokines.

P0108

OVEREXPRESSION OF THE GENETIC EFFECTOR PATHWAY OF INFLAMMASOME IN PERIPHERAL BLOOD MONONUCLEATED CELLS (PBMC) OF PATIENTS WITH ACUTE ON CHRONIC LIVER FAILURE

E. Gola[1], A. Brocca[1], S. Piano[1,2], A. Sticca[1], F. Morando[1], S. Rosi[1], M. Cavallin[1], M. Stanco[1], A. Romano[1], S. Fasolato[2], P. Angeli[1,2]. *[1]Department of Medicine, [2]Unit of Hepatic Emergencies and Liver Transplantation, University of Padova, Padova, Italy*
E-mail: pangeli@unipd.it

Background and Aims: Acute on chronic liver failure (ACLF) is a severe complication of cirrhosis characterized by organs failure and a high short-term mortality. Inflammation may be relevant in the pathophysiology of ACLF. Inflammasome is a multi-complex protein involved in the inflammatory immune response. We aimed to investigate the expression of genetic effector pathway of inflammasome in PBMCs of patients with ACLF and its prognostic relevance.
Methods: Seventy-two consecutive patients hospitalized for an acute decompensation of cirrhosis were included in the study and followed prospectively (group 1). Fifteen outpatients with uncomplicated cirrhosis were also included (group 2). Clinical, laboratory data and blood sample were collected at the admission in patients of group 1 and during a scheduled visit in those of group 2. Plasma levels of TNF-α, IL-6 were assessed by ELISA. Gene expression levels of NF-kB, Caspase-3, Caspase-1, TNF-α and IL-1β in peripheral blood mononucleated cells (PBMCs) was assessed by means of real time PCR.
Results: ACLF was diagnosed in 21 (29.2%) of patients in group 1. Patients with ACLF showed higher MELD score (26.5vs14; $p<0.001$) and CTP (11vs10; $p<0.05$). Plasma levels of TNF-α and IL-6 were found to be significantly higher patients in group 1 than in patients in group 2 ($p<0.05$ and $p<0.001$, respectively). In group 1, the plasma levels of TNF-α and IL-6 were found to be significantly higher in patients with ACLF than in those without ACLF (38.9vs20.2 pg/mL, $p<0.05$; 34.9vs15.4 pg/mL, $p<0.05$, respectively). Gene expression levels of NF-kB (35.26 vs 2.18; $p<0.03$), caspase-3 (29.55 vs 1.8; $p<0.03$), caspase-1 (75.57 vs 3.25; $p<0.05$), TNF-α (95.01 vs 2.8; $p<0.05$) e IL-1β (65.12 vs 18; $p<0.05$) were significantly higher in PBMCs from ACLF vs no-ACLF patients. In group 1, the mortality rate was significantly higher in patients with ACLF vs patients without ACLF (77.8 vs 37.5%; $p<0.004$). In group 1, gene expression levels of NF-kB (34.84 vs 2.18; $p<0.01$), Casp1 (69.56 vs 3.25; $p<0.03$), Casp3 (32.38 vs 1.89; $p<0.005$), TNFα (71.82 vs 2.81; $p<0.01$), IL-1β (63.66 vs 15.62; $p<0.03$) were higher in non survivors than in survivors.
Conclusions: Our data confirm that an excessive inflammation is involved in the pathophysiology of ACLF in patients admitted to hospital for an acute decompensation of cirrhosis. An overexpression of the genetic effector pathway of inflammasome in PBMC is a relevant mechanism of the excessive inflammation in patients with ACLF with a potential negative impact on survival.

ELEVATION OF CATHEPSIN L AND B EXPRESSION IN LIVER FIBROSIS: A STUDY IN MICE MODELS AND PATIENTS

M. Manchanda[1], E. Roeb[2], M. Roderfield[2], S.D. Gupta[3], P. Das[3], R. Singh[1], S.S. Chauhan[1]. *[1]Biochemistry, All India Institute of Medical Sciences, Delhi, India; [2]Gastroenterology, Justus-Liebig-University, University Hospital UKGM, Giessen, Germany; [3]Pathology, All India Institute of Medical Sciences, Delhi, India*
E-mail: mansimann16@gmail.com

Background and Aims: Liver fibrosis and cirrhosis are characterized by excessive accumulation of extracellular matrix proteins as a result of wound healing response of liver to sustained injury. Extracellular matrix proteins deposited during liver fibrosis are well known substrates of cathepsin L (CTSL) and B (CTSB) which exhibits potent collagenolytic and elastinolytic activity. Present study was undertaken to investigate the expression of the potent ECM degrading proteases CTSL and CTSB in two different murine hepatofibrotic models and archival liver biopsy of patients.
Methods: In vivo hepatic fibrosis was induced by repeated intraperitoneal injections of CCl_4 for 10weeks in Swiss albino mice. Establishment of fibrosis was confirmed and expression of CTSL and CTSB as measured by qRT-PCR and immunohistochemistry (IHC). Liver tissues of phospholipid flippase ($Mdr2^{-/-}$) knockout mice at 4, 8 and16 weeks of age displaying the characteristics of primary biliary fibrosis were also included in the study to quantify the expression of CTSL and CTSB by qRT-PCR and (IHC). Further the expression of CTSL and CTSB by IHC was evaluated in patients with

severe liver cirrhosis and in patients with mild or no fibrosis along with biopsies of normal livers.
Results: CTSL was found to be significantly up regulated in CCL4 induced fibrotic mice (n = 5) at both RNA and protein level as compared to control mice olive oil treated (n = 6) while no significant change was evident in CTSB levels. The level of CTSL was found to be significantly upregulated by 1.5 and 1.8 fold in mdr2$^{-/-}$ as compared to wild type controls in 4 (n = 7) and 8 weeks (n = 8) old group of mice respectively whereas no changes was observed in 16 week old mdr2$^{-/-}$ mice as compared to the age matched wild type controls. Similarly CTSB expression was observed to be significantly higher in 4 week old mdr2$^{-/-}$ mice as compared to the wild type counterparts where as 8 and 16 old cohort of mice did not show any significant changes. Similar results were obtained when liver tissues from these groups of mice were stained for CTSL and CTSB. CTSL was found to be upregulated in liver samples of fibrotic patients (n = 10) as assessed by IHC and its expression increases with increasing grade of liver fibrosis. However, no significant changes in CTSB expression were observed in these samples.
Conclusions: CTSL expression increases with the extent of the severity of liver fibrosis in different murine models as well as in patient diagnosed with this pathology.

P0110
ACTIVATION OF MYOSTATIN AND MURF-1 IS INVOLVED IN MUSCLE WASTING IN MICE MODEL OF PRIMARY BILIARY CIRRHOSIS

M. Giusto[1], A. Musarò[1], F. Di Sario[1], E. Rizzuto[1], C. Nicoletti[1], A. Renzi[1], E. Gaudio[1], M. Merli[1]. *[1]"Sapienza" University of Rome, Rome, Italy*
E-mail: gmichela82@yahoo.it

Background and Aims: Muscle wasting is a common feature in cirrhosis. Myostatin is well recognized as a negative regulator of muscle growth and differentiation. We therefore investigated if myostatin also contributes to muscle wasting in an experimental model of primary biliary cirrhosis (PBC).
Methods: 12-week old male wild-type (FVB) mice were used. PBC was induced by bile duct ligation (BDL). Control animals underwent bile duct exposure only (sham operated, SO). Five weeks after BDL, body weight was recorded and mice were sacrificed. Liver and spleen were removed and weighted. Liver histological analysis was performed to confirm PBC. Peripheral muscles were rapidly dissected at the sacrifice and weighed. Contractile properties of extensor digitorum longus (EDL) and soleus were studied in vitro in both isometric and isotonic conditions. Muscle samples were then rapidly stored for histological and biological analysis. mRNA expression for myostatin was evaluated together with components of the ubiquitin-proteasome system.
Results: Results refer to ten mice, 5 BDL and 5 SO. At the end of 5 weeks, a significant reduction in whole body weight of BDL mice respect to SO was observed. PBC was histological confirmed in all the BDL mice. Compared with SO controls, BDL mice had a reduction in skeletal muscle weights, mainly in quadriceps and gastrocnemius. A significant reduction in muscle cross sectional area was also observed. Muscle wasting was also associated with a reduction in maximum specific force and with a decrease in the resistance to fatigue in EDL muscles. A significant increase in myostatin expression in BDL mice with respect to SO was observed. Because previous studies on cachectic experimental animal models suggest that myostatin induces muscle atrophy by activating the expression of components of the ubiquitin-proteasome, we have also investigated the expression of Atrogin-1 and MuRF-1. An upregulation of MuRF-1 expression was confirmed in BDL mice with respect to SO control, while atrogin expression was similar in the two groups.
Conclusions: Muscle wasting is a characteristic complication in experimental models of PBC. Loss of skeletal muscle mass is associated with a reduction of muscle contractile capability, with a more selective involvement of fast-twitch fibers. The increased expression of myostatin and MuRF-1 suggested that a reduction in protein synthesis together with the activation of ubiquitin pathway are responsible for muscle wasting in this model of liver cirrhosis.

P0111
WHAT MIGHT BE THE ROLE OF DUCTULAR REACTION IN LIVER CIRRHOSIS?

A.A. Rókusz[1], K. Dezső[1], E. Bugyik[1], V. Szabó[1], A. Szücs[1], S. Paku[2], P. Nagy[1]. *[1]Ist Department of Pathology and Experimental Cancer Research, Semmelweis University, [2]Tumor Progression Research Group, Joint Research Organization of the Hungarian Academy of Sciences and Semmelweis University, Semmelweis University, Ist Department of Pathology and Experimental Cancer Research, Budapest, Hungary*
E-mail: rokusza@hotmail.com

Background and Aims: The ductular reaction is a standard component of liver cirrhosis. However, its role in the process is debated. The close relationship between the ductular cells and myofibroblasts suggests a function for them in the process of fibrogenesis. It has been also proposed that the decreasing mitotic activity of the senescent hepatocytes is balanced or replaced by the proliferation and differentiation of ductular cells. We have addressed these issues in human cirrhotic livers and studied the dynamics of hepatic fibrosis in two well-known experimental models.
Methods: Fifty-six explanted human cirrhotic livers were analyzed by morphometry. The extent of fibrosis was characterized by Picro-Sirius red staining, smooth muscle actin (SMA), cytokeratin 7 (CK7) and Ki-67 immunohistochemical staining was also performed on representative histological sections.
Hepatic fibrosis was induced in male C57Bl/6 mice by thioacetamide (TAA; 300 mg/l in drinking water) and phenobarbital/carbon tetrachloride (PhB/CCl_4; 0.5 g/l in drinking water/0.2 ml/kg twice a week). The animals were sacrificed after 6, 9, 12, 15 and 18 weeks of treatment. The same morphometric parameters were studied as on the human samples (except SMA), and the proliferative activity was characterized by bromodeoxyuridine (BrdU) incorporation.
Results: In the human samples the Picro-Sirius stained fibrotic area correlated positively with the thickness of fibrous bundles, and the extent of SMA (myofibroblast) positivity. The extent of SMA staining increased parallelly with the CK7 positive ductular reaction. We found low proliferative activity in hepatocytes and ductular cells in all of our samples (in most cases below 1%). The proliferative activity of the hepatocytes correlated positively with the Ki-67 labeling of the ductular cells but inversely with the septum thickness. Both experimental animal models were characterized by slowly progressing fibrosis, with low but mostly constant level of hepatocyte proliferation. The extent of ductular reaction slowly increased, however the proliferative activity of the ductular cells decreased with time in the TAA model. Neither of these two parameters changed significantly in the PhB/CCl_4 model.
Conclusions: Both our human and experimental data support the potential connection among ductular reaction, myofibroblast activity and fibrosis, but contradict the proposed compensatory growth function of the ductular cells.

CYTOPATHOLOGICAL CHANGES ASSOCIATED WITH HEPATOCYTE SENESCENCE DURING EVOLUTION OF CIRRHOSIS AND MONITORING SENESCENCE IN CELL CULTURE SYSTEM (Huh7 CELLS)

B. Sen[1], C. Bihari[2], A. Rastogi[2], N. Trehanpati[1], S. Sharma[1], S.K. Sarin[3], G. Ramakrishna[1]. *[1]Research, [2]Pathology, [3]Hepatology, institute of liver and biliary sciences, new delhi, India*
E-mail: gayatrirama1@gmail.com

Background and Aims: Cellular senescence is a permanent growth arrest condition involved in process of ageing and tumor suppression. Identification of senescent cells is challenging particularly in primary tissues. Purpose of this study was to evaluate cytopathological features associated with senescence in conditions of cirrhosis and following doxorubicin treatment in hepatocellular carcinoma cell line (Huh7).
Methods: Huh7 cells were treated with low dose of doxorubicin (2μM, 2 hr) to induce premature senescence, which was evaluated by morphology (bright field microscopy and electron microscopy), SA-β-galactosidase staining and p21 expression. Liver sections from pre-cirrhotic (Metavir stage3) and cirrhotic conditions (Metavir stage4) were evaluated for presence of senescent like cells by combination of p21 expression together with cytomorphological feature of nuclear enlargement and vacuolation.
Results: Doxorubicin treated Huh7 cells showed enlarged cytomorphology, multinucleation, and positivity for SA-β-galactosidase activity coupled with G2/M phase cell cycle arrest indicative of premature senescence. Huh7 senescent cells showed accumulation of autophagic vacuoles, prominent lysosomes and mitochondrial-endoplasmic reticulum coupling. Compared to pre-cirrhotic condition, the hepatocytes in cirrhotic liver showed higher percentage of p21 nuclear immunoreactivity with prominent nuclear vacuolation (Precirrhotic 2.74+ 0.33, Cirrhotic 7.35+1.6; $P < 0.006$) and increased nuclear volume (Precirrhotic 147.46+9.28, Cirrhotic 202.32+10.2, $P < 0.0005$). In cirrhosis, p21 expression was more around periseptal region whereas in precirrhosis, it appeared uniform throughout the lobule.
Conclusions: Premature senescence in both in vitro and in vivo conditions showed cytomorphological changes indicative of adaptive response of senescent cells. Additionally increased p21 expression coupled to nuclear vacuolation appears as a good marker to identify senescent cells in primary tissues.

P0113

REGIONAL CEREBRAL WATER CONTENT IN HEPATIC ENCEPHALOPATHY MEASURED BY MRI

G. Dam[1], K.L. Thomsen[1], V. Gras[2], H. Vilstrup[1], P. Ott[1], M. Wintherdahl[3]. *[1]Department of Hepatology and Gastroenterology, Aarhus University Hospital, Aarhus, Denmark; [2]Institute of Neuroscience and Medicine, Jülich, Germany; [3]Department of Nuclear Medicine and PET Center, Aarhus University Hospital, Aarhus, Denmark*
E-mail: gitte_dam@hotmail.com

Background and Aims: The pathophysiology of hepatic encephalopathy (HE) may involve cellular cerebral edema due to osmotic swelling caused by glutamine accumulation. However, this has only been studied in patients with covert HE or by indirect methods like diffusion tensor imaging (DTI). DTI parameters only give information about water molecule diffusion whereas quantitative estimation of absolute brain tissue water content by magnetic resonance imaging (MRI) offers precise characterization of the micro-structural changes.
Methods: We measured the absolute brain water contents and DTI parameters with anatomical resolution by MRI in 8 cirrhosis patients during an episode of overt HE type C. Six patients with cirrhosis and no history of HE and 12 healthy age matched control subjects were also scanned. Three of the HE patients were rescanned after recovery from HE. The images were normalized to the Montreal Neurological Institute Standard Brain and volumes of interest from a probabilistic brain atlas were used for image analysis.
Results: Temporal lobe water was 86±0.03%, 85±0.04%, and 82±0.04% in HE, cirrhosis, and controls, respectively. The corresponding cerebellum water was 86±0.02%, 84±0.03%, and 82±0.02%. The frontal lobe water was 84±0.03% in both HE and cirrhosis patients and 82±0.02% in the controls ($P < 0.05$, all regions HE vs. controls). The whole brain water contents of the three patients with overt HE fell after recovery by 1±0.02%. DTI parameters revealed changes in the white matter that correlated with the absolute water content.
Conclusions: Our data quantitatively demonstrate low-grade cerebral edema in several brain regions in patients with overt HE and suggest that the brain edema may be reversible with recovery from HE. Furthermore our data support that changes in DTI parameters can be used as an indirect measure of alterations in the absolute water content.

P0114

CIRRHOSIS IS ASSOCIATED WITH AVASCULAR NECROSIS, BUT NOT OSTEOARTHRITIS – A DANISH POPULATION-BASED STUDY

T. Deleuran[1,2], H. Vilstrup[1], S. Overgaard[3,4], P. Jepsen[1,2]. *[1]Department of Hepatology and Gastroenterology, [2]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, [3]Department of Orthopedic Surgery and Traumatology, Odense University Hospital, [4]Institute of Clinical Research, University of Southern Denmark, Odense, Denmark*
E-mail: thomas.deleuran@dce.au.dk

Background and Aims: Cirrhosis causes systemic inflammation, but it is unclear whether it increases the risk of joint disease. We aimed to examined the association between cirrhosis and two joint diseases: osteoarthritis of the hip or knee, and avascular necrosis.
Methods: We used the Danish National Patient Registry to identify all Danish residents diagnosed with cirrhosis in 1994–2011 and matched them 1:5 by age and gender to non-cirrhotic reference individuals from the general population. We excluded persons with a previous diagnosis for osteoarthritis, avascular necrosis, and fractures of the hip, distal femur, patella or proximal tibia. We used stratified Cox regression to compute the hazard ratios (HR) for osteoarthritis and avascular necrosis for cirrhosis patients vs. reference individuals adjusted for comorbidity including alcohol related disease. We used the cumulative incidence function with death as competing risk to compute the 5-year risk of osteoarthritis and avascular necrosis.
Results: We identified 52,752 patients with cirrhosis and 263,760 reference individuals. The median age was 57 years, and 65% were men. We excluded 40% of cirrhosis patients and reference individuals because they had a history of an outcome or a relevant fracture. The HR for osteoarthritis in cirrhosis patients compared to reference individuals was 0.94 (95% CI: 0.54–1.66). Cirrhosis patients' HR for avascular necrosis was 8.42 (95% CI: 2.44–29.1). The 5-year risk of developing osteoarthritis was highest for reference individuals (3.3% vs. 2.2%) and both groups' 5-year risk of avascular necrosis was less than 0.1%.
Conclusions: Cirrhosis is unrelated to osteoarthritis, but is a strong risk factor for avascular necrosis, although it remains a rare condition.

P0115

SERUM BILE ACIDS IN CIRRHOSIS DEPEND ON AETIOLOGY

A. Horvath[1], B. Leber[2], E. Krones[1], G. Zollner[1], F. Durchschein[1], W. Spindelboeck[1], S. Lemesch[1], P. Douschan[1], G. Fauler[3], T. Stojakovic[3], P. Fickert[1], R. Stauber[1], P. Stiegler[2], V. Stadlbauer[1].
[1]Division for Gastroenterology and Hepatology, [2]Department for Tranplantation Surgery, [3]Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University of Graz, Graz, Austria
E-mail: angela.horvath@medunigraz.at

Background and Aims: Elevated serum levels of bile acids are suggested to be diagnostic tools as well as predictors for mortality. Bile acids are metabolized by gut bacteria and therefore their composition depends on microbiome alterations. Furthermore bile acids can modulate gut permeability. Both microbiome and gut permeability are likely to differ between aetiologies. Therefore we hypothesize that bile acid concentrations in serum of various forms of cirrhosis are different form each other.
Methods: Bile acid profiles (cholic acid, deoxycholic acid, chenodeoxycholic acid, lithocholic acid, ursodeoxycholic acid) of 101 cirrhotic patients (56 alcoholic, 20 chronic hepatitis C, 25 others) and 10 healthy controls were determined as unconjugated acids and as taurine and glycine conjugates using a tandem mass spectrometry method. Gut permeability marker diamine oxidase and sCD14 were measured by ELISA, sucrose recovery and lactulose-mannitol-ratio by differential sugar absorption test (HPLC).
Results: When compared to healthy controls all cirrhotic groups show a higher abundance of conjugated bile acids in the serum which is particularly high in alcoholic cirrhosis. Patients with hepatitis C induced cirrhosis show normal values of unconjungated bile acids, while alcoholic and other aetiologies have significantly increased levels. Alcoholic cirrhosis is associated with the steepest increase in serum bile acids, with average values approximately 20 times higher than in healthy controls and 2–3 times higher than in other types of cirrhosis. Gut permeability is also elevated in all cirrhosis groups and highest in alcoholic cirrhosis. Nevertheless no clear association between serum bile acids and permeability marker could be found. Also ursodeoxycholic acid levels in serum were not associated with gut permeability.
Conclusions: Serum bile acid concentration and composition is strongly dependent on aetiology of cirrhosis. A possible explanation could be that the microbiome is subjected to different modulators like alcohol consumption, low bowel motility, antibiotic treatments etc. which might vary considerably between aetiologies. A closer look into the microbiome of cirrhotic patients could bring valuable answers. Associations between gut permeability were weak and their clinical relevance is questionable.

INFECTION IN HOSPITALIZED CIRRHOTIC PATIENTS AND DIABETES MELLITUS: IS THERE A LINK?

S. Giestas[1], A. Giestas[2], C. Agostinho[1], C. Sofia[1]. *[1]Gastroenterologia, Centro Hospitalar Universitario Coimbra, Coimbra, [2]Endocrinologia, Centro Hospitalar Entre o Douro e Vouga, Santa Maria feira, Portugal*
E-mail: silviagiestas@gmail.com

Background and Aims: Infection is a frequent complication in patients with chronic hepatic disease (CHD) which contribute to a significant morbidity and mortality. Diabetes mellitus (DM) is a predictive factor for infection and its prevalence is higher in patients with CHD. Aims: To evaluate the prevalence of DM in patients with CHD and determinate the association between DM and infection.
Methods: Retrospective analysis of the clinic data of hospitalized patients with CHD admitted in a gastroenterology ward. Patients were divided in two groups: A-with infection, B-without infection. Basic demographic data, past medical history, clinic and laboratory data, type of infection, severity of liver disease and mortality were compared in both groups. Excluded: incomplete data, patients with neoplasm or immunosuppressed, hospitalization or use of antibiotics/immunosuppressive drugs in the last 3 months, gastrointestinal bleeding, institutionalized patients.
Results: 100 patients were included (A-55, B-45), 81.6% were male and mean age was 61.2±11.4 years. DM prevalence was 33% (A-23, B-10), significantly higher in group A (41.8% vs 22.2%). Main causes of infection: spontaneous bacterial peritonitis (34.5%), urinary tract infection (29%) and respiratory infection (25.5%). There was no statistically significant difference in the cause of infection between both groups ($p > 0.05$). Demographic data, etiology and severity of liver disease were similar in both groups ($p > 0.05$) and between diabetic and non-diabetic patients ($p < 0.05$). Univariate analysis of laboratory parameters shows significant difference ($p < 0.05$) in both groups (A-B) regarding fasting blood glucose (187±37.4 vs 95.8±9.2 mg/dL) serum albumin (2.9±0.4 vs 3.3±0.68 mg/dL), leukocytes (11.7±2.3 vs 5.4±1.8×10^9/L) and c-reactive protein levels (5.2±3.2 vs 1.9±2.4 mg/dL). The number of hospitalization days (18.2±4.2 vs 9.8±3.8 days) and mortality rate (27.3% vs 4.4%) was higher in group A ($p < 0.05$), without difference between diabetic and non-diabetic patients ($p > 0.05$).
Conclusions: This study concludes that there is a higher prevalence of diabetes mellitus in hospitalized patients with CHD, mainly those with infection.

PHASE 1–2 CLINICAL TRIAL IN PATIENTS WITH DECOMPENSATED LIVER CIRRHOSIS TREATED WITH BONE-MARROW DERIVED ENDOTHELIAL PROGENITOR CELLS

D. D'Avola[1], V. Fernandez-Ruiz[2], F. Carmona de la Torre[3], M. Mendez[2], F. Prosper[4], E. Andreu[4], J.I. Herrero[1], M. Iñarrairaegui[1], C. Fuertes[3], B. Sangro[1], J. Prieto[1,2], J.I. Bilbao[5], J. Quiroga[1]. *[1]Liver Unit and Ciberehd, Clinica Universidad de Navarra, [2]Hepatology and Gene therapy, Centro de Investigación Medica Aplicada (CIMA), [3]Liver Unit, [4]Hematology and Cell Therapy, [5]Radiology, Clinica Universidad de Navarra, Pamplona, Spain*
E-mail: ddavola@unav.es

Background and Aims: Bone marrow-derived endothelial progenitor cells (EPC) seem to promote liver regeneration and improve survival in animal models of acute and chronic liver disease.
The aim of this clinical trial was to evaluate the safety, the efficacy and the feasibility of the treatment with autologous EPC in decompensated liver cirrhosis and to analyse the relation between the characteristics of the cellular product and the effect on liver funtion and portal pressure.
Methods: Patients with Child–Pugh ≥8 liver cirrhosis were included. Bone marrow (BM) blood (50 ml) was withdrawn for *ex vivo* differentiation and selection of EPC. The final product was resuspended in 50 ml and injected via hepatic artery. Patients underwent clinical, biochemical and radiological follow-up for 12 months. Surface markers (CD133, CD34, CD117, VEGFR-2 and-1, CD31, vWF) and functional activity of EPC (acLDL-uptake and Ulex-lectin binding) were analysed by flow cytometry. HGF, VEGF, IGF-1, IL-6, EGF, SDF-1 and CT-1 were determined by ELISA in supernatant before administration.
Results: Twelve out the 14 patients included underwent BM harvest. EPCs were generated from BM mononuclear cells and 11 patients were treated (global feasibility 91%). Three patients died

at day 25, 85 and 166. No treatment-related severe adverse events after a median follow-up of 182 days (range 27–364) were observed. A significant improvement of MELD score (p 0.042) and INR (p 0.012) was observed in the first 90 days after treatment. Considering the 9 patients alive at 90 days, hepatic venous portal pressure (HVPG) improved in 5 patients (55.5%), remained stable in 2 (22.2%) and worsened in 2 patients (22.5%). Phenotype analysis showed that patients with an improvement of MELD score received an higher amount of cells expressing VEGFR-2 (13.8% vs 23.2%;p 0.024), vWF (72% vs 98%;p 0.048) and Ac-LDL uptake ability (21.7% vs 72.1%;p 0.048) compared to patients who did not improved. Moreover, the cells infused in patients showing MELD score improvement tended to produce higher amounts of IGF-1 and HGF

Conclusions: The treatment with BM-EPCs in patients with decompensated cirrhosis is safe an feasible and might have therapeutic potential. Patients treated with a cellular solution with an higher amount of functionally active EPC showed an improvement of liver function suggesting that these cells could be useful for the treatment of liver cirrhosis. A refinement in the process of cell selection may be critical in order to enhance the therapeutic effect.

P0119

VALIDATION OF THE NACSELD INFECTION-RELATED ACUTE-ON-CHRONIC LIVER FAILURE (I-ACLF) SCORE IN AN INDEPENDENT MULTICENTER COHORT

J.G. O'Leary[1], K.R. Reddy[2], G. Garcia-Tsao[3], S.W. Biggins[4], F. Wong[5], M.B. Fallon[6], R. Subramanian[7], P.S. Kamath[8], P. Thuluvath[9], B. Maliakkal[10], H. Patton[11], P. Tandon[12], L.R. Thacker[13], J.S. Bajaj[13], on behalf of NACSESLD. *[1]Medicine, Baylor University Medical Center, Dallas, [2]Medicine, University of Pennsylvania, Philadelphia, [3]Medicine, Yale University, New Haven, [4]Medicine, University of Colorado, Denver, United States; [5]Medicine, University of Toronto, Toronto, Canada; [6]Medicine, University of Texas, Houston, Houston, [7]Medicine, Emory University, Dallas, [8]Medicine, Mayo Clinic, Rochester, [9]Medicine, Mercy Medical Center, Baltimore, [10]Medicine, University of Rochester, Rochester, [11]Medicine, University of California San Diego, San Diego, United States; [12]Medicine, University of Alberta, Edmondton, Canada; [13]Medicine, Virginia Commonwealth University, Richmond, United States*
E-mail: jacquelo@baylorhealth.edu

Background and Aims: The infection-related acute-on-chronic liver failure (I-ACLF; ≥2 extra-hepatic organ failures) assessment is based on extra-hepatic organ failures, and was developed in a prior multicenter prospectively enrolled cohort of infected cirrhotic patients (NACSELD North American Consortium for the Study of End-Stage Liver Disease, Hepatology 2014). Assessment of extra-hepatic organ failures has been proposed as a simple bedside tool to assess mortality risk in admitted infected cirrhotic patients. *Aim:* To validate the accuracy of I-ACLF's ability to predict 30-day mortality (defined as in-hospital death or discharge to hospice) in a separate multicenter prospectively enrolled cohort of infected cirrhotic patients.
Methods: We utilized another cohort in the NACSELD database of tertiary care hepatology centers that prospectively enroll admitted cirrhotic patients (n = 816). We selected patients with an infection (n = 336) for this comparison with the original cohort. Organ failures assessed were: (1) shock, (2) encephalopathy (West-haven grade III/IV; HE), (3) renal (need for dialysis), and (4) respiratory (mechanical ventilation).
Results: Infected cirrhotic patients were most commonly Caucasian (79%) men (61%) with a mean age of 57 who had alcohol-induced cirrhosis (43%). Admission lab values were: creatinine 1.43 mg/dL, serum albumin 2.64 mg/dL, and median MELD and Child score were 19, and 10 respectively. Similar to the prior experience, we found that 30-day survival decreased with increasing numbers of organ failures; survival was 95% in patients without organ failure, 68% in those with 1, 46% in those with 2, and 33% in those with 3 organ failures (Table 1). The greatest decrement in survival occurred when patients met criteria for I-ACLF. Multivariable modeling documented that I-ACLF was the strongest predictor of death (OR of survival = 0.10, CI 0.04–0.25) after controlling for admission MELD (OR = 0.93, CI 0.88–0.98), WBC (OR = 0.71, CI 0.42–1.21), serum albumin (OR = 1.06, CI 0.55–2.04), and second infection (OR = 1.30, CI 0.47–3.56).

Table 1

	30-day survival		
Organ failure	Without organ failure	With organ failure	p-value
HE	91%	64%	<0.0001
Renal	91%	43%	<0.0001
Shock	93%	50%	<0.0001
Renal	91%	43%	<0.0001
Any One	95%	68%	<0.0001
I-ACLF (Extra-hepatic organ failures)			
Any two	94%	46%	<0.0001
Any three	91%	33%	<0.0001

Conclusions: I-ACLF has been independently validated in a separate large multicenter prospective trial as a simple bed-side tool to predict 30-day mortality in admitted infected cirrhotic patients.

P0120

THE 3-MONTH READMISSION RATE REMAINS UNACCEPTABLY HIGH IN A LARGE MULTI-CENTER COHORT OF CIRRHOTIC PATIENTS

J.S. Bajaj[1], K R. Reddy[2], G. Garcia-Tsao[3], F. Wong[4], M.B. Fallon[5], R. Subramanian[6], S.W. Biggins[7], B. Maliakkal[8], P.S. Kamath[9], P. Thuluvath[10], L.R. Thacker[1], J.G. O'leary[11], on behalf of NACSELD. *[1]Virginia Commonwealth University and McGuire VAMC, Richmond, [2]University of Pennsylvania, Philadelphia, [3]Yale University, New Haven, United States; [4]University of Toronto, Toronto, Canada; [5]University of Texas, Houston, [6]Emory University, Atlandta, [7]University of Colorado, Denver, [8]University of Rochester, [9]Mayo Clinic, Rochester, [10]Mercy Medical Center, Baltimore, [11]Baylor University Medical Center, Dallas, United States*
E-mail: jasmohan@hotmail.com

Background and Aims: Readmissions after discharge are an important indicator of care quality. However, factors associated with readmissions in cirrhosis are unclear from a multi-center perspective. *Aim:* To evaluate determinants of 3-month readmissions in a multi-center cohort of hospitalized cirrhotics.
Methods: NACSELD (North American Consortium for the Study of End-stage Liver Disease) is a multi-center database of liver centers that enroll inpatient cirrhotics. Data collected include reasons for index (when pt was enrolled) and re-admissions, medications (PPI, rifaximin, lactulose, SBP prophylaxis), cirrhosis severity at admission/discharge days. Pts discharged home were followed for 3 mths for readmissions, transplant and death. Readmission determinants were analyzed using logistic regression.
Results: 578 patients were enrolled. During index hospitalization, 77 died/went to hospice and 20 were transplanted. Thus, 481 pts (age 56 yr, 55% men, 37% HCV, 30% infection as admission reason) were analyzed. *3 month outcomes:* 77% were alive without transplant, 11% were transplanted, 12% died. *Readmissions:* 50% of patients were readmitted at least once; 56% had 1, 28% had 2, and 16% had ≥3 readmissions. These rates were similar between those admitted with/without infection (50% vs 51%, p = 0.8) during the index hospitalization. Most readmissions were infections (40%) followed by liver-related complications (17% anasarca, 11% GI bleed, 9% TIPS, 7% AKI, 5% HE) and 11% others.
Two regression models were created; *Using index hospitalization day of admission values:* A high MELD score (OR 1.1, p = 0.001),

lactulose use (corollary for HE, OR 1.6, p = 0.05) and male gender (OR 1.6, p = 0.05) predicted readmission while high serum albumin was protective (OR 0.57, p = 0.004). Infection as the index admission reason, diabetes or WBC were not predictive. *Using index hospitalization discharge values:* The only predictors of 3-month readmissions on discharge were MELD (OR 1.1, p = 0.002) and SBP prophylaxis (OR 1.95, p = 0.05). Nosocomial infections, diabetes, infections on admission and other medications were not predictive.
Conclusions: Readmissions occurred in 50% of hospitalized cirrhotics within 3 months of discharge, regardless of infections being the reason for the index admission, in this prospective multi-center study. Without intervention, these pateints likely be readmitted, most commonly for infections. Strategies to prevent readmissions are urgently needed, especially in higher MELD patients with HE and lower serum albumin who are on SBP prophylaxis.

ANGIOTENSIN II INHIBITION TO TREAT SEVERE LIVER FIBROSIS: A DOUBLE-BLIND RANDOMIZED TRIAL (ANRS HC19)

P. Cales[1], Y. Bacq[2], C. Bonny[3], J.L. Payen[4], D. Guyader[5], A. Tran[6], D. Larrey[7], C. Silvain[8], M.C. Rousselet[9], M. Simony[10], F. Oberti[11], F. Carrat[12], FIBROSAR study group. *[1]Hepatology, CHU, Angers, [2]Hepatology, CHU, Tours, [3]Hepatology, CHU, Clermont Ferrand, [4]Hepato-Gastroenterology, Hospital, Montauban, [5]Hepatology, CHU, Rennes, [6]Hepatology, CHU, Nice, [7]Hepato-Gastroenterology, CHU, Montpellier, [8]Hepato-Gastroenterology, CHU, Poitiers, [9]Pathology, CHU Angers, Angers, [10]ANRS, Paris, [11]Hepatology, CHU Angers, Angers, [12]Public Health, University, Paris, France*
E-mail: paul.cales@univ-angers.fr

Background and Aims: Cirrhosis prevention is a major target in chronic liver disease treatment. Angiotensin II type 1 receptor antagonists (ARA2) have shown anti-fibrotic properties in numerous pre-clinical and clinical studies. We thus evaluated ARA2 administration in a large patient population.
Methods: 166 patients with chronic hepatitis C (CHC) and Metavir F stages 2 or 3 were allocated to receive either irbesartan (I) 150 mg/d or a placebo (P) per os for 2 years in 27 centers. All patients had contraindications for or refused IFN-based regimens. The patients had clinical evaluation, liver biopsy, and non-invasive fibrosis tests (blood and stiffness) at inclusion and end of follow-up. Liver biopsies were centrally evaluated with Metavir staging by expert consensus and detailed automated morphometric measures including 44 descriptors, among which was porto-septal fibrosis area (main judgment criteria, Sandrini Modern Pathol 2014), to obtain morphometric scores for significant fibrosis (SF) and cirrhosis (F4).
Results: Baseline characteristics were: 58% male, age 56±9 yrs. Treatment groups were well balanced except for Metavir F at central reading, P vs I respectively, F1: 4.9 vs 1.2%, F2: 75.6 vs 63.1%, F3: 17.1 vs 33.3%, F4: 2.4 vs 2.4% (p = 0.048); this was also suggested by morphometric F4 score: 0.13±0.30 vs 0.16±0.31, p = 0.07. Paired liver biopsies were available in 79% of patients but analyzed in ITT. Changes in morphometry were, P vs I respectively: porto-septal fibrosis area: 0.43±2.19 vs 0.26±2.40%, p = 0.73; morphometric SF score: 0.02±0.28 vs 0.02±0.25, p = 0.75; morphometric F4 score: 0.08±0.36 vs 0.07±0.36, p = 0.20. There was an interaction (p = 0.002) between treatment and fibrosis stage in F4 score with opposite treatment effects between F1+F2 (0.12±0.29 vs 0.03±0.25, p = 0.04) and F3+F4 (−0.07±0.55 vs 0.15±0.49, p = 0.24). The rates of Metavir progression/regression (≥1F/≤1F) were, P vs I respectively: 12.1 vs 16.9% / 16.7 vs 14.8%, p = 0.84. Changes in liver blood fibrosis tests and stiffness were not significantly different between both treatment groups. No serious adverse events were attributed to treatment. Mean arterial pressure changes were: −3.5±11.3 vs −9.3±17.0 mmHg, p = 0.06.
Conclusions: A 2-year regimen of Irbesartan 150 mg/d did not significantly alter the course of liver fibrosis pathological patterns in CHC, even as assessed by precise morphometry. However, anti-fibrotic effect might depend on baseline fibrosis level, as already suggested.

P0122
TYPE 2 DIABETES REDUCES OVERALL SURVIVAL AND INCREASES THE RISK OF HEPATIC DECOMPENSATION IN HCV-RELATED LIVER CIRRHOSIS. RESULTS FROM A PROSPECTIVE LONG-TERM STUDY DURING 8 YEARS

E. Vilar-Gomez[1,2], L. Calzadilla Bertot[1], A. Yasells Garcia[1], Y. Martinez Perez[1], M. Romero-Gomez[2], M. Diago[3]. *[1]Hepatology, National Institute of Gastrioenterology, Havana, Cuba; [2]Unit for the Clinical Management of Digestive Diseases, Valme University Hospital, Seville, [3]Liver Unit, Valencia University Hospital, Valencia, Spain*
E-mail: eduardovilar2000@yahoo.com

Background and Aims: Type 2 diabetes mellitus (DM) frequently coexists with liver cirrhosis, and may be associated with an increased risk of complications and mortality. We examined the influence of DM/insulin resistance (IR) on overall survival and liver-related complications.
Methods: This is a prospective inception cohort study of 250 subjects with compensated HCV-related cirrhosis followed during 416 weeks. Patients with HCV who were non-responders to, ineligible for and intolerant of peginterferon plus ribavirin were included. Significant prognostic indicators for overall survival or presence of a first event of hepatic decompensation were determined using univariable and multivariable Cox regression.
Results: At baseline, 67 patients (27%) had DM. During the follow-up, 28 deaths (6 nonliver- and 22 liver-related deaths or transplant) and 55 first events of decompensation occurred. After adjustment for covariates, the overall survival was significantly lower in diabetic patients (74%; 95% CI: 67–82) than those without diabetes (88%; 95% CI: 83–92), P = 0.04. Similarly, the occurrence of a first event of hepatic decompensation was higher in presence of diabetes (64%, 95% CI: 59–70) as compared with nondiabetic patients (41%, 95% CI: 33–47), P = 0.01. Additionally, subjects with a HOMA-IR >5 showed lower rates of survival (76%, 95% CI: 67–82) than those with HOMA-IR between 3 and 5 (88%, 95% CI: 84–94), and <3 (96%, 95% CI: 91–99), P = 0.04. The presence of hepatic decompensation were higher in patients with HOMA-IR between 3 and 5 (58%, 95% CI: 52–65) and >5 (66%, 95% CI: 61–74) than those with HOMA-IR <3 (34%, 95% CI: 30–41), P < 0.001; however, no differences were found between subjects with HOMA-IR ranging between 3 and 5 and HOMA-IR >5. Cox regression analysis revealed that presence of varices (HR = 2.5), male sex (HR = 2.4), DM (HR = 1.9), platelets count (HR = 0.98), HOMA-IR >5 (HR = 1.9) and TGO/TGP ratio (HR = 2.6) were independently associated to overall mortality. In addition, presence of varices (HR = 2.9), DM (HR = 2.1), mean arterial pressure (HR = 0.95), platelets (HR = 0.98) and HOMA-IR >3 (HR = 1.98) were predictors of hepatic decompensation.
Conclusions: Our study showed that presence of DM might reduce the overall survival and increase the risk of hepatic decompensation in compensated HCV-related cirrhotic patients. Likewise, a marked IR is associated to reduced survival and increased risk of hepatic decompensation.

P0123
IMPACT OF SHUNT NEGATIVE HYPOXEMIA ON SURVIVAL IN LIVER TRANSPLANT CANDIDATES

S. Siddiqui[1], S. Batra[1], D.S. Goldberg[2], S. Kawut[2], M.B. Fallon[1], Pulmonary Vascular Complications of Liver Disease Group.
[1]Internal Medicine, Gastroenterology & Hepatology, University of Texas-Houston, Houston, [2]Internal Medicine, Gastroenterology & Hepatology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States
E-mail: sachin.batra@uth.tmc.edu

Background and Aims: Hepatopulmonary syndrome [HPS] results when intrapulmonary shunting causes hypoxemia in cirrhosis. It occurs in up to 30% cirrhotics and increases mortality. However, hypoxemia has also been observed in the absence of intrapulmonary shunting and without evidence of intrinsic lung disease in cirrhosis, but is not well characterized. We studied shunt negative hypoxemic (SNH) cirrhotics relative to control and HPS patients in a multicenter cohort of liver transplant evaluants.
Methods: Patients undergoing LT evaluation at 7 US centers (Pulmonary Vascular Complications of Liver disease Group) underwent contrast echocardiography (CE), arterial blood gases, pulmonary function tests (PFT) and chest imaging. Those with moderate to severe PFT abnormalities, portopulmonary hypertension, or intracardiac shunting were excluded. HPS was diagnosed by delayed (≥3 beats) right to left shunt on CE with an elevated A-a gradient. SNH was defined by an elevated A-a gradient without shunt on CE. Controls were defined as patients with normal A-a gradient with or without delayed shunt on CE. We compared clinico-demographic and outcome data. Overall mortality was determined using OLT as a time varying covariate and waitlist mortality with transplant as competing event.
Results: 212 patients were included with 69 (33%) HPS, 36 (17%) SNH and 107 (50%) controls. HPS, SNH and controls were similar in all clinico-demographic features except for a higher prevalence of current or past smoking, right ventricular hypertrophy, elevated A-a Gradient and reduced DLco in the SNH and HPS groups (table). Chest imaging findings were similar in all three groups. HPS and SNH had lower FVC values than controls. Over a median follow-up of 15 months, waitlist mortality occurred in 9 (25%) patients with SNH, 18 (26%) with HPS and 9 (12%) controls. On multivariate analysis adjusting for MELD, age, gender and race, risk of waitlist mortality relative to controls was found to be 6 fold (SHR: 5.7, 95% CI: 1.61–20) higher for SNH and 5 fold for HPS (SHR: 4.9, 95% CI: 1.4–17.3) patients. Overall mortality on multivariate analysis was 3 fold higher in HPS (HR: 3, 95% CI: 1.5–6) and SNH (HR: 3, 95% CI: 1.3–6) than controls.
Conclusions: Patients with SNH have increased mortality relative to controls and similar clinical-demographic features relative to HPS. Further studies are required to ascertain if SNH represents undetected intrapulmonary shunting, extrapulmonary shunting or a distinct process that alters gas exchange.

	Controls (n = 107)	HPS (n = 69)	SNH (n = 36)	p
Age	53±9	52±9	52±10	0.8
MELD	14±5	13±4	12±5	0.06

P0124
AUTOLOGOUS CD34+ STEM CELL INFUSION AS A BRIDGE TO LIVER TRANSPLANT IN DECOMPENSATED CIRRHOSIS

M. Sharma[1], S. Mitnala[1], P.N. Rao[1], D.N. Reddy[1]. *[1]Asian Institute of Gastroenterology, Hyderabad, India*
E-mail: drmithunsharma@gmail.com

Background and Aims: The increasing prevalence of liver cirrhosis coupled with the paucity of donor tissues and high cost for liver transplantation, has paved the way for evaluation of cell based regenerative therapies, particularly adult hemopoetic stem cell based treatment as an alternative of bridge to liver transplant. The aim of this study was to evaluate the effect of autologus CD 34+ stem cell infusion in decompensated cirrhosis.
Methods: Patients with liver cirrhosis having MELD score >14 were included in the study and divided into 2 groups – control (n = 23) and study group (n = 22) based on opting for standard of care treatment and autologus CD34+ cell infusion respectively. The study population were not willing for immediate living donor liver transplant (LDLT) and did not wish to be enrolled in the deceased donor liver transplant (DDLT) waiting list. The patients in the control group did not have eligible donor for LDLT and were included DDLT waiting list. In the study group, Granulocyte-Colony stimulating factor (G-CSF) was given @ 5 μgm/kg body weight for 3 consecutive days followed by leukapheresis and isolation of CD34+ cells using immune magnetic separation. CD34+ cells (count 10^6-10^8) were infused through the hepatic artery under radiological guidance. Patients were monitored and discharged within 24 hours and evaluated 4 weeks and at 3 months.
Results: The procedure was safe with no treatment related side effects. There was no incidence of hepatic artery thrombosis post procedure. At 4 weeks, in the study group, the mean serum albumin showed statistically significant (2.83±0.36 vs 2.43±0.42, p = 0.001) which was however not maintained at end of 3 months. At 3 months, there was significant improvement in serum creatinine (1.01±0.32 vs 1.24±0.50, p = 0.06) and MELD score in the study group (15.73±3.35 vs 19.42±6.52 p = 0.02). There was no significant difference in the transplant free survival between the two groups, but due to the small sample size a Kaplan Meyer graph could not be drawn.
Conclusions: Autologous stem cell therapy is a safe and effective therapy which improves MELD score at end of 3 months. It can be used to delay but not as an alternative to liver transplant. It serves as a bridge to transplant and provides a window period during which transplant may be delayed. Whether repeated infusions of stem cells can further delay or improve prognosis has to be evaluated

P0125
HEPATOPULMONARY SYNDROME (HPS) SCREENING IN PATIENTS WITH CHILD A/B LIVER CIRRHOSIS

C.A. Navascues[1], M. Angel de Jorge[1], L. González-Diéguez[1], V. Cadahía[1], M. Varela[1], S. Hevia[2], R. Fernández[3], M. Rodríguez[1].
[1]Hepatology Unit, [2]Cardiology Department, [3]Department of Respiratory Medicine, Hospital Universitario Central de Asturias, Oviedo, Spain
E-mail: canavascues99@movistar.es

Background and Aims: Most data about HPS prevalence come from studies in liver transplantation (LT) candidates. The aim of this study was to analyze HPS prevalence in patients with Child A/B cirrhosis, its natural history and the incidence of new cases along the follow up.
Methods: Arterial blood gases, spirometry and difussion study were done in all Child A/B cirrhotic patients without contraindications for LT who consulted in our Unit from 2007 to 2014. HPS was diagnosed in those with $P(A\text{-}a)O_2$ ≥15 and pulmonary vasodilatation showed in subsequent contrast ECO-cardiography. In those without HPS the study was repeated yearly through the follow up.

Variables recorded were: age, sex, tobacco, BMI, diabetes, HIV infection, etiology of the cirrhosis, Child and MELD scores, previous decompensations, presence of varices and platelet count. Data were analyzed by SPSS.

Results: 360 patients were studied, 286 male, mean age 52.09±7.09 years. Child score was A in 292 and B in 68 and mean MELD score 10±3.3. 152 patients were active smokers, HIV infection was present in 43, diabetes in 86 and gastroesophageal varices in 260. 213 patients had had liver decompensations previous to the inclusion. The etiology of the cirrhosis was alcohol in 238, HCV in 50, both in 33, HBV in 20 and others in 19.

171/360 (45.2%) patients had $P(A\text{-}a)O_2$ ≥15 mmHg in the first study. Contrast ECO-cardiography was done in 137 and showed pulmonary vasodilatation in 29; 27 of them had PO_2 >60 mmHg and only 2 PO_2 <60 mmHg. 21 patients with mild or moderate HPS were followed more than 6 months (mean follow-up 39.3±18.3 months;12–75) and none of them progressed to severe HPS. The incidence of new cases of HPS was 0.7 cases/100 persons-year (5/198 patients followed more than 1 year with a mean follow-up of 43.87±24.9 months; 6–113).

Patients with HPS were younger (49.9±6.2 vs 52.2±7, p = 0.08), had more frequently Child B score (37.9% vs 18.8%, p = 0.015) and had a higher MELD score (11.28±3.3 vs 10.03±3.3, p = 0.07) than those without HPS. There were no significant differences in the rest of the variables analyzed.

Conclusions: HPS prevalence in Child A/B cirrhotic patients was about 10%; most of them had mild or moderate hypoxemia, which remained stable through follow up. The incidence of new cases was low. Patients with HPS were younger and had more severe liver disease than those without it.

P0126

THE STROOP APP CAN PREDICT THE DEVELOPMENT OF OVERT HEPATIC ENCEPHALOPATHY IN A MULTI-CENTER STUDY

J.S. Bajaj[1], S. Allampati[2], A. Duarte-Rojo[3], K. Patidar[1], M. White[1], A. Unser[1], E. Gavis[1], J. Hovermale[1], D.M. Heuman[1], D.S. Barnes[2], B. John[2], J.S. Klair[3], C. Flud[3], L. Thacker[4]. *[1]Virginia Commonwealth University and McGuire VAMC, Richmond, [2]Medicine, Cleveland Clinic, Cleveland, [3]Medicine, University of Arkansas, Little Rock, [4]Biostatistics, Virginia Commonwealth University and McGuire VAMC, Richmond, United States*

E-mail: jasmohan@hotmail.com

Background and Aims: Testing for covert HE (CHE) is not routinely performed in part due to the unclear effect on outcomes. The Stroop App is a good test for CHE. Aim: evaluate the ability of Stroop App to predict overt HE (OHE) in a multi-center study.

Methods: Three sites [Virginia (VA), Ohio (OH) Arkansas (AR)] enrolled outpt cirrhotics (+/− OHE) and age-matched healthy controls. All subjects were given the Stroop App, psychometric hepatic encephalopathy score (PHES) and inhibitory control test (ICT). Impaired performance on PHES and ICT beyond controls was calculated to diagnose CHE as two separate gold standards to which the App OffTime+OnTime ROC analysis was compared. The cut-off with the highest AUC was used to define CHE on the Stroop App. Patients were followed for at least 6 mths till OHE development (defined as ≥ grade 2 and hospitalization). Time-dependent Cox-regression models for OHE development were created using age, baseline OHE, MELD and CHE on Stroop using either ICT or PHES as gold standards for all pts. A similar model was also tested for those without prior OHE for time to first OHE.

Results: We enrolled 387 cirrhotic patients (230 VA, 107 OH, 50 AR) and 302 controls who were used to judge impaired PHES or ICT. Patients were similar in age (57 VA, 58 OH, 56 AR, p = 0.4) but VA pts had higher %OHE (41% VA, 30% OH, 30% AR, p = 0.05). Using ICT as the gold standard (OffTime + OnTime = 181.9 seconds), 54% total (53% VA, 55% OH, 58% AR) had CHE while using PHES (OffTime + OnTime = 195.9 seconds), 39% total (40% VA, 41% OH, 26% AR) had CHE.

Entire group outcomes: On a median follow-up of 11 (IQR 8–15) mths, 13% pts developed an OHE episode (12% VA, 14% OH, 20% AR). On regression, time to OHE was predicted by MELD (HR 1.05, p = 0.03), baseline OHE (HR 1.95, p = 0.04) and Stroop impairment based on ICT (HR 2.1, p = 0.05). Stroop impairment with PHES and age were not predictive.

Without prior OHE: in the 252 pts without prior OHE, on a median follow-up of 10 (IQR 8–15) months, 9% pts developed their first OHE episode (7% VA, 9% OH, 13% AR). On regression, in the first model, time to the first OHE was predicted by MELD (HR 1.14, p = 0.0004) and Stroop impairment by PHES (HR 7.4, p = 0.0006). In the second model, Stroop impairment by ICT was also predictive for first OHE (HR 4.1, p = 0.02) independent of MELD score (HR 1.14, p = 0.0004).

Conclusions: Impaired performance on the Stroop App can predict the development of subsequent OHE episodes in patients with and without OHE at baseline independent of the MELD score in this multi-center study.

P0127

PATIENT-REPORTED HEALTH-RELATED QUALITY OF LIFE OUTCOMES INDEPENDENTLY PREDICT DEATH, TRANSPLANT, HOSPITALIZATION AND HEPATIC ENCEPHALOPATHY IN CIRRHOSIS

K. Patidar[1], L. Thacker[2], J. Wade[3], M. White[1], A. Unser[1], E. Gavis[1], J. Hovermale[1], R.K. Sterling[1], M. Fuchs[1], M.S. Siddiqui[1], S. Matherly[1], R.T. Stravitz[1], A. Sanyal[1], P. Puri[1], V. Luketic[1], J.S. Bajaj[1]. *[1]Virginia Commonwealth University and McGuire VAMC, Richmond, United States; [2]Biostatistics, [3]Psychiatry, Virginia Commonwealth University and McGuire VAMC, Richmond, United States*

E-mail: jasmohan@hotmail.com

Background and Aims: Patient-reported outcomes such as the measures of quality of life (QOL) in PROMIS (Patient Reported Outcomes Measurement Information System) tools are important to evaluate effectiveness of treatments. However their role in predicting outcomes in cirrhosis beyond current models is unclear. *Aim:* Analyze the additive impact of PROMIS QOLtools in predicting time to death/transplant, all hospitalizations and hepatic encephalopathy (HE)-related hospitalizations in cirrhosis

Methods: Outpt cirrhotics were administered PROMIS computerized tools for 11 domains (anger, anxiety, depression, physical function, pain behavior & impact, sleep & wake disturbances and social activities & roles). PROMIS scores, MELD score, HE status, age, sex and alcoholic etiology were then entered into a Cox-regression model for times to composite death/transplant, all hospitalizations and HE-related hospitalization. To analyze the impact beyond HE, a separate PROMIS+HE only model was also studied.

Results: 207 cirrhotics (57 yrs, MELD 12, 64% men, 29% HE, 44% HCV, 18% alcohol) were enrolled. HE pts had a higher MELD (16 vs 10, p < 0.0001) and were impaired on all PROMIS tools (p < 0.001) compared to no-HE pts except anger, anxiety and depression. *Follow-up:* Pts were followed for 38mths (IQR 22–47 mths), during which 35% had death/transplant (20% transplant/15% died), 33% were hospitalized and 12% were hospitalized for HE.

Model with all variables: *Time to death/transplant*: HE, MELD and 4 PROMIS domains (Anger, fatigue, pain behavior and wake disturbances) were significantly predictive. *Time to hospitalization*: MELD with 2 PROMIS domains (Anger, Physical function) were predictors. *Time to HE-related hospitalization*: MELD, Anger, depression, sleep & wake disturbances were predictive. Age, gender and alcohol etiology were not predictors for any outcome.

HE+PROMIS model: *Time to death/transplant*: HE with anger, fatigue, physical function, pain behavior and wake disturbance were predictors. *Time to hospitalization*: HE, anger, depression, pain impairment and physical function. *Time to HE-hospitalization*: HE,

anger, depression, sleep & wake disturbances were predictive. Thus PROMIS results add to prognostication provided by HE alone.
Conclusions: Patient reported QOL outcomes add to current prognostic models of death/transplant and hospitalizations in cirrhosis independent of HE status and liver disease severity. Inclusion of patient-reported outcomes could improve our study of cirrhosis research effectiveness and encourage inquiry into QOL issues.

P0128
LOW TESTOSTERONE LEVELS ARE ASSOCIATED WITH SARCOPENIA IN CIRRHOTIC PATIENTS

P. Tandon[1,2], G. Low[3], M. Mourtzakis[4], M.M. Ma[1,2], K.W. Burak[5], A.J. Montano-Loza[2]. *[1]Cirrhosis Care Clinic, [2]Medicine, [3]Radiology, University of Alberta, Edmonton, [4]Kinesiology, University of Waterloo, Waterloo, [5]Medicine, University of Calgary, Calgary, Canada*
E-mail: ptandon@ualberta.ca

Background and Aims: Sarcopenia is associated with increased mortality in cirrhosis. Hypogonadism has been associated with sarcopenia in several other chronic disease populations. We aimed to investigate if sarcopenia is associated with low testosterone levels in patients with cirrhosis.
Methods: A total of 211 cirrhotic patients were studied prospectively. Muscle mass was analyzed using computed tomography (CT) scans of paraspinal skeletal muscle at the level of the 3rd lumbar vertebral body (L3 SMI). Sarcopenia was defined according to a CT-based study in patients with solid tumors using optimal stratification, a statistical method similar to receiver operating characteristic (ROC) curve analysis that links specific threshold values for L3 SMI in relation to an outcome (death) [L3 SMI: ≤41 cm^2/m^2 for women and ≤53 cm^2/m^2 for men with body mass index (BMI) ≥25 $kg.m^2$ and ≤43 cm^2/m^2 in all patients with BMI <25 kg/m^2]. Morning testosterone levels were obtained in all patients: normal (nmol/L) = males: 10.3–29.5; females: 0.6–2.0. Results were described using the mean and standard deviation.
Results: 129 of 211 patients were males (55%). Cirrhosis was caused by HCV in 74 (35%), alcohol in 55 (26%), NASH/cryptogenic in 53 (25%), autoimmune liver disease in 18 (9%), HBV in 8 (4%), and other etiology in 3 patients (1%). 87 patients (41%) were sarcopenic. The mean testosterone level in males was 18.6±1.2 and 1.5±0.1 in females. 30% of males and 16% of females had levels below normal. Male sarcopenic patients had lower testosterone levels than non-sarcopenic patients (15±1 versus 22±1.2, P = 0.005); however, no significant differences in the testosterone levels were found between female sarcopenic and non-sarcopenic patients (1.29±0.2 versus 1.65±0.1, P = 0.2). There was a good correlation between the L3 SMI and the testosterone levels (r = 0.37, P < 0.001). Male gender (OR 5.26, 95% CI 2.13–12.98, P < 0.001) and testosterone levels (OR 0.95, 95% CI 0.91–0.99, P = 0.02) were associated with sarcopenia by multivariate regression analysis; but age, MELD score, and etiology of the cirrhosis were not.
Conclusions: Lower testosterone levels are associated with sarcopenia in male cirrhotic patients. Testosterone replacement therapy is a potential therapeutic strategy to improve muscle mass in male cirrhotic patients. The safety and efficacy of this treatment requires prospective evaluation.

P0129
PORTAL HYPERTENSION AND COLLATERAL CIRCULATION CAN INFLUENCE ON THE ESTIMATION OF LIVER STIFFNESS MEASUREMENT BY TRANSIENT ELASTOGRAPHY

S.K. Baik[1], Y.L. Lim[1], Y.Z. Cho[1], M.Y. Kim[1], Y.O. Jang[2], K.T. Suk[3], G.J. Cheon[4], Y.D. Kim[4], D.H. Choi[5]. *[1]Internal Medicine, [2]Cell Therapy and Tissue Engineering, Wonju Christian Hospital, Wonju, [3]Internal Medicine, Chuncheon Sacred Heart Hospital, Chuncheon, [4]Internal Medicine, Kangneung Asan Hospital, Kangneung, [5]Internal Medicine, Kangwon University School of Medicine, Chuncheon, Korea, South*
E-mail: youn07190720@naver.com

Background and Aims: Recently, some studies showed the relationship between LSM and hepatic venous pressure gradient (HVPG). However the influence of portal hypertension and secondary liver congestion by right heart preload increase has not been known. So, in this study, we evaluated the relationship between the change of LS and HVPG (ΔLS and ΔHVPG) after 3 months propranolol treatment and the change of strength of relationship between LS and histologic grade.
Methods: LSM and HVPG were performed at baseline and after 3month propranolol treatment in 61 consecutive cirrhotic patients [male, 52 (85.2%)] who had biopsy proven cirrhosis with HVPG≥12 mmHg were included. Linear regression analysis was performed for evaluation of relationship between ΔLS [%, (baseline LS − follow-up LSE)/baseline LS × 100] and ΔHVPG [%, (baseline HVPG − follow-up HVPG)/baseline HVPG × 100].
Results: The baseline mean HVPG and LS were 17.3±4.1 mmHg (12–27) and 45.3±18.3 kPa and these showed significant correlation ($r^2 = 0.24$, $p < 0.0001$). Follow up HVPG and LS [13.0±4.8 mmHg (4–21) and 33.3±17.4 kPa] after propranolol treatment also showed significant correlation ($r^2 = 0.46$, $p < 0.0001$). A strong positive relationship between ΔLS (%) and ΔHVPG (%) was also observed in the overall population ($r^2 = 0.34$, $p < 0.0001$). Thirty-three patients (37/61, 60.5%) were propranolol responders. In responder group, baseline LS correlated with the baseline HVPG ($r^2 = 0.29$, $p < 0.001$) and it more closely correlated with the HVPG after propranolol treatment ($r^2 = 0.58$, $p < 0.001$) but there was no correlation in nonresponders. Baseline LS correlated with the Laennec histologic grades ($r^2 = 0.27$, $p < 0.001$) and it showed more close correlation with histologic grades ($r^2 = 0.37$, $p < 0.001$) after propranolol treatment. In responder group, LS showed more significant improved correlation with the histologic grades ($r^2 = 0.27$ vs. $r^2 = 0.40$, $p < 0.001$) after propranolol treatment, however there was no significant change in nonresponder ($r^2 = 0.23$ vs. $r^2 = 0.27$, $p > 0.05$).
Conclusions: The interval change of LS showed significant correlation with the change of HVPG after propranolol treatment. Improved correlation of adjusted LSM by propranolol treatment with histologic grades suggested that LS is also influenced by portal hypertension in patients with clinically significant portal hypertension.

P0130
VITRO-SCORE (vWF-Ag/THROMBOCYTES) PREDICTS MORTALITY IN PATIENTS WITH LIVER CIRRHOSIS INDEPENDENT OF CHILD–PUGH STAGE AND MELD SCORE

A. Maieron[1], S. Hametner[1], A. Etschmaier[2], R. Schöfl[1], A. Ziachehabi[1], A. Ferlitsch[2]. *[1]Gastroenterology and Hepatology, Elisabeth hospital, Linz, [2]Gastroenterology and Hepatology, Medical university of Vienna, Vienna, Austria*
E-mail: andreas.maieron@elisabethinen.or.at

Background and Aims: vWF-Ag and VITRO Score are promising non-invasive markers in diagnosis and prognosis of liver cirrhosis. vWF-Ag levels are elevated in patients with liver cirrhosis and vWF-Ag shows adequate performance in predicting CSPH and mortality in cirrhotic patients. VITRO-score shows good

performance in predicting cirrhosis in chronic HCV patients. We hypothesized that VITRO-score can predict mortality in a cohort of cirrhotic patients.

Methods: We collected and analysed data of 294 cirrhotic patients. Routine clinical parameters and vWF-Ag levels were measured and VITRO-Score (vWF-Ag/platelets) was calculated. During follow-up, cases of transplantation or death were recorded. Descriptive analysis was performed to describe the baseline characteristics of the cohort. Furthermore we performed Kaplan–Meier analysis to detect differences in survival between vWF-Ag, VITRO and MELD.

Results: male 194 (66%), median age 60 (52–68; IQR); aetiology of liver disease: Hep C 44.22%, ALD 29.59%, NASH 9.86%, other or unknown 16.32%. 64.60% were categorized as CPS A, 29.30% as CPS B and 6.10% of our cohort as CPS C. According to D'Amico 187 (63.60%) were compensated.

Median follow-up time was 21 months (7–35; IQR).

73 (24.80%) patients died during follow-up or were censored due to liver transplantation. Overall median transplant-free survival time was 33 months with a 1-year survival rate of 84%. 25% mortality was reached after 26 months. Patients with VITRO-score ≥2.5 show significantly worse survival with a one-year mortality of 22% and 25% mortality after 14 months compared to a one-year mortality of 10% and a 25% mortality after >42 months in patients with VITRO-score <2.5 (log-rank <0.001).

Median VITRO-score is significantly higher in patients who died with 4.34 (1.91–5.40; IQR) compared to survivors with 2.47 (1.24–3.24; IQR) ($p < 0.001$).

VITRO equals MELD in mortality prediction with an AUC of 0.68 (0.62–0.74 95% CI) for VITRO and an AUC of 0.65 (0.59–0.71 95% CI) for MELD, ($P > 0.05$).

Conclusions: A VITRO-score cut-off of 2.5 is able to detect different survival in a cohort of cirrhotic patients independent of CPS and Meld-score.

VITRO Score as a predictor of mortality could be used as an easy accessible prognostic tool in clinical practice and may help to identify patients at risk and lead them to adequate treatment.

P0131

BACTERIAL DNA QUANTIFICATION IN ASCITES: A NOVEL TOOL TO DEFINE HIGH RISK PATIENTS?

C. Engelmann[1], S. Krohn[1], D. Prywerek[1], A. Boehlig[1], A. Herber[1], K. Zeller[1], S. Boehm[1], T. Berg[1]. [1]*University hospital of LeipzigDepartment of Gastroenterology/Hepatology, Leipzig, Germany*
E-mail: Cornelius.Engelmann@medizin.uni-leipzig.de

Background and Aims: Spontaneous bacterial peritonitis (SBP) represents a serious complication in patients with liver cirrhosis. Culture-based methods to detect bacteria in the ascites fluid showed limited sensitivity, and the diagnosis of SBP is therefore usually made by the surrogate of an increased total ascites leukocyte or neutrophil count. Culture-independent 16S rRNA-gene based amplification methods allowed for the detection of bacterial DNA (bactDNA) in both neutrocytic and non-neutrocytic AF but the significance of this novel tool is still debated. In the current study the impact of bactDNA quantification in ascites on the clinical outcome of patients with cirrhosis was evaluated.

Methods: AF-samples of 173 cirrhotic patients were collected between February 2011 and December 2012. BactDNA was quantified by using real-time PCR with broad range primers targeting the V3 and V4 variable region of 16S rRNA-Gene. Positive AF-samples were sequenced and chromatograms were identified using RipSeq. The detection of bactDNA in AF was correlated with routinely recorded clinical parameters and survival.

Results: BactDNA was detected in 57/144 (39.6%) non-leukocytic AF and 10/23 (43.5%) of leukocytic AF ($p = 0.724$). The median level of bactDNA was significantly lower in non-leukocytic than in leukocytic AF (5.7×10^2 copies/mL vs. 1.2×10^4 copies/mL, $p = 0.008$). The detection of a bactDNA level above the quantification limit of the assay but not the presence of leukocytic AF was significantly associated with a reduced 180-day survival [180-day survival rate 42.6% vs. 60.9% ($p = 0.030$)]. The bacterial spectrum detected by molecular methods was dominated by gram-positive strains such as Staphylococcus, Streptococcus, and Enterococcus species.

Conclusions: The presence of quantifiable concentrations of bacterial DNA in patients with non-leucocytic ascites fluid samples using culture-independent 16S rRNA-gene based methods may help to define a new risk group with reduced survival. Sequence analyses confirmed a shift to gram positive and multibacterial strains. Pre-emptive antibiotic therapy in bactDNA positive patients should be investigated in further prospective interventional trials.

P0132

EXTERNAL VALIDATION OF THE CLIF-SOFA IN CIRRHOTIC PATIENTS ADMITTED TO INTENSIVE CARE UNITS (ICUS): A META-ANALYSIS

D. Weil[1], V. Di Martino[1], E. Levesque[2], M. McPhail[3], R. Cavallazzi[4], E. Theocharidou[5], E. Cholongitas[6], A. Galbois[7], H.-C. Pan[8], C. Karvellas[9], B. Sauneuf[10], R. Robert[11], J. Fichet[12], G. Piton[13], G. Capellier[13], T. Thévenot[1], METAREACIR Group. [1]*Service d'hépatologie, CHU Jean Minjoz, Besançon,* [2]*Centre Hépatobiliaire, Hôpital Paul Brousse, Villejuif, France;* [3]*Liver Intensive care Unit, King's College, London, United Kingdom;* [4]*Intensive care Unit, University of Louisville, Louisville (KY), United States;* [5]*Sheila Sherlock Liver Center, Royal free hospital, London, United Kingdom;* [6]*Liver Department, Aristotle University, Thessaloniki, Greece;* [7]*Intensive care Unit, Hôpital Saint Antoine, Paris, France;* [8]*Nephrology Department, Chang Gung Memorial Hopsital, Taipei, Taiwan;* [9]*Intensive care Unit, University of Alberta, Edmonton, Canada;* [10]*Intensive care Unit, Hôpital Cochin, Paris,* [11]*Intensive care Unit, CHU Poitiers, Poitiers,* [12]*Intensive care Unit, CHU de Tours, Tours,* [13]*Intensive care Unit, CHU Jean Minjoz, Besançon, France*
E-mail: vdimartino@chu-besancon.fr

Background and Aims: The prognostic performance of the Chronic Liver Failure-Sequential Organ Failure Assessment (CLIF-SOFA) score in cirrhotic patients admitted to Intensive Care Units deserves large external validations. The aim of this meta-analysis was to assess the ability of the CLIF-SOFA to predict in-ICU, in-hospital, and 6-month mortality in ICU survivors.

Methods: The CLIF-SOFA was computed retrospectively in 6 studies including 1221 cirrhotic patients admitted between 1995 and 2012. Studies have been selected by the participation of the corresponding authors who responded to a standardized questionnaire. The prognostic performance of different cutoffs of the CLIF-SOFA to predict mortality at different timepoints was assessed by the weight-adjusted odds ratios and positive predictive values and compared to that of the SOFA, the modified SOFA (mSOFA) and the MELD.

Results: On admission, 72.1% of patients ($n = 880$) had a CLIF-SOFA ≤14 and only 1.1% ($n = 13$) had a CLIF-SOFA >22. Among all the available prognostic scores, the best predictor of in-ICU mortality was a CLIF-SOFA ≥22 (OR = 5.94, 95% CI 1.71–20.64; $p = 0.005$; PPV = 1.00), followed by a SOFA >19 (OR = 10.37, 95% CI 5.65–19.01; $p < 0.001$; PPV = 0.94). Predictive value of in-ICU mortality was better for a CLIF-SOFA ≥15 (OR = 7.44, 95% CI 3.43–16.12; $p < 0.01$; PPV = 0.81) than for an increased SOFA on day 3 (OR = 4.75, 95% CI 2.33–8.97; $p < 0.001$; PPV = 0.71) or a MELD score ≥26 (OR = 5.37, 95% CI 4.01–7.21; $p < 0.001$; PPV = 0.66). Prognostic value of in-hospital mortality was good for a CLIF-SOFA ≥15 (OR = 3.93, 95% CI 2.13–7.26; $p < 0.001$; PPV = 0.88), for a mSOFA >13 (OR = 11.92, 95% CI 4.59–30.94; $p < 0.001$; PPV = 0.94) and a SOFA >19 (OR = 11.56, 95% CI 3.23–41.32; $p < 0.001$; PPV = 0.94). Among ICU survivors, 6-month mortality was still predicted by a CLIF-SOFA ≥22 (OR = 7.43, 95% CI 1.18–46.62; $p = 0.032$; PPV = 1.00), and a MELD ≥26 (OR = 3.97, 95% CI

1.92–8.22; p < 0.001; PPV = 0.75), whereas high values of SOFA and mSOFA did not provide any significant prediction.
Conclusions: In critically ill cirrhotic patients, the CLIF-SOFA is able to predict both in-ICU mortality and 6-month mortality in ICU survivors, conversely to the SOFA and mSOFA. High values of CLIF-SOFA better predict in-ICU mortality than high values of SOFA or increase in SOFA on day three, and better predict 6-month mortality in ICU survivors than the MELD score. The CLIF-SOFA thus appears as the prognostic score of choice for the critically ill cirrhotic patients.

P0133
NUTRITION AND PHYSICAL THERAPY TARGETS ARE NOT BEING MET IN ADMITTED PATIENTS WITH CIRRHOSIS
R. Pai[1], T. Shaikh[1], M. Ma[1], J. Gonzalez-Abraldes[1], R. Ameen[1], A. Shah[1], S. Robbins[1], K. Qumosani[2], B. Aljudaibi[2], A. Rahman[2], P. Tandon[1]. *[1]University of Alberta, Edmonton, [2]University of Western Ontario, London, Canada*
E-mail: pai.rohitpai@gmail.com

Background and Aims: Low muscle mass and frailty are major determinants of morbidity and mortality in cirrhosis. Adequate nutritional therapy and early mobilization can impact these parameters. Current cirrhosis guidelines target daily caloric intake at 35–40 kcal/kg and protein intake at 1.2–1.5 g/kg. There are no formal guidelines for mobilization therapy in cirrhosis.
Aims: In hospitalized cirrhotic patients, to evaluate the adherence to nutritional guidelines and determine the proportion of cirrhotic patients who had early (within 72 h of study enrollment) mobilization therapy.
Methods: Multicenter prospective trial involving 3 hospitals (2 Alberta, 1 Ontario) with data collection over a 13-month period (June 2013-July 2014). All patients had cirrhosis and were recruited within 72 hours of admission. Patients with non-hepatocellular carcinoma related malignancy, palliative HCC, severe end-organ failure (eg. Dialysis, COPD on home oxygen, CHF) or Hepatic encephalopathy Conn's score >1 were excluded. Patients were followed for 30 days from initial assessment or until discharge from hospital. Detailed nutritional and mobilization data was collected over the first 3 days of assessment and at two centers, also at ~day 8.
Results: 137 patients were recruited. Baseline characteristics – Mean age 55.5 (SD: 10.3), 59% male, 77% Caucasian, mean MELD and CP scores 18.2 (6.6) and 9.5 (2.0) respectively. The top three etiologies of liver disease were alcohol (41%), HCV (33%) and autoimmune/cholestatic liver disease (12%). Eighty-two percent had at least mild ascites. The mean estimated dry weight BMI was 24.6 (5.3). By day 3, only 7% and 20% respectively met guideline based calorie and protein targets. In the 44 patients with ~day 8 data still only 11% and 14% of patients met calorie and protein targets respectively. A subset of 77 patients had mobilization data available. Over days 1–3, 22.1%, 38% and 55% of these patients were able to mobilize/be mobilized from their bed to outside of their hospital room. Only three patients had a formal physiotherapy consult.
Conclusions: There is an opportunity to improve on the early nutritional and mobilization therapy in cirrhotic inpatients. Less than 20% of patients met nutritional intake recommendations by day 3 of study enrollment and only 4% received a formal physiotherapy consult. National inpatient cirrhosis care guidelines and standardized orders would allow us to determine whether optimization of these variables can impact clinical outcomes in cirrhosis.

P0134
COMPLICATIONS OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PATIENTS WITH CIRRHOSIS
C. Leal[1], A. Fernandez Simon[1], O. Sendino[1], C. Zulli[1], C. Rodriguez de Miguel[1], A. Mendez-Bocanegra[1], D. Balderramo[1], J. Fernández[1], J. Llach[1], A. Cardenas[1]. *[1]Hospital clinic, barcelona, Spain*
E-mail: acardena@clinic.ub.es

Background and Aims: ERCP, which is commonly performed in cirrhotic patients with common bile duct stones and strictures, may be associated with significant complications such as pancreatitis, cholangitis, and bleeding. Patients with cirrhosis are at risk of bleeding and infectious complications after ERCP, but the incidence and risk factors in this population is not well described. The aim of this study was to examine the incidence and specific risk factors of post-ERCP complications in patients with cirrhosis.
Methods: We evaluated all ERCP's performed in patients with cirrhosis at Hospital Clinic, Barcelona from 2002–2013. We also analyzed a matched control group of non-cirrhotic patients with ERCP in the same period. Patient and procedure-related risk factors were analyzed. Predictive factors for post-ERCP complications were determined by univariate and multivariate analysis
Results: 256 ERCP's were analyzed (85 in cirrhotic and 171 in non-cirrhotic patients). Etiology of cirrhosis: HCV and alcohol (98%), median MELD 12, Child A/B/C (33%, 50%, 17%). Complications occurred in 12 patients (14%) in the cirrhosis group (11 mild, 1 severe): pancreatitis 3 cases (3.5%), cholangitis 3 cases (3.5%), and post-sphincterotomy bleeding 6 cases (7%). The overall rate of complications was significantly higher in patients with cirrhosis compared to non-cirrhotic patients (14% vs 6.4%, P = 0.04). Only bleeding occurred more commonly in patients with cirrhosis compared to non-cirrhotics [6/85 (7.0%) vs 3/117 (1.7%), P = 0.03]. The incidence of pancreatitis and cholangitis were not significantly different among both groups. Logistic regression identified sphincterotomy [OR 8.99 (CI 1.08–74.60), P = 0.04] and cirrhosis [OR 3.51 (CI 1.11–11.09), P = 0.03] as independent risk factors of post-ERCP complications, whereas cirrhosis was the only independent risk factor of post sphincterotomy bleeding [OR 4.12 (CI 1–16.93), P = 0.04].
Conclusions: The rate of complications after ERCP in patients with cirrhosis (14%) is higher than that of patients without cirrhosis. The majority of complications are mild and due to post-sphincterotomy bleeding. Cirrhosis and sphincterotomy are risk factors of post-ERCP complications. Further prospective studies that implement preventive strategies to avoid bleeding in patients with cirrhosis are needed

P0135
IMPACT OF VASOPRESSIN AVP1A RECEPTOR GENE POLYMORPHISMS ON MORTALITY AND RENAL FAILURE IN PATIENTS WITH ACUTE DECOMPENSATION OF CHRONIC LIVER DISEASE
J.J. Schaapman[1], A.C. Kerbert[1], J.J. van der Reijden[1], A. Amoros Navarro[2], M. Pavesi[2], B. van Hoek[1], V. Arroyo[3], M. Bernardi[4], G. Soriano[5], M.-V. Catalina[6], P. Aguilar[7], H.W. Verspaget[1], M.J. Coenraad[1]. *[1]Gastroenterology–Hepatology, Leiden University Medical Center, Leiden, Netherlands; [2]Data Management Centre, CLIF consortium, [3]Gastroenterology–Hepatology, University of Barcelona, Barcelona, Spain; [4]Gastroenterology–Hepatology, University of Bologna, Bologna, Italy; [5]Gastroenterology, Hospital de la Santa Creu i Sant Pau, Barcelona, [6]Gastroenterology–Hepatology, Hospital Gregorio Maranon, Madrid, [7]Gastroenterology–Hepatology, Hospital Reina Sofia, Cordoba, Spain*
E-mail: m.j.coenraad@lumc.nl

Background and Aims: Acute-on chronic liver failure (ACLF) is defined as an acute decompensation (AD) of former stable liver disease accompanied by organ failure and a high short-term

mortality. Systemic hemodynamic dysfunction and activation of endogenous vasoconstrictor systems are thought to contribute to the pathogenesis. Vasopressin is a key-regulator in hemodynamic homeostasis. Aim of the present study was to assess in patients with AD whether genetic variation of the human arginine vasopressin 1A receptor (AVP1aR) is associated with increased mortality or the development of ACLF, renal or circulatory failure.

Methods: Eight single nucleotide polymorphisms (SNPs) of AVP1aR with possible clinical relevance were identified. From 188 cirrhotic patients hospitalized for AD, clinical, laboratory and survival data from the CANONIC database were used. Presence of ACLF was defined according to the modified CLIF-sequential organ failure assessment (SOFA) score. All patients were genotyped for all eight SNPs using polymerase chain reaction followed by restriction fragment length polymorphism or PCR allele-specific amplification primers. Fisher's exact test and linear regression analysis were used to test for associations between genetic frequencies and dichotomous and continuous variables respectively. Cox proportional hazard analysis adjusted for age was performed to assess the association between AVP1a SNPs and mortality at set time points. $P < 0.05$ was considered significant.

Results: Ninety-three patients without ACLF and 95 patents with ACLF were included. As expected, mortality rate at 12 months of follow-up (FU) was higher in patients with ACLF (59%) than in patients with AD who did not develop ACLF (28%). Mutations in rs7298346 [HR 1.81 (95% CI 1.02–3.23), $p = 0.044$] and rs7308855 [HR 2.17 (1.17–4.01), $p = 0.013$] showed a clear trend towards a lower overall survival in all patients at 90 days of FU. For rs 7308855 this trend persisted until 180 days of FU [HR 1.87 (1.00–3.50), $p = 0.051$]. In addition, T>A mutation in rs7298346 was associated with the presence of renal failure in patients with ACLF ($p = 0.025$). No association was found between AVP1a SNPs and the occurrence of ACLF or circulatory failure.

Conclusions: There is a clear trend of AVP1a SNPs to be associated with increased mortality in patients with acute decompensation of liver disease and with the occurrence of renal failure in ACLF.

P0136

ALFAPUMP FOR THE TREATMENT OF REFRACTORY ASCITES IN CIRRHOTIC PATIENTS

G. Stirnimann[1], T. Berg[2], L. Spahr[3], S. Zeuzem[4], S. McPherson[5], F. Lammert[6], J. Babatz[7], V. Vargas[8], V. Banz[1], F. Storni[1], A. De Gottardi[1]. *[1]University Hospital Inselspital, Bern, Switzerland; [2]University Clinic Leipzig, Leipzig, Germany; [3]Geneva University Hospitals, Geneva, Switzerland; [4]University Hospital Frankfurt, Frankfurt, Germany; [5]Freeman Hospital, Newcastle, United Kingdom; [6]Saarland University Medical Center, Homburg, [7]Universitätsklinikum Carl Gustav Carus, Dresden, Germany; [8]Vall d'Hebron University Hospital, Barcelona, Spain*
E-mail: guido.stirnimann@insel.ch

Background and Aims: The automated low flow ascites pump (**alfa**pump) is a novel treatment for the management of refractory ascites in patients contraindicated for or with an ineffective TIPS. The aim of this study was to monitor safety and clinical performance.

Methods: From September 2012 data from patients with an alfapump have been collected in an international multicentre prospective registry. Inclusion criteria were refractory or recurrent ascites with no other treatment option than repetitive paracentesis, age >18 years, informed consent, ability to manage the alfapump system. Data points were analysed at baseline before surgery, perioperatively, and after 1, 3, 6, 12 and 18 months during follow-up.

Results: In total, 55 patients were included (76% men, 24% women), mean age was 61 (range 44–78). Aetiology of cirrhosis was alcohol (69.1%), chronic hepatitis C virus infection (9.1%), NASH (5.5%) and cryptogenic (5.5%).

The median duration of the implantation was 60 min (25th/75th percentile: 50/70) and the median length of hospital stay after implantation was 6 days (3/12). The number of large volume paracenteses per month decreased from 2.17 (1.4/4.3) to 0.0 (0.0/0.43), the volume of each paracentesis decreased from 7.0 litres (5.0/9.0) to 4.6 litres (3.0/6.0). The median volume of ascites pumped was 0.9 litres (0.7/1.1) per day.

The most frequent complication was obstruction of the peritoneal catheter in 11 patients, followed by pump failures due to technical problems in 7 patients and infections in 6 patients. Of 55 patients, 17 are ongoing, 18 died, 8 were transplanted, 10 were withdrawn, 1 completed the study and 1 was lost to follow-up. Mean survival was 6.33±5.33 months with a 6 month actuarial survival of 74%. Mean BMI was 25.3 kg/m^2 at baseline and 26.1 kg/m^2 at 18 months. Serum creatinine levels increased during follow-up from 98 μmol/L (86/117) to 124 μmol/L (107/206) at 18 months. Albumin was administered in 34.5% of patients post implant in the context of paracentesis. Median serum albumin decreased from 30.0 g/L at baseline to 25.0 g/L at 18 months. Mean Child and MELD scores were 8.8 (± 1.4) and 13.4 (± 4.3) at baseline and 8.0 (± 1.4) and 12.7 (± 4.4) at 18 months, respectively.

Conclusions: Implantation of alfapump was a safe procedure in patients with refractory ascites due to advanced cirrhosis and was associated with a marked reduction in the need for paracentesis and albumin.

P0137

SAFETY OF BOCEPREVIR-BASED TRIPLE THERAPY IN HCV CIRRHOTIC PATIENTS AWAITING LIVER TRANSPLANTATION. ANALYSIS FROM A FRENCH MULTICENTER, OPEN-LABEL STUDY (ANRS HC29 BOCEPRETRANSPLANT)

E-mail: helene.fontaine@cch.aphp.fr

Background and Aims: To analyze the safety of a boceprevir (BOC)-based triple therapy in HCV cirrhotic patients (pts) on waiting-list (WL) for liver transplantation (LT) in a French multicenter, open-label study.

Methods: HCV genotype 1 pts received PEG-IFN-α2a 180 μg/week (W) or PEG-IFN-α2b 1.5 μg/kg/W, weight-based RBV 1000–1200 mg/d during 48W, and BOC 800 mg/8 hours from W4 to W48 or until LT. Biological and clinical safety was assessed during treatment and 6 months after the end of treatment (EOT). Results on severe adverse events (SAE) occurrence are reported.

Results: 51 pts from 15 centers were included (80% males, median age 56 years). Hepatocellular carcinoma (HCC) was present in 59%

of pts, end-stage liver disease in 41%. At inclusion, the median MELD score was 9 (range 6–18); the Child–Pugh score was A in 65% and B in 35%. Treatment median duration was 13W. Therapy was discontinued because of SAE in 20 (39%) or virological inefficacy in 12 (24%). Seven pts (14%) died after a median duration of treatment of 9W because of sepsis (n = 4), HCC progression (n = 1), haemorrhagic shock (n = 1) and cerebral haemorrhage (n = 1). Three deaths were considered as possibly related to treatment. 114 SAE were observed in 43 pts (84%). Most common diagnoses were neutropenia (25%), GGT (20%) or AST elevation (12%), anemia (10%), thrombocytopenia (10%), hepatic encephalopathy (10%) and leucopenia (10%). Severe anemia (Hb <8 g/dL) was observed in 4%. Growth factors were used in 36 pts (71%), erythropoietin, thrombopoietin and G-CSF in 23, 9 and 11 pts, respectively. Undetectable HCV-RNA 24 weeks after the EOT (SVR24) was observed in 8 pts (16%). A LT was performed in 18 pts (35%) after a mean duration on WL and of treatment of 59 and 13 W, respectively. HCV RNA was undetectable in 19% at LT and was still negative after LT in 2 pts (W24 post-LT). Severe infection occurred in 12 pts (24%) including septicemia (n = 7), ascites infection (n = 3) and urinary infection (n = 1). One pt had multiple infections. Child–Pugh score B, low Hb, lymphocytes and albumin levels at baseline were associated with the occurrence of severe infection but multivariate analysis indicated that only low albumin level (<35 g/l) remained an independent predictive factor.

Conclusions: Safety of PEG-IFN/RBV/BOC combination is poor in pts awaiting LT, with a high risk of developing severe infection. Moreover, the limited efficacy confirms the necessity of IFN-free combinations in these pts.

P0138

THE EFFECT OF TREATMENT FOR HEPATIC ENCEPHALOPATHY WITH NONABSORBABLE DISACCHARIDES ON MORBIDITY AND MORTALITY IN PATIENTS WITH CIRRHOSIS: SYSTEMATIC REVIEW AND META-ANALYSES

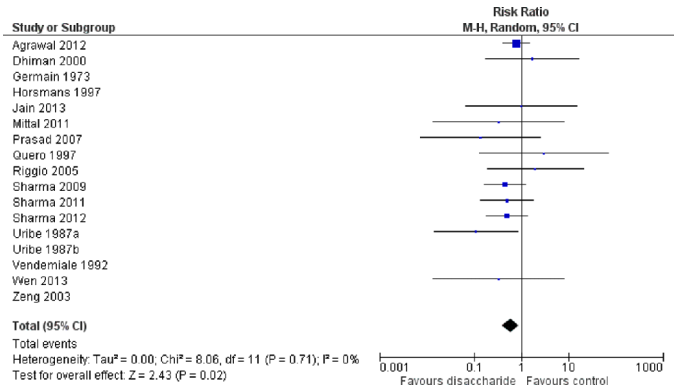
L.L. Gluud[1], H. Vilstrup[2], M.Y. Morgan[3]. *[1]Gastrounit, Hvidovre Hospital, Copenhagen University, Hvidovre, [2]Department of Hepatology and Gastroenterology, Aarhus Kommunehospital, Aarhus, Denmark; [3]UCL Institute for Liver & Digestive Health, Division of Medicine, Royal Free Campus, University College London, London, United Kingdom*
E-mail: liselottegluud@yahoo.dk

Background and Aims: The non-absorbable disaccharides (NADs), lactulose and lactitol, have been used to treat hepatic encephalopathy (HE), in patients with cirrhosis since 1966. However, a Cochrane systematic review concluded that there was insufficient high-quality evidence to support their use (Als-Nielsen *et al*, 2004). The advent of several new treatment trials requires this to be reappraised. The aim of this study was to assess the beneficial and harmful effects of NADs *vs*. placebo/no intervention in patients with cirrhosis and HE.

Methods: Randomized controlled trials published between 1966 and October 2014 were identified using a language/publication unrestricted electronic search of five data-bases; (ii) a manual search of relevant journals, symposia/conference proceedings; (ii) personal communications with investigators; and (iii) publication cross-referencing. Bias control was assessed using the Cochrane Hepato-Biliary Group domains; key outcome data were extracted. Sources of heterogeneity were sought. Small study effects, random and systematic errors were assessed and futility evaluated in sensitivity, subgroup, regression and trial sequential analyses.

Results: In total, 37 trials involving 1628 patients with overt HE (12 trials), minimal HE (14 trials) or else for primary/secondary prophylaxis (11 trials) were identified; the mean duration of treatment was 3 months. Compared with placebo/no intervention, use of NADs had a beneficial effect on HE (RR 0.56; 95% CI 0.47–0.68; participants = 1263; I^2 = 51%, 20 trials) both when used to treat the syndrome (RR 0.62; 95% CI 0.48–0.80) or else to prevent its occurrence (RR 0.47; 95% CI 0.37–0.59). The result was confirmed in analyses of high-quality trials. Use of NADs was associated with a reduction in mortality (RR 0.60; 95% CI 0.40–0.91; figure) and the risk of serious adverse events including severe infections and liver-related complications (RR 0.47; 95% CI 0.36–0.62); the risk of diarrhoea and bloating was increased. There were no differential effects in relation to the type of HE or use for treatment or prophylaxis; no clear differences were identified in treatment efficacy or safety between lactulose and lactitol. Overall the sample size was adequate and the findings statistically robust.

Conclusions: In patients with cirrhosis, NADs are beneficial for both the treatment and prevention of HE; their use is also associated with a significant reduction in liver-related morbidity and mortality.



P0139

PATIENTS EXPERIENCING REPEATED EPISODES OF HEPATIC ENCEPHALOPATHY HAVE INCREASING RISK OF DEATH. A POST HOC ANALYSIS OF RIFAXIMIN-α OPEN LABEL STUDY DATA

C.A. Bannister[1], P. Conway[2], A. Radwan[2], C.L. Morgan[3], E. Berni[3], C.J. Currie[1]. *[1]Cardiff University School of Medicine, Cardiff, [2]Norgine, Uxbridge, [3]Pharmatelligence, Cardiff, United Kingdom*
E-mail: ssheikh@norgine.com

Background and Aims: Hepatic encephalopathy (HE) is a chronic complication of cirrhosis. In recurrent, overt, episodic HE, which is the most common subcategory, its seriousness is due to the chronic debilitating effects of the recurrent episodes. The aim of this study was to characterise the impact of the number of prior HE episodes on the risk of death.

Methods: A post-hoc analysis was carried out using data from 322 patients with a history of HE from a phase 3, open-label study evaluating the long-term safety and tolerability of rifaximin-α 550 mg BID. All eligible patients had a Conn score of 0–2 at enrolment, and either successfully participated in a previous HE study with rifaximin-α (RFHE3001) or were new patients enrolled with ≥1 verifiable episode of HE within the preceding 12 months.

Results: 321 of 322 patients (650 observations) aged ≥18 years had all the necessary information required for analysis. The median duration of follow-up was 17 months (IQR 8.9–25.4). Stratifying patient observations by number of prior HE episodes and using the Kaplan–Meier method the year one survival was 0.947 (95% CI; 0.891–1.000), 0.898 (0.845–0.953) and 0.793 (0.735–0.856) and the year two survival was 0.910 (0.822–1.000), 0.808 (0.719–0.909) and 0.783 (0.677–0.0.828) for 'one', 'two' and 'three or more' prior HE episodes, respectively. Plotting the Kaplan–Meier curves of time to death, stratified by number of prior HE episodes, a clear association between decreased time to death and increased number of prior HE

episodes. Using log-rank tests there was no significant difference between the survival curves of one prior and two prior HE episodes [$\chi^2 = 0$ on 1 degree of freedom (d.f.), $p = 0.899$], however there were significant differences between survival curves of one prior or two prior episodes and greater numbers of prior episodes ($\chi^2 = 64$ on 2 d.f., $p < 0.001$).
Conclusions: As the number of prior HE episodes increases, the risk of death increases. In addition to impact on quality of life and health service utilisation, HE events may represent a prognostic marker of mortality.

P0140
FRAILTY ASSESSMENT IN CIRRHOSIS – VARIABLE PREVALENCE ACROSS SCREENING TOOLS
P. Tandon[1,2], L. Zenith[1], T. Shaikh[1], N. Mitchell[3], J.G. Abraldes[1,2], M. Carbonneau[1], K.W. Burak[4], R.J. Bailey[5], N. Tangri[6], M.M. Ma[1,2]. *[1]Cirrhosis Care Clinic, [2]Medicine, [3]Psychiatry, University of Alberta, Edmonton, [4]Medicine, University of Calgary, Calgary, [5]Royal Alexandra Hospital, Edmonton, [6]University of Manitoba, Winnipeg, Canada*
E-mail: ptandon@ualberta.ca

Background and Aims: Frailty is an important predictor of morbidity and mortality in cirrhosis, and can be assessed using multiple screening tools. Some of these tools are time-consuming for use in daily clinical practice, while others ignore important domains of cognitive function and mood. Moreover, a comparison of the prevalence of frailty and its association with outcomes using different assessment tools has not been conducted. In a prospective cohort of patients with cirrhosis, we aimed to evaluate (i) the prevalence of frailty using different frailty tools, (ii) the most commonly affected frailty domains and (iii) the impact of frailty on clinical outcomes.
Methods: Data was gathered prospectively on patients with cirrhosis seen in liver clinics in Edmonton and Calgary, the majority recruited during work-up for transplant. We examined frailty using the short physical performance battery (SPPB), the Clinical Frailty scale and the 5 and 7 variable Fried frailty criteria.
Results: Of the 296 included patients, 66% were male with a mean age of 57 years (SD 9.3), MELD score of 12 (4.9) and Child Pugh score of 7.5 (2.1). The top three etiologies of liver disease were Hepatitis C (34%), Alcohol (32%) and NAFLD/cryptogenic (17%). Seventeen percent of patients had HCC. The prevalence of frailty was 7% using the SPPB, 19% using a score of ≥5 on the Clinical Frailty scale, 36% by the 5 variable Fried physical frailty criteria and 55% if cognition and depression were also evaluated as part of the 7 variable Fried criteria. The most commonly affected domains were: cognition (62%), low physical activity level (49%), exhaustion (46%), weight loss (45%), weakness (45%), depression (32%), slowness (20%). Using logistic regression analysis, all of the frailty criteria (with the exception of the SPPB) were independent of liver function in predicting admission to hospital within 6 months of assessment (subset of 79 patients). The strongest association was seen using the 7 variable Fried criteria: OR: 8.9 (2.7 to 28.9), $p = 0.001$.
Conclusions: The prevalence of frailty varies widely depending upon the choice of screening tool, ranging from 7% to 55%. In our preliminary analysis of impact on clinical outcomes, all frailty tools (apart from the SPPB) were strongly predictive of the need for hospitalization. Both physical and cognitive/mood domains of frailty were affected, and should be considered when screening patients with cirrhosis for frailty or risk of hospitalization.

P0141
BLOOD–BRAIN BARRIER DYSFUNCTION ASSESSED BY PROTEIN S-100 BETA LEVELS IN CIRRHOTIC PATIENTS
S. Tripon[1], M. Mallet[1], D. Monneret[2], F. Imbert-Bismut[2], M. Rudler[1], N. Weiss[3], D. Thabut[1], on behalf of BLIPS: Brain–Liver Pitié-Salpêtrière Study Group. *[1]Hepatology ICU, [2]Biochemistry, APHP, UPMC, Groupement Hospitalier Pitié-Salpêtrière-Charles Foix, [3]Neurological ICU, APHP, UPMC, IHU-A, Groupement Hospitalier Pitié-Salpêtrière-Charles Foix, Paris, France*
E-mail: dominique.thabut@psl.aphp.fr

Background and Aims: The protein S-100 beta (PS-100) is a small dimeric cytosolic protein synthetized in astrocytes and Schwann cells. High serum levels of PS-100 are associated with brain lesions and altered blood–brain barrier permeability in traumatic brain injury, ischemic stroke, cerebral tumors and subarachnoid hemorrhage. Early brain damage has been detected in patients with cirrhosis. We hypothesized that those insults could be detected by the PS-100 serum levels (normal values <0.10 μg/L). Hence, the aim of the present study was to assess PS-100 levels in cirrhotic patients, and compare them to PS-100 levels in non-cirrhotic patients followed up in the same department for initial workup of elevated liver enzymes (controls).
Methods: We prospectively included a population of cirrhotic patients admitted for complication of cirrhosis in ICU and controls. Baseline data were recorded and levels of ammonemia and PS-100 determined at admission. Overt HE was diagnosed as a West-Haven score ranging between 2 and 4.
Results: Between October 2013 and October 2014, 124 cirrhotic patients (mean age: 63 years, male gender: 73%, etiology of cirrhosis: alcoholic 51%, viral 25%, other 24%, Child–Pugh 11 [8–12], MELD score 21 [14–26]) and 79 non-cirrhotic patients (mean age: 63 years, male 59%, etiology of elevated liver enzymes: alcoholic 5%, viral 44%, NASH 38%, other 13%, mean Fibroscan: 5.3 kPa, mean FibroTest: 0.15) were included. Among cirrhotic patients, 40 patients (33%) displayed HE at admission and 50 (41%) had an infection. Mean PS-100 level was 0.15±0.01 for cirrhotic patients and 0.07±0.01 for non-cirrhotic patients ($p < 0.0001$). In cirrhotic patients, PS-100 was correlated to AST ($p = 0.0027$), bilirubin ($p = 0.0001$), Child–Pugh score ($p = 0.001$) and MELD ($p = 0.0004$) and inversely correlated to albumin ($p = 0.04$), sodium ($p = 0.01$), PTT ($p = 0.001$), and FV ($p = 0.011$). PS-100 levels were not correlated to the presence of overt HE nor to infection. In multivariate analysis, levels of PS-100 were independently associated with MELD score ($p = 0.0006$), whereas overt HE was associated to hyperammonemia ($p = 0.002$) and the presence of infection ($p = 0.008$) but not to PS-100 levels.
Conclusions: Patients with cirrhosis display neurological insult or blood–brain barrier dysfunction even in the absence of overt HE. Brain damage is more frequent in patients with advanced liver disease.

P0142
MORTALITY RISK FACTORS IN CIRRHOTIC PATIENTS IN INTENSIVE CARE UNIT: A MONOCENTRIC RETROSPECTIVE STUDY AT BESANÇON'S UNIVERSITY HOSPITAL FROM 2002 TO 2014
C. Chaignat[1], G. Piton[1], G. Capellier[1], C. Patry[1], J.-P. Cervoni[2], V. Di Martino[2]. *[1]Intensive Care Unit, [2]Hepatology Unit, CHU de Besançon, Besançon, France*
E-mail: piton.gael@wanadoo.fr

Background and Aims: The prognostic in cirrhotic patients admitted in intensive care unit (ICU) is poor and those who will benefit from intensive care should be identified at early as possible. Objectives of this study were to assess the predictors of mortality in cirrhotic patients admitted in our medical ICU and to evaluate the relevance of a new prognostic score measured at baseline.
Methods: Retrospective cohort study including all cirrhotic patients consecutively admitted in our intensive care unit between January

2002 and May 2014. 170 clinical and paraclinical variables were collected for each patient. Multivariate analyses on survival used the logistic regression for in-ICU survival and Cox model for 28-day and 6-month survival.
Results: Of the 7427 admissions recorded during the study period, 258 (3.5%) concerned 218 cirrhotic patients (165 men; median age: 59). Alcoholism was the main cause of cirrhosis (85%). On admission, the medians of the different prognostic scores were as follows: Child–Pugh=11, MELD=28, SOFA=12, modified SOFA=10 and IGS II=59. 196 (90%) patients received mechanical ventilation; 187 patients (86%) received catecholamines and 112 (51%) required renal replacement therapy (RRT). The in-ICU, 28-day, 3-month and 6-month mortality rates were 47% (n = 103), 49% (n = 107), 62.5% (n = 130) and 66% (n = 136), respectively. Among the 115 patients who were discharged from ICU, only 7 patients underwent transplantation, whereas 48 had no clear contraindication. The best prediction of in-ICU (AUROC=0.94) and 28-day (AUROC=0.89) mortality was provided by the variation of SOFA between baseline and day 3. Multivariate analyses on in-ICU mortality identified 3 independent variables, incorporated in a new 3-variables prognostic model as follows: SOFA≥12 (OR = 5.8 [95% CI: 2.9–11.6]: 2 points), INR≥2.6 (OR = 1.7 [1.2–3.3]; 1 point) and RRT (OR = 4.2 [1.9–9.2]; 1 point). Those variables were also able to discriminate 28 days, 3 months and 6 months survivors. For a value of the 3-variables prognosis score at 4 (16% of patients), the prediction of in-ICU mortality was excellent (PPV = 91%), similar to that given by delta SOFA (PPV = 93%).
Conclusions: The prognostic assessment tools already available are effective, but are improved by using a new score grouping the SOFA, INR, and RRT. This score enabled us to identify patients in which the assessment on day 3 is not mandatory for predicting in-ICU mortality.

P0143
IMPULSIONAL, POINT AND BIDIMENSIONAL SHEAR WAVE ELASTOMETRY FOR PORTAL HYPERTENSION: SAME STIFFNESS THRESHOLDS?

H. Stefanescu[1,2], G. Allegretti[1], C. Serra[3], G. Marasco[4], N. Gamal[5], F. Conti[5], A. Colecchia[4], D. Festi[4], P. Andreone[5], L. Bolondi[1], F. Piscaglia[1]. *[1]Internal Medicine Unit, Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy; [2]Hepatology Unit, Regional Institute of Gastroenterology and Hepatology, Cluj-Napoca, Romania; [3]Department of Organ Insufficiencies and Transplant, Sant'Orsola-Malpighi University Hospital, [4]Gastroenterology Unit, Department of Medical and Surgical Sciences, [5]Medical Semiology Unit, Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy*
E-mail: horia.stefanescu@irgh.ro

Background and Aims: Liver stiffness (LS) values are becoming tested in chronic liver disease to investigate the presence of portal hypertension (PH). LS measured with Transient elastography (TE) correlates with HVPG, and 21.1 kPa proposed as best cut-off to predict the presence of clinically significant PH (CSPH). New elastographic techniques which may overcome some limitations of TE became recently available, but their diagnostic accuracy remain to be defined. We aimed to compare the performance of TE, point shear wave elastography (ElastPQ) and 2D-Shear Wave Elastography (2D SWE) to predict the grade of PH in a cohort of cirrhotic patients.
Methods: 65 consecutive patients (63.1%M, 60.2y) with chronic liver disease submitted to HVPG measurement and at least one elastographic technique, (TE based on impulsional elastography and/or ElastPQ – on a Philips IU22, and/or 2D SWE – on a Aixplorer by Supersonic Imagine) blindly each from another technique, were enrolled between December 2013 and November 2014.
Results: 44/65 patients (67.7%) had a baseline HVPG >10 mmHg, thus classified as CSPH. 40 patients (61.5%) underwent TE, 31 (47.7%) ElastPQ, 25 (38.5%) 2D-SWE measuring liver stiffness.
HVPG was well correlated with either TE (r = 0.695; p < 0.0001), ElastPQ (r = 0.684; p = 0.001), or 2D-SWE (r = 0.762; p < 0.0001).
The overall concordance between elastographic techniques (tested in 51 patients who underwent either 2 or 3 methods) was only moderate (ICC = 0.409). TE was concordant with both other techniques (ICC = 0.772 for ElastPQ, ICC = 0.754 for 2D-SWE), while ElastPQ and 2D-SWE were less concordant (ICC = 0.488).
No significant difference (p = ns, de Long test) was detected among AUROC of the 3 techniques for predicting CSPH (figure).
We used the previously validated cut-off value of 21.1 kPa, to test the ability of each technique to correctly classify CSPH, obtaining variable accuracies in identifying correctly classified patients: 85% (34/40) for TE, 55% (17/31) for ElastPQ and 76% (19/25) for 2D-SWE, respectively.

Table: ROC analysis of each elastographic technique for predicting CSPH (HVPG >10 mmHg)

	AUROC	95% CI	p	Cut-off	Se	Sp
TE (n = 40)	0.872	0.761–0.983	<0.0001	21.5 kPa	0.75	1
ElastPQ (n = 31)	0.962	0.900–1.000	<0.0001	13.5 kPa	0.81	1
2D-SWE (n = 25)	0.860	0.715–1.000	<0.0001	19.7 kPa	0.72	1

Conclusions: Our findings showed that liver stiffness, assessed by new elastographic techniques (ElastPQ and 2D-SWE), have similar performance to predict CSPH like TE. However the best diagnostic threshold for this diagnosis differs significantly among different elastography technologies and specific diagnostic accuracy studies appear warranted for each type of equipment.

Bajaj[4]. *[1]Medicine, Cleveland Clinic, Cleveland, [2]Medicine, University of Arkansas, Little Rock, [3]Biostatistics, [4]Virginia Commonwealth University and McGuire VAMC, Richmond, United States*
E-mail: jasmohan@hotmail.com

Background and Aims: The recent EASL/AASLD guidelines suggest using ≥2 modalities are needed to diagnose covert HE in multi-center studies in order to reduce instability of the diagnosis between different modalities. However this approach has not been tested prospectively due to a lack of such studies in CHE. Aim: to compare whether agreement between sites is improved with using two abnormal strategies compared to a single strategy to diagnose covert HE.
Methods: Three sites [Virginia (VA), Ohio (OH) and Arkansas (AR)] enrolled outpatient cirrhotics (with/without treated overt HE) and age-matched healthy controls without chronic diseases. All subjects were given the psychometric hepatic encephalopathy score (PHES) and inhibitory control test (ICT) independently. Both tests were used by CHE independently by PHES or by ICT as gold standards compared to controls. Combined CHE was diagnosed if both PHES and ICT were abnormal. The rates of CHE diagnosis and analysis of agreement between centers and between each center and combined results using that cut point on either PHES/ICT or both were performed using Kappa statistics.
Results: We enrolled 302 healthy controls (103 VA, 100 OH, 105 AR) and 436 cirrhotic patients (230 VA, 107 OH, 99 AR). Sites were similar with respect to age (57±7 VA, 58±11 OH, 56±7 AR, p = 0.4) but VA patients had higher MELD score (12.5±6 VA, 10±4 OH, 10±3 AR, p < 0.0001) and frequency of prior overt HE (41% VA, 30% OH, 30% AR, p = 0.05). The combined rate of CHE diagnosis with ICT was

41% (30% VA, 50% OH, 53% AR) while for PHES the combined rate was 37% (45%VA, 30%OH and 25%AR). When both ICT and PHES were considered, 19% subjects had CHE overall (20% VA, 19% OH, 20% AR). Use of 2 abnormal tests stabilized the agreement between sites (Table).

Kappa statistics	ICT only abnormal	PHES only abnormal	Both abnormal
VA vs. OH	0.72	0.54	0.55
VA vs. AR	0.75	0.60	0.91
OH vs. AR	0.54	0.91	0.58
VA vs. combined	0.75	0.92	0.96
OH vs. combined	0.45	0.48	0.53
AR vs. combined	1.0	0.53	0.96

Conclusions: In this multi-center study, use of 2 abnormal testing strategies as proposed by the EASL/AASLD guidelines, increases agreement between sites and stabilizes the rate of CHE diagnosis. This approach can be used for developing/planning multi-center CHE trials.

P0145

PROSPECTIVE ANALYSIS OF FACTORS IMPLICATED IN EARLY READMISSIONS IN PATIENTS WITH DECOMPENSATED CIRRHOSIS

L. Franco[1], J.A. Ferrusquía[1], S. Antón[2], A. Ríos[2], C. Fernández de Castro[1], O.K. Nuevo[1], L. González-Diéguez[1], V. Cadahía[1], M. Varela[1], C.A. Navascués[1], J. de la Vega[2], M. Rodríguez[1]. *[1]Hepatology Unit, Hospital Universitario Central de Asturias, Oviedo, [2]Gastroenterology Department, Hospital San Agustín, Avilés, Spain*
E-mail: canavascues99@movistar.es

Background and Aims: Early hospital readmissions (HR) in patients with decompensated cirrhosis (DC) increase health-care expenses and predict a poor outcome. The aim of this study was to identify the frequency and possible predictors of 30-day HR among patients with DC.
Methods: A total of 251 patients with DC discharged from 2 medical centers between October 2012 and September 2014 were followed. Patients with elective admissions or previous liver transplantation were excluded. Relationship between 30-day HR and multiple demographic, socioeconomic and clinical variables was studied by univariate and multivariate analyses.
Results: 75.3% were male, mean age was 62±12 years and 45% had previous admissions. Most frequent etiologies of cirrhosis were alcohol (66.5%) and hepatitis C (21.5%) and most common causes of admission ascites (29%), gastrointestinal bleeding (29%) and hepatic encephalopathy (HE) (17%). The median length of hospital stay was 7.7 days. Mean Child–Pugh and MELD scores and Charlson comorbidity index at discharge were 7.9±1.6, 13.3±5 and 4.3±1.8 respectively. 22% had an early HR (during the first 30 days after a hospital discharge). Univariate analyses showed that early HR were not significantly associated with sex (p = 0.3), age (p = 0.8), etiology of cirrhosis (p = 0.6), tobacco (p = 0.8), active alcohol use (p = 0.6), hepatocellular carcinoma (p = 0.9), history of previous admissions (p = 0.4) or level of education (p = 0.7). Early HR were significantly more frequent in patients who lived in urban areas (p = 0.05), not married (p = 0.04), admitted due to ascites or HE (p = 0.002), with Child–Pugh ≥10 (p < 0.001), MELD >15 (p < 0.001) or Charlson index >4 (p = 0.004) and in those with a length of hospital stay >12 days (p = 0.008). After adjusting for multiple covariates, independent predictors of early HR were admissions due to ascites or HE (OR 2.6 [95% CI: 1.3–5.1], p = 0.006), Child–Pugh ≥10 (OR 3.4 [95% CI: 1.6–7.2], p = 0.001), Charlson index >4 (OR 2.5 [95% CI: 1.2–5.3], p = 0.009) and a length of hospital stay >12 days (OR 3.1 [95% CI: 1.3–7.4], p = 0.008).
Conclusions: Almost 25% of patients with decompensated cirrhosis that required hospitalization have a HR within the first 30 days after discharge. The indication for index admission, severity of cirrhosis, presence of comorbidities and length of hospital stay are independent predictors of early HR. Conversely, socioeconomic factors do not seem to be related. It is necessary to develop and implement new strategies and interventions to prevent early re-hospitalization.

P0146

ORAL, ONCE-DAILY, CENICRIVIROC LEADS TO RAPID AND POTENT CCR2 AND CCR5 BLOCKADE IN SUBJECTS WITH ADVANCED LIVER DISEASE, SIMILAR TO EFFECTS SEEN IN HEALTHY VOLUNTEERS AND HIV-1 INFECTED SUBJECTS

N.S. Utay[1], M. Gottwald[2], W. Chang[2], M.S. Willett[3], E. Lefebvre[2]. *[1]University of Texas Medical Branch at Galveston, Galveston, TX, United States; [2]Tobira Therapeutics, Inc., South San Francisco, CA, United States; [3]Ready Clinical, LLC, Princeton, NJ, United States*
E-mail: neutay@UTMB.EDU

Background and Aims: Cenicriviroc (CVC), a potent, oral, once-daily CCR2/CCR5 antagonist, is in Phase 2b clinical development in adults with NASH and liver fibrosis, and is antifibrotic in animal models of liver and kidney disease, with favourable safety in ~580 subjects. CVC's antifibrotic activity is largely attributed to decreased monocyte/macrophage infiltration in the liver, leading to decreased hepatic stellate cell activation and reduced fibrogenesis. We aimed to characterise the immunologic effects of CVC across different populations.
Methods: Hepatic-impaired subjects (Child–Pugh class A or B; N = 15) and matched controls (N = 15) received CVC 150 mg daily for 2 weeks (Study 652–1–121). HIV-1-infected subjects (N = 52) re-

IQR, Interquartile range.

ceived CVC 200 mg daily with tenofovir/emtricitabine for ≤48 weeks (Study 652–2–202). MCP-1 (CCR2 ligand) and MIP-1β (CCR5 ligand) plasma levels were measured at baseline (BL) and after 1 and 2 weeks of CVC treatment in both studies; other CCR5 ligands (MIP-1α and RANTES), cytokines (IL-1β, IL-6, TNF-α) and microbial translocation markers (soluble CD14 [sCD14], LPS binding protein [LBP], intestinal fatty acid binding protein [I-FABP], flagellin) were measured in Study 121. Wilcoxon tests and Spearman correlations were used.
Results: Rapid and significant increases in MCP-1 and MIP-1β were observed after 1 and 2 weeks of treatment across all treatment groups (Table). In Study 121, as in Study 202, higher MCP-1 levels correlated with higher peak CVC concentration ($r = 0.39$, $p = 0.03$). In matched controls (moderate), TGF-β and RANTES increased during CVC treatment ($p = 0.008$, Week 2 vs BL). After 2 weeks of CVC treatment, there were no significant changes in MIP-1α, sCD14, LBP, I-FABP, flagellin, IL-1β, IL-6 or TNF-α. Flagellin correlated with I-FABP at BL ($r = 0.44$, $p = 0.01$) and Week 2 ($r = 0.40$, $p = 0.03$), and with ALT at BL ($r = 0.41$, $p = 0.02$) and Week 2 ($r = 0.45$, $p = 0.01$). In Study 202, sustained reductions in sCD14 were observed over 48-week CVC treatment ($p < 0.001$, CVC vs efavirenz).
Conclusions: CVC treatment led to rapid, reciprocal increases of MCP-1 and MIP-1β, due to effective CCR2 and CCR5 blockade across all treatment groups, regardless of underlying pathology; the greater magnitude in MIP-1β changes in HIV-1-infected subjects could be attributed to HIV binding to CCR5. Correlation between MCP-1 and CVC concentrations suggests a dose-dependent effect. Importantly, increased MCP-1 and MIP-1β levels were not associated with increased markers of intestinal damage, or hepatic or systemic inflammation.

P0147
MALNUTRITION AND ADHERENCE TO NUTRITIONAL RECOMMENDATION IN PATIENTS WITH CIRRHOSIS

B.D. Procopet[1], A. Epure[2], L. Filip[2], M. Grigorescu[1], A. Habic[1], C. Radu[1], M. Tantau[1], D. Crisan[1]. *[1]Gastroenterology, [2]Nutrition – Pharmacology, University of Medicine and Pharmacy "Iuliu Hatieganu" Cluj-Napoca, Cluj-Napoca, Romania*
E-mail: bogdanprocopet@gmail.com

Background and Aims: Malnutrition proved to be prevalent in patients with cirrhosis and has prognostic relevance. The aim of our study was to: check the prevalence of malnutrition in a population with decompensated cirrhosis and to evaluate the adherence to nutritional recommendations.
Methods: 101 consecutive patients with cirrhosis (64 hospitalized for decompensation and 37 compensated from outpatient ward) were prospectively evaluated for the presence of malnutrition using Subjective Global Assessment (SGA) criteria and mid-arm circumference (MAC). Malnutrition was defined as SGA class B and C and MAC <10th. All patients were interviewed regarding their food intake using an adapted questionnaire and the energy and main nutrients (proteins, lipids, carbohydrates and salt) intake was calculated.
Results: According to the SGA, in the decompensated group 48 patients (75%) had malnutrition, while only 9 patients (24%) were malnourished in the compensated group. Using the MAC criteria, malnutrition was present in 41 (64%) decompensated and 13 (35%) compensated patients. Only 13 (12.9%) patients had the recommended alimentary intake, 78 (77.2%) patients had a suboptimal energy intake and only 26 (25.7%) patients had the recommended protein intake. Only 26 (25.7%) among all and 16 (25%) among decompensated patients were adherent to low salt diet.
Lower cholesterol levels (HR = 0.97, $p = 0.001$), lower sodium (HR = 0.71, $p = 0.004$) and female sex (HR = 8.25, $p = 0.01$) are independently associated with presence of malnutrition.
Conclusions: Prevalence of malnutrition is high in patients with advanced cirrhosis and is related in part to a low adherence to nutritional recommendations.

P0149
SIX-MONTH MORTALITY OF CIRRHOTIC PATIENTS WHO SURVIVED INTENSIVE CARE: A META-ANALYSIS

D. Weil[1], V. Di Martino[1], E. Levesque[2], M. McPhail[3], R. Cavallazzi[4], E. Theocharidou[5], E. Cholongitas[6], A. Galbois[7], H.-C. Pan[8], C. Karvellas[9], B. Sauneuf[10], R. Robert[11], J. Fichet[12], G. Piton[13], G. Capellier[13], T. Thévenot[1], METAREACIR Group. *[1]Service d'hépatologie, CHU Jean Minjoz, Besançon, [2]Centre Hépatobiliaire, Hôpital Paul Brousse, Villejuif, France; [3]Liver Intensive care Unit, King's College, London, United Kingdom; [4]Intensive care Unit, University of Louisville, Louisville (KY), United States; [5]Sheila Sherlock Liver Center, Royal free hospital, London, United Kingdom; [6]Liver Department, Aristotle University, Thessaloniki, Greece; [7]Intensive care Unit, Hôpital Saint Antoine, Paris, France; [8]Nephrology Department, Chang Gung Memorial Hopsital, Taipei, Taiwan; [9]Intensive care Unit, University of Alberta, Edmonton, Canada; [10]Intensive care Unit, Hôpital Cochin, Paris, [11]Intensive care Unit, CHU Poitiers, Poitiers, [12]Intensive care Unit, CHU de Tours, Tours, [13]Intensive care Unit, CHU Jean Minjoz, Besançon, France*
E-mail: vdimartino@chu-besancon.fr

Background and Aims: The medium-term survival of cirrhotic patients who survived intensive care and its determinants have never been evaluated due to the small number of ICU survivors in the published studies. This meta-analysis evaluated the predictors of 6-month mortality in ICU survivors.
Methods: 13 studies (2695 cirrhotics) were analyzed after selection of original articles and response to a standardized questionnaire by the corresponding authors. The endpoint was 6-month mortality of ICU survivors. 95 pooled analyses concerned patient characteristics, reason for admission, organ replacement therapy, and composite scores.
Results: 5 studies reported the outcome of 412 ICU survivors. Only 48 patients (3.4%) were transplanted during follow-up. Six-month mortality was lower in high volume centers (OR = 0.45;95% CI:0.30–0.67;$p < 0.001$), in general ICUs (OR = 0.31;95% CI:0.21–0.47;$p < 0.001$) in centers with TIPS (OR = 0.42;95% CI:0.25–0.46;$p = 0.002$), but not with liver transplantation (OR = 2.21;95% CI:1.21–4.04;$p = 0.008$) available. Age, sex and alcohol-related cirrhosis had no significant impact on 6-month mortality. Unlike for in-ICU mortality, high values of SOFA did not predict 6-month mortality in ICU survivors. Eight parameters of liver and renal function were associated with 6-month mortality, including Child–Pugh C stage (OR = 2.43;95% CI:1.44–4.10;$p < 0.001$), MELD ≥26 on ICU admission (OR = 3.97;95% CI:1.92–8.22;$p < 0.0001$;PPV = 0.75), hepatorenal syndrome (OR = 4.67;95% CI:1.24–17.64;$p = 0.022$;PPV = 0.88) and admission for acute renal failure (OR = 3.29;95% CI:1.70–6.40;$p < 0.001$;PPV = 0.73). Septic shock (OR = 3.95;95% CI:1.38–11.30;$p = 0.010$;PPV = 0.62) and nosocomial infection on admission (OR = 2.72;95% CI:1.09–6.76;$p = 0.031$;PPV = 0.76) were also associated with higher 6-month mortality. Among medical interventions, only the use of norepinephrine (OR = 2.07;95% CI:1.07–4.00;$p = 0.029$;PPV = 0.61), given for hepatorenal syndrome, was predictive of 6-month mortality in ICU survivors.
Conclusions: Only a minority of ICU survivors undergo liver transplantation. Liver and renal failures in ICU have a sustained impact on long-term mortality. The prognostic performance of general ICU scores decreases over time, unlike Child–Pugh and MELD scores, even measured in the context of organ failure. Eligible patients could thus be listed for transplantation in ICUs or shortly after ICU discharge.

E-mail: armand.garioud@ghpso.fr

Background and Aims: Bacterial endocarditis (BE) is severe in patients (pts) with liver cirrhosis (LC); data rely on uncontrolled studies. Aims of this study were to compare clinical presentation and mortality of BE in LC pts with those of controls (CT) without cirrhosis matched for sex, age and diabetes.
Methods: Medical charts for all LC pts with BE seen in 23 liver units (2000–2013) were reviewed and compared with those of CT. Short-term mortality was analyzed by univariate and logistic regression analysis.
Results: 101 BE in LC pts and 101 BE in CT were analyzed. LC pts: 63.3 [42–87] years, CT: 65 [46–93]; 145 M (72%). LC causes: alcohol: 78 (67.2%), viral: 17 (14.6%), NAFLD: 14 (12%). Child–Pugh scores: A: 8.8% pts, B: 42.9% pts, C: 48.3%. In LC pts: total bilirubin was 67.8 μmol/l±77.7, prothrombin time (PT) 52.7±18.1%, serum albumin 25 g/l±5.9, serum creatinine (SC) 123.5 μmol/l±103.6. Blood cultures were positive in 181 pts (92%). 39 LC pts (40.2%) and 52 CT (53.6%) had a pre-existing heart disease (NS). At diagnosis, 43 LC (47.7%) and 31 CT (34.0%) exhibited heart failure (NS). Severe sepsis or septic shock was noted in 33 LC pts (33.3%) and 23 CT (23.0%) (NS). The source of contamination was digestive, urinary, or cutaneous (DUC) in 41 LC pts and in 21 CT (OR 2.4 [1.1–5.1], p < 0.01). The aortic valve was involved in 68.4% of LC pts and 47.7% CT (NS). The isolated bacteria (Staphylococcus n = 67: LC = 33, CT = 34; Streptococcus n = 92: LC = 48, CT = 44) were comparable as well as antibiotics and the duration of treatment. 26 LC (27.1%) and 44 CT (44.9%) had heart surgery (0.5 [0.2–0.9], p < 0.01). 56 LC (62.2%) and 25 CT (27.8%) died (OR: 6.1 [3–12.5], p < 0.0001). By univariate analysis death was related in CT pts with presence of severe sepsis or shock (p = 0.02). In LC pts mortality was related with PT <40% (OR 6.75 [1.6–32.7], p = 0.002), SC value (p < 0.03), ascites (OR 7.4 [1.7–34.2], p = 0.001) and total bilirubin (p = 0.02). By multivariate analysis, mortality was related in overall population with cirrhosis: (OR 2.35 [1.04–5.36], p = 0.04) and PT <40% (OR 7.52 [2.41–29.6], p < 0.001). In LC pts, mortality was related with PT <40% (OR 21.6 [2.9–508], p = 0.01) and ascites (OR 8.3 [1.4–69], p = 0.03).
Conclusions: Bacterial endocarditis is very severe in LC pts with less access to surgery. DUC sources of contamination are more frequent in LC pts than in controls. Cirrhosis is independently associated with mortality with and increased risk of death by 2.35. Predictors of death in cirrhotic patients are a PT <40% and the presence of ascites.

P0151
COVERT HEPATIC ENCEPHALOPATHY COMPRISES TWO CLINICALLY AND PATHOPHYSIOLOGICALLY DISTINCT SYNDROMES: A PROSPECTIVE LONGITUDINAL STUDY

K.L. Thomsen[1], J. Macnaughtan[1], G. Tritto[1], R. Mookerjee[1], R. Jalan[1]. *[1]UCL Institute of Liver and Digestive Health, University College London, London, United Kingdom*
E-mail: karethom@rm.dk

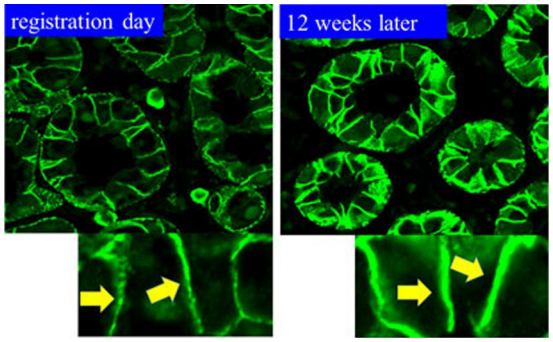
Background and Aims: EASL/AASLD hepatic encephalopathy (HE) guidelines proposed that Grade 1 HE and minimal HE (mHE) be combined into a single entity referred to as 'Covert HE'. However, prospective, longitudinal data to indicate that these are indeed a single entity are lacking. The study aims were to determine whether these entities were clinically and pathophysiologically similar. The end-points were (a) occurrence of complications of cirrhosis such as variceal bleeding, infection, ascites and HE requiring hospital admission and mortality (b) ammonia levels and inflammatory markers and (c) neutrophil function.
Methods: Clinically-stable liver cirrhosis out-patients (n = 106; age 58±10 years; 67 men; aetiology: viral: 44, alcohol: 43) with no previous history of HE were included over a 2-year period and classified as having no HE (n = 23), mHE (n = 39) or Grade 1 HE (n = 44) using the West-Haven criteria, EEG, psychometric tests (PHES) and critical flicker frequency (CFF). Patients were followed clinically and biochemically for a median of 241±110/234±105/229±93 days. Venous ammonia, bacterial DNA and neutrophil respiratory burst were measured at inclusion and the patients were followed for the occurrence of complications requiring hospitalisation and death.
Results: Patients with Grade 1 HE had more complications (infection 9/18/34%; HE 4/8/18%; other 9/13/14%; P = 0.02) and had significantly greater mortality (9/8/23%; P = 0.02) compared to patients with no HE or mHE respectively. Ammonia and white cell count were not different between patients with mHE and Grade 1 HE but ammonia was higher than no HE group (48±11/61±14/62±12 μmol/L; P < 0.001). Severity of liver disease was similar in the 3 groups (MELD score: no HE: 15±5, mHE: 13±6, Gr 1 HE: 16±6). However, patients with Grade 1 HE had increased bacterial translocation (57% vs. 36%; P = 0.02) and neutrophil spontaneous respiratory burst (22±22% vs. 13±14%; P = 0.02) compared to patients with mHE indicating susceptibility to infection in these patients.
Conclusions: The results of this study show for the first time that 'Covert HE' is a heterogeneous entity comprising two clinically and pathophysiologically distinct syndromes. The most common complication necessitating hospital admission in Grade 1 HE patients is infection and this is associated with bacterial translocation and neutrophil dysfunction. Future studies should address this novel finding of HE induced susceptibility to infection.

P0152

THE EFFECT OF IRSOGLADINE MALEATE FOR PORTAL HYPERTENSIVE GASTROPATHY (PHG)

K. Yokoyama[1], M. Irie[1], A. Anan[1], S. Fukuda[1], N. Thuchiya[1], A. Fukunaga[1], K. Takata[1], T. Tanaka[1], T. Hanano[1], G. Hirano[1], D. Morihara[1], Y. Takeyama[1], S. Shakado[1], T. Sohda[1], S. Sakisaka[1].
[1]*Department of Gastroenterology and Medicine, Fukuoka University Faculty of Medicine, Fukuoka, Japan*
E-mail: yokotin@minf.med.fukuoka-u.ac.jp

Background and Aims: Portal hypertensive gastropathy (PHG) due to portal hypertension (PH) is characterized by noninflammatory edema and vasodilatation of the lamina propria of mucous membrane. In addition, the decrease in intercellular junctional proteins and the dilatation of the endothelium gap is also said to be one of causes. Therefore, some relationship between PHG and tight junction (TJ) which is one of intercellular adhesions has been suggested. In this study, we examined the possibility that Irsogladine maleate would improve PHG by having restoration of TJ.
Methods: Eighteen patients with PHG were registered and randomly assigned in a ratio of 2:1 the irsogladine maleate administration group and the non-administration group. In the administration group, irsogladine maleate (4 mg/day) was administered orally from the registration day until 12 weeks later. Redness mucosas of the PHG were collected endoscopically at the registration day and 12 weeks later and compared. Evaluation methods for therapeutic effect determination were itemized as follows, (a) macroscopic findings by endoscope, (b) Immunological findings of claudin-3 protein (TJ protein) by laser microscope in gastric mucosal tissue, (c) quantification of claudin-3 protein (Western blotting) in gastric mucosal tissue.
Results: The macroscopic findings were improved in two of 12 patients in the administration group, and the laser microscope image which suggested restoration of TJ by immunological findings provided in eight patients. In addition, in a total of 21 samples in 12 patients of the administration group and a total of 12 samples in 6 patients of the non-administration group, the percentage of samples to increase in the claudin-3/β-actin (protein quantification/control) after 12 weeks was larger in the administration group than the non-administration group (66.7% vs 33.3%). Moreover in claudin-3/β-actin, the average value subtracted registration day value from 12 weeks later value in the administration group was significantly higher than the non-administration group ($p = 0.0386$). Therefore, it showed that higher effect of TJ restoration in the administration group.
Conclusions: In this study, we suggested the possibility that irsogladine maleate would prevent progression of PHG and bleeding by raising the ability for restoration of TJ failure.

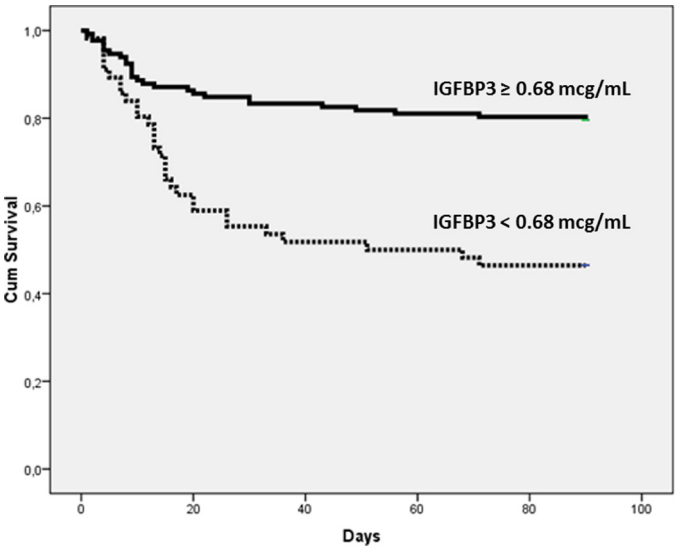


P0153

INSULIN-LIKE GROWTH FACTOR-BINDING PROTEIN 3 (IGFBP3) SERUM LEVELS ARE ASSOCIATED WITH PROGNOSIS IN PATIENTS ADMITTED FOR ACUTE DECOMPENSATION OF CIRRHOSIS

C.G. Correa[1], B.S. Colombo[1], M.F. Ronsoni[1], P.E. Soares e Silva[1], L. Fayad[1], L.M. Wildner[1], M.L. Bazzo[1], E. Dantas-Correa[1], J.L. Narciso-Schiavon[1], L.L. Schiavon[1]. [1]*Internal Medicine, Federal University of Santa Catarina, Florianópolis, Brazil*
E-mail: leo-jf@uol.com.br

Background and Aims: Decreased IGFBP3 serum levels have been reported in patients with cirrhosis and seem to correlate with hepatic dysfunction intensity. However, data about its prognostic significance is still lacking. We sought to investigate the relationship between serum IGFBP3 levels and short-term prognosis in patients admitted for acute decompensation of cirrhosis.
Methods: In this prospective cohort study, patients admitted in the emergency department were followed during their hospital stay and 90-day mortality was evaluated by phone call. ACLF criteria were applied according to the EASL-CLIF Consortium definition. Twenty-nine patients were also evaluated in the outpatient clinic after discharge and were compared in two moments (inpatient and outpatient evaluation).
Results: Between January 2011 and November 2013, 189 patients were included, with a mean age of 53.6±11.6 years, and a male predominance (73.0%). The mean MELD score was 16.3±6.5 and 39.7% of the individuals were Child–Pugh C. IGFBP3 levels positively correlated with sodium and albumin levels and negatively correlated with INR, CPR, total bilirubin and MELD score. Significantly lower IGF-1 levels were observed in Child–Pugh C ($P < 0.001$) and in ACLF ($P = 0.007$) patients. The 90-day mortality was 30.3% and it was associated in the bivariate analysis with active alcoholism, bacterial infection, ascites, hepatic encephalopathy, Child–Pugh C and ACLF at admission. Concerning laboratory data, 90-day mortality was associated with higher leucocyte count, creatinine, INR, CRP, venous lactate, total bilirubin, MELD and lower sodium, albumin and IGFBP3 at admission. Logistic regression analysis including variables with $P < 0.01$ in the bivariate analysis showed that MELD score, ascites at admission and IGFBP3 <0.68 mcg/mL were independently associated with 90-day mortality. The Kaplan–Meier survival probability (Figure) at 90-day was 79.5% in patients with IGFBP3 ≥0.68 mcg/mL and 46.4% for subjects with IGFBP3 <0.68 mcg/mL ($P < 0.001$). Significantly lower IGFBP3 levels were found at the time of acute decompensation of cirrhosis as compared to the outpatient evaluation (1.19±0.57 mcg/mL vs. 1.69±0.86 mcg/mL, $P = 0.001$).



Conclusions: IGFBP3 levels correlated with the severity of hepatic dysfunction and decrease during acute decompensation of cirrhosis. IGFBP3 was also independently associated with short-term mortality and thus may represent a promising tool in assessing prognosis of cirrhosis.

P0154

DIFFERENTIAL LEUKOCYTE COUNT AS AN ADJUNCTIVE BIOMARKER OF OUTCOME IN PATIENTS WITH ACUTE-ON-CHRONIC LIVER FAILURE

M.J. McPhail[1,2], C. Bernsmeier[1], E. Fatourou[2], A. Dhar[2], G. Auzinger[1], C. Willars[1], W. Bernal[1], M. Thursz[2], C. Antoniades[1,2], J.A. Wendon[1].
[1]Institute of Liver Studies, Kings College Hospital, [2]St Marys Hospital, Imperial College London, London, United Kingdom
E-mail: m.mcphail@imperial.ac.uk

Background and Aims: Susceptibility to bacterial infection and activation of systemic inflammatory responses (SIRS) are poor prognostic features in acute decompensation (AD) of cirrhosis and acute-on-chronic liver failure (ACLF). In non-hepatic systemic inflammatory disorders, circulating neutrophil to lymphocyte ratios are correlated with infectious complications and mortality. Peripheral blood leukocyte concentrations are not part of modern systems for outcome prediction such as the chronic liver failure sequential organ failure assessment (CLIF-SOFA). We determine the prognostic utility of differential leukocyte concentrations in patients with AD and ACLF.

Methods: 51 patients with ACLF were consecutively recruited. Peripheral blood leukocyte concentrations were measured on hospital or liver intensive care admission and correlated to MELD, CLIF-SOFA score, culture positive bacterial infection (CPBI) and hospital survival. A further 243 patients with ACLF and 67 patients with AD were used as a validation set.

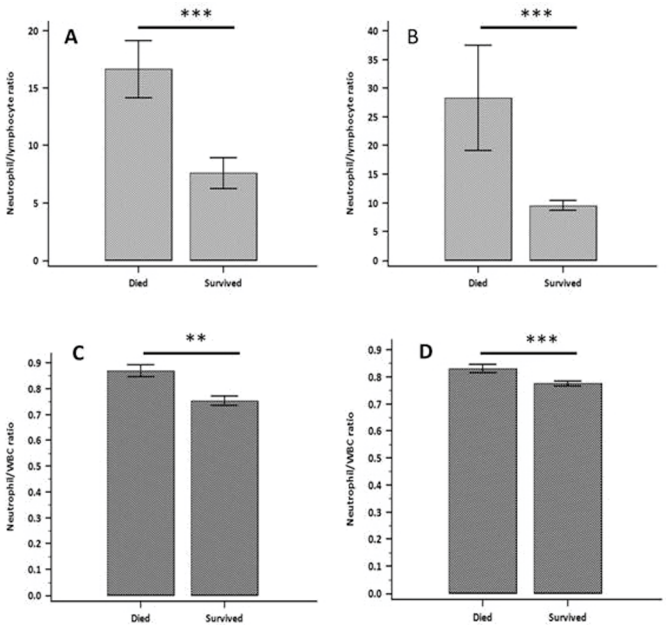


Figure 1. Mean (SEM) values of neutrophil/lymphocyte ratio and neutrophil/white blood cell (WBC) ratio in the derivation (A,B) and validation (C,D) ACLF cohorts (**p < 0.001; ***p < 0.0001).

Results: Total white cell count was not different between survivors or non-survivors. Non-survivors had higher neutrophil concentrations and lower lymphocyte concentrations. Both neutrophil/lymphocyte concentration ratio (NLR; p < 0.0001) and neutrophil/WBC ratio (NWCR; p < 0.001) were higher in non-survivors as was monocyte lymphocyte ratio (MLR). SIRS score, NLR and NWCR were not dependent on the presence of CPBI. Both NLR and NWCR correlated with CLIF-SOFA (r = 0.647, p < 0.001 and r = 0.619, p < 0.001). NLR AND NWCR predicted outcome with AUROC of 0.802 (95% CI 0.677–0.927) and 0.821 (95% CI 0.704–0.938) respectively. In the validation cohort NLR and NWCR were again higher in non-survivors (p < 0.0001 for both). Only MLR was predictive of CPBI [AUROC 0.706 (0.563–0.848), p = 0.004, cut-off >0.438]. Addition of NLR to SOFA score gave higher AUROCs (0.768 v 0.731, p = 0.03) but did not improve accuracy of CLIF-SOFA. In the AD validation set NLR predicted outcome but with a reduced accuracy [AUROC 0.681 (0.532–0.830), p = 0.017].

Conclusions: ACLF is associated with high neutrophil and low lymphocyte counts, reflecting activation of SIRS responses. NLR and NLWC are associated with higher organ failure scores and mortality rates. NLR improves the outcome predictive accuracy of SOFA but not CLIF-SOFA. NLR and NWCR are associated with multi-organ failure whereas MLR predicts the presence of BI. These parameters may be incorporated into established prognostic scoring systems for earlier prediction of bacterial infections.

P0155

VALIDITY AND RELIABILITY OF SPLENIC VOLUME MEASUREMENT BY ULTRASOUND AND ITS CLINICAL IMPLICATIONS TO DEFINE SPLENOMEGALY IN LIVER CIRRHOSIS

S.G. Kim[1], H.J. Jung[1], Y.S. Kim[1], S.H. Lee[2], S.W. Jeong[3], J.Y. Jang[3], Y.D. Kim[4], G.J. Cheon[4], H.S. Kim[2], B.S. Kim[1]. *[1]Soonchunhyang university Bucheon hospital, school of medicine, Bucheon, [2]Soonchunhyang university Cheonan hospital, school of medicine, Cheonan, [3]Soonchunhyang university Seoul hospital, school of medicine, Seoul, [4]Gangneung Asan hospital, Gangneung, Korea, South*
E-mail: mcnulty@schmc.ac.kr

Background and Aims: Presentation of splenomegaly is a typical sign of liver cirrhosis. However, there are few studies for establishing the definition of splenomegaly. In this study, we aimed to measure splenic volume (SV) using ultrasound (US) and compared with computed tomography (CT) image as a reference standard and also try to find out its relationship with portal hypertension and best cut-off value for discriminating cirrhosis from non-cirrhosis.

Methods: SV was measured with US in 1,256 patients with chronic liver disease from August 2007 to March 2014. SV was obtained by conventional prolated ellipsoid formula (0.524×length×width×height). We evaluated the reliability of SV measurement which was performed by two sonographers simultaneously from randomly selected 82 patients (164 cases) and assessed the validity by the source image of CT from 105 patients. Liver biopsy was done in 217 patients within 6 month from SV measurement. We also evaluated the relationship between liver fibrosis and hepatic venous pressure gradient (HVPG) and SV. We did a sensitivity analysis with SV adjusted by body surface area (BSA).

Results: The concordance correlation coefficient (CCC) between two sonographers was 0.9886 (95% confidence interval [CI], 0.9816–0.9930) and CCC between the measurement by US and CT was 0.9721 (95% CI, 0.9556–0.9826). SV was increased in male, young ages and significantly larger in viral liver cirrhosis than alcoholic liver cirrhosis. SV showed a positive correlation with Child–Pugh score, MELD score and was increased greatly in patients having esophageal varices, gastric varices or ascites compared to those who had not. There was a significant difference of SV between fibroscan score (≤12 versus >12 kPa) in viral liver cirrhosis, but not in alcoholic liver cirrhosis. The AUROC of SV for the prediction of F4 was 0.812 (95% CI, 0.749–0.865, p < 0.001) and the optimal cut-off value of SV was 300.3 cm^3. SV/BSA also showed a good prediction for F4 (AUC, 0.802; 95% CI, 0.736–0.857; p < 0.001). However, there was no significance of SV for predicting significant HVPG (≥12 mmHg) (AUC, 0.578; 95% CI, 0.499–0.654; p = 0.106).

Conclusions: Splenic volume measured by US is precise and accurate and highly associated with the incidence of liver cirrhosis complications. Splenic volume about 300 cm^3 was an optimal cut-off value to discriminate between cirrhosis and non-cirrhosis.

P0156

RISK FACTORS ASSOCIATED WITH OVERALL AND BLEEDING-RELATED MORTALITY IN PATIENTS WITH PORTAL VEIN THROMBOSIS ON THE WAITING LIST FOR LIVER TRANSPLANTATION

S. Iacob[1], C. Ester[1], R. Iacob[1], C. Gheorghe[1], I. Popescu[1], L. Gheorghe[1]. *[1]Fundeni Cinical Institute, Bucharest, Romania*
E-mail: msiacob@gmail.com

Background and Aims: The reported prevalence of PVT is increasing in patients with ESLD awaiting LT. It significantly affects waiting list survival, complicates the liver transplant operation and impacts post-transplant survival and morbidity. Anticoagulation is a challenging therapy in patients with ESLD because of the well-recognized coagulation abnormalities in cirrhotics, the increased risk of bleeding, and the lack of evidence of a real clinical benefit from the therapy. The aim of the study was to investigate the risk factors for overall and hemorrhage related death in a cohort of 104 cirrhotic patients with PVT included on the waiting list for LT.
Methods: We tested separately the association between different parameters and overall death while on the waiting list using Cox regression model.
Results: There were 68.3% men with a mean age of 53.0±9.8 years, 30.8% of patients had HCV and 36.5% had HBV-related cirrhosis. Overall death was encountered in 31.7% of patients, out of whom 14 (13.5%) were hemorrhage-related. As independent risk factors for overall death were identified the following: associated superior mesenteric vein thrombosis ($p = 0.04$), refractory ascites with frequent paracentesis ($p = 0.01$), shorter time from liver cirrhosis to PVT diagnosis ($p < 0.0001$). Hemorrhage-related death was associated only with the administration of anticoagulation therapy ($p = 0.002$).
Conclusions: Anticoagulant therapy is associated with higher risk of hemorrhage-related death, but not with overall death on the waiting list.

P0157

ADHERENCE AND SAFETY OF BETA-BLOCKERS IN ELDERLY PATIENTS WITH CIRRHOSIS AND PORTAL HYPERTENSION: A MULTI-CENTER CROSS-SECTIONAL STUDY

V. La Mura[1], C. Sylvestre[2], L. Pasina[2], A. Nobili[2], M. Primignani[3], A. Conca[1], L. Moroni[1], V. Monti[1], S. Accordino[1], G. Gobbo[1], P. Mannuccio Mannucci[3], F. Salerno[1]. *[1]IRCCS Policlinico San Donato, San Donato Milanese, [2]Mario Negri, [3]IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Italy*
E-mail: francesco.salerno@unimi.it

Background and Aims: In elderly patients co-morbidities are frequent and may affect therapy because of drug interactions. In patients with cirrhosis non-selective beta-blockers (NSBBs) can be given as a prophylaxis of variceal bleeding. The best protective effect is obtained with drug doses sufficient to stably reduce the heart rate below 60 bpm. However, the adherence to such a schedule in old cirrhotic patients with co-morbidities has never been investigated. The aim of the present study was to assess the adherence and safety of BBs in >65 years old in-patients with cirrhosis and co-morbidities.
Methods: One-hundred eighty-four cirrhotic patients admitted in 38 Italian internal medicine wards were prospectively studied during a period of 4 weeks. Their clinical and pharmacological history, the length of hospital stay (LOS), and the occurrence of adverse events were recorded and tested by uni- and multi-variable analysis to identify possible associations with the use of BBs.
Results: At admission 64 of 184 cirrhotic patients (35%) were receiving BBs. Thirty-two were receiving a NSBB and in 26 the main indication was the prophylaxis of portal hypertension related bleeding. In only 5 of these patients heart rate was <60 bpm. LOS was 8.6±6.3 days for cirrhotic patients not-receiving BBs, 10.4±6.3 for patients receiving BBs for portal hypertension, and 13.8±12.2 for patients receiving BBs for cardio-vascular disease ($p = 0.016$). Twenty-five patients had kidney failure associated with the use of BBs ($p < 0.01$). However, this association was lost after adjusting for other factors significantly associated to kidney failure. At multivariable analysis, only older age and PPI use were independently associated with kidney failure.
Conclusions: The doses of BBs given as a prophylaxis of bleeding in most elderly in-patients with cirrhosis and co-morbidities are probably insufficient being the patient HR >60 bpm in 80% of cases. The use of BBs in such patients is associated with longer LOS and kidney failure. However, a cause-effect relationship between BBs and renal function was excluded in our series. A better appropriateness in the BBs prescription should be recommended in elderly cirrhotic patients with portal hypertension.

P0158

INFLUENCE OF SUSTAINED VIRAL RESPONSE IN THE REGRESSION OF FIBROSIS AND PORTAL HYPERTENSION IN CIRRHOTIC HCV GENOTYPE 1 PATIENTS TREATED WITH TRIPLE THERAPY

A. Puente[1,2], J. Cabezas[1,2], M.T. Arias Loste[1,2], A. Estébanez[2], J.I. Fortea[1,2], A. Cuadrado[1,2], E. Fábrega[1,2], F. Casafont[1,2], J. Crespo[1,2]. *[1]Hepatology Unit. Gastroenterology and Hepatology department, Marqués de Valdecilla University Hospital, [2]Clinical Trials Unit, IDIVAL, Santander, Spain*
E-mail: angelapuente@hotmail.com

Background and Aims: Treatment with protease inhibitors has allowed a SVR above 50% in HCV genotype 1 cirrhotic patients. However, regression of liver fibrosis and portal hypertension (PH) has not been studied. Our objective was to evaluate the influence of SVR in portal pressure gradient (HVPG), and non-invasive parameters of PH and fibrosis by Fibroscan®. Also, predictors of SVR were studied.
Methods: From November 2012 to August 2013, 16 compensated HCV genotype 1 cirrhotic patients with PH (HVPG >6 mmHg), without beta-blocker therapy, candidates to PEGα2a+RBV+BOC (48 weeks, lead-in). An hemodynamic study and a FibroScan® were performed at baseline, 8 weeks and, in the case of SVR, 24 weeks after treatment. In each hemodynamic study serum samples of inflammatory biomarkers associated with PH were analyzed (VCAM1, IL-1β and IL-1Rα) and renin/aldosterone. Statistical analysis was performed using the SPSSv20 program.
Results: Baseline characteristics: age 55±8years, 6 males (37%), previous response (naive n = 10; n = 5 null response; relapsers n = 1), 130±58*103platelets/L, albumin 4±0.4 mg/dl, bilirubin 0.9±0.4 mg/dL, ALT 61±6 IU/L, renin 7.4±4 ng /mL, aldosterone 62.9±51.7 ng/mL, Child–Pugh 5±0.5, MELD 6.6±1, Fibroscan®21.3±14.5 kPa, HVPG 10.6±4.3 mmHg, esophagueal varices (small n = 2; large n = 2). 8 patients achieved SVR, 5 relapsed, and treatment was stopped due to non-response to lead-in (n = 1) and decrease <3 log viral load at week 8 (n = 2). Compared to baseline, at weeks 8 and 72 there was a significant decrease in HVPG (10.6±4.3 vs 9.4±5.04 vs 6.1±3.61 mmHg, $p < 0.0001$) and Fibroscan® values (21.3±14.5 vs 16.2±9.5 vs 6.4±4.5 kPa, $p < 0.0001$). In the multivariate analysis, factors predicting SVR were a prior null response ($p = 0.042$) and renin baseline value ($p = 0.038$). The HVPG average decrease in SVR was 38.5±18%, achieving a HVPG <6 mmHg in 5 patients (62.5%) and Fibroscan® <7.1 kPa in n = 3 (37.5%). There was also a significant decrease at weeks 8 and 72 in VCAM1, IL-1β and IL-1Rα values ($p < 0.0001$) with a strong positive

correlation with Renin/Angiotensine axis r = 0.875 p = 0.016 in SVR patients.
Conclusions: Complete hemodynamic response (HVPG <6 mmHg) and fibrosis regression (Fibroscan® <7.1 kPa) were observed in more than half and one third of SVR patients, respectively. We strongly suggest that HVPG and fibrosis response must be evaluated in SVR-cirrhotic patients due to their potential influence on risk of liver decompensation and hepatocellular carcinoma. The new direct antiviral agents should also be evaluated in these terms.

P0159
NON INVASIVE BLOOD FLOW MEASUREMENT BY "ARTERIAL SPIN LABELING" DETECTS MINIMAL HEPATIC ENCEPHALOPATHY

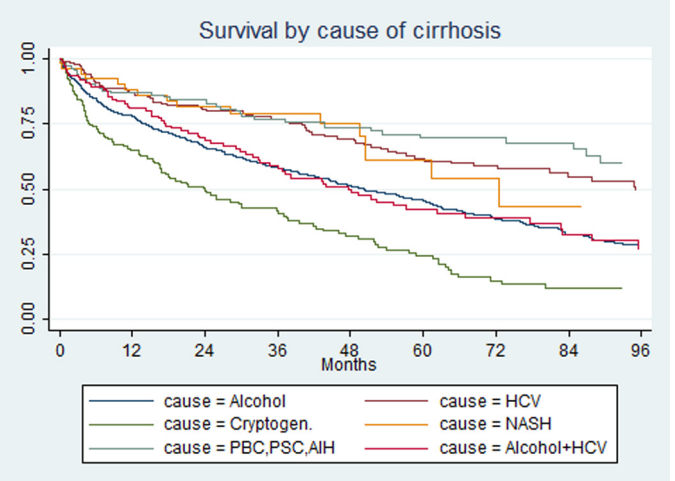
A. Urios[1], C. Gímenez-Gascó[2], A. Agustí[1], A. Mangas-Losadas[1], R. Garcia[2], A. Escudero-Sanchis[3], D. Escudero-García[4], O. González[3], M.A. Serra[4], R. Giner-Durán[3], V. Belloch[5], V. Felipo[2], C. Montoliu[1].
[1]Fundacion Investigacion Hospital Clinico Universitario de Valencia. INCLIVA, [2]Laboratorio de Neurobiología, Centro Investigación Príncipe Felipe de Valencia, [3]Servicio de Digestivo, Hospital Arnau de Vilanova de Valencia, [4]Grupo Hepatología, Servicio Aparato Digestivo, Hospital Clínico de Valencia, [5]ERESA, Unidad de RM de Valencia, Valencia, Spain
E-mail: cmontoliu@incliva.es

Background and Aims: To assess whether non invasive blood flow measurement by arterial spin labeling in several brain regions detects minimal hepatic encephalopathy
Methods: Blood flow (BF) was analyzed by arterial spin labeling (ASL) in different brain areas of 14 controls, 24 cirrhotic patients without and 16 cirrhotic patients with minimal hepatic encephalopathy (MHE).
Images were collected using a 3 Tesla MR scanner (Achieva 3T-TX, Philips, Netherlands). Pulsed ASL was performed. Patients showing MHE were detected using the battery Psychometric Hepatic Encephalopathy Score (PHES) consisting of five tests. Different cognitive and motor functions were also assessed: alterations in selective attention were evaluated using the Stroop test. Patients and controls also performed visuo-motor and bimanual coordination tests. Several biochemical parameters were measured: serum pro-inflammatory interleukins (IL-6 and IL-18), 3-nitrotyrosine, cGMP and nitrates+nitrites in plasma, and blood ammonia. Bivariate correlations were evaluated.
Results: In patients with MHE, BF was increased in cerebellar hemisphere (P = 0.03) and vermis (P = 0.012) and reduced in occipital lobe (P = 0.017). BF in cerebellar hemisphere was also increased in patients without MHE (P = 0.02). Bimanual coordination was impaired in patients without MHE (P = 0.05) and much more in patients with MHE (P < 0.0001). Visuo-motor coordination was impaired only in patients with MHE (P < 0.0001). Attention was slightly affected in patients without MHE and more strongly in patients with MHE (P < 0.0001). BF in cerebellar hemisphere and vermis correlated with performance in most tests of PHES [number connection tests A (NCT-A), B (NCT-B) and line tracing test] and in the congruent task of Stroop test. BF in frontal lobe correlated with NCT-A. Performance in bimanual and visuomotor coordination tests correlated only with BF in cerebellar hemisphere. BF in occipital lobe correlates with performance in the PHES battery and with CFF. BF in cerebellar hemisphere correlates with plasma cGMP and nitric oxide (NO) metabolites. BF in vermis cerebellar also correlates with NO metabolites and with 3-nitrotyrosine. IL-18 in plasma correlates with BF in thalamus and occipital lobe.
Conclusions: Non invasive BF determination in cerebellum using ASL may detect MHE earlier than the PHES. Altered NO-cGMP pathway seems to be associated to altered BF in cerebellum.

P0160
LIVER CIRRHOSIS IN SOUTHERN SWEDEN 2001–2011: A POPULATION-BASED STUDY

E. Nilsson[1], K. Sargenti[1], H. Anderson[2], H. Prytz[1]. *[1]Region Skåne, Lund University, [2]Lund University, Lund, Sweden*
E-mail: emma.nilsson@skane.se

Background and Aims: In Sweden, the most common causes of liver cirrhosis are alcohol overconsumption and hepatitis C. While epidemiological data suggest that Sweden has a low cirrhosis-related mortality compared with other European countries, recent data on the incidence, prevalence and outcome of cirrhosis are scarce. We undertook a systematic, population-based study of liver cirrhosis in southern Sweden.
Methods: We carried out a retrospective study in Skåne county, the southernmost part of Sweden. The region has a population of 1,169,464 (year 2005) and has a single-provider system for hospital care. Using population-based diagnosis registries, we identified 4,210 patients with liver disease (ICD-10 codes K70.3, K74.6, K74.3, B18.2G, B18.1G, K76.0, K83.0, K73.2, K75.4, I.85.0, I85.9 and C22.9). Following review of medical records and histopathology data, we identified and included 1,263 patients who were diagnosed with cirrhosis between January 2001 and December 2010. The aetiology was classified as alcohol-induced, HCV, cryptogenic, NASH, PBC, PSC, AIH, or other. Clinical parameters were registered, including age at diagnosis, complications at diagnosis, and date of death. All patients were followed until death or December 2011. The median observation time was 4.8 years for surviving patients. The median age at diagnosis was 60 years.
Results: The crude annual incidence of cirrhosis in southern Sweden was estimated at 14.8/100,000, 9.8 for women and 20.1 for men. No changes in incidence were observed during the study period. The most common aetiology was alcohol overconsumption (57%) followed by HCV (13%) and cryptogenic cirrhosis (11%). The most common complications at diagnosis were ascites (43%), variceal bleeding (6%) and overt encephalopathy (4%). The total one- and five-year survival rates were 79% and 48%, respectively. In patients with complications at diagnosis these survival rates were 69% and 37%. Patients with cryptogenic cirrhosis showed the highest mortality followed by alcoholic cirrhosis with or without concomitant HCV (Figure 1).
Conclusions: We present the largest population-based study describing baseline cirrhosis epidemiology in Sweden to date. Our results support that the incidence of cirrhosis in Sweden is comparable with that observed in other European countries. Mortality varies with aetiology. Notably, cirrhosis on the basis of HCV and alcohol in combination showed as poor outcome as alcoholic cirrhosis alone.



P0161

INCIDENCE AND RISK FACTORS FOR FALLS IN PATIENTS WITH COMPENSATED CIRRHOSIS

E. Román[1,2,3], C. Gely[1], M. Torrens[4], M. Poca[1,5], I.J. Gich[1,6], V. Vargas[3,4,5], J. Cordoba[3,4,5], C. Guarner[1,3,5], G. Soriano[1,3,5]. *[1]Hospital de la Santa Creu i Sant Pau, [2]Escola Universitària d'Infermeria EUI-Sant Pau, Barcelona, [3]CIBERehd, Instituto de Salud Carlos III, Madrid, [4]Hospital Vall d'Hebron, Barcelona, [5]Universitat Autònoma de Barcelona, Cerdanyola del Vallès, [6]CIBERsam, Instituto de Salud Carlos III, Madrid, Spain*
E-mail: gsoriano@santpau.cat

Background and Aims: Falls are frequent in patients with decompensated cirrhosis, particularly in those with subclinical cognitive dysfunction (CD). However, the incidence and risk factors for falls in patients with compensated cirrhosis are not known. The aims were to analyze the difference in the incidence of falls between patients with compensated cirrhosis and those with decompensated cirrhosis, and to evaluate risk factors for falls in the two groups.
Methods: We studied a cohort of outpatients with compensated or decompensated cirrhosis. The presence of CD was evaluated by the Psychometric Hepatic Encephalopathy Score (PHES). Patients were considered to have CD when their PHES was <−4. We prospectively recorded the incidence of falls during follow-up by evaluation every three months. The predictive factors associated with falls were determined by Cox regression analysis, and the probability of falls was estimated by Kaplan–Meier method.
Results: We included 302 patients, 189 men and 113 women. Mean age was 63.0±10.8 years and 83/302 (27.4%) had CD. Mean follow-up was 28.8±18.5 months. We found 32/122 (26.2%) patients with compensated cirrhosis fell during follow-up, compared to 49/180 patients (27.2%) with decompensated cirrhosis ($p = 0.89$). The independent predictive factors of falls in the multivariate analysis were CD (HR 2.7, 95% CI 1.2–6.2, $p = 0.01$) and age (HR 1.065, 95% CI 1.024–1.108, $p = 0.002$) in compensated patients; and CD (HR 3.0, 95% CI 1.6–5.6, $p < 0.001$), previous falls (HR 2.4, 95% CI 1.3–4.5, $p < 0.007$), viral etiology of cirrhosis (HR 2.3, 95% CI 1.2–4.3, $p = 0.008$) and comorbidity degree (HR 1.323, 95% CI 1.123–1.558, $p = 0.001$) in decompensated patients. The 2-year probability of falls was 24.8% in compensated patients: 63.0% in patients with CD and 18.7% in patients without CD ($p < 0.001$); and 23.8% in decompensated patients ($p = 0.38$ with respect to compensated patients): 50.3% in patients with CD and 12.0% in patients without CD ($p < 0.001$). Injuries caused by the falls were more severe in decompensated patients than in compensated patients ($p = 0.01$), but no differences were found between patients with and without CD.
Conclusions: The risk of falling in patients with compensated cirrhosis is similar to that in patients with decompensated cirrhosis. Among patients with compensated cirrhosis, the independent predictive factors associated with an increased risk of falls during follow-up are CD and older age.

P0162

CRITICAL FLICKER FREQUENCY IN DIAGNOSIS OF MINIMAL HEPATIC ENCEPHALOPATHY IN PATIENTS WITH CIRRHOSIS: AGE-DEPENDENT EFFECT

M. Nadinskaya[1], T. Khrustaleva[1], E. Sredina[1]. *[1]Department of Propaedeutics, I.M. Sechenov First MSMU, Moscow, Russia*
E-mail: marianad@rambler.ru

Background and Aims: Minimal hepatic encephalopathy (MHE) has a great sociomedical relevance. Currently psychometric tests and critical flicker frequency (CFF) are widely used to diagnose MHE. It is well known that, there are age-based normative data of psychometric tests, but not for CFF. According to several studies there is age among of individual parameters affecting the CFF results. The aim of the study was to evaluate CFF in different age groups in controls and compare CFF in patient with HE with controls age-adjusted data.
Methods: We performed CFF analysis and psychometric tests (digit symbol test and number connection test) on 104 patients with cirrhosis (40 men, 64 women, age 24–74) and 302 without (controls). Patients in control group (137 men, 165 women, age 18–83) were divided into 6 age groups with 10 years intervals about 50 people in each. Patients with liver cirrhosis were also evaluated using West Haven criteria for overt hepatic encephalopathy (HE).
Results: CFF frequencies in the control population depended on age groups. The values peak of CFF frequency (mean±1SD) was between the ages of 18 and 30 years old (45.1±2.9 Hz), and then begin to drop: 31–40 years old 44.0±2.9 Hz, 41–50 years old 44.2±3.7 Hz, 51–60 years old 42.4±3.2 Hz, 61–70 years old 41.2±3.5 Hz; CFF values were the least in persons more than 71 year old 40.5±4.2 Hz ($p < 0.001$). There was heterogeneous CFF in people more than 50 years old: arterial hypertension, ischemic heart disease and diabetes were factors associated with decreasing CFF. Among 102 patients with cirrhosis overt HE was diagnosed in 39 patients (according West Haven criteria HE I grade in 27 patients, II grade in 12), MHE – in 16 patients (abnormal results of psychometric tests). CFF distinguished between patients with overt HE, MHE and without minimal or overt HE in the entire population cirrhotic patients: HE II stage 36.1±3.5 Hz, HE I grade 37.3±2.8 Hz, MHE 40.2±3.4 Hz, without MHE 42.8±2.1 Hz ($p < 0.005$). There was difference CFF in patients with MHE depending on age. Patients without MHE had similar CFF with age-matched controls.
Conclusions: In controls values of CFF decreased depending on age. Although in cirrhotic group there was considerable overlap between patients with overt HE, MHE and without MHE, decreasing trend CFF according severity of HE was found. Patients without MHE had similar CFF with age-matched controls. In patients with MHE there was difference CFF depending on age.

P0163

MONITORING HEART RATE VARIABILITY DURING ACUTE DECOMPENSATION PREDICTS MORTALITY AND POTENTIAL RISK OF RECURRENT HOSPITALISATION

R. Sawhney[1], D.A. Chatterjee[1], A.G. Leon[2], R. Jalan[1], R.P. Mookerjee[1]. *[1]Institute of Liver and Digestive Health, University College London, Royal Free Hospital, London, [2]Isansys, Abingdon, Oxfordshire, United Kingdom*
E-mail: r.sawhney@ucl.ac.uk

Background and Aims: In advanced cirrhosis, hospital re-admissions are common and mortality high from inter-current illness. The aim of this study was to use heart rate variability (HRV), previously correlated with cirrhosis severity, to determine patient outcome following admission to hospital with an acute decompensation.
Methods: Using a wireless-monitoring technology, Lifetouch®, we assessed HRV (via the parameter SDNN) remotely in 32 patients (69% male; mean age 51.8±12.3 years; 75% alcoholic cirrhosis) admitted to Royal Free Hospital with acute decompensation. Patients were followed until discharge and data collected on subsequent death, transplantation or last date of follow-up to assess re-admission rate and disease severity. HRV data was compared with clinical and biochemical indices and correlated to patients' outcome.
Results: HRV, as determined by SDNN, was significantly lower in patients who died or who required liver transplantation ($p = 0.02$). Lower SDNN was associated with the presence of ACLF ($p = 0.03$). SDNN inversely correlated with Child–Pugh, MELD-Na and CLIF-AD scores ($p \leq 0.0001$ for all; $r = -0.47$, -0.52 and -0.62, respectively). ROC curve analysis demonstrated utility of SDNN for predicting mortality (AUC 0.75; $p = 0.02$) and this was better than Child–

Pugh, MELD-Na and CLIF-AD in this cohort. Based on this analysis, an SDNN cut-off of 19.65 ms for predicting death was selected with sensitivity 90%, specificity 57% and NPV 92% (p = 0.01). Further application of this cut-off using time-to-event analyses showed patients with SDNN >19.65 ms had significantly longer transplant-free survival (p = 0.004). Amongst patients discharged from hospital, there was a trend to delayed readmission to hospital with an SDNN >19.65 ms (p = 0.07). Three patients died or were transplanted during their index admission and all had very low SDNN (<11 ms). 67% of patients with subsequent readmission (median 109 days from discharge) and 75% of patients with multiple admissions had SDNN <19.65 ms.

Conclusions: This study shows HRV to be an important prognostic criterion for mortality, transplant-free survival and potential risk for readmission following acute decompensation of cirrhosis. HRV using the Lifetouch device can be used remotely to allow monitoring of patients at home and therefore could be a novel approach providing warning signals to trigger early intervention.

CLINICAL SIGNIFICANCE OF SUBCLINICAL ASCITES IN KOREAN PATIENTS WITH HEPATITIS B VIRUS-RELATED LIVER CIRRHOSIS: A MULTICENTER, RETROSPECTIVE STUDY

S.Y. Yim[1], H. Ahn[2], J.-H. Lee[2], S.U. Kim[3], S.G. Kim[4], Y.S. Kim[5], J.H. Kim[6], W.H. Choe[6], T.Y. Kim[7], Y.K. Jung[8], S.J. Suh[8], K.T. Suk[9], Y.S. Seo[1], S.H. Um[1]. *[1]Internal Medicine, Korea University Hospital, [2]Internal Medicine, Seoul National University Hospital, [3]Internal Medicine, Yonsei University Hospital, Seoul, [4]Internal Medicine, Soonchunhyang University Hospital, Bucheon, [5]Internal Medicine, Soonchunhyang University Hospital, Bucehon, [6]Internal Medicine, Konkuk University Hospital, Seoul, [7]Internal Medicine, Hanyang University Hospital, Guri, [8]Internal Medicine, Korea University Hospital, Ansan, [9]Internal Medicine, Hallym University, Chuncheon, Korea, South*
E-mail: eug203@naver.com

Background and Aims: Effective suppression of HBV DNA with antiviral therapy in HBV-related cirrhotic patients reduces the risk of hepatic events and mortality. However, clinical prognosis of patients with subclinical ascites (SA) compared to those without is still unclear. Therefore, we aimed to evaluate the clinical significance of SA in HBV-related cirrhotic patients treated with nucleot(s)ide analogues.

Methods: This multicenter retrospective study involving 8 hospitals enrolled patients with HBV-related cirrhosis in whom lamivudine (LMV) or entecavir (ETV) was started from January 2007 to December 2009. Patients were classified into 3 groups according to the degree of ascites: (1) No ascites (NA) group, no ascites detected by imaging study and no diuretics, (2) Subclinical ascites (SA) group, small amount of ascites detected by imaging study but no diuretics, (3) Clinical ascites (CA) group, either moderate/severe ascites or any grade of ascites with diuretics.

Results: A total of 501 patients were enrolled where 336 (67.7%), 51 (10.2%) and 114 (22.8%) patients were classified as NA, SA and CA groups, respectively while 100 (20%) and 401 (80%) patients received LMV and ETV, respectively. Serum alanine aminotransferase, creatinine, sodium level, platelet count and hepatic encephalopathy grade significantly differed between NA and SA group while gender, serum alpha-fetoprotein level and types of antiviral treatment differed between SA and CA groups (all, $P < 0.05$). The proportion of ETV-treated patients was significantly lower in CA group (81/114 patients, 71%) compared to NA group (275/336 patients, 82%) and SA group (44/51 patients, 86%) (both, $P < 0.05$). During 58±24 months of follow-up, 45 patients showed liver-related mortality. Survival rate was significantly lower in CA group compared to NA and SA group (both, $P < 0.001$) but there was no significant difference between NA and SA group ($P = 0.444$) even when subgroup analysis was done according to types of antiviral treatment. In univariate analysis, platelet count, INR, serum bilirubin, albumin, BUN, creatinine, sodium level, degree of ascites (CA), hepatic encephalopathy grade, MELD index, Child–Pugh grade and types of antiviral treatment were significantly associated with survival (all, $P < 0.05$). In multivariate analysis, only INR, serum albumin level and degree of ascites (CA) remained as independent factors (all, $P < 0.05$).

Conclusions: Subclinical ascites had no role in the prognosis of HBV-related cirrhotic patients treated with nucleot(s)ide analogues.

P0165

NON-MALIGNANT PORTAL VEIN THROMBOSIS IN PATIENTS WITH CIRRHOSIS. RESPONSE TO TREATMENT

T. Artaza[1], M. Lopes[1], D. Muñoz[1], M. Romero[1], C. González[1], G. de la Cruz[1], J.J. Sánchez[1], R. Gómez[1]. *[1]Gastroenterology, Hospital Virgen Salud Toledo, Toledo, Spain*
E-mail: tdeartaza@gmail.com

Background and Aims: The prevalence of nonmalignant portal vein thrombosis (PVT) ranges from 10 to 25% in patients with liver cirrhosis and it is associated with a worsening of its natural course. Optimal management of PVT in cirrhosis is not available in any consensus publication. Nevertheless, it seems that anticoagulation may constitute the initial treatment. *The aim* of our study was to evaluate the results of anticoagulation therapy in a group of cirrhotic patients with non-malignant PVT.

Methods: 27 cirrhotic patients with non-malignant PVT were studied retrospectively in our hospital between March 2009 and March 2014. Both diagnosis and follow-up of patients were performed by Doppler and contrast-enhanced ultrasound and by computed tomography.

Results: 27 patients (14 women, mean age: 59±11.8 years) were evaluated. All cases were incidental findings during routine ultrasonography. The mean MELD score was 10 (range: 6–22). 11% were on active liver transplant list. 26 patients received anticoagulation: 23 low-molecular-weight heparin and three oral anticoagulation. The median time from diagnosis to the initiation of treatment was 2 weeks. The outcome in 18/26 patients was recanalization, 15 complete (57.6%). The median time until achieving this complete response was 10 months (95% CI: 3–17). Rethrombosis occurred in five of the patients who had discontinued treatment after complete recanalization (35.7%). Patients with no response to treatment, did not show progression of thrombosis. Only two patients, one of them with 30,000 platelets, presented a bleeding complication (mild in both cases). No significant differences regarding the appearance of portal hypertension-related complications were observed. Patients with MELD score below 8 achieved recanalization in a significantly shorter time compared to the other patients (p = 0.04). Six patients died, four from complications of liver disease, but not related with anticoagulation. Thrombophilia testing was performed in 22 patients and five of them had a positive result: three with Factor V Leiden mutation, one with JAK2 gene mutation and another with hyperhomocysteinemia.

Conclusions: In cirrhotic patients with nonmalignant PVT, anticoagulation therapy led to recanalization in over half of cases, with a broad safety profile. Best outcomes seem to be achieved in a less advanced stage of liver disease. Due to the existing rethrombosis rate, long-term anticoagulation should be considered.

P0166

ANTICOAGULATION DOES NOT INCREASE PORTAL HYPERTENSION RELATED BLEEDING, BUT EXPOSES PATIENTS WITH CIRRHOSIS TO A HIGH RISK OF MINOR HEMORRHAGES. RESULTS FROM A COMPARATIVE COHORT STUDY

V. La Mura[1,2], S. Braham[3], F. Branchi[4], M. Moia[3], A.L. Fracanzani[5], M. Colombo[1], A. Tripodi[3], M. Primignani[1]. *[1]U.O. Gastroenterologia-1, IRCCS-Ca' Granda, Ospedale Maggiore Policlinico, Università degli studi di Milano, Milan, [2]U.O. Medicina Interna, IRCCS-San Donato, Dipartimento di Scienze Biomediche per la Salute, Università degli studi di Milano, Miilan, [3]Centro Emofilia e Trombosi Angelo Bianchi Bonomi, [4]U.O. Gastroenterologia-2, [5]U.O. Medicina Interna, IRCCS-Ca' Granda, Ospedale Maggiore Policlinico, Università degli studi di Milano, Milan, Italy*
E-mail: vin.lamura@gmail.com

Background and Aims: Anticoagulation with vitamin K antagonists (VKAs) is an effective and relatively safe therapy for patients with portal vein thrombosis (PVT). However, the haemorrhagic risk of VKAs in relation with the presence of cirrhosis, has poorly been investigated
Methods: We compared the VKAs-related bleeding risk in cirrhotic patients with *de novo* PVT (PVT-cohort, n = 62) *vs* non-cirrhotic patients with a thromboembolic event (TE-cohort, n = 160). Any bleeding during four years of follow-up or up to withdrawal of anticoagulation therapy, was recorded. The quality of anticoagulation control was measured by the time in therapeutic range (TTR) of the INR. Bleeding risk due to portal hypertension (PHT) in the PVT-cohort was compared with an independent series of cirrhotics with PHT unexposed to VKAs during follow-up (CH-cohort, n = 53). Major bleeding episodes under anticoagulation were intracranial or retroperitoneal events, fatal bleeding events, need of hospitalization or transfusion, otherwise they were considered minor bleedings. All patients with cirrhosis were under prophylaxis for PHT-related bleeding according to current guidelines.
Results: TE-cohort and PVT-cohort were comparable for age, sex. The mean of TTR was 67.7±20.9% for the former, 70.5±19.1% for the latter (p = 0.379) but treatment with VKAs was longer for the TE-cohort (31.1±16.9 vs 23.0±16.2 months, p = 0.001). Overall, 41 patients under anticoagulation experienced a bleeding episode (14 major/27 minor). The actuarial probability of major/minor bleedings was higher in PVT-cohort (23%/30%) than in the TE-cohort (6%/20%) (p < 0.001). However, the risk of upper-gastro-intestinal bleeding in PVT-cohort (15%) was the same as in the CH-cohort (13%) also adjusting for potential confounders, confirming the lack of impact of VKAs on the risk of bleeding due to PHT. Finally, the exclusion of the upper-gastrointestinal bleeding in the PVT-cohort led to a significant reduction of major bleedings accountable for VKAs, leaving a significant residual risk only for minor bleeding episodes (p < 0.05).
Conclusions: VKAs expose patients with cirrhosis and PVT to an additional risk of minor bleedings. This should be taken into account in future clinical studies to ameliorate the benefit/risk ratio of anticoagulation in this clinical setting.

P0167

ENDOSCOPIC VARICEAL LIGATION FOLLOWED BY ARGON PLASMA COAGULATION VERSUS ENDOSCOPIC VARICEAL LIGATION ALONE: A RANDOMIZED CONTROLLED TRIAL

A. Abd Elmoety[1], Y. Hamza[1], A. Zeid[1], A. Kamal[1], R. Ibrahim[1], A. Sidkey[1], M. Badr[1]. *[1]Alexandria university, Faculty of medicine, Alexandria, Egypt*
E-mail: ahmed.kamal.med.scientific@gmail.com

Background and Aims: After the first attack of acute variceal hemorrhage patients have a very high risk of recurrent variceal bleeding and death. Rebleeding rates after endoscopic variceal ligation (EVL) are high, thus current recommendation is to combine non selective beta-blockers (NSBB) to EVL but side effects and relative contraindications to NSBB are common and hinder treatment or require discontinuation in 15–20% of cirrhotic patients. Induction of fibrosis of distal esophageal mucosa using argon plasma coagulation (APC) may suppress capillary proliferation and invasion of perforating veins thus decreasing esophageal varices (EV) recurrence.
Methods: This study included 40 subjects with post viral liver cirrhosis and previous history of upper gastrointestinal bleeding. They were submitted for EVL and eradication of varices. After ensuring complete eradication of EV, patients were randomly assigned to either APC (group 1) or just observation (group 2). Both groups were followed up by endoscopy every 3 months for 24 months. Recurrence of EV was defined as development of EV grade 1 or more. Recurrence free rates and rebanding free rates were analysed using Kaplan–Meier statystical analysis.
Results: Post-treatment transient fever was significantly higher in group 1 while there were no significant differences in both groups regarding other post-treatment side effects and complications. None of subjects in both groups developed hemorrhage, perforation or stricture. During 2 year follow up 20% of subjects in group 1 experienced EV recurrence but no one needed rebanding. In group 2, 68.4% experienced EV recurrence (p = 0.002) and 63.2% underwent rebanding (P < 0.001) (Figure). No subject in group 1 experienced rebleeding during the 2 year follow up, while 10.5% of subjects in group 2 experienced rebleeding from EV (p = 0.231). No subject in both groups showed development of gastric varices. 3 subjects in group 1 and 4 subjects in group 2 showed development of new severe portal hypertensive gastropathy (p = 0.695).
Conclusions: APC after esophageal variceal eradication using EVL can decrease the risk of recurrence of EV and the need for rebanding. APC after EVL may be recommended in secondary prophylaxis against esophageal variceal bleeding especially in those who have contraindications, intolerant or non-compliant to NSBB.

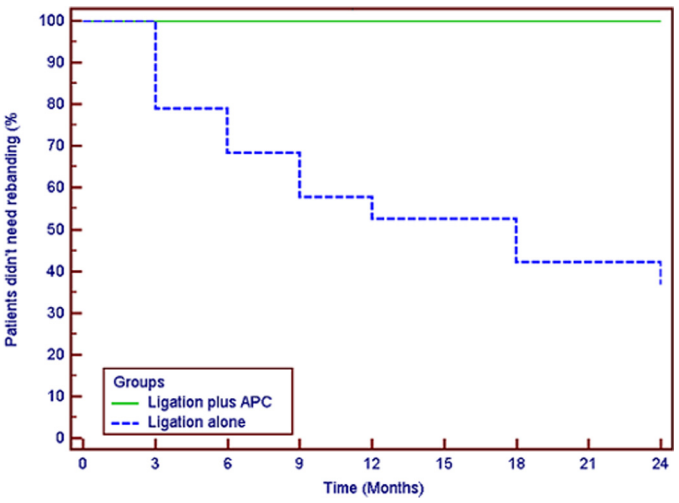

Figure: Kaplan–Meier analysis of cumulative rebanding free curves.

P0168

THE IMPACT ON HOSPITAL RESOURCE UTILISATION OF RIFAXIMIN-ALPHA FOR HEPATIC ENCEPHALOPATHY IN ROUTINE CLINICAL PRACTICE: REAL WORLD DATA FROM SEVEN UK LIVER CENTRES

J.G. Orr[1,2], A. Goel[3], K. Moriarty[3], A. Sinha[4], F.H. Gordon[4], A. Dethier[5], J. Dillon[5], V. Patel[6], D.L. Shawcross[6], K. Clark[7], P. Richardson[7], H. Preedy[8], R. Aspinall[8], C.J. Currie[9], M. Hudson[1,2]. *[1]Liver Unit, Freeman Hospital, [2]Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, [3]Gastroenterology, Royal Bolton Hospital, Bolton, [4]Liver Unit, Bristol Royal Infirmary, Bristol, [5]Gastroenterology, Ninewells Hospital, Dundee, [6]Institute of Liver Studies and Transplantation, King's College London School of Medicine at King's College Hospital, London, [7]Gastroenterology, The Royal Liverpool University Hospital, Liverpool, [8]Gastroenterology and Hepatology, Queen Alexandra Hospital, Portsmouth, [9]School of Medicine, Cardiff University, Cardiff, United Kingdom*
E-mail: james.orr@ncl.ac.uk

Background and Aims: Rifaximin-α (RFX) has been shown to reduce recurrence of overt hepatic encephalopathy (HE) in patients with cirrhosis. However, there is concern over the cost-effectiveness of the drug with average annual treatment with RFX costing £3,379 (€4,228). Early observational data suggested that treatment might reduce hospital admissions and decrease hospital length of stay (HLOS). The aim of this study was to determine the impact of treatment with RFX on hospital resource utilisation, using data from multiple liver centres from across the UK.
Methods: All seven participating centres agreed a standardised data collection pro-forma. Details of hospital admissions were requested at three, six and 12 months prior to RFX exposure, and for the same periods during RFX treatment. Where data were unavailable for any particular patient, data were annualised from the observation(s) provided. Clinical data were recorded at baseline, at three months, and at the end of the study period. Inpatient costs were estimated in UK£ (€@1.2×£) at 2008/9 prices from published National Health Service sources: mean £487 (€580) per day for admissions for liver disease.
Results: Data were available from 295 patients, 30% female, mean age 58 (SD 12) years, aetiologies: ARLD 60%, NAFLD 14%, viral 10%. 92% were taking concurrent lactulose. Mean baseline MELD score was 15.3 (SD 6.2). Mortality at 30 days, 90 days and 1 year were 5%, 10% and 21%, respectively, with significantly higher MELD scores at each time point (all $p < 0.001$). The mean number of hospital admissions decreased from 2.9 admissions per person per year before RFX to 1.7 during treatment (Δ 41%, $p < 0.001$). The mean hospital length of stay per admission decreased from 11.0 days before to 9.5 days during RFX treatment (Δ 13%, $p < 0.001$). This resulted in a reduction in mean annual bed occupancy from 31.7 days before to 16.4 days during RFX treatment (Δ 48%, $p < 0.001$), representing an annual reduction in inpatient liver care costs of £7,463 (€8,956) per patient. There was no change from baseline MELD at 3 months and 1 year (Δ −0.4 and −0.2 respectively). In addition, there was no clear correlation between MELD score and admissions.
Conclusions: RFX was associated with a marked reduction in the number of admissions and hospital length of stay, factors that should be taken into account when determining cost effectiveness. The likelihood of admission was independent of MELD score and the response to RFX may not be solely determined by disease severity.

P0169

CRITICAL FLICKER FREQUENCY PREDICTS SURVIVAL IN PATIENTS WITH LIVER CIRRHOSIS

J. Ampuero[1], M. Simón[2], C. Montoliú[3], R. Jover[4], M.Á. Serra[3], J. Córdoba[2], M. Romero-Gómez[1]. *[1]Unit for the Clinical Management of Digestive Diseases, Valme University Hospital, Sevilla, [2]Hospital Vall d'Hebrón, Barcelona, [3]Hospital Clínico, Valencia, [4]Hospital General Universitario, Alicante, Spain*
E-mail: javi.ampuero@gmail.com

Background and Aims: Minimal hepatic encephalopathy (MHE) predicts overt hepatic encephalopathy (oHE), and this latter is associated with poor survival in patients with liver cirrhosis. However, the direct impact of MHE on the survival of cirrhotics is controversial. Therefore, we aimed to analyze the impact of MHE on long-term survival of patients suffering from liver cirrhosis.
Methods: Prospective and multicenter study including two independent cohorts of patients with liver cirrhosis. Estimation cohort (n = 151) was followed-up during 4.7±2.8 years and validation cohort (n = 117) during 4.4±3.9 years. All patients underwent: (a) critical flicker frequency (CFF) (pathological value <39 Hz); (b) Psychometric Hepatic Encephalopathy Score (PHES) (pathological value <−4 points). Outcomes to finish the follow-up were liver transplantation or death. Liver function was measured by MELD score. We used Kaplan–Meier method for univariate analysis (qualitative variables) and Cox regression for univariate (continuous variables) and for multivariate analysis.
Results: Overt HE was associated with higher mortality [42.5% (34/80) *vs.* no oHE 20.7% (38/184); logRank 26.744, $p = 0.0001$]. In the estimation cohort, univariate analysis showed that CFF <39 Hz did not predict mortality at 1 year [5.7% (2/35) *vs.* >39 Hz 1.6% (1/61); logRank 1.435, $p = 0.231$], but did at 3 years [17.1% (6/35) *vs.* >39 Hz 4.9% (3/61); logRank 4.765, $p = 0.029$] and at 5 years [28.6% (10/35) *vs.* >39 Hz 9.8% (6/61); logRank 7.835, $p = 0.005$] of follow-up (Table). Similarly, PHES <−4 did not predict mortality at 1 year [2.6% (1/38) *vs.* PHES >−4 4.1% (3/74); logRank 0.129, $p = 0.719$], but did at 5 years [34.2% (13/38) *vs.* PHES >−4 14.9% (11/74); logRank 4.944, $p = 0.026$]. In the multivariate analysis, CFF <39 Hz [HR 4.36 (95% CI 1.67–11.37); $p = 0.003$], age [HR 1.07 (95% CI 1.02–1.12); $p = 0.009$] and MELD score [HR 1.40 (95% CI 1.21–1.63); $p = 0.0001$] predicted independently the mortality. In the validation cohort, findings were very similar. In univariate analysis, CFF <39 Hz, PHES <−4, age, MELD score and a previous event of oHE were related to increased mortality. In multivariate analysis, CFF <39 Hz, age and MELD score remained independently associated with mortality.
Conclusions: Critical flicker frequency, together with age and MELD score, predicted mortality in two independent cohorts of patients with liver cirrhosis. Controversy about the impact of minimal hepatic encephalopathy on survival could be associated with a short follow-up of studies.

	Mortality		
	1 year	3 year	5 year
CFF <39 Hz	5.7% (2/35)	17.1% (6/35)	28.6% (10/35)
CFF >39 Hz	1.6% (1/61)	4.9% (3/61)	9.8% (6/61)

P0170

EFFECTS OF NUTRITIONAL THERAPY ON COGNITIVE FUNCTIONS AND HEALTH RELATED QUALITY OF LIFE IN PATIENTS OF LIVER CIRRHOSIS WITH MINIMAL HEPATIC ENCEPHALOPATHY – AN OPEN LABEL RANDOMIZED CONTROLLED TRIAL

S. Maharshi[1], B. Chander Sharma[1], S. Srivastava[1]. *[1]Gastroenterology, G B Pant Hospital, New delhi, India*
E-mail: sudhir.maharshi@gmail.com

Background and Aims: Minimal hepatic encephalopathy (MHE) impairs health related quality of life (HRQOL), predicts development

of overt hepatic encephalopathy (HE) and associated with poor prognosis. Preliminary studies showed improvement in cognitive functions and HRQOL with nutritional supplementation in MHE but there is no study on nutritional management in patients with MHE. We assessed the effects of nutritional therapy on cognitive functions and HRQOL in patients of cirrhosis with MHE.

Methods: Consecutive patients of cirrhosis with MHE were randomized to group A received nutritional therapy (30–35 kcal/kg/day and 1.0–1.5 gram of vegetable protein/kg/day) and group B on no nutritional therapy (diet as patient was taking before) for 6 months. MHE was diagnosed based on psychometry hepatic encephalopathy score (PHES) and HRQOL assessed by Sickness impact profile (SIP) questionnaire. Primary endpoints were improvement or worsening in MHE and improvement in HRQOL.

Results: 120 patients were randomized into two groups; group-A (n = 60, age 42.1±10.3 yr, 48 men) and group-B (n = 60, age 42.4±9.6 yr, 47 men). There was no significant difference in baseline characteristics between the two groups. Baseline PHES (−8.12±1.32 *vs* −8.53±1.38; p = 0.08) and SIP score (14.25±5.8 *vs* 15.44±5.03; p = 0.85) were similar in both the groups. Reversal of MHE was higher in group A (71.1% *vs* 22.8%; p = 0.001) and improvement in HRQOL was also higher in group A (Δ SIP 3.24±3.63 *vs* 0.54±3.58; p = 0.001) compared to group B.

Conclusions: Nutritional therapy is effective in treatment of MHE and associated with improvement in HRQOL.

P0171
INVASIVE FUNGAL INFECTIONS IN PATIENTS WITH CIRRHOSIS – SUBANALYSIS OF THE FUNGAL INFECTION RISK EVALUATION (FIRE) STUDY

E. Theocharidou[1], B. Agarwal[2], G. Jeffrey[3], R. Jalan[1], D. Harrison[4], A. Burroughs[1], C. Kibbler[5]. *[1]Hepatology, Royal Free Hospital, University College London, [2]Intensive Care Unit, Royal Free Hospital, London, United Kingdom; [3]Western Australian Liver Transplantation Service, Sir Charles Gairdner Hospital, Perth, Australia; [4]Intensive Care National Audit and Research Centre, [5]Department of Medical Microbiology, Royal Free Hospital, University College London, London, United Kingdom*
E-mail: eltheocharidou@hotmail.com

Background and Aims: Infections in patients with cirrhosis are associated with increased risk of complications and mortality. Fungal infections are poorly defined in this cohort particularly the lack of distinction between colonization and invasive disease. The aim of this study was to assess the incidence and implications of invasive fungal disease (IFD) in patients with cirrhosis admitted to intensive care unit (ICU).

Methods: This is a sub-analysis of the large multi-centre Fungal Infection Risk Evaluation (FIRE) study. Clinical and laboratory parameters for 1655 patients with cirrhosis were analyzed and compared with 967 patients with very severe cardiovascular disease (CVD). The incidence of IFD and potential associations with outcomes were assessed. IFD was defined as a blood culture or sample from a normally sterile site that was positive for fungi.

Results: Variceal bleeding and pneumonia accounted for the main indication for ICU admission in liver and CVD patients respectively. CVD patients were older and had more co-morbidities (diabetes mellitus, end-stage renal disease and severe respiratory disease), and higher APACHE II score (22 vs 20; p < 0.0005). Liver patients had more invasive lines and urinary catheters, and received systemic antimicrobials more frequently.

While the incidence of IFD was similar in the two groups (0.6% in liver patients, 0.7% in CVD; p = 0.175), fungal colonization was more common in liver patients (14.2% vs 7.7%; p < 0.0005). Liver patients exhibited higher ICU and in-hospital mortality (5% vs 3.3%; p = 0.05, and 7.7% vs 4.6%; p = 0.002, respectively), and longer ICU length of stay (LOS) (70 vs 51 hours; p < 0.0005). Fungal colonization, and in particular more than one fungal isolates, was associated with higher ICU and hospital LOS but not mortality, whereas no correlation existed between IFD and clinical outcomes. Higher proportion of liver patients received antifungal therapy (15.4% vs 4.1%; p < 0.0005).

Conclusions: The prevalence of fungal colonization is high in patients with cirrhosis and is associated with higher LOS. Whether this is a marker of disease severity or has a direct effect on clinical outcomes needs further evaluation. Similarly, the role of antifungal therapy to prevent or treat fungal colonization in these patients also remains unclear. Contrary to popular belief and evidence from small studies, the incidence of IFD in patients with cirrhosis is low and not associated with mortality or LOS.

P0172
PROTON PUMP INHIBITORS INCREASE THE RISK FOR HEPATIC ENCEPHALOPATHY IN CIRRHOSIS

G. Dam[1], H. Vilstrup[1], H. Watson[2], P. Jepsen[1,3]. *[1]Department of Hepatology and Gastroenterology, Aarhus University Hospital, Aarhus, Denmark; [2]Sanofi Aventis R&D, Paris, France; [3]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark*
E-mail: gitte_dam@hotmail.com

Background and Aims: Proton pump inhibitors (PPIs) are commonly prescribed to cirrhosis patients. PPIs predispose to bacterial overgrowth, translocation and spontaneous bacterial peritonitis. Our aim was to determine whether PPI use is a risk factor for hepatic encephalopathy (HE).

Methods: We used the complete original data from three randomized trials of satavaptan treatment of ascites. We included all 865 patients who had not previously had HE. They were examined for HE every four weeks for 52 weeks, and satavaptan did not affect their HE risk. We used Cox regression to compare HE rates between users (340 users at entry and further 108 during follow-up) and nonusers of PPI, adjusting for gender, age, cirrhosis etiology, MELD score, variceal bleeding, P-sodium, -albumin, -platelets, and use of lactulose and diuretics. These data were updated at every visit.

Results: There were 189 HE episodes during the follow-up. The risk of developing an HE episode was 24% for those who used PPIs at inclusion vs. 20% for those who did not. Current PPI use also increased the HE rate (adjusted hazard ratio = 1.36, 95% CI 1.01–1.84), and even more so when we counted only the 92 HE episodes of grade 2 or higher (adjusted hazard ratio = 1.81, 95% CI 1.17–2.86).

Conclusions: More than half of the patients used PPIs, and they had higher HE risk after adjustment for other risk factors. These findings may serve as a warning against indiscriminate prescribing of PPIs to cirrhosis patients.

P0173
PREDICTORS OF MORTALITY IN CIRRHOTIC PATIENTS ADMITTED TO INTENSIVE CARE UNIT: COMPARISON OF DIFFERENT SCORING SYSTEMS INCLUDING THE NEW ROYAL FREE HOSPITAL SCORE

N. Naksuk[1], T. Peeraphatdit[2], C. Thongprayoon[3], L.R. Roberts[4], R. Chaiteerakij[4,5]. *[1]Cardiology, Mayo Clinic, Rochester, [2]Internal Medicine, University of Minnesota, Minneapolis, [3]Anesthesiology, [4]Gastroenterology and Hepatology, Mayo Clinic, Rochester, United States; [5]Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand*
E-mail: peera004@umn.edu

Background and Aims: The Royal Free Hospital (RFH) score was recently developed and shown to be a better predictor for in-hospital mortality than traditional scores in cirrhotic patients admitted to the intensive care unit (ICU). However, its performance in predicting 90-day mortality has not been studied. Our aim was to evaluate the RFH score in predicting 90-day mortality and

externally validate its predictive value for in-hospital mortality. We also compared the RFH score with Acute Physiology and Chronic Health Evaluation (APACHE) III, Sequential Organ Failure Assessment (SOFA), Model for End-Stage Liver Disease (MELD) and MELD-Na scores.

Methods: We included 314 consecutive cirrhotic patients admitted to the ICU between 2003 and 2013 who had available laboratory parameters to calculate the RFH score, which comprises bilirubin, international normalized ratio, lactate, alveolar-arterial partial pressure oxygen gradient and blood urea nitrogen. Associations between the initial scores at time of ICU admission and 90-day and in-hospital mortality were calculated using logistic regression analysis. Performances of the RFH, APACHE III, SOFA, MELD and MELD-Na scores in predicting mortality were then compared using the area under the receiver operating characteristic curve (AUC).

Results: Mean age was 59±12 years and 58% were male. Etiologies of cirrhosis were alcoholic (34%), hepatitis C (29%) and non-alcoholic fatty liver disease (23%). Diagnoses during ICU admission were hepatic encephalopathy (41%), septic shock (26%), spontaneous bacterial peritonitis (12%), acute variceal bleeding (11%) and hepatorenal syndrome (10%). Of all patients, 66%, 54% and 23% required mechanical ventilation, vasopressor and renal replacement therapy, respectively. The 90-day mortality was 45% and in-hospital mortality was 29%. The AUC of RFH score in predicting 90-day and in-hospital mortality were 0.75 and 0.76, respectively. However, in comparison between scores, RFH score was not superior to APACHE III, SOFA, MELD or MELD-Na scores, ($p > 0.05$ for comparison to the RFH score), (Table).

Conclusions: The RFH score is a good predictor for both in-hospital and 90-day mortality among cirrhotic patients admitted to the ICU, but the RFH score was not superior to others. Since the arterial blood gas is not required for calculating MELD and MELD-Na scores, there may be more utility in using these scores in patients who otherwise do not require arterial blood gas measurement for other clinical indications.

Table: Comparison of receiver operating characteristic curves for RFH, APACHE III, SOFA, MELD and MELD-Na scores in predicting the 90-day and in-hospital mortality in cirrhotic patients admitted to the ICU

Prognostic model	90-day mortality		In-hospital mortality	
	AUC (95% CI)	P value	AUC (95% CI)	P value
RFH score	0.75 (0.69–0.79)	Reference	0.76 (0.70–0.80)	Reference
APACHE III score	0.73 (0.68–0.78)	0.60	0.74 (0.68–0.78)	0.52
SOFA store	0.72 (0.67–0.77)	0.46	0.79 (0.74–0.83)	0.42
MELD score	0.77 (0.71–0.81)	0.51	0.76 (0.71–0.80)	0.93
MELD-Na score	0.76 (0.71–0.81)	0.52	0.75 (0.70–0.80)	0.95

Abbreviations: RFH, Royal Free Hospital; APACHE, Acute Physiology and Chronic Health Evaluation; SOFA, Sequential Organ Failure Assessment; MELD, Model for End-Stage Liver Disease; Na, sodium.

P0174

SOLUBLE CD163 (SCD163) IS A MARKER OF INFECTION IN PATIENTS WITH CIRRHOSIS AND ACUTE DECOMPENSATION AND AN INDEPENDENT PREDICTOR OF THE SHORT-TERM MORTALITY

T. Tornai[1], D. Tornai[1], N. Sipeki[1], I. Foldi[1], T. Dinya[2], Z. Vitalis[1], P. Antal-Szalmas[3], I. Tornai[4], M. Papp[1]. *[1]Department of Gastroenterology, [2]Institute of Surgery, [3]Department of Laboratory Medicine, University of Debrecen, Clinical Center, [4]Department of Gastroenterology, University of Debrecen, Clinical, Debrecen, Hungary*
E-mail: tornaitamas@gmail.com

Background and Aims: sCD163 is shed from macrophages by a protease related mechanism in response to inflammatory stimuli and has benn suggested to modulate the inflammatory response. We aimed to determine the predictive potential of sCD163 levels in the determination of disease phenotype and disease course in a prospective referral cirrhotic cohort.

Methods: 378 consecutive patients with cirrhosis (LC) of different etiology (54.0% males, 70.6% alcoholic) and severity (ChildA/B/C: 39.2/38.1/22.7%, acute decompensation [AD]: 48.9%) were enrolled and followed until death or last attendance. Serum levels obtained at enrollment were assayed for sCD163 by ELISA. Detailed clinical phenotypes regarding first decompensation event (ascites formation, variceal bleeding [VB], hepatic encephalopathy or systemic bacterial infection [INF]), development of hepatocellular carcinoma [HCC] and mortality were determined prospectively during the follow-up (median [IQR], 778 [182–1720] days). Control group comprised 150 healthy subjects (HC).

Results: Serum levels of sCD163 were significantly higher in patients with LC compared to HC (median, 3724 vs. 1104 ng/ml, $p < 0.001$). In LC, sCD163 levels were associated to disease severity, as rated by the Child–Pugh stage ($p < 0.001$) but not to the presence of varices or prior VB. In non-AD patients, sCD163 levels were not able to predict the advent of the first decompensation events, development of HCC and also not the long-term mortality. In patients with AD episodes, sCD163 levels were significantly higher compared to non-AD patients but only in the presence of INF (AD-INF: 4969, AD-NON-INF: 3497 and NON-AD: 3471 ng/ml, $p < 0.001$ for both). Furthermore, during INF episodes ($n = 119$), sCD163 levels were significantly higher in those complicated with organ failure (31%) and increased gradually according to ACLF grade (No-ACLF: 4121, ACLF gr1: 7335, gr2: 7490, gr3: 12610 ng/ml, $p = 0.001$). Rate of 28-day mortality was higher among patients with sCD163 level >7110 ng/ml compared to those with ≤7110 ng/ml (46.5% vs. 15.8%, $p < 0.001$). This cut-off level of sCD163 was associated with a shorter time to death (pLogRank <0.001) in Kaplan–Meier analysis and was identified as an independent predictor in multivariate Cox regression model (HR: 2.91, 95% CI: 1.34–6.32, $p = 0.007$) comprising age, gender, etiology, co-morbidity and MELD score as covariates.

Conclusions: Admission sCD163 levels may be an additional help in rapid identification of patients with high-risk for death during AD episodes complicated with INF in LC.

P0175

ASSESSMENT OF SERUM GLYCOMICS (GLYCOCIRRHOTEST) FOR RISK PREDICTION OF HEPATOCELLULAR CARCINOMA DEVELOPMENT IN PATIENTS WITH CIRRHOSIS

X. Verhelst[1,2], D. Vanderschaeghe[3], L. Castera[4,5], A. Geerts[1,2], N. Goutté[4], C. Francoz[4,5], F. Durand[4,5], N. Callewaert[3,6], H. Van Vlierberghe[1,2]. *[1]Department of Gastroenterology and Hepatology, Ghent University Hospital, [2]Laboratory of Hepatology, Ghent University, [3]Unit for Medical Biotechnology, Inflammation Research Center, VIB Ghent, Ghent, Belgium; [4]Department of Hepatology, Hôpital Beaujon, Clichy, [5]INSERM U773, Université Denis Diderot, Paris-7, Paris, France; [6]Laboratory for Protein Biochemistry and Biomolecular Engineering, Department of Biochemistry and Microbiology, Ghent University, Ghent, Belgium*
E-mail: xavier.verhelst@uzgent.be

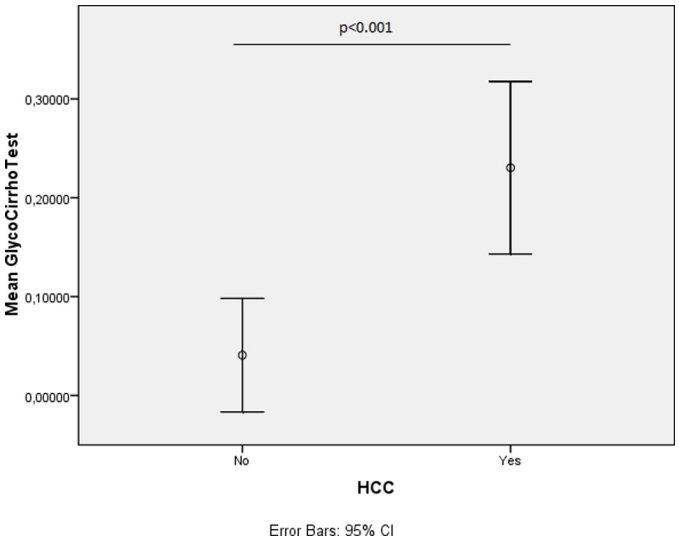
Background and Aims: Cirrhosis is a major predisposing factor for the development of hepatocellular carcinoma (HCC) with a yearly incidence ranging from 1 to 8%. EASL guidelines recommend systematic screening with liver ultrasound at 6 months interval in cirrhotic patients. GlycoCirrhoTest, based on to the respective abundance of bisecting GlcNAc residues and triantenarry glycans on serum proteins, has shown a 79% sensitivity and 86% specificity for the diagnosis of cirrhosis among patients with chronic liver diseases. The aim of the present study was to determine whether serum glycomics are predictive for the development of HCC in patients with compensated cirrhosis.

Methods: We analysed blood samples of 132 cirrhotic patients collected between 1995 and 2005. All patients had biopsy proven cirrhosis at the moment of serum sampling (Child A or B). Seventy percent of the patients had HCV infection. In the remaining patients,

the cause of cirrhosis was HBV infection, alcohol and autoimmune diseases. The patients were followed until the appearance of a HCC, death or liver transplantation. At the moment of serum sampling there was no evidence of HCC. GlycoCirrhoTest was performed using capillary electrophoreses as previously described by Callewaert et al. (Nature Medicine 2004).

Results: Thirty-five (26.5%) of the patients developed a HCC after a median follow up of 4 years (IQR: 3.6–8.06). Mean follow up in the patients who did not develop HCC was 3.7 years (IQR: 3.4–9.9; ns). There was a significant increase of the mean baseline GlycoCirrhoTest value in the patients who developed a HCC during follow up ($p < 0.001$) as compared to those who did not (Figure 1). ROC curve analysis showed an AUC of 0.716 (95% CI: 0.611–0.820) for the prediction of HCC in the patients with a follow up of at least 1 year. An 0.1 increase in the value of the GlycoCirrhoTest was associated with a 27% increase in the risk for developing HCC (OR 1.27; 95% CI: 1.098–1.475). In 81 patients (65 without HCC and 16 with HCC) baseline AFP values were available. Combining GlycoCirrhoTest and AFP using logistic regression increased the predictive value (AUC = 0.789; 95% CI: 0.677–0.900).

Conclusions: This study suggests that glycomics analysis could represent a useful biomarker for the identification of patients with cirrhosis at high risk for developing HCC. GlycoCirrhoTest may help stratify cirrhotic patients according to the risk of HCC and optimize screening.



P0176

COPEPTIN IS AN INDEPENDENT PROGNOSTIC FACTOR IN LIVER CIRRHOSIS

A.J. Kerbert[1], D. Weil[2], H.W. Verspaget[1], J.-P. Moréno[2], B. van Hoek[1], V. Di Martino[2], M.J. Coenraad[1], T. Thevenot[2]. *[1]Department of Gastroenterology and Hepatology, Leiden University Medical Center, Leiden, Netherlands; [2]Department of Hepatology, Jean Minjoz Hospital, Besançon, France*
E-mail: j.c.kerbert@lumc.nl

Background and Aims: Copeptin is a stable cleavage product of the arginine vasopressin (AVP) precursor and is equimolarly secreted with AVP. Copeptin is currently considered as a reliable prognostic marker in a wide variety of diseases. In liver cirrhosis, however, the prognostic significance of copeptin remains unknown. We aimed to investigate the association between the severity of cirrhosis and serum copeptin concentration and to evaluate the prognostic value of serum copeptin concentration in cirrhotic patients on one-year mortality.

Methods: Cirrhotic patients hospitalized in two tertiary referral centres in the Netherlands and France were studied. Serum copeptin concentration at admission was measured using an assay in the chemiluminescence-coated tube format. The Kruskal–Wallis test was used to evaluate the effect of the severity of cirrhosis on copeptin concentrations. Cox proportional hazard regression analysis was performed to evaluate the effect of serum copeptin concentration, laboratory and clinical data on outcome. The optimal cut-off point of serum copeptin concentration was determined using the Youden Index. With the use of this cut-off point, one-year survival analysis stratified according to serum copeptin concentrations was performed using Kaplan–Meier analysis.

Results: Copeptin was measured in 186 cirrhotic patients (43 Child–Pugh A, 69 Child–Pugh B and 72 Child–Pugh C). At one year of follow-up, 35 (18.8%) patients had died and 41 (22.0%) were transplanted. Deceased or transplanted patients had significantly higher serum copeptin concentrations than the survivors [median (IQR): 17.1 (6.9–36.9) vs. 11.2 (5.2–28.9) vs. 8.2 (4.7–14.9) pmol/L, $p < 0.01$]. Median copeptin concentrations increased significantly and gradually through Child–Pugh classes A, B and C [5.4 (3.1–10.7) vs. 9.6 (6.0–17.6) vs. 13.8 (5.8–34.1) pmol/L, $p < 0.01$]. In univariate analysis, a high serum copeptin concentration (i.e., >12.3 pmol/L) showed a significant association with one-year mortality (HR = 3.35, 95% CI 1.69–6.66, $p < 0.01$, Kaplan–Meier, see figure). In multivariate analysis, patients with a high serum copeptin concentration displayed higher one-year mortality rates after adjusting for MELD (HR = 2.46, 95% CI 1.21–5.00, $p = 0.01$) or MELD-sodium score (HR = 2.80, 95% CI 1.39–5.60, $p < 0.01$).

Conclusions: Serum copeptin concentrations increase along with the severity of liver cirrhosis. Moreover, a high serum copeptin concentration was found to be of prognostic significance in hospitalized cirrhotic patients.

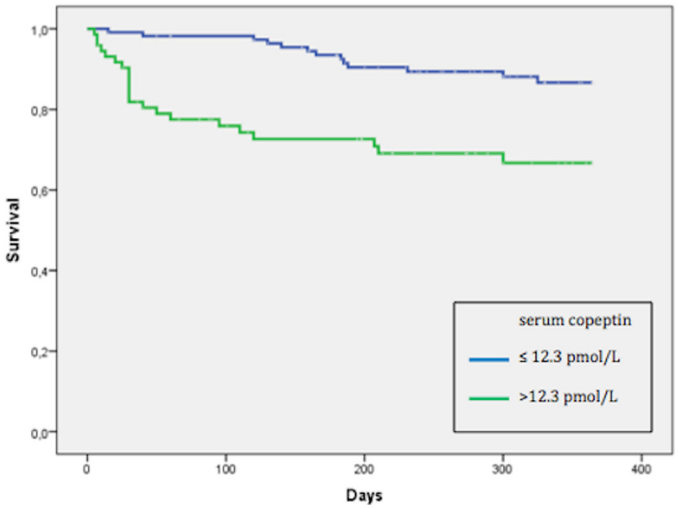


Figure: One-year survival of 186 cirrhotic patients stratified according to serum copeptin concentrations (pmol/L).

P0177

A SIMPLE OPERATIVE CRITERION TO ASSESS PATIENTS WITH LOW GRADE OF HEPATIC ENCEPHALOPATHY

F. Campagna[1], S. Montagnese[1], L. Ridola[2], S. Schiff[1], D. Aprile[1], G. Testa[1], M. De Rui[1], M. Senzolo[3], S. Nardelli[2], I. Pentassuglio[2], C. Pasquale[2], A. Gatta[1], C. Merkel[1], O. Riggio[2], P. Amodio[1].
[1]Department of Medicine DIMED, University of Padua, Padua, [2]Department of Gastroenterology, La Sapienza University, Rome, [3]Department of Surgical and Gastroenterological Sciences, University of Padua, Padua, Italy
E-mail: francescacampagna3@gmail.com

Background and Aims: The term 'covert hepatic encephalopathy' (CHE) encompasses a spectrum of conditions ranging from subclin-

ical to mild clinical alterations which do not meet the criteria for a diagnosis of overt HE (OHE). The tools to screen for CHE have not been defined. Thus, the aim of this study was to test the usefulness of the Animal Naming Test (ANT), i.e. the enumeration of the maximum number of animals in 1 min, within this clinical contest.

Methods: 208 healthy subjects stratified by decade of age (mean age 54±19 years) and 327 consecutive patients with cirrhosis (172 in Padua and 155 in Rome) underwent the ANT. Patients with cirrhosis were also assessed by the Psychometric Hepatic Encephalopathy Score (PHES), which was scored based on Italian norms and utilized to define CHE. A subgroup of 146 patients underwent a quantified electroencephalogram (EEG) and critical flicker frequency (CFF). Clinical assessment for the presence/grade of OHE was performed by expert clinicians.

Results: In controls, the ANT was found to be influenced only by extremely low levels of education (<7 yrs; $p < 0.001$) and older age (>80 yrs; $p < 0.001$). Of patients with cirrhosis, 169 were qualified as unimpaired, 126 as having CHE (abnormal PHES) and 32 as having OHE (grades II or III). Patients with CHE had significantly lower ANT performance than unimpaired patients (11±1 *vs* 15±1; $p < 0.001$). OHE patients had significantly worse ANT performance than CHE patients (3±1 *vs* 11±1; $p < 0.001$). Based on the above results, a simpler model was devised qualifying a patient as having CHE if ANT≤10 (or ≤7 for patients with less than 7 yrs of education or over 80 yrs of age; ≤4 for patients with less than 7 yrs of education and over 80 yrs of age). This adjusted threshold had 23% (95% CI=16–30) sensitivity and 91% (95% CI=87–95) specificity for CHE diagnosis. MELD score and a history of OHE were found to be independent predictors of abnormal ANT ($p < 0.01$). A significant correlation was observed between ANT performance and EEG spectral parameters (mean dominant frequency: r = 0.23 $p < 0.001$; relative theta power: r = −0.23 $p = 0.005$) but not with CFF (r = −0.009 $p = 0.93$).

Conclusions: The simple ANT test, which does not even require paper and pencil and takes 1 minute to perform and virtually no time to score, can be used as an operative criterion to improve the clinical assessment of CHE.

P0178

SARCOPENIA AND MALNUTRITION PREDICT EARLY POST-LIVER TRANSPLANTATION OUTCOMES INDEPENDENTLY OF THE MELD SCORE: IMPLICATIONS FOR ORGAN ALLOCATION

M. Kalafateli[1], K. Mantzoukis[1], C.Y. Yau[2], A.O. Mohammad[3], S. Arora[1], S. Rodrigues[1], M. de Vos[1], K. Papadimitriou[1], D. Thorburn[1], J. O'Beirne[1], D. Patch[1], M. Pinzani[1], M.Y. Morgan[1], B. Agarwal[3], D. Yu[2], A.K. Burroughs[1], E.A. Tsochatzis[1]. *[1]UCL Institute for Liver and Digestive Health, [2]Department of Radiology, [3]Department of Intensive Care Unit, Royal Free Hospital, London, United Kingdom*
E-mail: mariakalaf@hotmail.com

Background and Aims: Although malnutrition and sarcopenia are prevalent in cirrhosis, their impact on clinical outcomes following liver transplantation (LT) is not well documented. We evaluated the associations of nutritional status and sarcopenia with in-hospital overall infections, time on mechanical ventilation (MV), and length of ICU and hospital stay post-LT.

Methods: We included 232 consecutive LT recipients (Males: 162, mean age: 53 years) with available pre-LT CT scan including the third lumbar (L3) vertebrae. The Royal Free Hospital-Global Assessment index (RFH-GA) was used for nutritional assessment and the L3-psoas muscle index (L3-PMI) was used for assessing sarcopenia.

Results: A wide range of RFH-GA and L3-PMI values were observed within similar MELD sub-categories (Figure 1). Malnutrition and sarcopenia were independent predictors of all evaluated outcomes. Post-LT infections were associated with MELD (OR = 1.055, 95% CI 1.002–1.11) and severe malnutrition (OR = 6.55, 95% CI 1.99–21.5) as determined by RFH-GA; MV >24 hours with MELD (OR = 1.1, 95% CI 1.036–1.168), severe malnutrition (OR = 8.5, 95% CI 1.48–48.87) and suboptimal donor liver (OR = 2.326, 95% CI 1.056–5.12); ICU stay >5 days with age (OR = 1.054, 95% CI 1.004–1.106), MELD (OR = 1.137, 95% CI 1.057–1.223) and severe malnutrition (OR = 7.46, 95% CI 1.57–35.43); hospital stay >20 days with male gender (OR = 2.107, 95% CI 1.004–4.419) and L3-PMI (OR = 0.996, 95% CI 0.994–0.999). Patients at the lowest L3-PMI who received a suboptimal graft with a cold ischemia time >12 hours had longer ICU/hospital stay and higher incidence of infections.

Conclusions: Sarcopenia and malnutrition are associated with early post-LT morbidity and their extent is not reflected into current allocation scores. Our data imply that higher quality grafts should be allocated in malnourished patients, but this needs to be further elucidated.

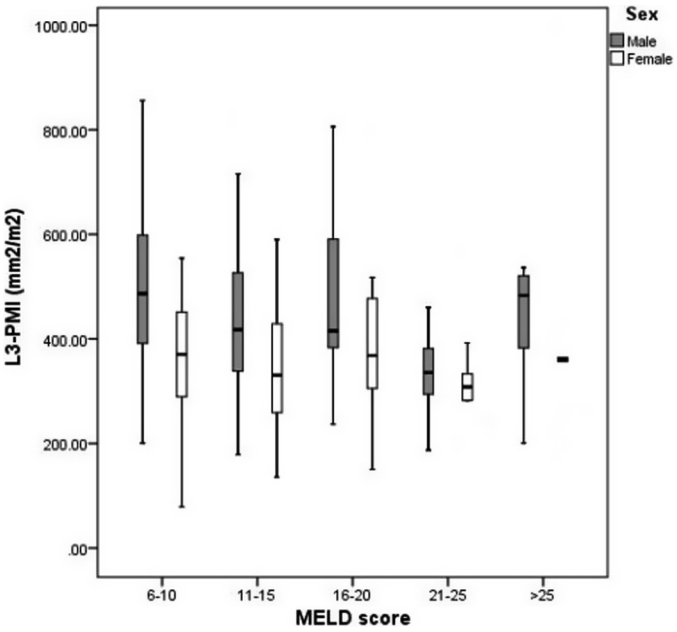

Figure 1.

P0179

THE MODEL FOR CRITICALLY ILL CIRRHOTICS (MCIC): A NOVEL PROGNOSTIC SCORE FOR PREDICTING MORTALITY IN CRITICALLY ILL CIRRHOTICS ADMITTED TO ICU

A. Sahney[1], A. Choudhary[1], C.P. Abby[1], A.K. Sinha[1], T. Vyas[1], R. Maiwall[1], M. Sharma[1], L. Mitra[2], V. Saluja[2], M. Premkumar[1], A. Bhadoria[3], S.K. Sarin[1]. *[1]Hepatology, [2]Critical Care, [3]Clinical research, ILBS, New Delhi, India*
E-mail: amrish.sahney@gmail.com

Background and Aims: Cirrhotic patients admitted to an Intensive Care Unit (ICU) generally have a poorer outcome than patients with other illnesses. Early stratification and prediction of outcome is therefore crucial in management of cirrhosis. We prospectively studied two critically ill cirrhotic cohorts to determine prognostic variables and a prediction model.

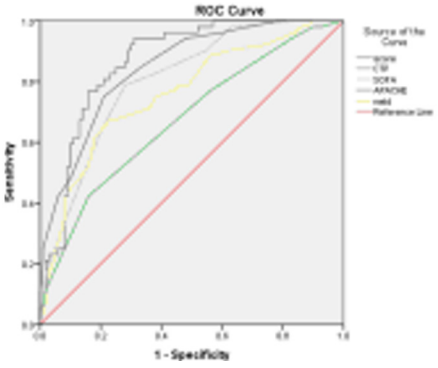
Methods: 380 consecutive cirrhotic patients admitted between (February–September 2014) to Liver ICU were followed since admission till discharge or death. The first 152 patients were evaluated and a logistic regression analysis was done to derive the predictors of mortality. A score was derived using these predictors, which was validated in a subsequent cohort of 228 patients. The predictive accuracy of this score was evaluated using AUROC.

Results: Mean age of patients was (51.2±11 and 50.4±11 yr) with male dominance (92.5% and 87.5%) in derivation and validation cohort respectively. Both cohorts were comparable in etiology of cirrhosis with majority related to ethanol (58.8%, 52%), reasons for admission to ICU, 28 daysICU mortality (34%, 37%) with sepsis

being the most common cause (78% and 81%) of death, respectively. The predictors of mortality in multivariate analysis in derivation set were baseline INR, serum creatinine (CR) and time weighted average serum lactate over first 24 hours ($\mathbf{Lac_{TW24}}$). The MCIC score was derived as an equation using forward logistic regression. The classification accuracy was 78% and 77% in derivative and validation cohorts respectively. The AUROC for the **MCIC** score was 0.87 and that for SOFA, MELD, APACHE II and CTP score were 0.80, 0.76, 0.84 and 0.67 respectively. In validation cohort, the AUROC for MCIC was 0.86, SOFA: 0.82, MELD: 0.73 and APACHE: 0.75. The dynamic blood lactate level as assessed by $\mathbf{Lac_{TW24}}$ was an important independent predictor of mortality with AUROC of 0.75 and enhanced the predictive accuracy of MELD – $\mathbf{Lac_{TW24}}$: 0.78, SOFA – $\mathbf{Lac_{TW24}}$: 0.86, and APACHE – $\mathbf{Lac_{TW24}}$: 0.83.

Conclusions: The MCIC score is the first model using dynamic lactate index in addition to liver specific INR and associated organ failure i.e. creatinine, in predicting early mortality among critically ill cirrhotic patients. This score has a better discriminative ability than the currently used indices to predict mortality and need for emergency liver transplantation, which may be useful in clinical decision-making

Validation set	Cut off	Sensitivity	Specificity	PPV	NPV
MCIC	>.55	78	76	68	84
SOFA	10.5	75	72	68	83
APACHEII	16	75	76	58	78
MELD	26	73	73	64	80
CTP	12	75	50	50	78



P0180
INCREASE IN GUT PERMEABILITY IS AN EARLY EVENT IN CIRRHOSIS AND IS NOT ASSOCIATED WITH BACTERIAL TRANSLOCATION, SYSTEMIC INFLAMMATION OR CLINICAL FEATURES: A PROSPECTIVE LONGITUDINAL STUDY

J. Macnaughtan[1], F. Figorilli[1], A. Moratalla[2], R.P. Mookerjee[1], N. Davies[1], R. Jalan[1]. *[1]Liver Failure Group, UCL Institute for Liver and Digestive Health, UCL Medical School, Royal Free Campus, London NW3 2PF, United Kingdom; [2]Liver Unit, Hospital General Universitario de Alicante, CIBER de Enfermedades Hepáticas y Digestivas (CIBERehd), Alicante, Spain*
E-mail: francesco.figorilli@gmail.com

Background and Aims: In cirrhosis, bacterial translocation (BT) is an early event and predicts occurrence of complications such as infection and mortality. In advanced liver failure, this is associated with increased gut permeability (GP) but the data in well-compensated cirrhosis is lacking. The aim of this study was to determine whether (a) GP is altered in patients with well-compensated cirrhosis (b) this was associated with bacterial translocation and (c) complications of cirrhosis.

Methods: Fifty-two stable cirrhotic patients (male: 33; age: 57.1±8.36; Child A: 84.6%, Child B: 15.4%) were included and studied longitudinally at the time of inclusion and 1-month afterwards. Clinical and biochemical variables and complications were recorded. GP was measured using standard sugar probe-based assays. Bacterial DNA was measured in serum samples by PCR reaction for the 16S ribosomal RNA gene.

Results: 19 patients (36.5%) had an abnormal GP (>0.033). There are no differences in gender, age, aetiology; diabetes, WCC, MELD (9.0±2.7 vs 9.4±3.5) and complications of cirrhosis (infection: 18.2% vs 10.5%, ascites: 54.5% vs 31.6%; HE 15.2% vs 10.5% and varices: 42.4% vs 52.6%). Only 2 patients showed evidence of BT. At 1-month, in patients with a GP < 0.033, 69% showed an increase, 7 (24.1%) a decrease and 2 were unchanged in the GP rate. In patients with abnormal GP, it worsened in 31.3%, and in 68.7% it improved. The two patients that showed evidence of BT became negative after one month and both of them displayed an improvement of their GP. 3-patients became positive after 1-month, with two showing worsening of GP. Conversely, all of these changes were not associated with any complications of cirrhosis.

Conclusions: The data of this prospective longitudinal study shows that alteration in GP occurs in a third of well-compensated cirrhosis and is a dynamic abnormalities that improves or worsens with no apparent clinical sequaela. Increased GP is not associated with evidence of bacterial translocation, clinical characteristics or systemic inflammation in well-compensated cirrhosis. It is likely that increased gut permeability is an early event but bacterial translocation in humans occurs late and factors other than translocated bacteria such as its products or metabolites contribute to clinical manifestations.

P0181
DEVELOPMENT AND VALIDATION OF A MATHEMATICAL FORMULA TO ESTIMATE GFR IN PATIENTS WITH CIRRHOSIS

M. Kalafateli[1], M. Burniston[2], C. Wickham[2], E. Theocharidou[1], S. Arora[1], A.K. Burroughs[1], E. Tsochatzis[1]. *[1]UCL Institute for Liver and Digestive Health, [2]Department of Nuclear Medicine, Royal Free Hospital, London, United Kingdom*
E-mail: mariakalaf@hotmail.com

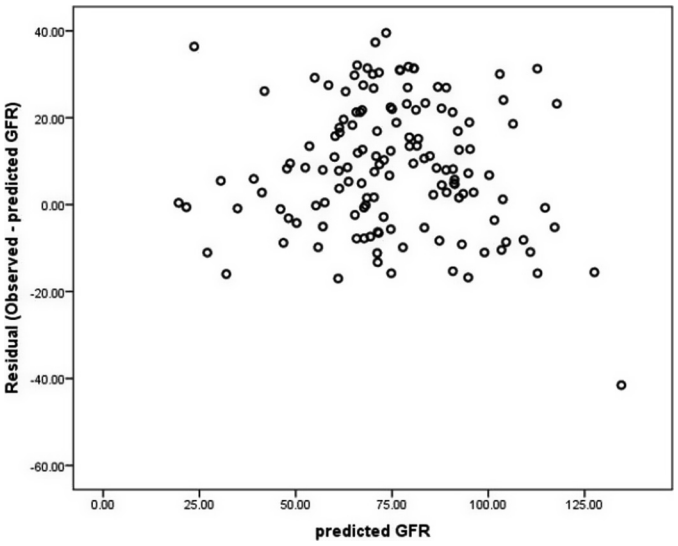
Background and Aims: Serum creatinine overestimates renal function in patients with cirrhosis leading to significant differences between "true" and calculated (MDRD equation) glomerular filtration rate (GFR). We compared the performance of MDRD with "true" GFR and the impact of this difference on MELD calculation. We further developed and validated an equation for GFR calculation in cirrhosis.

Methods: We included 469 consecutive patients (mean age: 53±11, males: 69%), who had a transplant work-up assessment between 2011–2014. "True" GFR was estimated using the gold standard of Tc-99m DTPA, which includes bolus administration of the radioactive tracer, followed by serial serum measurements at 2, 4, 8 and 24 hours according to a technique validated in patients with ascites. A corrected "true" creatinine was derived from the DTPA GFR after application of the MDRD formula. Subsequently, a corrected MELD was calculated and was compared with the conventionally calculated MELD. Stepwise multiple linear regression on log-transformed data was used to derive a GFR equation. This was compared with the observed GFRs in a validation set of 138 patients with cirrhosis assessed between 2006 and 2011.

Results: Mean DTPA GFR was 66.75±25 1.73/ml/m^2. A difference >20 ml/min/1.73 m^2 between MDRD and DTPA GFR was observed in 276 (59%) patients. Such difference was independently associated with sex (OR: 4.52, 95% CI: 2.62–7.79), black race (OR: 5.55, 95% CI: 1.52–20.33), decreased creatinine (OR: 0.94, 95% CI: 0.93–0.96) and sodium (OR: 0.92, 95% CI: 0.87–0.98) levels and ascites (OR: 2.38, 95% CI: 1.36–4.16). The corrected MELD score was ≥3 points higher in 177 (37.7%) patients. The proportion of patients with ≥3 points difference progressively increased with higher MELD scores (p < 0.001). The predicted equation derived

with the maximal R^2 (75.3%) was: GFR = 62.5·(creatinine$^{-0.839}$) × (urea$^{-0.213}$) × (INR$^{-0.186}$) × (age$^{0.123}$) × (sodium$^{0.898}$) × 1.256(if male) × 0.906(if severe ascites). The mean difference between observed/predicted GFRs (residual) in the validation set was 8.6±14.9. According to the residual plots the model was a good fit.

Conclusions: Measured creatinine overestimates renal function and leads to systematic biases in MELD calculation especially in high MELD scores. We developed and validated a new well-fitted model for renal function assessment in cirrhosis. This remains to be incorporated in prognostic scores in patients with cirrhosis.



P0182

DUODENAL MICROBIOTA IS NOT THE ORIGIN FOR BACTERIAL TRANSLOCATION IN LIVER CIRRHOSIS

S. Krohn[1], C. Engelmann[1], P. Raatz[1], A. Hoffmeister[1], A. Böhlig[1], K. Zeller[1], S. Böhm[1], A. Chatzinotas[2], T. Berg[1]. *[1]Division of Gastroenterology and Hepatology, University Hospital Leipzig, [2]Helmholtz Centre for Environmental Research-UFZ, Leipzig, Germany*
E-mail: sandra.krohn@medizin.uni-leipzig.de

Background and Aims: Intestinal dysbiosis and bacterial translocation (BT) in cirrhosis has been regarded as the main driver for infections. Although the small intestine has been considered having the greatest potential for BT further results promoted that the colon has the largest rate of BT and permeability. We therefore investigated duodenal fluid and blood of liver disease patients regarding its bactDNA content and composition.

Methods: 156 blood and duodenal samples were collected in cirrhotics (n = 114) and controls without liver disease (n = 42). Samples were analysed for bactDNA content using quantitative 16S rRNA gene based real time PCR. To define the microbial composition of bactDNA positive samples terminal restriction fragment length polymorphism (T-RFLP) was used and clone library analyses provided the assignment of sequence types to operational taxonomic units (OTU).

Results: All 156 duodenal samples were tested positive for bactDNA with a median of 4.6×10^8 copies/ml (1.0×10^4–7.7×10^{10}). In total, 19/156 (12.2%) blood samples [cirrhosis 52.6% (n = 10) vs. non-cirrhosis 47.4% (n = 9)] were bactDNA positive (median 5.8×10^3 copies/ml; 1.7×10^3–1.5×10^5). According to T-RFLP analyses of 142/156 (91.0%) duodenal and so far 5/19 (26.3%) blood samples of patients with cirrhosis (n = 4; 80%) a division into four clusters could be performed. Cluster I (n = 10, 6.8%) revealed the lowest number of 16S rRNA gene copies (median 1.7×10^4; 3.1×10^3–7.1×10^5) and included 80% of bactDNA positive blood samples. Its microbial composition differed highly from the remaining groups. Cluster II (n = 115, 78.2%) showed two distinct OTU predominantly comprising streptococci and staphylococci and cluster III (n = 13, 8.8%) revealed a dominant OTU belonging to *Granulicatella* spp. Streptococci OTU were missing in Cluster IV (n = 9, 6.1%). Blood samples and corresponding duodenal fluids revealed in all cases (n = 5) a different microbial composition and could never be assigned to the same T-RFLP cluster.

Conclusions: The preliminary findings of different microbial clusters observed in blood and duodenal fluid from patients with cirrhosis argues against bacterial translocation originating from the duodenum.

P0183

MEASUREMENT OF SPLEEN AND LIVER STIFFNESS BY SHEAR WAVE ELASTOGRAPHY TO NONINVASIVELY EVALUATE HEPATIC VENOUS PRESSURE GRADIENT AND PORTAL HYPERTENSION

L. Vonghia[1], W. Verlinden[1], T. Vanwolleghem[1], P. Michielsen[1], S. Francque[1]. *[1]Gastroenterology Hepatology, University Hospital Antwerp, Edegem, Belgium*
E-mail: wim.verlinden@uza.be

Background and Aims: Hepatic venous pressure gradient (HVPG) is the gold standard used to determine the degree of sinusoidal portal hypertension and an important prognostic factor for patients with cirrhosis. HVPG can only be determined invasively in specialized centers. Recent data demonstrated that measurement of spleen stiffness (SS) and liver stiffness (LS) by transient elastography correlates with HVPG levels. To date, the performance of swear wave elastography (SWE) in this setting has not been reported. Therefore, the aim of the present study was to assess the diagnostic performance of SS and LS, measured by SWE, as noninvasive predictor of portal hypertension (PH) using HVPG as the gold standard.

Methods: We measured SS and LS in patients with liver disease undergoing HVPG measurement.

Results: Between September 2013 and October 2014, 63 patients were consecutively included. 67% were male and mean age was 55.3±12.4 years. Main aetiologies of liver disease were alcohol (41%), non-alcoholic fatty liver disease (29%), hepatitis B (14%) and autoimmune hepatitis (8%). Linear regression showed a significant correlation between HVPG and SS (R^2 0.433, $p < 0.001$), LS (R^2 0.468, $p < 0.0001$) and SS/LS combined (R^2 0.540, $p < 0.0001$). AUROC of SS for HVPG <10 mmHg versus ≥10 mmHg and HVPG <12 mmHg versus ≥12 mmHg was 0.86 and 0.84, respectively. A SS cut-off value of 29.6 kPa had a sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of 74%, 90%, 85% and 81%, and of 78%, 82%, 70% and 88% for HVPG ≥10 mmHg and HVPG ≥12 mmHg, respectively. AUROC of LS for HVPG <10 mmHg versus ≥10 mmHg and HVPG <12 mmHg versus ≥12 mmHg was 0.85 and 0.80, respectively. A LS cut-off value of 15.9 kPa had a sensitivity, specificity, PPV and NPV of 96%, 69%, 73% and 96%, and of 95%, 56%, 54% and 96% for HVPG ≥10 mmHg and HVPG ≥12 mmHg, respectively.

Conclusions: This is the first study of SWE measurement of SS and correlation with HVPG. Measurement of SS can be used for noninvasive assessment of PH, and is a slightly better predictor than LS.

P0184

HEPATOPULMONARY SYNDROME IS NOT ASSOCIATED WITH HIGHER RATES OF LEFT VENTRICLE DIASTOLIC DYSFUNCTION IN PATIENTS WITH CIRRHOSIS

A. Voiosu[1], I. Daha[2], T. Voiosu[1], M. Diculescu[3], ACCEPT. *[1]Gastroenterology, [2]Cardiology, Colentina Clinical Hospital, [3]Gastroenterology, Fundeni Clinical Institute, Bucharest, Romania*
E-mail: andreivoiosu@yahoo.com

Background and Aims: Hepatopulmonary syndrome (HPS) and cirrhotic cardiomyopathy are common complications of liver cirrhosis but their real prevalence and importance are not yet known. Common pathogenetic mechanisms may be involved and some studies have shown possible links between HPS and left

ventricle diastolic dysfunction. We aimed to further investigate the relationship between HPS and echocardiographic parameters of diastolic dysfunction in cirrhotic patients.
Methods: Consecutive patients with cirrhosis and no preexisting heart or lung conditions were included in a prospective observational study. Transthoracic echocardiography (TTE) with injected agitated saline was performed in all patients. HPS was diagnosed in the presence of increased age-adjusted alveolar-arterial gradient and intrapulmonary vascular dilatations detected by contrast TTE. Diastolic dysfunction of the left ventricle was assessed through TTE measurements of left atrial volume (LAV), early (E′) and late (A′) diastolic mitral annular velocity, mitral early (E-wave) and late diastolic filling (A-wave) velocities, E/A ratio, mitral inflow E velocity to tissue Doppler E′ (E/E′) ratio, deceleration time (DT) of early filling velocity and isovolumetric relaxation time (IVRT). N-terminal prohormone of brain natriuretic peptide (NT-proBNP) levels were also measured in all patients. These variables were compared in univariate and multivariate analysis (using binary logistic regression) between patients with and those without HPS.
Results: Fifty-four patients with cirrhosis (21 female, mean age 59 years) were included. 32 were Child–Pugh class A, 12 were Child Pugh B and 10 Child Pugh C. 28 patients had intrapulmonary vascular dilatations but only 17 (31%) fulfilled all criteria for HPS. Mean NT-proBNP levels did not differ between patients with and those without HPS (260 vs. 251 pg/mL, p = 0.88 student t test). None of the evaluated echocardiographic parameters (LAV, E′, A′, E/E′, IVRT, E/A and DT) correlated significantly with the presence of HPS in either univariate or multivariate analysis.
Conclusions: In this cohort of 54 consecutive cirrhotic patients the presence of hepatopulmonary syndrome did not associate with increased rates of left ventricle diastolic dysfunction as evaluated by echocardiographic parameters or NT-proBNP levels.
Acknowledgments: This study is part of the ACCEPT initiative and POSDRU 159/1.5/S/141531.

E-mail: pgines@clinic.ub.es

Background and Aims: Acute-on-Chronic Liver Failure (ACLF) is a frequent syndrome that occurs in patients with cirrhosis that is associated with high short-term mortality. Frequently, it occurs in the context of systemic inflammatory response caused by bacterial infections. However, in some cases, ACLF occurs without an identifiable bacterial infection. Although there is information about ACLF associated with infections, information about characteristics and outcome of ACLF not associated with infections is very limited. The aim of this study is to investigate the characteristics, evolution and survival of patients with ACLF not associated with infections.
Methods: We analyzed 302 patients with ACLF included in the European multicentric CANONIC study of EASL-CLIF consortium. Patients were classified into two groups according to the absence or presence of bacterial infections (ACLF-noinf and ACLF-inf, respectively). Diagnosis of bacterial infection was based on standard procedures.
Results: One-hundred and forty-three patients (47%) had ACLF-noinf, while 159 had ACLF-inf (53%). Among patients with ACLF-noinf no precipitating event could be found in 54% despite extensive assessment. In the remaining patients, precipitating events were active alcoholism, gastrointestinal bleeding or miscellaneous causes. Comparison of frequencies of organ failures included in the definition of ACLF showed a similar frequency of kidney, liver, and coagulation failures and a significantly lower frequency of brain, circulatory, and lung failures in patients with ACLF-noinf compared to patients with ACLF-inf. Patients with ACLF-noinf had higher leukocyte count and C-reactive protein levels than those of patients without ACLF, yet lower compared to values of patients with ACLF-inf. CLIF-Organ failure and CLIF-C-ACLF scores, two classifications to assess severity of ACLF, were significantly higher in patients with ACLF-inf than in those with ACLF-noinf. However, 3-month mortality of patients with ACLF-noinf was similar to that of patients with ACLF-inf, and close to 50%. In patients with ACLF-noinf leukocyte count was an independent predictive factor of 3-month mortality.
Conclusions: ACLF-noinf is common and associated with poor prognosis. Current findings suggest that ACLF-noinf occurs in the setting of a systemic inflammatory response, the severity of which is associated with prognosis. Further studies are needed to investigate characteristics of this inflammatory response and identify new therapeutic targets.

P0186
A MODEL TO PREDICT MORTALITY IN CIRRHOTICS PRESENTING WITH CELLULITIS

C.A. Philips[1], R. Prabhat[1], A. Sahney[1], L. Anand[1], D. Rangegowda[1], A. Kumar[1], G. Kumar[2], V. Bhatia[1], S.K. Sarin[1]. *[1]Hepatology, [2]Research, Institute of Liver and Biliary Sciences, New Delhi, India*
E-mail: abbyphilips@gmail.com

Background and Aims: Infections are arguably the commonest cause of mortality in cirrhosis patients. Due to significant hemodynamic alterations, pedal edema, ascites, coagulopathy and cirrhosis associated immune deficiency syndrome, skin and soft tissue infections (SSTI) are not uncommon in cirrhotics. Prevalence and outcome of cirrhotics presenting with SSTI and predictors of mortality have not been adequately studied.
Methods: From Aug 2012 to Oct 2014, 2368 patients of cirrhosis and acute on chronic liver failure (defined as per Asian Pacific Association for Study of Liver criteria) were admitted. The electronic records were analysed retrospectively for presentation with regards to SSTI and their influence on mortality. A model was developed to predict mortality due to SSTI.
Results: Two hundred and fifty patients (9.47%, M-212, F-38) were diagnosed to have cellulitis or severe skin infections. The commonest aetiology was HBV related cirrhosis, followed by non-alcoholic fatty liver and alcoholic liver disease. Fifty-three patients died due to refractory septic shock (M-49, F-4; 21.2%). The commonest organism cultured from wound site was E. coli, followed by Klebsiella and Acinetobacter species. Commonest systemic infection associated with SSTI was pneumonia. The most

significant extracutaneous infection that predicted mortality was spontaneous peritonitis ($p < 0.001$) as was the need for surgical management ($p < 0.05$). After univariate and multivariate analysis, the significant independent predictors of mortality were presence of spur cells, persistence of toxic granulations on peripheral smear on day 3, necrotizing fasciitis at admission, mean arterial pressure (MAP) ≤62 mmHg, blood urea (BU) ≥54 mg/dL, Child–Pugh score (CTP) ≥12 and serum lactate (Slac) on day of admission >5.75 mmol/dL with each at p-value <0.05. These independently predicted mortality accurately in 97.6% of patients. Comparative ROCs of independent risk factors revealed that lactate level at admission was the predominant factor predicting mortality in cirrhosis patients with cellulitis.

Table 1. Multivariate analysis – regression model significant variables

Variables in equation

Table 2. Area Under the Curve

Test Result Variable(s)	Area	Std error[a]	Asymptotic sig.[b]	Asymptotic 95% confidence interval	
				Lower bound	Upper bound
Spurcells	0.638	0.047	0.002	0.545	0.731
Necrosis	0.713	0.046	0.000	0.623	0.803
ToxicGran	0.731	0.045	0.000	0.643	0.819
MAP	0.716	0.040	0.000	0.637	0.794
CTP	0.788	0.035	0.000	0.720	0.857
BU	0.635	0.043	0.002	0.551	0.720
Lac	0.870	0.033	0.000	0.805	0.935

Table 3. Prediction model

Observed outcome	Predicted outcome		
	0	1	Percentage correct
Alive	195	2	99.0
Dead	4	49	92.5
	Overall percentage		97.6

Conclusions: SSTI are not uncommon and if severe, carry significant mortality in cirrhotics. The regression model showed presence of spur cells, persistence of toxic granulations in the initial 72 hours after admission, low MAP (≤62), higher BU (≥52), CTP score (≥12) and high Slac at presentation (≥5.75) carry high mortality. Patients presenting with these factors at admission need to be aggressively managed with the sepsis bundles of care for early and timely salvage.

P0187

A RANDOMIZED CONTROLLED TRIAL COMPARING THE ALFAPUMP© WITH PARACENTESIS IN PATIENTS WITH REFRACTORY ASCITES: CLINICAL AND PATHOPHYSIOLOGICAL EFFECTS ON CARDIAC, HAEMODYNAMIC, INFLAMMATORY, RENAL AND NUTRITIONAL PARAMETERS

D. Adebayo[1], A. Mohammed[1], S. Arora[1], F. De Chiara[2], C. Trepte[3], S. Whitaker[3], V. Mishra[4], D. Cohen[4], D. Sharma[5], M. Malago[5], R. Jalan[1]. *[1]Department of Hepatology, Royal Free NHS Trust, [2]Institute for Liver and Digestive Health, Royal Free Hospital, London, United Kingdom; [3]Sequana Medical, Baarerstrasse 10, 6304 Zug, Zurich, Switzerland; [4]Department of Urology, [5]Department of HPB Surgery And Liver Transplantation, Royal Free NHS Trust, London, United Kingdom*

E-mail: danielle.adebayo.11@ucl.ac.uk

Background and Aims: Cirrhotic patients with refractory ascites (RA) who require regular paracentesis find it distressing, is associated with poor quality of life and a high mortality. A novel, implantable, programmable device (alfapump©, Sequana Medical) that transfers ascites into the bladder to enable passing ascitic fluid into the urine has been shown to be safe in treating RA in uncontrolled studies. However, its effects on pathophysiological variables are lacking. The aims of this study were to determine the effect of the alfapump© on cardiac, haemodynamic, inflammatory and nutritional parameters.

Methods: 17 patients with RA (age: 62±7 years, 75% males) not suitable for TIPS were randomised to either the alfapump© (**AP**) or paracentesis (**P**) in a sub-study of a European trial (primary end point: paracentesis free survival). Patients were followed up for at 1 and 3-months. Cardiac hemodynamics (including cardiac output), neurohormones (BNP, renin), inflammatory markers (cytokines), urinary biomarkers (NGAL, KIM-1) and nutritional parameters were measured. Data were analysed using time dependent non-parametric statistics.

Results: 15 (**AP**: 7; **P**: 8, *2 withdrawals*) were analysed. Patients were well-matched for age, sex, aetiology and severity [MELD: **AP**: 14.5 (13–22); **P**: 15 (11–22)]. 1 patient required large volume paracentesis (LVP) in the **AP** group compared with all in the **P** group ($p < 0.001$); [LVP/month: [0 (0–0.3) in **AP**] and [1.3 (0.2–2.1) in **P**]. Transient acute kidney injury was observed in the post-operative period in all 7 **AP** patients, which resolved spontaneously, with hepatorenal syndrome in 1 **AP** patient. Serum creatinine ($p = 0.08$) and renin increased insignificantly (0.06) and albumin decreased insignificantly (0.08) in the AP group with no significant differences in cardiovascular parameters, urinary injury markers and cytokines. There was a significantly greater improvement in the estimated dry body weight ($p < 0.001$), mid-arm muscle circumference ($p < 0.001$), triceps skin fold thickness ($p < 0.001$) and hand-grip ($p < 0.001$) in the **AP** group compared with **P**.

Conclusions: The results of this study suggest that the alfapump© is safe and effective in RA and improves the nutritional state of patients with RA. Transient AKI episodes are reversible with volume expansion and the non-significant changes in creatinine and renin in AP group are related to relative reduction in serum albumin. Future studies should evaluate albumin supplementation in AP patients.

P0188

HEPATOPULMONARY SYNDROME. PREVALENCE, ASSOCIATED FACTORS AND IMPACT IN SURVIVAL AFTER LIVER TRANSPLANTATION

E. Dueñas[1], R. Rota[1], J. Ribas[2], A. Ruiz-Mayoral[3], M.E. González[4], A. Amador[1], C. Baliellas[1], J. Fabregat[4], X. Xiol[1], J. Castellote[1].
[1]Hepatology and Liver Transplant Unit. Gastroenterology Department, [2]Pneumology Department, [3]Cardiology Department, [4]Hepatology and Liver Transplant Unit. Digestive Surgery Department, Hospital Universitari de Bellvitge – IDIBELL, L'Hospitalet de Llobregat, Barcelona, Spain
E-mail: eduenas@bellvitgehospital.cat

Background and Aims: Hepatopulmonary syndrome is frequent in liver cirrhosis (LC) but the association between liver dysfunction and impact in survival after liver transplantation remains controversial. The aim of this study was to determine the prevalence of HPS in a cohort of patients with LC and the possible associated factors and the impact on survival at month and at year after LT.
Methods: We prospectively studied 204 patients who were evaluated for LT between November 2010 and June 2014. An arterial blood gas analysis, a transthoracic contrast echocardiography and lung functional test were performed in all patients for LT evaluation. HPS was defined by a positive contrast echocardiography and alveolar-arterial oxygen gradient ≥15 mmHg or partial pressure of arterial oxygen <80 mmHg. Demographic, clinical variables and survival at one month and one year after LT were compared in patients with and without HPS.
Results: HPS prevalence was 34.3% (44, 21 and 5 patients with mild, moderate and severe degree respectively). Women (OR = 2.4, 95% CI: 1.21–4.90), hepatocellular carcinoma (OR = 0.38, 95% CI: 0.21–0.7) and liver function measured by MELD score (16.87±5.10 vs. 13.72±5.81; p = 0.000), Child–Pugh score (8.74±2.24 vs. 7.64±2.29; p = 0.001) and their components (including ascites and encephalopathy), were associated with HPS. Only women, Child–Pugh score and INR were independently associated with HPS in the multivariate analysis. Until now, 111 patients were transplanted (38 with HPS). No differences in survival after one month and one year after LT were observed in patients with and without HPS or depending on severity of HPS.
Conclusions: Prevalence of HPS is high and is independently associated with female sex, poor liver function as reflected by Child–Pugh score and with INR. The survival among the first year after LT was not impacted by the presence of HPS or their severity.

P0189

PROTON PUMP INHIBITOR TREATMENT IS ASSOCIATED WITH INCREASED MORTALITY IN PATIENTS WITH CIRRHOSIS

G. Dultz[1], A. Piiper[1], S. Zeuzem[1], B. Kronenberger[1], O. Waidmann[1].
[1]Medizinische Klinik 1, Klinikum der Johann Wolfgang Goethe-Universität, Frankfurt, Germany
E-mail: georg.dultz@kgu.de

Background and Aims: In recent years the wide use of proton pump inhibitors (PPI) in patients with cirrhosis was questioned after several studies indicated an increased number of infectious complications under PPI treatment. Since the prognostic relevance of PPI treatment in patients with cirrhosis is still unknown we performed a prospective study investigating the relation of PPI treatment and overall survival (OS) in cirrhotic individuals.
Methods: Patients with cirrhosis were prospectively enrolled into the study and followed until death, liver transplantation or last contact. Overall survival was the primary end point. At the day of the study inclusion data on PPI treatment as well as further clinical and laboratory data were assessed. Univariate and multivariate Cox regression hazard models were used to identify independent predictors of survival.
Results: A total of 272 cirrhotic patients were included in the study. 213 (78.3%) patients received PPI. PPI treatment was associated with higher MELD scores (median MELD 16 vs. 12, p < 0.027) and ascites (77.0% vs. 55.9%, p = 0.039) at baseline in a multivariate logistic regression analysis. In the multivariate Cox regression model PPI use was identified as an independent predictor of mortality (hazard ratio 2.330, 95% confidence interval 1.264–4.296, p = 0.007) together with the model of end stage liver disease (MELD) score (1.097, 1.059–1.137, p < 0.001), hepatocellular carcinoma (4.971, 2.909–8.498, p = 0.001) and hepatic decompensation (2.211, 1.208–4.4045, p = 0.01).
Conclusions: Treatment with PPI was identified as an independent risk factor for mortality in patients with cirrhosis. Although the study design cannot ultimately prove a causative role for the increased mortality, the common prescription of PPI in patients with cirrhosis should be considered carefully taking into account its potential adverse effects.

IMIM, [5]Clinical Epidemiology, Hospital de la Santa Creu i Sant Pau, Barcelona, [6]CIBERsam. Instituto de Salud Carlos III, [7]CIBERehd. Instituto de Salud Carlos III, Madrid, Spain
E-mail: MPoca@santpau.cat

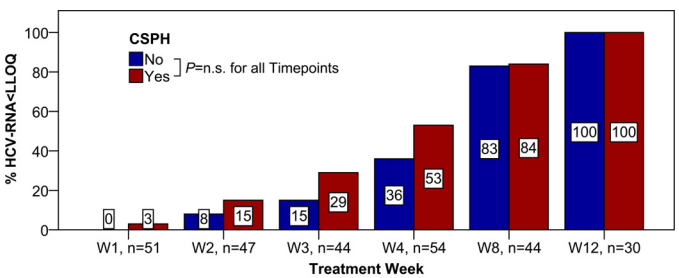
Background and Aims: Hospital mortality in high-risk spontaneous bacterial peritonitis (SBP) patients is high despite albumin treatment. The aim of this study was to develop and validate a model to identify SBP patients with high risk of mortality in spite of receiving the standard treatment with antibiotics and albumin.
Methods: We analyzed all cirrhotic patients with SBP and high risk of mortality treated with albumin over a 10-year period in a third level hospital. We defined high risk of mortality when patients presented urea ≥11 mmol/L and/or bilirubin ≥68 μmol/L at SBP diagnosis. We developed a predictive model of in-hospital mortality that afterwards was validated in an external cohort from two different third level hospitals in the same area.
Results: We included 118 high-risk SBP episodes treated with albumin and antibiotics. In-hospital mortality was 33/118 (28%). The independent predictive factors of in-hospital mortality were serum urea (OR 1.131, 95% CI 1.051–1.218, p = 0.001), blood leukocyte count (OR 1.063, 95% CI 1.010–1.118, p = 0.02), Child–Pugh score (OR 1.555, 95% CI 1.114–2.171, p = 0.009) and mean arterial pressure (OR 0.947, 95CI% 0.907–0.989, p = 0.01) at SBP diagnosis. A predictive model including these four variables was established, showing a discrimination accuracy (AUC) of 0.850, 95% CI 0.777–0.922. A cut-off point of 0.245 was selected with a sensitivity of 0.85 and specificity of 0.75. In-hospital mortality was higher among patients with a model value ≥0.245 (28/49, 57.1%) than in patients with model value <0.245 (5/69, 7.2%) (p < 0.001). The validation series included 123 patients. In-hospital mortality was 33/123 (26.8%). The discrimination accuracy of the model in the validation series was 0.760, 95% CI 0.654–0.867. The in-hospital mortality was 24/57 (42.1%) and 9/66 (13.6%) in patients with a model value ≥ and <0.245, respectively.
Conclusions: A predictive model of mortality has been established and validated in SBP patients with high risk of mortality, including urea, blood leukocyte count, Child–Pugh score and mean arterial pressure. These findings may contribute to identify patients that could benefit from additional therapeutic strategies.

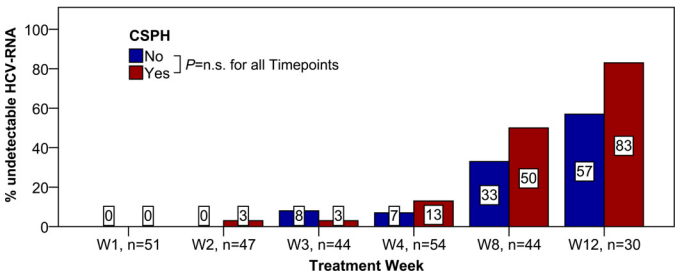
P0191

IFN-FREE REGIMENS OVERCOME THE NEGATIVE EFFECT OF PORTAL HYPERTENSION ON VIROLOGIC RESPONSE AND VIRAL KINETICS IN PATIENTS WITH CIRRHOSIS

M. Mandorfer[1], K. Kozbial[1], C. Freissmuth[1], P. Schwabl[1], A.F. Stättermayer[1], T. Reiberger[1], S. Beinhardt[1], R. Schwarzer[1], M. Trauner[1], A. Ferlitsch[1], H. Hofer[1], M. Peck-Radosavljevic[1], P. Ferenci[1], on behalf of Vienna Hepatic Hemodynamic Lab.
[1]*Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria*
E-mail: mattias.mandorfer@meduniwien.ac.at

Background and Aims: Clinically significant portal hypertension (CSPH) is the strongest predictor of virologic response to pegylated interferon/ribavirin in patients with cirrhosis. However, the availability of interferon (IFN)-free regimens has ushered in a new era in the treatment of chronic hepatitis C (CHC). We aimed to investigate the impact of portal pressure assessed by hepatic venous pressure gradient (HVPG) measurement on on-treatment response and viral kinetics in patients treated with IFN-free regimens outside of clinical trials.
Methods: Fifty-six patients with CHC and cirrhosis who underwent HVPG measurement before starting an IFN-free therapy were retrospectively studied. CSPH and pronounced portal hypertension (PPH) were defined as HVPG ≥10 mmHg and ≥16 mmHg, respectively. HCV-RNA was assessed using the Abbott RealTime HCV assay with a lower limit of quantification (LLOQ) and detection of 12 IU/mL. Continuous variables were reported as mean±standard deviation or median (interquartile range).
Results: Sofosbuvir/daclatasvir, sofosbuvir/ribavirin and sofosbuvir/simeprevir were used in 32 (57%), 12 (21%) and 11 (20%) patients, respectively. One patient (2%) was treated with simeprevir/daclatasvir. CSPH and PPH were observed in 41 (73%) and 31 (55%) patients, respectively. The distribution of treatment regimens was comparable between patients with or without CSPH/PPH. Patients with CSPH/PPH had lower platelet counts and albumin levels, while bilirubin levels, INR, MELD and Child–Pugh scores were higher than in patients without CSPH/PPH. Overall, on-treatment response was impaired. At treatment week 4, only 26/54 (48%) and 6/54 (11%) patients had HCV-RNA <LLOQ and undetectable HCV-RNA, respectively. Moreover, at treatment week 12, undetectable HCV-RNA was achieved in 23/30 (77%) patients, while all patients had HCV-RNA <LLOQ. Importantly, on-treatment response and viral kinetics were neither affected by CSPH, nor by PPH at any time point.
Sustained virologic response (SVR) rates will be available at the time of the meeting.





Conclusions: This is the first study investigating the impact of HVPG on on-treatment response and viral kinetics in a real-life cohort including patients treated with a combination of two DAAs. IFN-free regimens overcome the negative effect of portal hypertension on on-treatment response and viral kinetics. The upcoming data will allow for the assessment of the impact of portal hypertension on relapse rates.

P0192

ASSESSMENT OF LIVER FUNCTION BY THE EXHALED BREATH-PRINT DURING CHRONIC LIVER DISEASE

A. De Vincentis[1], U. Vespasiani-Gentilucci[1], G. Galati[1], P. Gallo[1], G. Colarusso[1], G. Pennazza[2], M. Santonico[2], C. Vernile[2], R. Antonelli-Incalzi[3], A. Picardi[1]. [1]*Liver Unit,* [2]*Unit of Electronics for sensor systems,* [3]*Unit of Geriatrics, Campus Bio-Medico University, Rome, Italy*
E-mail: antonio.devincentis@gmail.com

Background and Aims: Since the liver plays a key metabolic role, the pattern of volatile organic compounds (VOCs) in the exhaled breath might change with type and severity of liver disease. Gas sensor array technology (commonly dubbed electronic nose, e-nose) is a novel technique, which provides a sort of fingerprint of exhaled breath (breath-print, BP) by detecting VOCs through multiple sensors. It has so far never been tested in patients with chronic liver disease. We aimed to assess discriminative and classificatory properties of the e-nose in liver diseases by analysing the BP of patients affected by chronic hepatitis (CH) and by liver cirrhosis (LC) with different Child–Pugh classes (CPC).
Methods: Thirty-nine patients with CH (19 infective, 2 alcoholic and 18 metabolic) and 65 patients with LC (24 infective, 30 alcoholic and 11 metabolic), were recruited. Clinical and biochemical data were collected. Patients underwent breath collection by Pneumopipe®. Breath analysis was obtained through e-nose (gas sensor array BIONOTE), which gives a BP made up of a sequence of four 7-dimensional data arrays, composed of the responses of a 7-dimensional gas sensor array at four temperatures (50–100–150–200°C).
Results: Partial Least Square Discriminant Analysis (PLS-DA) was performed to build models able to distinguish CH from LC patients and, among LC patients, different CPC. A discriminative model for CH vs LC was obtained only after excluding patients with hepatic encephalopathy (17 subjects). The accuracy of these models were then tested for their classificatory properties, showing a sensibility, specificity and positive predictive value for LC vs CH of 74.5%, 63.6% and 66.7%, and for CPC A-B vs C of 87.5%, 64.7% and 87.5%, respectively. The 16 cirrhotic patients misclassified as CH by our model showed a trend towards a better CPC ($p = 0.07$), and a significantly higher glomerular filtration rate ($p = 0.01$), compared to correctly classified cirrhotics.
Conclusions: For the first time we report original results concerning the performance of the e-nose technology during chronic liver disease. These data are proof of concept that the e-nose could be a valid non-invasive instrument to characterize and monitor hepatic function. The observed classificatory properties might be further improved by refining stage-specific BP and considering the impact of comorbidities, such as renal failure, in a larger series of patients.

P0193

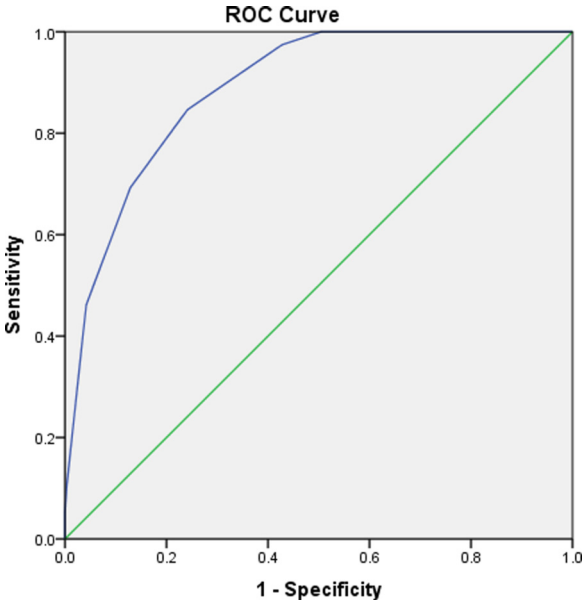
A NOVEL SCORING SYSTEM FOR PREDICTION OF CONTRAST INDUCED NEPHROPATHY IN CIRRHOSIS – THE 'CINIC SCORE'

C.A. Philips[1], A. Sahney[1], A. Kumar[1], L. Anand[1], G. Kumar[2], S.L. Nayak[3], R. Maiwall[1], S.K. Sarin[1]. [1]*Hepatology,* [2]*Research,* [3]*Nephrology, Institute of Liver and Biliary Sciences, New Delhi, India*
E-mail: abbyphilips@gmail.com

Background and Aims: Contrast induced nephropathy (CIN) is described in patients undergoing interventional cardiac procedures and a grading system for the same has been in use. The predictors of development of CIN in cirrhotics (CP) has not been studied adequately. It is well known that CP have low creatinine (Cr) clearance and renal reserve and maybe at risk, to develop CIN. We devised a novel scoring system (**C**ontrast **I**nduced **N**ephropathy **I**n **C**irrhosis, **CINIC** score) to predict CIN in CP using a derivative group (DG) which was validated in a separate cohort (VG).

Methods: DG of 350 CP [M = 281, F = 69; alcohol = 86, HBV = 190, others = 74] with or without decompensation undergoing contrast enhanced computed tomography [CECT, Omnipaque 300 (Iohexol, 1 ml/kg; 300 mg/ml Iodine)], of abdomen were prospectively studied for development of CIN. CIN was defined as an absolute increase of 0.5 mg/dL Cr from baseline or increase in Cr >25% within 48 to 72 hrs. Independent risk factors were identified on multivariate analysis, a score derived, based on regression coefficient values rounded for each variable, providing a total score. This was validated in independent VG of 150 CP undergoing CECT.

Results: 39 (11.1%) patients developed CIN. On univariate analysis severity of ascites ($p < 0.001$), hepatic encephalopathy ($p < 0.001$), diabetes (DM, $p < 0.05$), hypertension (HTN, $p < 0.01$), hyponatremia ($p < 0.01$), hypoalbuminemia ($p < 0.001$), baseline uric acid (UA, <0.001), CTP and MELD (<0.001) were significantly associated with CIN. On multivariate analysis, only UA [OR 3.089 (95% CI 1.371–6.957), $p < 0.05$], CTP [43.12 (9.29–200.19), <0.001], DM [6.828 (2.411–19.336), <0.001] and HTN [6.072 (2.650–19.336), <0.001] were found significant. Regression coefficient values for each variable were rounded off to give points – UA 1 (>6.2 mg/dL, Sen 60%), DM & HTN, 2 each, and CTP 4 (>11, Sen 93%), for a total score of 9. Prediction of CIN was made at a total score of ≥4.5, rounded off to 5 [sensitivity 84%, specificity 76%, AUROC 0.889 (95% CI 0.845–0.933), $p < 0.001$]. Patients in DG and VG were comparable. In VG, CINIC score predicted CIN with AUROC 96.3 (Sen 80%, Spe 90.4%, PPV 48%, NPV 97.6%).



Coordinates of the ROC curve

Test Result Variable(s): score Positive if Greater Than or Equal To[a]	Sensitivity	1 – Specificity
−1.0000	1.000	1.000
.5000	1.000	.797
1.5000	1.000	.627
2.5000	1.000	.505
3.5000	.974	.428
4.5000	**.846**	**.241**
5.5000	.692	.129
6.5000	.462	.042

8.5000	.051	.000
10.0000	.000	.000

Area Under the Curve

Test Result Variable(s): score

Area	Std. Error[a]	Asymptotic Sig.[b]	Asymptotic 95% Confidence Interval	
			Lower bound	Upper bound
.889	.023	.000	.845	.933

The CINIC Score

Parameter	Score	
	Present	Absent
Baseline uric acid >6.2 mg/dL	1	0
Presence of diabetes mellitus	2	0
Presence of hypertension	2	0
Child score >11 points	4	0
Total	9	–

Score >5 predicts CIN development.

Conclusions: In CP, independent risk factors of CIN include CTP >11, DM, HTN and baseline UA (>6.2 mg/dL). The CINIC score ≥5 predicted CIN in 89% of CP, which on validation yielded an AUROC 96.3%. The presence of CTP >11 along with any other significant independent variable, or presence of all 3 independent variables apart from CTP, predicted CIN. Based on CINIC, preventive measures prior to CECT warrant evaluation.

P0194

SEVERE 25-HYDROXYVITAMIN D DEFICIENCY IS ASSOCIATED WITH INFECTIONS AND MORTALITY IN CIRRHOSIS

F. Finkelmeier[1], B. Kronenberger[1], S. Zeuzem[1], A. Piiper[1], O. Waidmann[1]. [1]*Gastroenterology, University clinic Frankfurt am Main, Frankfurt am Main, Germany*
E-mail: fabian.finkelmeier@kgu.de

Background and Aims: Vitamin D, best known to regulate bone mineralization, has numerous additional roles including regulation inflammatory pathways. Recently, an increased incidence of 25-hydroxyvitamin D3 [25(OH)D3] deficiency has been found in subjects suffering from liver diseases. We here investigated if low vitamin D levels might be associated with prognosis, inflammation and infectious complications in patients with cirrhosis.

Methods: We performed a prospective cohort study investigating the relation between 25(OH)D3 levels and stages of cirrhosis, mortality and complications of cirrhosis, including infections. 25(OH)D3 levels were quantified by radioimmunoassay from serum samples obtained at study inclusion.

Results: 270 patients with cirrhosis were enrolled into the present prospective cohort study. The mean follow-up time was 422±399 days with a range of 1–1382 days. 37 (13.7%) patients underwent liver transplantation and 85 (31.5%) individuals died within the study. The mean serum 25(OH)D3 concentration was

9.3±7.5 ng/ml with a range of 0.9 to 46.1 ng/ml. 25(OH)D3 levels differed significantly between Child Pugh scores and showed a negative correlation with the model of end stage liver disease (MELD) score. Patients with decompensated liver disease had significantly lowered 25(OH)D3 levels. 25(OH)D3 levels significantly differed between patients with infectious complications compared to those with none and individuals with SBP (spontaneous bacterial peritonitis) had significantly lower 25(OH)D3 levels compared to patients without SBP. 25(OH)D3 levels ≤6 ng/ml as well as serum 25(OH)D3 concentrations ≤10 ng/ml levels were associated with higher mortality compared to higher 25(OH)D3 levels (HR 1.82 for 6 ng/ml and HR 1.71 for 10 ng/ml, respectively).
In a multivariate Cox regression model 25(OH)D3 levels were independently associated with shorter OS.
Conclusions: 25(OH)D3 deficiency is associated with advanced liver disease and low 25(OH)D3 levels are an indicator for a poor outcome and are associated with infectious complications.

P0195
DEVELOPMENT OF A SMARTPHONE APPLICATION TO ENABLE REMOTE MONITORING IN THE OUTPATIENT MANAGEMENT OF CIRRHOTIC ASCITES

P. Ha[1], S. Warner[1,2], P. O'Neil[1,2], P. Anderson[1,2], A. Dev[1,2], D. Ratnam[2], S. Le[1,2], W. Sievert[1,2]. *[1]Faculty of Medicine, Monash University, [2]Department of Gastroenterology and Hepatology, Monash Health, Melbourne, Australia*
E-mail: ptha28@student.monash.edu

Background and Aims: Patients who develop hepatic decompensation with ascites have a poor prognosis and often experience other complications including spontaneous bacterial peritonitis, hepatic encephalopathy and variceal bleeding. We hypothesised that smartphone (SP)-enabled remote monitoring of patients with ascites may enable early detection of infection and acute decompensation, facilitate timely intervention and improve patient outcomes. This pilot study aimed to design, develop and implement a remote monitoring system (RMS) for outpatients with cirrhotic ascites.
Methods: Surveys were undertaken with patients and hepatologists to quantify the demand for a RMS and identify issues regarding implementation. Two applications (apps) were developed – a native app for Android SP and a web-based app for all internet-enabled devices (computers, tablets, other SP). Patients used the RMS in a 6-week prospective non-randomised trial.
Results: 27 patients (mean age 56 years, 67% male, 54% Child–Pugh B, 74% alcoholic liver disease) and 5 hepatologists were surveyed. 65% of patients reported that they would use a RMS. The system schematic (Figure 1) was designed based on survey data, and an Android and a Web app were developed. 9 patients used the RMS for a mean 40.3days and entered 15±14.5 updates. A total of 13 automated alerts occurred, 85% during office hours. 30% of automated alerts resulted in clinically significant changes to management (inpatient admission n = 1, outpatient appointment n = 2, avoided admission n = 1). Isolated weight gain (3 kg) had the least predictive value for requiring intervention (12.5%); presence of symptoms had the highest predictive value for changing management (60%).
Conclusions: We have successfully designed an internet-enabled RMS for outpatients with cirrhotic ascites that could be an adjunct to nurse-led clinics. Future studies will optimise the alert thresholds, assess long-term patient adoption and quantify clinical impact.

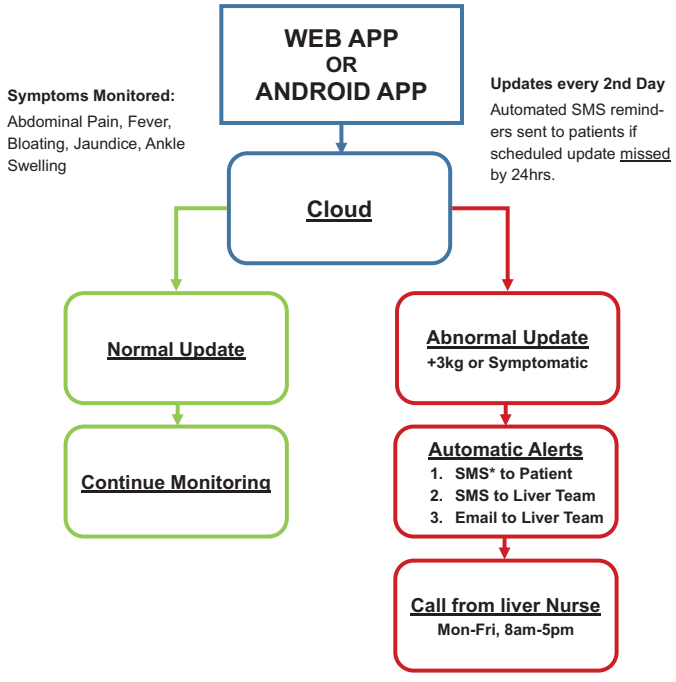

Figure 1.

P0196
NUTRITIONAL STATUS EVALUATION OF NONHOSPITALIZED PATIENTS WITH ALCOHOLIC LIVER CIRRHOSIS

S. Giestas[1], A. Giestas[2], C. Agostinho[1], C. Sofia[1]. *[1]Gastroenterologia, Centro Hospitalar Universitario Coimbra, Coimbra, [2]Endocrinologia, Centro Hospitalar Entre o Douro e Vouga, Santa Maria feira, Portugal*
E-mail: silviagiestas@gmail.com

Background and Aims: Malnutrition in cirrhotic patients is common and the degree of nutrition debilitation can play an important role in the complications and cause a negative impact on prognosis. However, the assessment of the malnutrition in these patients is still a problem because liver disease can affect the results of many of the traditional techniques currently used to evaluate nutritional status. The best method of nutritional evaluation in cirrhotic patients remains controversial. Aim: To evaluate the frequency of malnutrition in outpatients with alcoholic cirrhosis (AC) using different assessment methods of nutritional state
Methods: Prospective study of AC outpatients (diagnosis based on histological evidence and/or high clinic, biochemical, imagiological suspicion). Exclusion criteria: malabsorption syndrome, chronic pancreatitis, inflammatory bowel disease, chronic kidney disease, acquired immunodeficiency syndrome, neuromuscular diseases and oncologic advanced disease. Included patients were classified according to the disease severity through Child–Pugh score. Nutritional state was determined by Subjective global assessment (SGA), Nutritional index (NRI), Maastricht index (MI), Instant nutritional assessment (INA), Mid arm circumference (MAC) and Triceps skinfold thickness (TST). Based on this evaluation patients were classified into the three groups: well, moderately and severely malnourished. Food intake was retrospectively evaluated using 24-hour dietary recall data.
Results: Include 80 AC patients, 60% were male and men age were 52.3±8.2 years. Concerning cirrhosis severity 51.3% were Child–Pugh A, 32.5% were B and 16.2% were C. Variable degrees of malnutrition were diagnosed: 12.5% patients by TST, 17.5% by MAC, 26.3% by SGA, 63.7% by NRI, 66.3% by INA and 81.3% by MI. MI detected malnutrition in early stages of hepatic disease with more sensibility and specificity than the others methods. The prevalence malnutrition increased according to the severity of AC. Fat reserves were more depleted in females than in males, whereas muscle reserves were more depleted in males. More advanced malnutrition was associated with lower energy and protein intake.

Conclusions: The diagnostic of malnutrition varies according to the nutritional evaluation method used. Traditional nutritional assessment, although easier, underestimated the prevalence and severity of malnutrition in patients with cirrhosis. The IM was the best single score to identify the patients who had malnutrition, including early stage.

P0197

THE THROMBOEMBOLIC RISK AMONG HOSPITALIZED CIRRHOTIC PATIENTS AND LOW-MOLECULAR-WEIGHT HEPARIN SAFETY

M. Mahamid[1], B. Melamod[1], S. Mosab[1,2], A. Taha[2], G. Eran[1]. [1]*Sharee Zedek Medical Center, Jerusalem,* [2]*Holy Family Hospital, Nazareth, Israel*
E-mail: mahmudmahamid@yahoo.com

Background and Aims: *Background:* The cirrhotic patient represents a unique subset of patients who are at risk for both bleeding and developing venous thromboembolic events (VTE). It has been commonly misunderstood that these patients are naturally protected from thrombosis by deficiencies in coagulation factors. As a result, the cirrhosis population is often falsely perceived to be "autoanticoagulated". While patients with cirrhosis may have a bleeding predisposition, not uncommonly they also experience thrombotic events.
Aim: The aim of our study is to evaluate the risk of VTE among cirrhotic patients admitted to the hospital compared with age-gender mach control group.
Methods: Retrospective study that enrolled all cirrhotic patients admitted to the internal medicine departments of the Holy Family Hospital at Nazareth, and Sharee Zedek Medical Center at Jerusalem between 2005and 2012, all cases of VTE were analyzed and charts were extracted to determine the incidence and risk factors of VTE among cirrhotic patients compared with control group.
Results: 792 admissions of cirrhotic patients were documented between 2005and 2012, and 500 admissions match age-gender control group. During this period among the cirrhotic patients were 5 documented new VTE events; 0.68% of all admissions of cirrhotic patients resulted in a new diagnosis of VTE event. Multivariate analysis shows that the severity of liver disease (MELD/Child), and laboratory parameters not affected the risk of VTE.
Regarding the control group 3 new VTE events were documented; 0.6% of all admissions of control group (P = NS).
Regarding the 5 events within the cirrhotic group, 3 (60%) were DVT, 1 (20%) was PE only, and 1 (20%) involved both PE and DVT. From the 4 cases of the DVT, 3 were proximal and one distal, from the 2 PEs, one was massive and the other segmental. The 3 case among the control group were one case of isolated DVT, one isolated PE, and one PE + DVT.
All patients with VTE were treated with LMWH according to the guidelines, no bleeding complication were documented in both groups.
Conclusions: The risk of VTE, among cirrhotic patients appears to be similar to other admitted patients. Traditional markers of coagulation such PT, INR, platelets count were not predictive for VTE. The DVT among cirrhotic may be predominantly proximal. The uses of LMWH appear to be safe in treatment cirrhotic patients diagnosed with VTE.

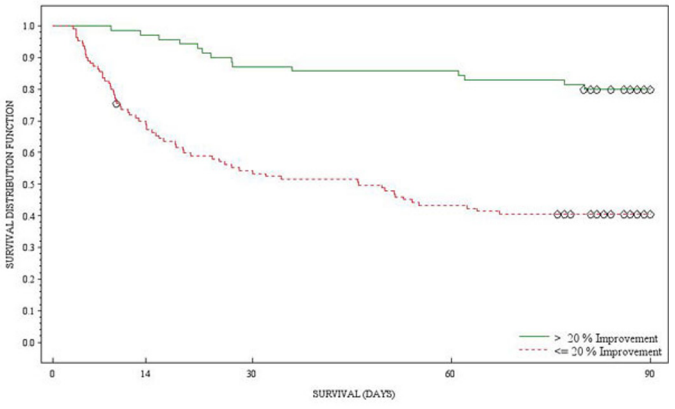
Cirrhosis and its complications: c. Bleeding, Hepatorenal syndrome and Ascites

P0198

PERCENTAGE CHANGE IN SERUM CREATININE (SCR) IS A SENSITIVE INDICATOR OF THERAPEUTIC RESPONSE TO TERLIPRESSIN IN HEPATORENAL SYNDROME TYPE 1 (HRS-1)

T.D. Boyer[1], A.J. Sanyal[2], S.C. Pappas[3], F. Wong[4], K. Jamil[5], on behalf of The REVERSE Study Investigators. [1]*University of Arizona, Tucson,* [2]*Virginia Commonwealth University, Richmond,* [3]*Orphan Therapeutics, Lebanon, United States;* [4]*University of Toronto, Toronto, Canada;* [5]*Ikaria, Hampton, United States*
E-mail: spappas1@comcast.net

Background and Aims: The definition of response in most studies of terlipressin for HRS-1 has been HRS reversal, defined as a decrease of SCr to below 1.5 mg/dL, and partial response, a decrease in SCr by ≥50% but still ≥1.5 mg/dL. Recently, criteria for acute kidney injury (AKI) have focused on change in SCr rather than an absolute value to define AKI. The REVERSE study, the largest placebo controlled trial of terlipressin plus albumin vs. albumin alone for the treatment of HRS-1 has provided the opportunity to further examine improvement in SCr as a marker of response to treatment.
Methods: Subjects with HRS-1 were randomized to terlipressin (1 mg IV every 6 hours) or placebo, plus albumin in both groups. Endpoints evaluated included confirmed HRS reversal (CHRSR – 2 SCr values ≤1.5 mg/dL 48 hrs apart), HRS reversal, the percent change in SCr from baseline to the last day of dosing by 20% increments or decrements, overall survival, and survival at Day 90 without renal replacement therapy (RRT).



20% improvement is improvement from baseline to the last SCr on the date of last dose.
The p-value comparing the survival estimates is from a two-sample log-rank test stratified by qualifying Serum Creatinine and alcoholic hepatitis. P-Value= < 0.0001

Results: Linear regression analysis showed that survival is highly correlated with percent change in SCr (r2 = 0.9568; p < 0.0001). All subjects with CHRSR or HRS reversal had a >20% decrease in SCr from baseline; however, 38/70 (45.7%) subjects with >20% decrease in SCr did not achieve HRS reversal. The survival of subjects with >20% improvement in SCr was significantly higher than subjects with ≤20% improvement in SCr (p < 0.0001) (Figure). In addition, the survival of subjects with >20% improvement in SCr without CHRSR was similar to that seen when subjects with CHRSR were included and was significantly higher compared to subjects with ≤20% improvement (p < 0.0001). The number of subjects with >20% improvement in SCr with terlipressin (42/97, 43.3%) was significantly greater compared to placebo (28/99, 28.3%) (p < 0.05). In subjects with >20% improvement in SCr, 31/34 (91%) in the

terlipressin group were alive without RRT at Day 90 vs. 15/22 (68%) in the placebo group ($p < 0.05$).
Conclusions: These data show that a survival benefit occurs in subjects with HRS-1 with a >20% improvement in SCr from baseline even in the absence of HRS reversal. More subjects treated with terlipressin and albumin have a >20% decrease in SCr and have a better outcome at Day 90 compared to subjects treated with albumin alone. A percentage change in SCr from baseline may provide a more inclusive and sensitive indicator of response to terlipressin in HRS-1.

P0199
ACUTE KIDNEY INJURY IN CIRRHOSIS: BASELINE SERUM CREATININE PREDICTS PATIENT OUTCOMES

E-mail: florence.wong@utoronto.ca

Background and Aims: Various definitions of acute kidney injury (AKI) using different changes in renal function from baseline have recently been applied to determine prognosis in patients with cirrhosis. Reported patient outcome varies according to AKI definition. The International Ascites Club (IAC) has defined Stage 1 AKI in cirrhosis as an increase in serum creatinine (SCr) by ≥0.3 mg/dL in ≤48 hours, or ≥50% increase from a stable baseline SCr (B-SCr) in ≤3 months. It is unclear what influence B-SCr may have on post-AKI patient and renal outcomes.
Aim: To determine the association between B-SCr and the course of AKI and patient survival.
Methods: NACSELD (North American Consortium for the Study of End-Stage Liver Disease) is a consortium of tertiary-care hepatology centers that prospectively enrols non-elective cirrhotic inpatients. Patients with AKI as defined by IAC were included in the study. Course of AKI and 30-day survival were compared between patients with different levels of B-SCr (≤0.5 mg/dL, 0.51–1.0 mg/dL, 1.01–1.5 mg/dL, >1.5 mg/dL).
Results: 653 middle-aged (56.7±10 yrs old, 64% men) cirrhotic inpatients with mostly alcohol (26%) and hepatitis C (23%) induced cirrhosis were included. 30% were admitted with an infection, with equal frequency amongst groups ($p = 0.8$). Patients with the highest B-SCr more often had concomitant diabetes. 303 patients developed AKI, significantly more so in patients with B-SCr of >1.5 mg/dL, who also had a significantly greater increase in SCr ($p < 0.001$). AKI outcomes were defined as progressive (SCr worsened and ended in dialysis), persistent (SCr remained high) or transient (SCr returned to baseline). Significantly more patients developed progressive AKI, associated with a significantly decreased 30-day survival, as the B-SCr increases. Patients whose B-SCr was ≤1.0 mg/dl mostly had transient AKI with excellent 30-day survival (95%). Multivariate logistic regression shows that both B-SCr and ΔSCr during AKI are the only 2 significant factors impacting 30-day survival ($p < 0.001$).
Conclusions: Cirrhotic patients with pre-existing renal dysfunction, as indicated by a high B-SCr, are at higher risk for developing AKI, irrespective of admission indication. This risk increases with increasing B-SCr, and is strongly associated with an increased likelihood of AKI progression and death. Therefore, patients with high B-SCr may be considered a high-risk group for worst outcome.

Variable	B-SCr ≤0.50 mg/dL (n = 18)	B-SCr 0.51–1.00 mg/dL (n = 283)	B-SCr 1.01–1.50 mg/dL (n = 209)	B-SCr >1.50 mg/dL (n = 143)	p-value
B-SCr (SD)	0.45 (0.04)	0.77 (0.13)	1.18 (0.15)	2.46 (1.21)	<0.0001
Peak SCr (SD)	0.67 (0.12)	1.19 (0.75)	1.85 (1.05)	3.60 (1.82)	<0.0001
Diabetes	41%	27%	41%	48%	<0.0001
AKI (n = 303)	12%	26%	54%	69%	<0.0001

EARLY TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT IN CIRRHOTIC PATIENTS WITH ACUTE VARICEAL BLEEDING: A META-ANALYSIS OF CONTROLLED TRIALS

P. Deltenre[1], E. Trépo[2], M. Rudler[3], A. Monescillo[4], M. Fraga[1], A. Denys[1], C. Doerig[1], N. Fournier[5], C. Moreno[2], D. Moradpour[1], C. Bureau[6], D. Thabut[3]. *[1]CHUV, Lausanne, Switzerland; [2]Hôpital Erasme, Brussels, Belgium; [3]Hôpital Pitié-Salpêtrière, Paris, France; [4]Hospital Universitario Insular de Gran Canaria, Gran Canaria, Spain; [5]Université de Lausanne, Lausanne, Switzerland; [6]CHU Toulouse, Toulouse, France*
E-mail: pierre.deltenre@chuv.ch

Background and Aims: There is conflicting evidence regarding the benefit of early transjugular intrahepatic portosystemic shunt (TIPSS) on survival of cirrhotic patients with acute variceal bleeding (AVB). Aim: To assess the effect of early TIPSS on patient prognosis.
Methods: We performed a meta-analysis of controlled trials evaluating TIPSS performed within 72 hours of the initial endoscopy in cirrhotic patients with AVB treated with the standard-of-care.
Results: Four studies including 252 patients were included. Early TIPSS was associated with fewer deaths (OR = 0.38, 95% CI=0.17–0.83, $p = 0.02$). There was a moderate heterogeneity between studies ($p = 0.15$, I^2=44%). After exclusion of a study in which patients allocated to TIPSS were compared to historical control and which included patients with very severe liver disease, there was a significant effect of early TIPSS on mortality (OR = 0.26, 95% CI=0.13–0.51, $p < 0.001$) with no significant heterogeneity ($p = 0.9$, I^2=0%). Among Child–Pugh B patients, early TIPSS was not significantly associated with fewer deaths (OR = 0.35, 95% CI=0.10–1.17, $p = 0.087$). There was no heterogeneity between studies ($p = 0.6$, I^2=0%). Among Child–Pugh C patients, early TIPSS was not significantly associated with fewer deaths (OR = 0.34, 95% CI=0.10–1.11, $p = 0.074$). There was a high heterogeneity between studies ($p = 0.06$, I^2=60%). After exclusion of a study in which patients allocated to TIPSS were compared to historical control, there was a significant effect of early TIPSS on mortality (OR = 0.21, 95% CI=0.07–0.66, $p = 0.007$) with less heterogeneity ($p = 0.22$, I^2=33%). Early TIPSS was also associated with better 6-week (OR = 3.03, 95% CI=1.41–6.49, $p = 0.004$) and 1-year (OR = 2.42, 95% CI=1.03–5.67, $p = 0.04$) survivals. Less patients treated with early TIPSS reached the composite endpoint defined as failure to control bleeding or failure to prevent clinically significant bleeding within one year (OR = 0.08, 95% CI=0.04–0.17, $p < 0.001$), with no heterogeneity between studies ($p = 0.7$, I^2=0%). Results were similar among Child–Pugh B (OR = 0.15, 95% CI=0.05–0.47, $p = 0.001$) and Child–Pugh C patients (OR = 0.05, 95% CI=0.02–0.15, $p < 0.001$). Early TIPSS was not associated with higher rates of encephalopathy (OR = 0.84, 95% CI=0.50–1.42, $p = 0.5$).
Conclusions: Cirrhotic patients with AVB treated with early TIPSS had lower death rates and improved 6-week and 1-year survivals as compared to patients treated without early TIPSS. Child–Pugh C patients with AVB may also benefit from early TIPSS.

P0201

OUTCOMES AND PREDICTORS OF SURVIVAL IN PATIENTS WITH ACUTE-ON-CHRONIC LIVER FAILURE AND SUPERIMPOSED ACUTE KIDNEY INJURY REQUIRING DIALYSIS

S. Nayak[1], R. Sivaramakrishnan[1], R.P. Mathur[1], A. Kataria[1], S. Sarin[1].
[1]*Institute of liver and biliary sciences, New Delhi, India*
E-mail: sumanmassu2000@yahoo.co.in

Background and Aims: Acute-on chronic liver failure (ACLF), a heterogeneous clinical entity is defined as acute hepatic insult, manifesting as jaundice and coagulopathy, complicated within 4 weeks by ascites and/or encephalopathy in a patient with previously diagnosed or undiagnosed chronic liver disease. It is often complicated with acute kidney injury (AKI) due to the underlying hemodynamic alterations. Patients with ACLF, especially with a superimposed AKI have higher morbidity and mortality. Apart from conventional hemodialysis (HD) or continuous renal replacement therapies (CRRT), hybrid therapies like Sustained low efficiency dialysis (SLED) are often used in this setting. There is paucity of literature to help identify patients who will benefit more with RRT than others and patient outcomes and predictors of survival in this setting are not completely known.
Methods: We conducted a prospective observational study between May 2009 and September 2013 and followed 170 patients having an admission diagnosis of ACLF and had AKI at any time during the hospitalization. A diagnosis of ACLF was made as per the 2008 guidelines of Asian Pacific Association for the study of the liver (APASL) ACLF working group. Their clinical courses, requirement of RRT and laboratory parameters were noted. Conventional HD and SLED were the only RRT modalities available.
Results: Out of a total of 170 patients, 117 were provided RRT (conventional HD or SLED). The mean MELD and SOFA scores were 42.3 and 12.8 respectively. SLED using a femoral venous catheter was the commonest modality used. 53% of all patients had intra-dialytic complication, most common being hypotension. The mean survival after the initiation of RRT was 11.6±2.02 days. A multivariate analysis (Table 2) showed that higher CTP score (mean 12.5 versus 10.5, $p < 0.001$), higher SOFA score (mean 7.1 versus 14.1, $p < 0.001$), higher mean MELD score and a lower serum creatinine level were independent predictors of mortality.

Table: Multivariate analysis of clinical and laboratory features of survivors and non-survivors

	ACLF survived on RRT	ACLF died on RRT	P value
Acute onset ascites	33.3%	94.4%	**<0.001**
Hepatic encephalopathy	66.6%	96.6%	**<0.001**
MELD score	40	43	**0.02**
CTP score	10.5	12	**<0.001**
Total bilirubin	21	33.5	**<0.001**
INR	2.2	3.04	**0.003**
Serum albumin	2.3	2.4	0.5
Mean blood urea	120.8	175.1	**<0.001**
Mean serum creatinine	4.3	3.5	**0.01**
Mean SOFA score	7.8	14.1	**<0.001**
Inotrope requirement			**<0.001**
1. Low dose	25%	0	
2. Moderate dose	62.5%	2.2%	
3. High dose	0	37.7%	
4. Double/triple inotrope	0.4%	0.4%	
Complication on RRT			
1. Hypotension	0	43.7%	**<0.001**
2. Cardiac arrhythmia	4.1%	18.8%	

Conclusions: ACLF patients with AKI requiring RRT (HD and SLED) have a very high mortality. Higher CTP, SOFA, MELD scores along with lower serum creatinine levels (probably signifying sarcopenia and lower creatinine generation) are independently associated with a higher mortality. Large prospective trials are necessary to select appropriate patients who would benefit most with RRT in addition to defining appropriate mode, timing and dose of RRT.

PLACEMENT OF A PERMANENT, TUNNELLED PERITONEAL DRAINAGE CATHETER (PLEURX) FOR REFRACTORY MALIGNANT AND PORTAL-HYPERTENSIVE ASCITES IN A MULTICENTRE STUDY

G.-M. Semadeni[1], C. Gubler[2], A. Nagy[3], C. Manser[2], J. Borovicka[1], D. Semela[1]. [1]*Division of Gastroenterology and Hepatology, Kantonsspital St. Gallen, St. Gallen,* [2]*Division of Gastroenterology and Hepatology, University Hospital, Zurich,* [3]*Division of Gastroenterology and Hepatology, Kantonsspital Luzern, Luzern, Switzerland*
E-mail: david.semela@unibas.ch

Background and Aims: Repeated large-volume paracentesis is the best-established treatment option in malignant ascites and in treatment refractory portal-hypertensive ascites with contraindications to TIPS. However, rapid reaccumulation of ascites requires frequent hospital visits and punctures in this frail patient population. A one-time implantation of a permanent tunnelled catheter is frequently used for treatment of malignant pleural effusions. Our aim was to study feasibility and safety of this easy to use home drainage system in patients with refractory ascites.
Methods: Retrospective analysis from three Swiss tertiary centers after subcutaneous implantation of a 15.5 French peritoneal catheter (PleurX®, CareFusion) under conscious sedation (propofol) and antibiotic prophylaxis (ceftriaxone i.v. 30 min before procedure) by trained gastroenterologists in patients with refractory ascites and contraindication to TIPS. Patients received instructions on handling of drainage bottles to perform home based paracentesis through the PleurX catheter as needed.
Results: Between 03/2013 and 11/2014, 32 PleurX® catheters were implanted in 32 patients [age 29–77, mean age 55, 15/32 (47%) women]. Indications were malignant ascites (23 patients), portal-hypertensive ascites with (3 patients) and without (6 patients) advanced HCC. Success rate for catheter implantation was 97% (31/32) with 1 failure due to peritoneal cancer infiltration. PleurX® insertion lead to immediate symptom relief without the need of additional catheter intervention or separate therapeutic paracentesis after catheter placement. No procedure-related deaths or major placement complications occurred. No serious adverse events were reported. Three cases of bacterial peritonitis (2 in HCC patients, 1 in malignant ascites without portal hypertension) were successfully treated with antibiotics. Twenty-one patients died during follow up due to disease progression (3–227 days after intervention, mean 38 days). Catheter survival ranged from 3 to 291 days (mean 64 days, 1,977 cumulative catheter-days). Four catheters were removed 17–143 days after implantation due to liver transplantation (n = 1), resolution of ascites (n = 2) and local infection (n = 1).
Conclusions: Placement of a permanent, tunnelled peritoneal drainage catheter is an easy to perform and safe alternative to repeated paracentesis in selected patients with refractory ascites.

P0203

SOLUTE-FREE WATER RETENTION IN EXPERIMENTAL ASCITIC CIRRHOSIS: VASOPRESSIN (ADH) IS NOT THE ONLY AGENT TO BLAME

G. Sansoe[1], M. Aragno[2], R. Mastrocola[2], M. Parola[2]. [1]*Division of Gastroenterology, Gradenigo Hospital,* [2]*Dpt. of Clinical and Biological Sciences, University of Torino, Torino, Italy*
E-mail: giovannisan@iol.it

Background and Aims: Increased adrenergic function causes proximal tubular fluid retention and reduces renal excretion of solute-free water, but, in advanced cirrhosis, non-osmotic hypersecretion of vasopressin (ADH) is considered the cause of water retention and hyponatremia. Aim. Since ADH V2 receptor

antagonists are not beneficial in long-term treatment of ascites, we hypothesize that water retention in experimental ascitic cirrhosis depend also on adrenergic hyperfunction.
Methods: Hormonal status, renal function and tubular free-water reabsorption (TFWR) were assessed in 6 groups of rats with ascitic cirrhosis: rats with cirrhosis due to 13-week CCl_4 administration (group G1); cirrhotic rats receiving daily diuretics (0.5 mg/kg furosemide plus 2 mg/kg K+-canrenoate) during 11th-13th weeks of CCl_4 (G2); cirrhotic rats treated daily with diuretics associated with guanfacine oral prodrug (α2A adrenergic receptor agonist and sympatholytic agent) 2 (G3), 7 (G4), or 10 mg/kg (G5), or SSP-004240F1 (V2 receptor antagonist) 1 mg/kg (G6) during 11th-13th weeks of CCl_4.
Results: Sodium excretion was lower in G1 than G2–G4 and G6 (all $P < 0.05$). TFWR was higher in G1 (untreated cirrhosis, 32±11 microL/min) than in G6 (diuretics + V2-antagonists, 21±9 microL/min) or G3 (diuretics + guanfacine 2 mg/kg, 20±8 microL/min) (all $P < 0.03$). Guanfacine, added in G3 to sole diuretics (G2), reduced serum norepinephrine from 423±122 to 211±111 ng/L ($P < 0.01$), plasma renin activity from 25±12 to 9±7 ng/mL/h ($P < 0.03$), and TFWR from 45±18 to 20±8 microL/min ($P < 0.01$). Among all rats, TFWR did not correlate with ADH levels ($r = 0.02$, P: n.s.), but did with plasma aldosterone ($r = 0.51$, $P < 0.01$) and urinary potassium excretion ($r = 0.90$, $P < 0.001$).
Conclusions: In ascitic cirrhosis, reduced volaemia, adrenergic hypertone, and secondary aldosteronism, especially when exacerbated by loop diuretics, cause tubular retention of water. Sympatholytic agents are as effective as V_2-antagonists to blunt tubular free water retention.

P0204
NONINVASIVE PREDICTION OF HEMODYNAMIC RESPONSE TO BETA-BLOCKER THERAPY IN CIRRHOTIC PATIENTS WITH ESOPHAGEAL VARICES

H.Y. Kim[1], W. Kim[1], Y.J. Jung[1], S.K. Joo[1], Y.H. So[2], H. Woo[2].
[1]Department of Internal Medicine, [2]Department of Radiology, Seoul National University Boramae Medical Center, Seoul, Korea, South
E-mail: ivtec@naver.com

Background and Aims: Nonselective beta-blocker (NSBB) is a mainstay of both primary and secondary prophylaxis of esophageal variceal bleeding in cirrhotic patients. Although hepatic venous pressure gradient (HVPG) is an essential method to evaluate hemodynamic response to NSBB, measuring HVPG is invasive and requires special facility and expertise. The aim was to investigate whether noninvasive markers of portal hypertension correlate with hemodynamic response to NSBB in cirrhotic patients with esophageal varices.
Methods: In this prospective study, 160 cirrhotic patients with esophageal varices who were indicated for primary or secondary prophylaxis of hemorrhage were enrolled between May 2013 and July 2014. As of October 2014, 76 patients completed paired measurements of HVPG, liver stiffness (LS) and spleen stiffness (SS) both at the beginning and at the end of dose titration (maximal tolerated dose) of carvedilol therapy. LS and SS were measured using acoustic radiation force impulse imaging.
Results: Mean age was 59 years, and male patients were 55 (72.4%). Main etiologies of cirrhosis were viral [HBV, 25 (32.9%); HCV, 9 (11.8%)] and alcoholic [32 (42.1%)]. Primary and secondary prophylaxes were done in 41 (53.9%) and 35 (46.1%), respectively. Size of varices were F2 or 3 in 57 (75%) and red color sign was shown in 36 (47.4%). Child–Pugh class was mostly A (38, 50%) or B (27, 35.5%). Baseline HVPG was 19 mmHg (12–39). Baseline median LS and SS were 2.45 m/s and 3.13 m/s, respectively. Hemodynamic response (decrease in HVPG ≥20% from baseline or to absolute value <12 mmHg) was achieved in 42 (55.3%) on a median 25 mg of carvedilol. Responders showed 7.2 mmHg mean decline of HVPG from their baseline level. Both LS values at baseline (LS1, 2.29 vs. 2.63 m/s; $P = 0.037$) and at the end of dose titration (LS2, 2.13 vs. 2.58 m/s; $P < 0.001$) were significantly lower in responders than in nonresponders. SS values did not show differences between responders and nonresponders. Areas under the receiver operating curves for predicting hemodynamic response were 0.665 for LS1 and 0.737 for LS2, respectively.
Conclusions: Liver stiffness at baseline and at the end of dose titration may be predictive of hemodynamic response to carvedilol therapy as primary or secondary prophylaxis for hemorrhage in cirrhotic patients with esophageal varices.

MANAGEMENT OF GASTRIC VARICES: A FRENCH NATIONAL SURVEY

D. Weil[1], J.P. Cervoni[1], N. Fares[2], M. Rudler[3], C. Bureau[2], A. Plessier[4], T. Dao[5], A. Pauwels[6], D. Thabut[3], P. Castellani[7], F. Oberti[8], N. Carbonell[9], V. Di Martino[1], T. Thévenot[1], Club Francophone pour l'Etude de l'Hypertension Portale. *[1]Service d'hépatologie, CHU Jean Minjoz, Besançon, [2]Service d'hépatogastroentérologie, CHU Purpan, Toulouse, [3]Service d'hépatogastroentérologie, CHU Pitié Salpêtrière, Paris, [4]Service d'hépatogastroentérologie, CHU Beaujon, Clichy, [5]Service d'hépatogastroentérologie, CHU de Caen, Caen, [6]Service d'hépatogastroentérologie, Hôpital de Gonesse, Gonesse, [7]Service d'hépatogastroentérologie, Hôpital Saint Joseph, Marseille, [8]Service D'hépatogastroentérologie, CHU Angers, Angers, [9]Service d'hépatogastroentérologie, CHU Saint Antoine, Paris, France*
E-mail: jpcervoni@chu-besancon.fr

Background and Aims: Gastric variceal bleeding accounts for 10% of upper gastrointestinal bleeding related to portal hypertension. Level of evidence in managing gastric varices is low. We aimed to determine the modalities of management of non-GOV1 gastric varices in France.
Methods: Hepato-gastroenterologists (HGE) working in general hospitals (GH) or in university hospitals (UH) received a self-administered questionnaire.
Results: One hundred and fifty-four HGE from 109 centers (37 UH, 72 GH) among the 336 (32.4%) contacted responded. Regarding primary prophylaxis, beta-blockers were used by 96% of HGE. Only 17.2% of HGE used glue obliteration (UH: 27.7% *vs* GH: 9.3%; $p = 0.004$), 8% used TIPS and 5.3% proposed no treatment. Most HGE (77.6%) estimated that they had local access to glue obliteration but 64.2% declared that TIPS placement required transfer to another center. Obliteration was performed under general anesthesia by 86% of HGE. N-butyl-2-cyanoacrylate plus methacryloxysulfolane (Glubran®) and N-butyl-2-cyanoacrylate (Histoacryl®) were used respectively in 48.2% and 55.9% of cases (3.5% of HGE used both). Dilution with lipiodol was performed in 78% of cases. The technique of obliteration was variable between centers and within the same center: maximal dilution was 1/10; injected volume varied from 0.5 to 20 mL per varix and from 1 to 30 mL per procedure. To control active bleeding, 77.6% of HGE used obliteration (UH: 85.7% vs GH: 70.9%, $p = 0.04$) and 34% used band ligation (UH: 28.6% vs GH: 38.8%; $p = 0.02$). Early-TIPS was proposed by 56.3% of HGE (UH: 71.7% vs GH: 39.2%, $p < 0.001$). Regarding secondary prophylaxis, 74.4% used beta-blockers, 66% used obliteration (UH: 76.6% vs GH: 56.6%; $p = 0.014$) and 14% used TIPS. Endoscopic control was performed by 62.6% of HGE, 70% evaluated the varix stiffness with a closed biopsy forceps. Side effects of obliteration were reported by 59.5% of HGE (UH: 70.4% vs GH: 41.2%; $p = 0.08$) and concerned mainly glue migration (UH: 66.7% vs GH: 33.3%; $p < 0.001$), an event systematically searched by 22.9%.
Conclusions: The management of gastric varices in France is very heterogeneous between centers and even within the same center. University hospitals have a better access to obliteration and especially to TIPS. Obliteration as a primary prophylaxis procedure was rarely performed. Glue migration was frequently

observed although probably underreported. Specific guidelines on the management of gastric varices should be established by expert groups to standardize clinical practices.

P0206

PREVENTION OF BLEEDING FOLLOWING INVASIVE PROCEDURES IN CIRRHOTIC PATIENTS: A SINGLE CENTER EXPERIENCE

F. Invernizzi[1], G. Tosetti[1], V. La Mura[2], A. Aghemo[1], M. Primignani[1], A. Sanvgiovanni[1], M.F. Donato[1], A. Nicolini[3], M. Iavarone[1], M. Colombo[1]. [1]*Division of Gastroenterology and Hepatology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano,* [2]*Università degli Studi di Milano,* [3]*Division of Radiology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, Milan, Italy*
E-mail: massimo.colombo@unimi.it

Background and Aims: Risk of bleeding in cirrhosis has predominantly been associated with coagulopathy and thrombocytopenia due to impaired liver function and splenomegaly. The evaluation of the actual bleeding risk in cirrhotic patients undergoing invasive procedures is a critical point to optimize management in terms of platelet (Plt) or plasma prophylactic transfusions.
Methods: From January 2013 to December 2013, 480 cirrhotic patients underwent diagnostic or therapeutic invasive procedures at our Liver Unit (Fondazione IRCCS Ca Granda, Ospedale Maggiore Policlinico, Milan, Italy). Per protocol, Plt transfusion was deemed necessary for Plt count less than 50,000/mmc while fresh frozen plasma was infused to patients with international normalized ratio (INR) >1.5, except those undergoing paracentesis. Low-molecular-weight-heparin was discontinued 24 hours before any procedure while antiaggregant therapy was interrupted five days before any procedure except oesophageal varices band ligation and paracentesis. Major hemorrhagic events were those requiring hospitalisation or blood transfusion; minor events was a haemoglobin decline >1.5 g/dl post procedure not requiring hospitalization and without bleeding evidence.
Results: 174 Transarterial Chemo Embolization (TACE), 16 Radio-Frequency Termal Alblation (RFTA), 214 paracentesis, 59 oesophageal varices banding, 6 trans-jugular liver biopsy (LB) and 11 Percutaneous Ethanol Injection (PEI), were performed. Overall, 61 procedures met the criteria for plasma or Plt infusion and major bleeding complications occurred in 3 patients (0.6%). In 2 patients, anemia-related paracentesis was treated by blood transfusions whereas one patient following variceal band ligation, had to be hospitalized for severe anemia. Major complications rate was 1.6% in Plt/plasma infusion exposed patients versus 0.47% in unexposed patients (p = 0.28). Minor events with a >1.5 g/dl haemoglobin decline occurred in 17 patients (15 paracentesis and 2 band ligations), the rate was 3.2% in Plt/plasma infusion exposed patients versus 3.5% in unexposed (p = 0.9).
Conclusions: Pre-treatment platelet transfusion in cirrhotic patients with Plt count less than 50,000/mmc and plasma infusion for those with INR >1.5, was associated with a negligible risk of bleeding and appeared as a safe, cost/effective strategy.

P0207

GUANFACINE (SPECIFIC ALPHA-2A ADRENOCEPTOR AGONIST) RESTORES NATRIURESIS IN EXPERIMENTAL CIRRHOTIC ASCITES RESISTANT TO CLONIDINE AND STANDARD DIURETICS

G. Sansoe[1], M. Aragno[2], R. Mastrocola[2], M. Parola[2]. [1]*Division of Gastroenterology, Gradenigo Hospital,* [2]*Dpt. of Clinical and Biological Sciences, University of Torino, Torino, Italy*
E-mail: giovannisan@iol.it

Background and Aims: In human cirrhosis, adrenergic hyperfunction causes proximal tubular fluid retention and contributes to refractory ascites; clonidine, a sympatholytic drug, plus diuretics improve natriuresis in otherwise refractory ascites.
Aim: To compare clonidine (aspecific α2-adrenoceptor agonist) and SSP-002021R (specific α2A-receptor agonist and prodrug of guanfacine), both associated with diuretics, in cirrhotic refractory ascites.
Methods: Seven groups of 12 rats were studied: controls (G1); controls receiving furosemide and potassium canrenoate (G2); rats with ascitic cirrhosis due to 14 CCl_4 weeks (G3); cirrhotic rats treated with furosemide and canrenoate over the 11th–14th CCl_4 weeks (G4); cirrhotic rats treated with furosemide, canrenoate and clonidine (0.5 mcg) (G5); cirrhotic rats treated with diuretics and low-dose clonidine (0.3 mcg) (G6); cirrhotic rats treated with diuretics and SSP002021R (5 mg/kg b.w.) (G7). Three rats in each group had their hormonal status and renal function assessed at the end of 11th, 12th, 13th, and 14th CCl_4 weeks.
Results: Cirrhotic rats in G3 and G4 gained weight over the 11th–14th CCl_4 weeks. In G4, brief increase in sodium excretion due to diuretics (12th week) preceded worsening of inulin clearance and natriuresis (diuretic resistance). The addition of low-dose clonidine (G6) or guanfacine (G7) to diuretics increased, respectively, electrolytes excretion over the 11th–12th CCl_4 weeks, or GFR and electrolytes excretion over the 13th–14th CCl_4 weeks. Natriuretic responses in G6 and G7 were accompanied by significantly reduced catecholamines' serum levels vs. G3 and G4 (all $P < 0.03$).
Conclusions: Clonidine briefly potentiates diuretics-dependent natriuresis. Guanfacine (α2A-receptor agonist) restore glomerular filtration rate and natriuresis, and prevent refractory ascites in experimental advanced cirrhosis.

P0208

HEMODYNAMIC RESPONSE TO NON-SELECTIVE BETA-BLOCKERS IS NOT INFLUENCED BY THE PRESENCE OF METABOLIC SYNDROME

S. Bota[1], P. Schwabl[1], M. Mandorfer[1], P. Salzl[1], R. Schwarzer[1], A. Ferlitsch[1], M. Trauner[1], M. Peck-Radosavljevic[1], T. Reiberger[1]. [1]*Vienna Hepatic Hemodynamic Laboratory, Div. of Gastroenterology & Hepatology, Dept. of Internal Medicine III, Medical University of Vienna, Vienna, Austria*
E-mail: bota_simona1982@yahoo.com

Background and Aims: Insulin resistance and the metabolic syndrome have been associated with the severity of portal hypertension (PHT) in patients with cirrhosis. Response to non-selective betablockers (NSBBs) is evaluated by sequential measurements of the hepatic venous pressure gradient (HVPG), and defined as complete response (CR: decrease of HVPG ≥20% or to absolute values <12 mmHg), partial response (PR: HVPG decrease 10–<20%), or nonresponse (NR: HVPG decrease <10%). We aimed to assess the relationship between metabolic syndrome (MS) and hemodynamic response rate to NSBBs in patients with cirrhosis.
Methods: We retrospectively included patients with paired HVPG measurements. MS was diagnosed by the International Diabetes Federation criteria in paients with obesity (body mass index – BMI >30 kg/m^2) presenting with at least two of the following critiria: (1) elevated triglycerides >150 mg/dL; (2) reduced HDL cholesterol <40 mg/dL in males or <50 mg/dL in females; (3) arterial hypertension: systolic BP >130 mmHg or diastolic BP >85 mmHg; (4) elevated fasting plasma glucose >100 mg/dL, or previously diagnosed type 2 diabetes. Patients with BMI >30 kg/m^2 due to grade II/III ascites were not considered as having MS and were excluded (n = 5).
Results: 278 patients with paired HVPG measurements were included (55.1% propranolol, 44.9% carvedilol). MS was diagnosed in 11.1% (31/278 patients), the proportion of patients treated with propranolol and carvedilol was similar in patients with MS (44.9% vs. 45.2%, p = 0.87) as well as the doses of NSBBs (p = 0.72

for propranolol, and p = 0.45 for carvedilol). Overall 46.8%, 16.5%, and 36.7% of patients had CR, PR, and NR, respectively. The baseline HVPG (mmHg) was similar in patients without and with MS: 20.1±4.6 vs. 18.8±4.3 (p = 0.16). The median HVPG reduction was similar in patients without and with MS: −15.7% (IQR: −3.73 to −27.7) vs. −17.3% (IQR: +6.07 to −25; p = 0.26). The distribution of NSBB response was comparable between patients without or with MS: CR: 46.9% vs. 45.2% (p = 0.99); PR: 17% vs. 12.9% (p = 0.74); and NR: 36.1% vs. 41.9% (p = 0.66).
Conclusions: The hemodynamic response rate to NSBBs in cirrhotic patients with PHT is not influenced by the presence of the metabolic syndrome.

P0209
A COMMON POLYMORPHISM OF TUMOR NECROSIS FACTOR RECEPTOR-ASSOCIATED FACTOR 6 (TRAF6) IS ASSOCIATED WITH AN INCREASED RISK FOR SPONTANEOUS BACTERIAL PERITONITIS

M. Mai[1], S. Stengel[2], E. Al-Herwi[2], P. Reuken[2], A. Stallmach[2], T. Bruns[2]. [1]*Center for Sepsis Control and Care,* [2]*Department of Internal Medicine IV, Jena University Hospital, Jena, Germany*
E-mail: martina.mai@med.uni-jena.de

Background and Aims: Spontaneous bacterial infection (SBP) is a frequent complication of decompensated cirrhosis with high mortality. Monocytes and peritoneal macrophages are cellular immune regulators exhibiting pattern-recognition-receptors (PRR) to detect bacterial infections. We hypothesized that genetic polymorphisms of tumor necrosis factor receptor-associated factor 6 (TRAF6) are associated with an increased risk of SBP by modulating monocytic immune responses in patients with decompensated cirrhosis.
Methods: TRAF6 haplotype-tagging single nucleotide polymorphisms (SNPs) rs331457 (G/A) and rs5030419 (C/G) were determined by Fluorescence Resonance Energy Transfer/ Melt Curve analysis in 404 prospectively characterized hospitalized patients with decompensated cirrhosis. Episodes of SBP were identified from electronic records. We investigated mRNA expression of regulated genes by qRT-PCR in immunomagnetically isolated monocytes and peritoneal macrophages.
Results: The minor allele frequency for rs331457 was 16.5% and for rs5030419 was 14.4%. 193 (48%) presented with the TRAF6 wild-type (GGCC), 113 (28%) patients were carriers of the rs5030419 mutation (AGCG/GGCG/GGGG) and 98 (24%) patients were carriers of a haplotype with the rs5030419 wild-type and the rs331457 mutation (AGCC/AACC). 117 (29%) patients presented with at least one episode of SBP. Patients carrying the AGCC/AACC genotype had an increased risk of SBP (OR 1.93; 95% CI 1.20–3.12; p = 0.007) compared to patients not carrying this variant. Peritoneal macrophages from genotypically identified patients at risk demonstrated a lower expression of the neutrophil recruiting chemokine CXCL8.
Conclusions: A common variant in TLR signaling is associated with an increased risk of SBP in patients with decompensated cirrhosis, which may be employed for genotype-based primary prophylaxis.

P0210
COMBINED PARTIAL SPLENIC EMBOLIZATION (PSE) ALLOWS REDUCING TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT (TIPS) DIAMETER IN HYPERSPLENIC CIRRHOTIC PATIENTS: A PILOT STUDY

D. Regnault[1], A. Geffray[2], C. Nicolas[1], L. D'Alteroche[1], J. Pucheux[2], M. Sainz Barriga[3], P. Bucur[3], E. Salame[3], J.-M. Perarnau[1].
[1]*Hepatology,* [2]*Radiology,* [3]*Digestive Surgery and liver transplantation, CHRU Tours, Chambray-lès-Tours, France*
E-mail: davidregnault@hotmail.fr

Background and Aims: Portal hypertension (PHT) results from increased hepatic resistance and splanchnic volume. TIPS reduces hepatic resistance but worsen the hemodynamic stress. Such effect can be detrimental for the effectiveness of TIPS on PHT and promotes cardiac complications. Hypersplenism affect 40% of TIPS patients. The combination of PSE and TIPS by reducing the splenic venous backflow should decrease splanchnic volume and pressure. Furthermore, it may allow the creation of smaller calibre TIPS thus reducing the risk of encephalopathy. Additional expected beneficial effects of PSE are reduction of thrombocytopenia and an improved hepatic arterial perfusion.
Aim of our study was to evaluate the efficacy on PHT and safety of a combined procedure of PSE and TIPS in hypersplenic and cirrhotic patients candidates for a TIPS.
Methods: 14 cirrhotic patients with hypersplenism (defined by a platelet count <100,000/mm^3) gave their consent for a combined technique. Indication for TIPS was prevention of variceal re-bleeding prevention (n = 5), refractory ascites (n = 5), both (n = 2) and before surgery (n = 2). 8 patients were CHILD B, 4 were CHILD C and 2 Child A. Combined PSE was applied to allow further invasive procedures such as liver or orthopaedic surgery. The technique consisted in a transjugular portal catheterization with measurement of hepatic venous pressure gradient (HVPG) before and after PSE and after TIPS. PSE was performed by a non-selective injection in the splenic artery hilum of 1.5 to 3 vials of 900–1200 μm Embospheres®. TIPS was then performed by using Viatorr® stents, calibrated to obtain a HVPG <12 mmHg.
Results: After PSE, HVPG fell from 15.6±4.5 mmHg to 11.5±4.2 mmHg. After TIPS, HVPG fell to 6.2±2.5 mmHg representing a 59% reduction. In 8/14 procedures, TIPS could be undersized at 6 mm (57%). No complication occurred due to PSE.
Thirteen patients (93%) had no complication after a mean 4-months follow-up (±4).
Platelets count increased from 59±22 g/L to 248±113 one month after procedure.
One patient died from hepatic encephalopathy five months later.
Conclusions: This combined therapy, effective on the two components of PHT, has been shown as effective and safe in our pilot study, allowing the realization of smaller calibre TIPS. A randomized controlled study is needed to evaluate the other possible benefits of this approach on encephalopathy, liver function and cardiac complications of splanchnic hemodynamic stress in TIPS patients with hypersplenism.

P0211
HUMAN MICROFIBRIL-ASSOCIATED PROTEIN 4 (MFAP4) IN ASCITES FLUID PREDICTS SURVIVAL AND RISK OF COMPLICATIONS IN PATIENTS WITH ADVANCED CIRRHOSIS

M. Kjaergaard[1], B.S. Madsen[1], M. Thiele[1], A. Malchow-Møller[2], A. Schlosser[3], G.L. Sørensen[3], U. Holmskov[3], A. Krag[1]. [1]*Department of gastroenterology and hepatology, Odense University Hospital, Odense C,* [2]*Department of Medicine, Svendborg sygehus, Svendborg,* [3]*Department of Cardiovascular and Renal Research, University of Southern Denmark, Odense C, Denmark*
E-mail: maria.kjaergaard@rsyd.dk

Background and Aims: Patients with cirrhosis and ascites are at high risk of death and development of complications to cirrhosis. Biomarkers to make a better risk stratification of these patients are warranted. We therefore investigated two biomarkers in ascites: (1) Human microfibril-associated protein 4 (MFAP4), an extracellular matrix (ECM) associated protein related to ECM turnover, and (2) Surfactant protein D (SP-D) which has a protective role in the innate immune system.
Methods: From 2011 to 2013 we prospectively enrolled 54 patients that were followed for 12 months or until death. The outcome evaluated where death, hepatorenal syndrome, hepatic encephalopathy, spontaneous bacterial peritonitis (SBP), non-SBP infections and readmissions. Eligible patients were patients with

verified cirrhosis, who had undergone therapeutic or diagnostic paracentesis. Patients who had been treated with antibiotics within the prior week and patients with malignant ascites were excluded. MFAP4 and SP-D where measured by ELISA technique.

Results: Characteristics of the enrolled patients were: Age 60.5±10.2 years, males/females 37/17, Child–Pugh-score (CP-score) 10.5±1.8 (CP A/B/C = 0/15/39), MELD-score 11.9±2.2. Four patients had SBP at inclusion. MFAP4 and SP-D in ascites were 20.6±10.3 U/ml (range 6.5–55.9) and 310.8±222.8 ng/ml (range 22–1212), respectively. In this cohort neither CP- nor MELD-score were predictors of death or risk of complications. However, in patients with low MFAP4 (≤15 U/ml), 8/16 patients died compared to 10/37 in the group with MFAP4 >15 U/ml (incidence-rate comparison P = 0.079). Among patients with low MFAP4, 13/16 versus 18/37 patients with MFAP4 >15 U/ml developed complications to cirrhosis (incidence-rate comparison P < 0.001), Figure 1. In a Cox proportional hazard model including CP- and MELD-score, age, gender, SP-D and MFAP4, low-MFAP4 (hazard ratio 4.72, CI 1.82–12.26, P = 0.001) and gender (HR 0.18, CI 0.05–0.65, P = 0.009) were the only predictors of complications. Of the four patients with SBP at inclusion, three had low MFAP4 and two died. SP-D was not able to predict survival, nor was it associated with risk of complications.

Conclusions: Low MFAP4 in ascites predicts individual 1-year survival and risk of complications in patients with advanced cirrhosis and ascites better than standard scoring systems as CP- and MELD-score. Further investigations are warranted to confirm the prognostic accuracy of MFAP4.

IDENTIFYING THE TRIGGER MATTERS – OUTCOME OF SEVERE ACUTE KIDNEY INJURY IN PATIENTS WITH CIRRHOSIS AND ASCITES

T. Bucsics[1], M. Mandorfer[1], P. Schwabl[1], S. Bota[1], M. Trauner[1], W. Sieghart[1], A. Ferlitsch[1], M. Peck-Radosavljevic[1], T. Reiberger[1], Vienna Hepatic Hemodynamic Laboratory. [1]*Internal Medicine III, Medical University of Vienna, Vienna, Austria*
E-mail: theresa.bucsics@meduniwien.ac.at

Background and Aims: Renal failure (RF) is a common cause of death in patients with cirrhosis and ascites. Acute kidney injury (AKI) can be triggered by complications that are highly prevalent in these patients, whereas diagnosis of hepatorenal syndrome (HRS), a special form of AKI, requires the exclusion of certain triggers. We aimed to investigate the impact of several triggers of severe AKI (grades 2+3) on transplant-free survival (TFS) and if TFS changes depending on whether the criteria for HRS were met or not.

Methods: Patients with cirrhosis and portal-hypertensive ascites who underwent paracentesis at the Medical University of Vienna were included in this retrospective study and their first episode of AKI or HRS was documented. Severe AKI was defined as an increase in serum creatinine (SCr) either of ≥100%, or ≥0.5 mg/dL to ≥4 mg/dL SCr within 48 h, or anuria, or renal replacement therapy. HRS was diagnosed either by an increase of ≥100% to ≥2.5 mg/dL SCr within 14 days or an increase from 1.5 mg/dL SCr in the absence of renal parenchymal lesions, proteinuria ≥500 mg/L, hematuria ≥50/HPF, nephrotoxic drug intake, severe hypovolemia/shock, significant cardiovascular disease, or severe trauma. AKI was further stratified by trigger. Survival was assessed using the Kaplan–Meier-Method and group comparisons performed using the log-rank test.

Results: 497 patients were included. A total of 148 episodes of severe AKI and 60 cases of HRS were detected. Median TFS of the AKI group was comparable to the HRS group: 19 (IQR 3–386) days vs. 17 (3–223) days, respectively (p = 0.656). There were no significant differences between these groups regarding patient characteristics. However, TFS varied depending on the trigger: Median TFS was only 7 (6–109) days in severe AKI triggered by nephrotoxins/surgery (n = 10) and 14 (3–312) days after severe hypovolemia/shock (n = 79). With 139 days (10-end of FU), median TFS was longest when occurring on top of chronic kidney disease and/or cardiovascular disease (n = 12). Median TFS of untriggered RF (n = 18) was 42 (9–1455) days.

Conclusions: Outcome of severe AKI and HRS was similar in our patient cohort with cirrhosis and ascites, questioning the utility in making a distinction based on the above definitions. Yet TFS varied depending on the trigger, suggesting a classification on the distinct mechanism/trigger could be clinically relevant. Prospective studies are warranted to confirm these data and investigate the efficacy of therapeutic interventions for AKI depending on the underlying trigger.

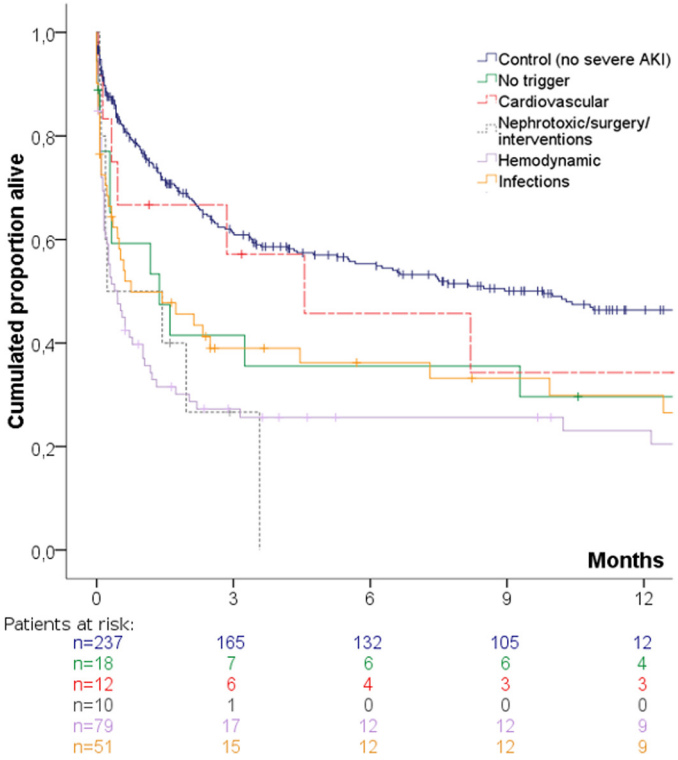

Figure: Transplant free survival of patients with cirrhosis and severe AKI according to trigger.

DIABETES IS A MAJOR DETERMINANT FOR REFRACTORY ASCITES IN PATIENTS WITH CIRHOSIS AND IS ASSOCIATED WITH HEPATIC MICROCIRCULATORY CHANGES

L. Elkrief[1], S. Buyse[1,2], X. Panhard[1], C. Baudry[2], R. Moreau[1], P.-E. Rautou[1], J. Belghiti[3], F. Durand[1], P. Bedossa[2], D. Valla[1], V. Paradis[2]. *[1]Service d'Hépatologie, Hôpital Beaujon – AP-HP, Université Paris Diderot, and INSERM U1149, Centre de Recherche sur l'Inflammation, [2]Service d'Anatomie et cytologie pathologiques, Hôpital Beaujon – AP-HP, Université Paris Diderot, and INSERM U1149, Centre de Recherche sur l'Inflammation, [3]Service de Chirurgie digestive Hôpital Beaujon – AP-HP, Université Paris Diderot, and INSERM U1149, Centre de Recherche sur l'Inflammation, Clichy, France*
E-mail: laure_elkrief@yahoo.fr

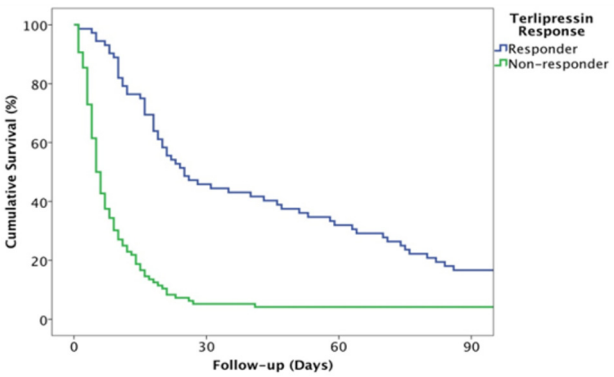
Background and Aims: The causal factors for refractory ascites are poorly understood. Diabetes is associated with the development of ascites. The aims of this study were (1) to clarify the association of diabetes with refractory ascites in patients with cirrhosis; and (2) to provide insight into the mechanisms of refractory ascites by performing a comprehensive analysis of liver microscopic hepatic lesions associated with refractory ascites.
Methods: Consecutive patients with cirrhosis who underwent liver transplantation were retrospectively included. Univariate and binary multivariate logistic regression analysis of patients' characteristics at the time of listing were performed according to the presence or absence of refractory ascites. A comprehensive histological analysis of explanted native livers of the included patients was performed to determine lesions associated with refractory ascites.
Results: Eighty-five patients were included (78% men, mean age 51 years), including 30 with refractory ascites and 55 without (34 patients without ascites and 21 patients with diuretic-sensitive ascites). MELD score was higher (25±6.1 *vs.* 19.9±6.0, $p = 0.001$), and serum sodium was lower (133.0±6.7 *vs.* 138±3.3 mmol/L, $p < 0.001$) in patients with refractory ascites than in those without. Alcohol was more frequently a cause of liver disease (80% vs. 42%, $p = 0.001$) in patients with refractory ascites. Diabetes was more frequently observed (57% *vs.* 27%, $p = 0.008$) and hemoglobin A1c levels were higher in patients with refractory ascites than in those without (6.5±2.7% vs. 4.5±1.1%, $p = 0.006$). By multivariate analysis, refractory ascites was independently associated with a higher MELD score ($p = 0.005$), a lower serum sodium ($p = 0.005$), alcohol as a cause of cirrhosis (0.048), and diabetes mellitus ($p = 0.002$). Neither the amount of fibrosis, nor features of non-alcoholic fatty liver disease (macrovesicular steatosis, hepatocyte ballooning and Mallory bodies) differed in the two groups. By contrast, microvascular changes, namely sinusoidal dilatation ($p < 0.001$) and perisinusoidal fibrosis ($p = 0.001$), were more frequently observed in the livers of patients with refractory ascites.
Conclusions: Diabetes is associated with refractory ascites, independently of MELD score. Microscopic vascular lesions of diabetic microangiopathy are observed in the liver of patients with refractory ascites. This suggests a specific role of diabetes in the development of refractory ascites.

P0214

PREDICTORS OF RESPONSE AND OUTCOME TO TERLIPRESSIN IN PATIENTS WITH HEPATORENAL SYNDROME

S. Vinit[1], A. Kumar[1], P. Sharma[1], R.K. Bansal[1], P. Tyagi[1], N. Bansal[1], V. Singla[1], M. Kumar[1], P. Ranjan[1], M.K. Sachdeva[1], A. Arora[1]. *[1]Gastroenterology and Hepatology, Sir Ganga Ram Hospital, New Delhi, India*
E-mail: drvinitshah@gmail.com

Background and Aims: Renal failure is the most powerful predictor of death in decompensated cirrhosis. We conducted this prospective, observational, cohort study to determine the factors influencing hepatorenal syndrome (HRS) development, survival and determine predictors of response and outcome in terlipressin responders.
Methods: Cirrhotic patients were diagnosed with AKI as per (IAC/ADQI – International Ascites Club/Acute Dialysis Quality Initiative) definition and evaluated as per the study protocol after taking written informed consent and applying inclusion exclusion criteria. The patients who received terlipressin were analysed for predictors of terlipressin response. Those patients with diagnosis of HRS were analysed for the factors influencing its development and survival.
Results: 395 consecutive cirrhotic patients with renal impairment defined as per protocol definitions were included. Out of these AKI patients HRS was seen in 85 patients (21.5%). Terlipressin was given to 162 patients, 72 (44%) patients responded to terlipressin as per the study definition. 90 (56%) patients were terlipressin non responders. HRS had the worst survival outcome, around 20% at 30 days and less than 10% at 90 days. Significantly worst survival was seen in terlipressin non responders at around 10% and less than 10% at 30 days and 90 days respectively as compared to terlipressin responders with 30 day survival around 50% and 90 day survival at around 20% respectively. Higher MELD score, low Serum albumin, presence of SBP and presence of hypotension with inotrope requirement were more significantly associated with HRS/ATN development whereas HRS mortality did not get affected with infection related parameters Longer duration of hospitalization, higher CTP and MELD score, male gender, presence of HE and hypotension with inotropic support requirement correlated significantly with response to terlipressin on univariate analysis. Presence of hypotension requiring inotropic support was the only factor on multivariate analysis to correlate with terlipressin non response.
Conclusions: Development of HRS is associated with significantly reduced survival than other types of AKI in cirrhotics with especially dismal survival in terlipressin non responders. The terlipressin response rate in our cohort was 44%. Development of hypotension with inotropic requirement was the single most important predictor of terlipressin non response.



P0215

METFORMIN REDUCES HYPERAMMONEMIA IN PORTACAVAL SHUNTED RATS INHIBITING GLUTAMINASE ACTIVITY

A. Gil-Gómez[1], I. Ranchal[1], A.I. Gómez-Sotelo[1], J. Ampuero[1], M. García-Valdecasas[1], Á. Rojas[1], R. Gallego-Durán[1], J.A. Del Campo[1], M. Romero-Gómez[1]. *[1]Valme University Hospital, Sevilla, Spain*
E-mail: antoniogilgom@hotmail.com

Background and Aims: Metformin has been found able to protect cirrhotic patients against hepatic encephalopathy (HE) (Ampuero et al. 2012). K-type glutaminase activity is increased in HE and it has been proposed as the main source of ammonia in liver disease. The gut, kidney and muscle are the key organs implicated

on HE. The aim of this work was to analyze the effect of metformin on glutaminase (GLS1) gene expression and K-type glutaminase enzyme activity in a rat model of HE.
Methods: RT-PCR and glutaminase activity assays were performed in different tissues from 16 male Wistar rats that underwent portacaval shunt (PCS). Eight animals were treated with 30 mg/kg/day of metformin for two weeks. RT-PCRs were made using SensiFAST™ SYBR Lo-ROX One-Step Kit (Bioline, EEUU) in presence of *Gapdh* and *Gls1* primers (QIAGEN, Germany) in an Eco™ Real Time PCR System (illumina®, EEUU). Glutaminase activity was assayed following the colorimetric protocol described by Heini. Plasma ammonia was measured following the glutamate-dehidrogenase enzymatic assay in a COBAS Integra® 700 (ROCHE, Switzerland).
Results: No changes in *Gls1* gene expression levels in gut, kidney and muscles were found associated with metformin use in PCS rats. However, metformin was associated with a significant inhibition of glutaminase activity levels in small intestine (0.277±0.11 mU/μg vs 0.142±0.07 mU/μg); $p < 0.05$, but not in muscle (0.075±0.054 mU/μg vs 0.054±0.006 mU/μg); p = ns, neither kidneys (0.337±0.22 mU/μg vs 0.286±0.22 mU/μg); p = ns. In non-treated PCS rats, plasma ammonia level reached 238.8±166.1 μg/dL and in PCS rats treated with metformin ammonia levels decreased significantly to 110.0±49.1 μg/dL; $p < 0.01$ (Figure 1).
Conclusions: Metformin treatment reduces hyperammonemia in PCS rats modulating glutaminase activity in small intestine but with and inconsistent effect in muscle and kidneys. No changes in gene expression suggests a postranscriptional effect.

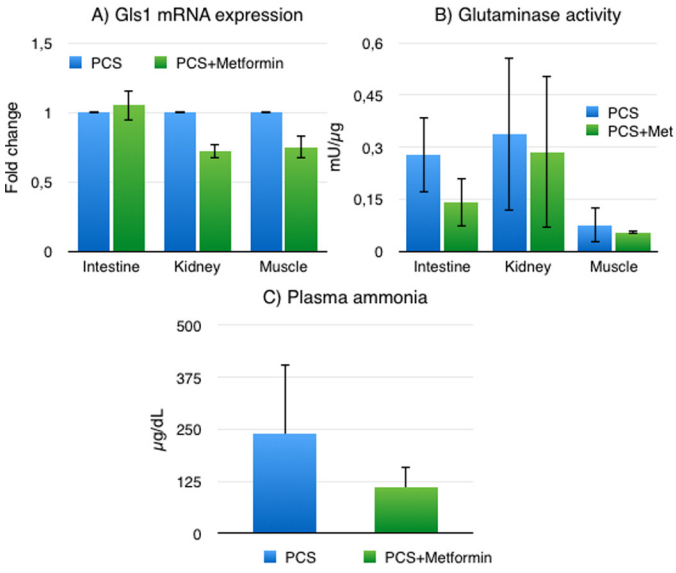


Figure 1. (A) mRNA expression of Gls1 in different tissues after 30 mg/kg/day of metformin treatment. (B) Glutaminase activity results obtained in the same animals. (C) Plasma ammonia.

P0216
INFLUENCE OF PREVIOUS DECOMPENSATION OF CIRRHOSIS ON HYPERDYNAMIC CIRCULATION AND RESPONSE TO β-BLOCKERS IN PRIMARY PROPHYLAXIS OF VARICEAL BLEEDING

E.A. Alvarado[1], O. Pavel[1], A. Ardèvol[1], I. Graupera[1], P. Huelin[1], A. Colomo[1], M. Martinez[1], N.C. Escajadillo[1], M.A. Ríos[1], C. Guarner Aguilar[1], C. Villanueva[1]. [1]*Hospital de la Santa Creu i Sant Pau, Barcelona, Spain*
E-mail: Edilmar_a@hotmail.com

Background and Aims: In cirrhosis with portal hypertension and varices, worsening of liver function increases the risk of variceal bleeding. Hyperdynamic circulation is more developed in decompensated than in compensated cirrhosis, but it is unknown whether it influences the response to β-blockers. The aim of this study was to evaluate whether decompensation of cirrhosis influence the hemodynamic response to β-blockers in primary prophylaxis.
Methods: Patients with cirrhosis and high-risk esophageal varices without previous bleeding, who were referred for primary prophylaxis, were consecutively included in the study. A hepatic and systemic hemodynamic assessment was performed and portal pressure gradient (PPG) was measured before and after i.v. administration of propranolol (0.15 mg / kg). Development of hyperdynamic circulation and response to β-blockers was compared in patients with and in those without previous decompensation of cirrhosis
Results: Among 203 patients included, 114 (56%) had previous decompensation of cirrhosis (ascites in 80%). As compared to patients with compensated cirrhosis, those with previous decompensation had worse Child–Pugh score (5.5±1 vs 7.6±1; $P < 0.001$) as well as each of its components. Alcoholic etiology of cirrhosis was more frequent in patients with decompensation (12% vs 47% $p < 0.001$) while platelet count and rates of splenomegaly and collateral circulation on ultrasound and of gastric varices on endoscopy, were similar in both groups. Patients with decompensation had a more developed hyperdynamic circulation, as indicated by higher cardiac index (4.1±1.3 vs 4.5±1.3 L/min/m^2; P = 0.03) and lower systemic vascular resistance (1042±307 vs 858±282 dyn·s·cm^{-5}; $P < 0.001$). PPG was higher in those decompensated both at baseline (17.5±4 vs 19.3±4 mmHg; P = 0.005) and after β-blocker (P = 0.01). The decrease in GPP achieved with propranolol was lower in patients decompensated, both considering absolute (−2.7±1.8 vs −1.8±2.9 mmHg; P = 0.02) and percentage reduction (−15±9% vs −11±9% mmHg; P = 0.01).
Conclusions: Patients with decompensated cirrhotic and high-risk esophageal varices without previous bleeding have, as compared with those with compensated cirrhosis, in addition to a greater development of hyperdynamic circulation, higher portal pressure gradient and worse acute hemodynamic response to β-blockers

P0217
USE OF BETA-BLOCKERS AT THE ONSET OF SPONTANEOUS BACTERIAL PERITONITIS MAY BE BENEFICIAL DUE TO MODULATION OF IMMUNE RESPONSE

P. Lutz[1,2], H.D. Nischalke[1,2], B. Kraemer[1,2], B. Langhans[1,2], S. Schlabe[1], J. Nattermann[1,2], A. Hoerauf[2,3], C.P. Strassburg[1,2], U. Spengler[1,2]. [1]*Department of Internal Medicine I, University of Bonn,* [2]*DZIF,* [3]*Institute for Medical Microbiology, Immunology and Parasitology, University of Bonn, Bonn, Germany*
E-mail: philuweltweit@web.de

Background and Aims: After spontaneous bacterial peritonitis (SBP), use of beta-blockers is associated with poor longterm survival. However, animal models suggest a beneficial effect of blocking sympathetic nerve signals during peritonitis. To clarify this issue in humans, we studied the effect of beta-blockers in patients with SBP.
Methods: We determined transplant-free 30-day survival in cirrhotic patients who developed SBP between March 2012 and October 2014 in our department and stratified them for use of beta-blockers. Ascites cells were stimulated with lipopolysaccharide (LPS) for 5 hours after pre-incubation with propanolol. Interleukin 8 (IL-8) was measured with ELISA.
Results: The study population comprised 60 patients with SBP [35 (58%) male, median age 59 years]. Cirrhosis was due to alcohol in 38 (63%) patients, to viral hepatitis in 11 (18%) patients. Seven (12%) patients had hepatocellular carcinoma (HCC). Median MELD score was 21.5, and 46 (77%) patients were classified as Child–Pugh stage C. 37 (62%) and 23 (38%) patients were without

and with beta-blockers at time of SBP, respectively: 14 (61%) with propranolol, the rest with metoprolol, bisoprolol, nebivolol or carvedilol. Clinical and laboratory data were comparable between patients with and without beta-blockers when diagnosis of SBP was made.
30-day survival was 62% (n = 37). Patients on beta-blockers survived longer than patients without beta-blockers (p = 0.033). Poor survival was also associated with the presence of HCC (p = 0.010) and MELD score >22 (p < 0.001). A forward conditional Cox logistic regression analysis confirmed MELD score >22 (p < 0.001) and use of beta-blockers (p = 0.032) as prognostic factors of 30-day survival. Frequency of acute kidney failure during the 30 days after SBP was comparable between patients with (63%) and without (81%) beta-blockers (p = 0.22).
Patiens with beta-blockers had higher fractions of mononuclear cells among the ascites leukocytes (0.26) compared to patients without beta-blockers (0.19; p = 0.029). In addition, IL-8 levels in a subgroup (n = 20) of patients where ascites was available were lower in patients with (513 pg/ml) compared to patients without beta-blockers (1035 pg/ml) (p = n.s.) Pre-treatment with 5 μg/ml propanolol attenuated the increase of IL-8 production when non-infected ascites was stimulated in-vitro with LPS to mimick SBP (p = 0.033).
Conclusions: Use of beta-blockers at the onset of SBP may be beneficial due to modulation of immune response.

P0218

FACTORS ASSOCIATED WITH HEMODYNAMIC RESPONSE TO PROPRANOLOL AND CARVEDILOL IN CIRRHOTIC PATIENTS

S. Bota[1], T. Reiberger[1], M. Mandorfer[1], R. Schwarzer[1], P. Schwabl[1], M. Trauner[1], A. Ferlitsch[1], M. Peck-Radosavljevic[1]. *[1]Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria*
E-mail: bota_simona1982@yahoo.com

Background and Aims: Sequential measurements of hepatic venous pressure gradient (HVPG) are used to assess the response to non-selective betablockers (NSBBs). We explored the association of different baseline parameters, changes in heart rate (HR), blood pressure during NSBBs, NSBBs doses and HVPG response.
Methods: Our retrospective study included 284 patients with paired HVPG measurements. The association between different baseline demographic characteristics, laboratory parameters, etiology and severity of liver disease, NSBBs doses, baseline HR/blood pressure and changes in HR/blood pressure and achievement of HVPG response was analyzed. Response (R) to NSBB was defined as decrease of HVPG – drop ≥20% or to absolute values <12 mmHg, while partial response (PR) was defined as HVPG decrease ≥10% but <20%, and non-response (NR) as a HVPG decrease <10%.
Results: 133 patients (46.8%) were responders, 47 (16.6%) partial responders, and 104 (36.6%) were non-responders (NR).
For propranolol (154 paired measurements), the following parameters were associated in univariate analysis with achievement of HVPG response: absence of history of variceal bleeding, lower baseline HVPG values, lower GGT, lower Forns score, higher basal HR and pronounced decrease in HR (Table). The following parameters did not influence the achievement of HVPG response to propranolol: age, gender, BMI, etiology of liver disease, HCC presence, presence/history of ascites or hepatic encephalopathy, Child–Pugh class, baseline bilirubin, albumin, AST, ALT, platelet count, MELD score, APRI, FIB-4, Fibrosis Index score, King's, Lok score, propranolol dose, baseline systolic, diastolic or mean blood pressure, decrease in systolic, diastolic or mean blood pressure. In multivariate analysis, decrease in HR (p = 0.0003) and Forns score (p = 0.02) reached the statistical significance.
A decrease in HR >22% had 57.6% Se, 71.8% Sp, 66.6% PPV, 63.6% NPV and 64.9% accuracy for predicting HVPG full response to propranolol (AUC = 0.688), while a Forns score <9.8 had 76% Se, 44.2% Sp, 56.8% PPV, 65.3% NPV and 59.7% accuracy (AUC = 0.623).
For carvedilol (130 paired measurements), only the decrease of systolic blood pressure reached the significance in univariate analysis (Table).
A decrease in systolic blood pressure >12% had 49.1% Se, 74% Sp, 59.5% PPV, 65.1% NPV and 63.1% accuracy for predicting HVPG full response to carvedilol (AUC = 0.629).
Conclusions: None of the baseline characteristics, laboratory tests or changes in HR or blood pressure during NSBB treatment can predict HVPG response to propranolol or carvedilol with sufficient accuracy.

Table (abstract P0218).

Factor	Responders (R)	Partial responders (PR)	Non-responders (NR)	p values

PROPHYLACTIC ADMINISTRATION OF BLOOD PRODUCTS DOES NOT PREVENT BLEEDING AFTER ENDOSCOPIC BAND LIGATION OF VARICES

A. Blasi[1], R. Risco[1], A. Fernandez Simon[1], C. Rodriguez de Miguel[1], A. Diaz-Gonzalez[1], A. Mendez-Bocanegra[1], J. Llach[1], A. Cardenas[1], G. Martinez[1]. [1]*Hospital Clinic, Barcelona, Spain*
E-mail: acardena@clinic.ub.es

Background and Aims: Prophylactic administration of platelets and fresh frozen plasma (FFP) is recommended in cirrhotic patients with low platelets/prolonged INR and esophageal varices (EV) that are submitted to endoscopic band ligation (EBL); however it is unknown if this measure prevents post-EBL bleeding. In this analysis we evaluated the outcome of patients undergoing EBL and the role of pre-procedure administration of blood products in this setting.
Methods: Retrospective analysis of consecutive EBL procedures in patients with cirrhosis and EV performed at Hospital Clinic, Barcelona from 2010 to 2013. FFP and platelet transfusion were administered if INR was >1.5 and/or platelet count $<50\times10^9$/L. Complications related to post-EBL bleeding and the relationship with administered blood products were recorded.
Results: 516 EBL procedures were performed in 231 patients (70% male), etiology: HCV and alcohol (77%), median MELD 12, Child A/B/C (40/45/15%). EBL procedures were performed for primary (127, 25%) or secondary (290, 55%) prophylaxis and for acute variceal bleeding (AVB) (99, 20%). Median procedure per patient was 2 (1–3). Bleeding occurred in 25 procedures (4.8%). Bleeding complications were not different between Child A/B vs. Child C patients ($p = 0.5$) and occurred independently of cut-off values and FFP/platelet transfusion (Table 1). FFP and platelets were given in 41 (7.9%) and 39 (7.6%) procedures respectively. Multivariate analysis showed that MELD score (OR, 1.1; 95% CI, 1.0–1.2; $p < 0.01$) and AVB (OR, 3.4; 95% CI, 1.6–7.0;$p < 0.01$) emerged as a predictive factors for post-EVL bleeding.
Conclusions: Pre-procedure administration of FFP and platelets in cirrhotic patients undergoing EBL does not confer a benefit as a prophylactic measure of post-EBL bleeding. Post-EBL bleeding is independent of pre-procedure cut-off values and FFP/platelet administration. MELD score and AVB are risk factors for post-EBL bleeding. Prospective studies are needed to determine the role of routine administration of blood products prior to EBL in patients with cirrhosis.

Table 1. Blood products prior to EBL according to pre-set cut off values

	n	Post-EBL bleeding, n (%)		*p* value
		Yes	No	
INR >1.5				0.17
+ FFP transfusion	41	4 (9.8%)	37 (90.2%)	
no FFP transfusion	48	1 (2.1%)	47 (97.7%)	
Platelets $<50\times10^9$/L				0.57
+ platelet transfusion	39	1 (2.6%)	38 (97.4%)	
no platelet transfusion	29	2 (6.9%)	27 (93.1%)

JNK SIGNALING ACTIVATED BY PLATELET-DERIVED GROWTH FACTOR D (PDGF-D) STIMULATES SECRETION OF VASCULAR ENDOTHELIAL GROWTH FACTOR-C (VEGF-C) BY CANCER-ASSOCIATED FIBROBLASTS TO PROMOTE LYMPHANGIOGENESIS AND EARLY METASTASIZATION IN CHOLANGIOCARCINOMA

M. Cadamuro[1,2], M. Vismara[1], S. Brivio[1], A. Furlanetto[3], M. Strazzabosco[1,4], L. Fabris[1,2,4]. [1]*Dep. of Surgery & Translational Medicine, University of Milan-Bicocca, Milan,* [2]*Dep. of Molecular Medicine, University of Padua, Padua,* [3]*Pathology Unit, Treviso Regional Hospital, Treviso, Italy;* [4]*Section of Digestive Diseases, Yale University School of Medicine, New Haven, United States*
E-mail: luca.fabris@unipd.it

Background and Aims: Cholangiocarcinoma (CCA) is a highly invasive malignancy with a poor prognosis. Currently, <30% of CCA patients are candidates to surgical resection, due to the early lymph node metastasization. In CCA, lymphangiogenesis develops within an abundant stroma, mainly composed by cancer-associated fibroblasts (CAF) recruited, among others, by PDGF-D secreted by CCA cells. Mechanisms governing lymphangiogenesis in CCA are not known. We aimed to investigate the role of PDGF-D-mediated epithelial–mesenchymal interactions in promoting lymphangiogenesis.
Methods: Immunohistochemical studies of human CCA specimens ($n = 6$), were performed to understand the relationship among lymphatic vessels ($D2\text{–}40^+$), blood vessels ($CD34^+$), CCA cells and CAF (αSMA^+), and the expression of PDGF-D, PDGFRβ, VEGF-C and VEGFR3, as compared with the peritumoural areas. Furthermore, lymphatic microvessel density (LMVD) and vascular microvessel density (VMVD) were calculated in CCA and compared with hepatoma (HCC) ($n = 6$). Secretion of lymphangiogenic growth factors (VEGF-C, Ang-1 and Ang-2) was measured by ELISA in cultures of primary fibroblasts challenged with PDGF-D with/without the PDGFRβ inhibitor, imatinib mesylate (IM), and the JNK inhibitor, SP600126. Using Boyden chambers, we next evaluated the motility of human lymphatic endothelial cells (LEC) following stimulation with conditioned medium of PDGF-D-challenged fibroblasts with/without SP600126.
Results: With respect to HCC, CCA was characterized by a marked increase in LMVD and a reduction in VMVD. In CCA, LEC laid in close vicinity to CAF and to cancer cells. We observed a specific expression of PDGF-D on CCA cells, PDGFRβ and VEGF-C on CAF, and VEGFR-3 on LEC, suggesting a sequential cross talk from tumoral bile ducts to lymphatic vessels via CAF. This was confirmed by *in vitro* results showing that upon PDGF-D stimulation, fibroblasts secreted VEGF-C but not Ang-1 (Ang-2 was not expressed), an effect significantly reduced by IM, and by SP600126. Conditioned medium of PDGF-D-stimulated fibroblasts induced a significantly stronger effect on LEC recruitment than that of unstimulated fibroblasts, and this effect was significantly hampered by JNK inhibition.
Conclusions: PDGF-D released by CCA cells stimulates CAF to secrete VEGF-C by activating JNK signaling. In turn, VEGF-C secreted by CAF stimulates LEC recruitment. This cross-talk identifies PDGFRβ and JNK as targets for antilymphagiogenic therapies in CCA.

ACQUIRED RESISTANCE TO SORAFENIB IN HEPATOCELLULAR CARCINOMA IS MEDIATED BY TUMOR INITIATING CELLS (CANCER STEM CELLS)

V. Tovar[1], H. Cornellà[1], A. Moeni[1], S. Vidal[2], Y. Hoshida[3], D. Sia[1,4], J. Peix[1], C. Alsinet[1], I.M. Quetglas[1], M. Solé[1], J. Domingo-Domenech[2], A. Villanueva[1,3], J.M. Llovet[1,3,5]. *[1]Liver Cancer Translational Research Laboratory, BCLC group, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS)-Hospital Clínic, Liver Unit, CIBEREHD, Universitat de Barcelona, Barcelona, Catalonia, Spain; [2]Department of Pathology, Icahn School of Medicine at Mount Sinai, [3]Liver Cancer Program, Division of Liver Diseases, Department of Medicine, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, United States; [4]Gastrointestinal Surgery and Liver Transplantation Unit, National Cancer Institute, Milan, Italy; [5]Institució Catalana de Recerca i Estudis Avançats, Barcelona, Catalonia, Spain*
E-mail: vtovar@clinic.ub.es

Background and Aims: Sorafenib is the only systemic therapy approved for the treatment of hepatocellular carcinoma (HCC), but most patients ultimately relapse resulting in disease progression. The precise molecular mechanisms underlying acquired resistance relevant for planning second line therapies are yet unknown. Herein, we explore the role of tumour-initiating cells (T-ICs) – *cancer stem cells* – in the acquisition of resistance to sorafenib and the signalling pathways involved in this process.
Methods: HCC xenograft mice treated with sorafenib (n = 26) were explored for long-term sensitivity (n = 5) and development of acquired resistance (n = 17, median= 42 days). To underscore the mechanism of acquired resistance we assess: (1) the role of T-ICs by in vitro sphere formation assays, and in vivo tumorigenesis assays using NOD/SCID mice, (2) the role of alternative signaling as mediator of resistance and (3) the efficacy of anti-FGF therapy in a mouse model of HCC. Gene expression profiling (microarray, qRT-PCR) and protein analysis (immunohistochemistry) were conducted. Gene pattern modules were used to generate a gene signature of sorafenib resistance and tested in 2 independent cohorts of HCC patients (n = 442).
Results: Acquired resistance to sorafenib developed after a median of 42 days in 65% of mice. There was a significant enrichment of T-ICs in sorafenib-acquired resistant tumours (164 cells needed to create a tumour) vs. sorafenib-sensitive tumours (13400 cells needed) and vs. non-treated tumours (1292 cells needed), $p < 0.001$. Tumours with sorafenib-acquired resistance were enriched with IGF and FGF signaling activation cascades and gene sets of resistance to antitumoral therapies (FDR <0.05). We generated a sorafenib-resistance 175-gene signature that was enriched with progenitor-cell features and predicted poor survival in two independent cohorts of HCC patients (n = 223 and n = 219, respectively), $p < 0.05$. This gene signature was associated with molecular subclasses of poor outcome and aggressive tumours. Furthermore, mice showing acquired resistance treated with an FGF-inhibitor (brivanib) vs. sorafenib showed delayed tumor growth, improved survival, and inhibition of FGFR1 activity and downstream signaling.
Conclusions: Sorafenib-induced acquired resistance is mainly driven by T-ICs with enrichment of progenitor markers and activation of IGF and FGF signaling. Inhibition of these pathways would benefit a subset of patients after sorafenib progression.

RELEVANCE OF ORGANIC CATION TRANSPORTER OCT1 (SLC22A1) IN DIETHYLNITROSAMINE-INITIATED AND PHENOBARBITAL-PROMOTED HEPATOCELLULAR CARCINOMA IN OCT3-KNOCKOUT MICE

J. Knapstein[1], P. Fuchs[1], D. Grimm[1], A. Lautem[2], M. Hoppe-Lotichius[2], M.A. Woerns[1], H. Lang[2], P.R. Galle[1], T. Zimmermann[1]. *[1]Center for Cirrhosis Mainz (CCM), Department of Medicine I, [2]Department of hepatoboliary and transplantation Surgery, University Hospital Mainz, Mainz, Germany*
E-mail: johanna.knapstein@unimedizin-mainz.de

Background and Aims: We have recently shown a down-regulation of OCT1 (SLC22A1) and OCT3 (SLC22A3) in human hepatocellular carcinoma (HCC) and human cholangiocarcinoma (CCC), associated with tumor progression and a worse patient survival. The OCT1 down-regulation in HCC may affect the ability of sorafenib and platin derivates to reach active intracellular concentrations in these tumors.
Methods: Liver tumors were induced in OCT3-knockout ($OCT3^{-/-}$) mice and wildtype (WT) mice with Diethylnitrosamine (DEN) and Phenobarbital over 10 month. SLC22A1 mRNA expression was measured in tumors and corresponding non-neoplastic tumor surrounding tissue (TST) by real time (RT)-PCR. Protein expression was determined by western blot analysis. Tumor characteristics and blood parameters were assembled. $OCT3^{-/-}$ and WT mice underwent bile duct ligation (BDL) or placebo surgery (Sham operation). After 7 days mice were sacrificed and SLC22A1, TNF-α, TGFβ, IL-10 and col1α1 mRNA expression were measured by RT-PCR in liver tissue. Fibrosis was quantified by Sirius Red staining. Finally mRNA and protein expression of potentially regulatory factors and pathways were investigated by RT-PCR and western blot analysis respectively.
Results: In accordance to the findings in human HCC SLC22A1 mRNA and protein expression were down regulated in liver tumors compared to TST in $OCT3^{-/-}$ mice ($p = 0.001$). Though $OCT3^{-/-}$ mice do not present an obvious phenotype, tumor size ($p < 0.01$) and quantity ($p = 0.001$) were enhanced in comparison to WT mice. Tumors in $OCT3^{-/-}$mice showed significant higher proliferation ($p \leq 0.01$), apoptosis ($p = 0.002$), fibrosis ($p = 0.004$), steatosis ($p < 0.001$) and inflammation ($p = 0.047$). $OCT3^{-/-}$ mice developed significantly more fibrosis 7 days after BDL. OCT1 mRNA expression was up regulated in ligated and Sham operated $OCT3^{-/-}$mice and tended to decrease after BDL. We found increased levels of TNF-α, TGFβ and col1α1 mRNA expression and a decrease in Il-10 mRNA expression in ligated $OCT3^{-/-}$ mice. Finally HNF4α and PPAR-α mRNA expression were down regulated in tumors vs. TST in $OCT3^{-/-}$ mice. Western blot analysis showed significant alterations in Ras-Raf-MEK-ERK, JNK and mTOR signaling pathways.
Conclusions: The down-regulation of OCT1 in liver tumors in $OCT3^{-/-}$ mice is associated with enhanced tumor growth and $OCT3^{-/-}$ mice are more susceptible for liver damage. The expression of OCT1 might be regulated via HNF4α and PPAR-α in $OCT3^{-/-}$ mice and different signaling pathways are involved.

P0223

ROLE OF ARL6IP5 IN HCV-RELATED HEPATOCELLULAR CARCINOMA

Z. Hu[1,2], G.S. Wilson[1], J. George[1], L. Qiao[1]. *[1]Medicine, Storr Liver Centre, Westmead Millennium Institute for Medical research, The Western Clinical School of the Faculty of Medicine, The University of Australia, Westmead, Australia; [2]Gastroenterology and Hepatology, the First Hospital of Lanzhou University, Lanzhou, 730000, China*
E-mail: liang.qiao@sydney.edu.au

Background and Aims: Recent studies have suggested that ARL6IP5 (ADP-ribosylation-like factor 6 interacting protein 5) may function as a tumour suppressor gene in cancers. Our preliminary studies

have revealed significantly increased expression level of ARL6IP5 in HCV-infected individuals, particularly in HCV-related HCC tissues. The aim of this study was to examine the biological role of ARL6IP5 in the development of liver cancer.
Methods: Real time quantitative PCR (qPCR) and Western blot were used to examine the expression of ARL6IP5 in human hepatocellular carcinoma (HCC) tissues and matched non-cancerous liver. HuH7 cells stably over-expressing ARL6IP5 and cells with stable silencing of ARL6IP5 were used to test for tumorigenesis in nude mice. The effect of ARL6IP5 modulation on cell proliferation, migration and invasion was tested in HCC cells using BrDU incorporation, wound healing, and Boyden Chamber assays, respectively.
Results: Higher levels of ARL6IP5 were found in HCC tissues than in non-HCC tissues. In HCC tumors, those derived from HCV infected individuals had higher levels of ARL6IP5 than those without prior HCV infection. Following acute DEN treatment of mice, there was a transient increase in the hepatic expression of ARL6IP5, which was paralleled with enhanced expression of hepatic IL-6. In DEN-induced mouse HCC, hepatic expression of ARL6IP5 in the tumors was significantly higher than that in adjacent non-cancerous liver. In nude mice studies, xenograft tumors derived from ARL6IP5 overexpressing HuH7 cells showed no difference compared to xenografts derived from control vector expressing cells with regard to tumor volume and growth velocity. In contrast, xenograft tumors derived from HuH7 cells with stable ARL6IP5 knockdown showed significantly reduced tumor growth velocity and tumor volume. *In vitro* studies showed that transfection of HuH7 cells with HCV core JFH1 led to a marked increase in the expression of ARL6IP5 both at the mRNA and protein levels, and the HCV-induced increase of ARL6IP5 was partially reversed by treatment with interferon a2A. Down-regulation of ARL6IP5 in HCC cells by siRNA-ARL6IP5 led to decreased cell proliferation, decreased migration, and reduced cellular invasion.
Conclusions: These findings strongly suggest that ARL6IP5 may be an important mediator for HCV-induced inflammation, and it may play an important oncogenic role in liver cancer formation.

P0224
NINTEDANIB PREVENTS THE DEVELOPMENT OF HEPATOCELLULAR CARCINOMA IN A MOUSE MODEL OF FIBROSIS
V. Tovar[1], A. Moeni[1], S. Torrecilla[1], M. Higuera[1], J. Peix[1], I.M. Quetglas[1], L. Rodriguez-Carunchio[1], M. Solé[1], J.M. Llovet[1,2,3].
[1]Liver Cancer Translational Research Laboratory, BCLC group, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS)-Hospital Clínic, Liver Unit, CIBEREHD, Universitat de Barcelona, Barcelona, Catalonia, Spain; [2]Mount Sinai Liver Cancer Program, Icahn School of Medicine at Mount Sinai, New York, United States; [3]Institució Catalana de Recerca i Estudis Avançats, Barcelona, Catalonia, Spain
E-mail: vtovar@clinic.ub.es

Background and Aims: Hepatocellular carcinoma (HCC) affects 30% of cirrhotic patients, which represents 1% of the world population. To date, no molecular therapies have been approved for HCC prevention in these patients. In this study, we aimed to evaluate the chemopreventive efficacy of the tyrosine kinase inhibitor (TKI) nintedanib (VEGFR1–3, FGFR1–3, PDGFRα/β inhibitor; Boehringer Ingelheim) in a mouse model of HCC.
Methods: HCC was induced in the context of fibrosis in C57Bl/6 male mice (n = 55) by a single intraperitoneal (i.p.) injection of DEN (25 mg/kg) at day 15 postpartum followed by weekly i.p. injections of CCl_4 (0.5 ml/kg) from 4 weeks of age. 12 weeks-old mice were then randomized to receive nintedanib (50 mg/kg) (n = 29) or vehicle (n = 26). Mice were sacrificed at 15, 17 and 18 weeks of age. Blood and liver samples were collected. Primary study end-points included HCC incidence, number and size of macroscopic tumours. Molecular analysis was assessed at gene expression (microarray) and protein level (western blot and immunohistochemistry). Drug tolerance was evaluated by body weight loss and plasma AST/ALT levels.
Results: Nintedanib was well tolerated and reduced HCC incidence in treated mice compared to control group at 15 weeks (13% vs 43%), 17 weeks (30% vs 89%, $p < 0.02$) and 18 weeks (90% vs 100%). The number of tumours/mouse significantly decreased at 17 weeks (0.9 vs 4.7, $p = 0.003$) and 18 weeks (3.5 vs 11.4, $p = 0.003$). Nintedanib also prevented the development of large number of tumours (>4 tumours) at 17 weeks ($p = 0.01$) and 18 weeks ($p = 0.008$). Tumour size was significantly reduced at 17 weeks (0.7 mm vs 6.4 mm, $p = 0.01$) and 18 weeks (4.8 mm vs 16.2 mm, $p = 0.001$). Gene expression profiling showed 471 deregulated genes (Fold change >1.5, $p < 0.05$) between the control and treated group. In addition, IPA and GSEA revealed the capacity of nintedanib to reverse the pro-carcinogenic phenotype of control mice (inflammation, tissue damage response, epithelial–mesenchymal transition, stem cell pluripotency) and to promote liver function in treated mice. Furthermore, nintedanib blocked the activation of VEGFR2 and the downstream effectors AKT and ERK. Histological analysis confirmed the development of HCC in the context of fibrosis.
Conclusions: Nintedanib is able to prevent the development of HCC in a fibrosis-based experimental model. These data provide the rationale for testing the therapeutic potential of TKIs in cirrhotic patients at high-risk to develop HCC.

P0225
COMBINATION OF CD40L CO-STIMULATION WITH ALPHA-FETOPROTEIN PULSED DENDRITIC CELLS INDUCED AN EARLY AND STRONG TH1-SHIFT IN THE TUMOR ENVIRONMENT AND SYNERGISTIC ANTITUMORAL EFFECTS IN SUBCUTANEOUS AND ORTHOTOPIC MURINE HEPATOCELLULAR CARCINOMA MODEL
A. Vogt[1], C. Schneider[1,2], T.H. Ayub[1], G. Decker[1], J. Prieto[3,4], S. Conchon[5], I.G. Schmidt-Wolf[6], C.P. Strassburg[1], M.A. Gonzalez-Carmona[1]. *[1]Department of Internal Medicine I, University of Bonn, Bonn, [2]Department of Medicine III, University Hospital Aachen, Aachen, Germany; [3]Liver Unit, Clínica Universitaria, [4]CIMA and Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Universidad de Navarra, Pamplona, Spain; [5]INSERM UMR1064 – ITUN, CHU Hotel Dieu, Université de Nantes, Nantes, France; [6]Center for Integrated Oncology (CIO), University of Bonn, Bonn, Germany*
E-mail: Annabelle.Vogt@ukb.uni-bonn.de

Background and Aims: Dendritic cells (DC) as professional antigen presenting cells can be used to prime T-cells against the tumor-associated antigen α-fetoprotein (AFP) for immunotherapy of hepatocellular carcinoma (HCC). However, a strong immunosuppressive tumor environment limits their efficacy in patients. The co-stimulation with CD40Ligand (CD40L) is critical in the maturation of DC and T-cell priming. In this study, the impact of CD40L to improve vaccination with murine (m)AFP-pulsed DC (Ad-mAFP-DC) was analyzed in poor immunogenic subcutaneous (s.c.) and orthotopic murine HCC.
Methods: Murine DC cultured with GM-CSF and IL-4 were adenovirally transduced with Ad-mAFP, Ad-CD40L or Ad-LacZ (control). Hepa129-mAFP-cells were injected into the right flank or the liver of C3H-mice to induce subcutaneous (s.c.) and orthotopic HCC. For treatments, 10^6 mAFP-pulsed DC were inoculated s.c. followed by 10^6 CD40L-expressing DC (Ad-CD40L-DC) injected intratumorally (i.t.).
Results: Ad-mAFP-DC, which were co-cultured with Ad-CD40L-DC showed a CD40L-dependent enhanced immunostimulatory capacity. S.c. inoculation with this mixed vaccine induced complete protection towards challenge with mAFP-positive HCC cells in more than 30% of animals compared to controls. In pre-

established tumors, intratumoral (i.t.) application of Ad-CD40L-DC combined with s.c. inoculation with Ad-mAFP-DC also enhanced the antitumoral effects, achieving complete remissions and long-term survival in 62% of animals. Analysis of the tumor environment at different time points revealed that s.c.-vaccination with Ad-mAFP-DC stimulates tumor-specific effector cells, allowing an earlier Th1 shift and recruitment of effector T-cells within the tumors. After i.t. co-stimulation with Ad-CD40L-DC, production of Th1-cytokines was strongly increased and accompanied by a robust tumor infiltration of mature DC, activated $CD4^+$-, $CD8^+$-T-cells as well as reduction of regulatory T-cells. Moreover, Ad-CD40L-DC induced tumor cell apoptosis.

Conclusions: Co-stimulation with CD40L significantly improves vaccination with Ad-mAFP-DC in a protective setting and in pre-established HCC *in vivo*. Combined therapy causes an early and strong Th1-shift in the tumor environment as well as higher tumor apoptosis, leading to effective and synergistic tumor regression of HCC. Thus, CD40L co-stimulation represents a promising tool for improving DC-based immunotherapies of HCC.

P0226

REDUCTION IN SUMOYLATION-DEPENDENT S100A4 NUCLEAR IMPORT IN CHOLANGIOCARCINOMA BY LOW DOSE PACLITAXEL HALTS TUMOR INVASIVENESS AND HEMATOGENOUS METASTATIZATION BY MODULATING RHO-A AND CDC42 ACTIVITIES

G. Spagnuolo[1], M. Cadamuro[1,2], L. Sambado[1], S. Indraccolo[3], G. Nardo[3], A. Rosato[3], E. Novelli[4], C. Spirlì[5], M. Strazzabosco[1,5], L. Fabris[1,2,5]. *[1]Dep. of Surgery & Translational Medicine, University of Milan-Bicocca, Milan, [2]Dep. of Molecular Medicine, University of Padua, [3]Istituto Oncologico Veneto, IRCCS, Padua, [4]Clinica San Gaudenzio, Novara, Italy; [5]Section of Digestive Diseases, Yale University School of Medicine, New Haven, United States*
E-mail: luca.fabris@unipd.it

Background and Aims: Cholangiocarcinoma (CCA) is characterized by early and strong invasiveness. Nuclear expression of the S100A4 protein is a marker of increased CCA invasiveness. We aimed at studying if S100A4 nuclear expression promotes CAA invasiveness and may be a druggable therapeutic target. Preliminary experiments showed that Paclitaxel (PTX), a microtubule stabilizing agent, is able to reduce the nuclear import of S100A4.

Methods: CCA cells expressing nuclear S100A4 (EGI-1) were treated with increasing PTX doses to study *in vitro* effects on nuclear and cytosolic S100A4 expression, nuclear S100A4 sumoylation (a process regulating nuclear import of several proteins), cytoskeletal integrity, cell proliferation, apoptosis, motility, invasiveness and Rho GTPases activity.

To confirm *in vitro* data, SCID mice were xenografted with EGI-1 by spleen injection. After confirming tumor engraftment by bioluminescence imaging, we treated mice with PTX at a low-dose metronomic regimen (2.6 mg/kg/die; n = 5) for 14 days; untreated mice served as controls (n = 5). We then evaluated PTX *in vivo* effects on primary tumor size, number of micrometastasis (MM) and isolated tumour cells (ITC) in liver and lung tissue samples, along with proliferation, apoptosis and S100A4 expression of EGI-1.

Results: PTX at 1.5 and 15nM induced a marked reduction in nuclear S100A4 without modifying its cytoplasmic levels. The decrease of nuclear S100A4 was linked with a significantly reduced sumoylated fraction and a relevant attenuation of both cell migration and invasiveness, without affecting proliferation/apoptosis or cytoskeletal integrity. Furthermore, Rho-A and Cdc42 activities were reduced. In xenografted mice, PTX induced a reduction in both the primary tumor size and number of lung MM and ITC. In the primary CCA mass of PTX-treated mice, the number of EGI-1 expressing nuclear S100A4, were significantly reduced, whereas proliferation/apoptosis rate did not change.

Conclusions: Down-regulation of nuclear S100A4 by PTX at doses well below those commonly used in chemotherapy regimens but able to interfere with the sumoylation process, results in a decrease of CCA cell motility and invasiveness in conjunction with a reduction of hematogenous spread. These effects do not depend on changes in cell proliferation, apoptosis or cytoskeleton integrity, but on the reduction of Rho-A and Cdc42 activities caused by reduced S100A4 nuclear translocation. This is a novel therapeutic target in CCA.

P0228

OVER-EXPRESSION OF SURVIVIN ENHANCES THE CHEMOTHERAPEUTIC EFFECTIVENESS OF YM155 IN HUMAN HEPATOCELLULAR CARCINOMA

H. Xia[1], J. Chen[1], M. Shi[2], A. Deivasigamani[1], L.L. Ooi[3], K.M. Hui[4]. *[1]National Cancer Centre Singapore, Singapore, Singapore; [2]Department of Hepatobiliary Oncology, Cancer Center, Sun Yat-sen University, Guangzhou, China; [3]Singapore General Hospital, [4]Cellular and Molecular Research, National Cancer Centre Singapore, Singapore, Singapore*
E-mail: cmrhkm@nccs.com.sg

Background and Aims: Hepatocellular carcinoma (HCC) is one of the leading causes of cancer-related deaths worldwide and displays inherent resistance to most of the chemotherapeutic drugs. Survivin (BIRC5) belongs to the family of inhibitor-of-apoptosis proteins (IAPs) which antagonizes the induction of cell death. Dysregulated expression of IAPs is frequently observed in cancers, and the comparative high levels of survivin in tumors make it an attractive target for pharmacological interventions. The small imidazolium-based compound YM155, a "survivin suppressant", has been employed to block the expression of survivin via inhibition of the survivin promoter. Although YM155 has been shown to be well tolerated, but unfortunately it's clinical efficacy has been insofar only moderate. Here, we have studied the molecular mechanism(s) that regulate the expression of survivin in HCC cells and to perform preclinical efficacy evaluation of the survivin inhibitor, YM155, as a therapeutic agent against HCC.

Methods: We have studied the quantitative expression of survivin in human HCC biopsies and a panel consisting of 25 HCC cancer cell lines. The orthotopic mouse xenograft model was employed to monitor the therapeutic effects of YM155 in vivo.

Results: We demonstrated the remarkable heterogeneity of survivin protein expression in human HCC biopsies and cell lines. High survivin expression in HCC patients' samples correlated with comparatively poorer survival. HCC cancer cell lines also exhibited a difference in sensitivity to YM155 with the high survivin expresssor cell lines were significantly more sensitive than the low expressor cells to YM155. The sensitivity of HCC cell lines to YM155 was associated with the increase expression of phosphorylated survivin. YM155 was found to inhibit cell growth and induced cell cycle arrest by altering the gene expressions of genes associated with DNA damage, cell cycle, and apoptosis in human HCC cells. Importantly, YM155 yielded significantly better therapeutic effects than sorafenib when tested in an orthotopic xenograft HCC model using HCC patient-derived xenografts with high survivin expression.

Conclusions: Biomarker-driven oncology trials represent a paradigm shift in drug discovery and the promise of precision medicine. Our results provide the scientific basis for designing actionable, targeted therapy of employing YM155 to treat HCC patients whose tumor express elevated level of phosphorylated survivin in "adaptive" clinical studies.

P0229

JAGGED2-MEDIATED NOTCH SIGNALING REGULATES CELLULAR PLASTICITY AND PROMOTES A CANCER STEM CELL PHENOTYPE IN HCC

G. Wu[1], G.S. Wilson[1], J. George[1], L. Qiao[1]. *[1]Medicine, Storr Liver Centre, Westmead Millennium Institute for Medical research, The Western Clinical School of the Faculty of Medicine, The University of Australia, Westmead, Australia*
E-mail: liang.qiao@sydney.edu.au

Background and Aims: Cancer cells within tumors can exist in various states of differentiation and can flux between these states, a phenomenon mediated by epigenetic changes. Determining epigenetic changes is critical for effective therapy because dedifferentiation can drive a cancer stem cell (CSC) phenotype with more aggressive behaviour that is resistant to current therapies. Notch signalling is a major mediator of cell fate and is a critical signalling pathway in maintaining the cells in an undifferentiated state. Our study characterises the role Notch signalling plays in maintaining a LCSC phenotype.
Methods: Undifferentiated cells with a liver cancer stem cell (LCSC) phenotype were isolated from HCC cell lines HuH7 and PLC/PRF/5 using flow cytometry based on the expression of the classical CSC marker Oct4. The expression of Notch signalling components were examined in these undifferentiated cells by Western blot. Tumour sphere assays and cell proliferation were undertaken on undifferentiated cells treated with recombinant human Jagged2 (rhJagged2) and siRNA specifically targeting Jagged2 (siRNA-Jagged2). The expression of transcription factors involved in dedifferentiation was then determined in the HCC cell lines. The expression of Jagged2 in tumor and adjacent non-tumor tissue from HCC patients was evaluated by Western blot.
Results: Increased expression of Jagged2 and the Notch functional receptor subunit NICD1 was observed in Oct4+ LCSCs. Treatment of LCSCs with rhJagged2 resulted in activation of Notch signalling as manifested by increased expression of Notch signalling components, particularly the Notch downstream targets Hey1 and NICD1. On the other hand, inhibition of Jagged2 by siRNA led to a significant reduction in the expression of Notch signalling components. rhJagged2-treated LCSCs showed increased cell proliferation and tumor sphere formation which were significantly blunted by siRNA-Jagged2. HCC cells PLC/PRF/5 and HuH7 treated with rhJagged2 resulted in a significant up-regulation of Sox-2. Increased expression of Jagged2 was also observed in human HCC tumour tissues compared to adjacent non-tumour liver.
Conclusions: Jagged2 is likely an important molecule in the maintenance of CSC phenotype and differentiation status; this in turn is involved in HCC development. Up-regulation of Jagged2 in HCC tissues suggests that Jagged2 targeting may be a therapeutic option for HCC. Studies are currently underway to explore the therapeutic benefit of targeting Jagged2 in HCC.

STARD1 OVEREXPRESSION EXACERBATES CHOLESTEROL-MEDIATED HEPATOCARCINOGENESIS

L. Conde de la Rosa[1], V. Ribas[1,2], C. García-Ruiz[1], J.C. Fernández-Checa[1,2]. *[1]Mitochondrial regulation of cell death, IIBB-CSIC, [2]Liver Unit, IDIBAPS, Barcelona, Spain*
E-mail: vribas@clinic.ub.es

Background and Aims: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related death worldwide and a complication of advanced liver disease. Cholesterol is an emerging factor promoting fatty liver disease. Moreover, StARD1, a protein responsible for cholesterol trafficking to mitochondria, has been found to have a role in steatohepatitis and HCC. Although recent findings showed that obesity and hepatic steatosis promotes tumorigenesis, the role of cholesterol in HCC progression has not been elucidated yet. Thus, the aim of this study was to investigate the role of cholesterol and StARD1 in chemically-induced hepatocarcinogenesis and the therapeutic effect of ezetimibe.
Methods: 14 days-old mice were injected i.p. with a single dose of diethylnitrosamine (DEN). 30 days later, mice were fed with high fat diet (60% calories from fat) containing cholesterol (0.5%) (HFCD) supplemented or not with ezetimibe (10 mg/kg/day) for 32 weeks. Overexpression of hepatic Stard1 was induced by genetically-engineered adenovirus in mice treated with DEN and fed the HFCD. Liver samples were processed to detect tumor markers by Western Blotting, IHC and qRT-PCR.
Results: Liver cholesterol was significantly higher in the HFCD fed group compared to HFCD+ezetimibe or regular diet group. The expression of the proliferation markers Ki-67 and PCNA induced by DEN was elevated in HFCD fed mice and this effect was reduced in mice treated with ezetimibe. In addition, DEN-induced fibrosis, measured by Sirius red staining, hydroxyproline, collagen1A1 and osteopontin expression was further exacerbated in mice fed the HFCD, and ezetimibe reversed this increase. DEN-induced expression of tumor markers CK-19, AFP and GP-73 was elevated in the HFCD group compared to HFCD+ezetimibe. The multiplicity (average of tumors/mice) and tumor burden (average weight of tumors/mice) observed after 8 months were significantly higher in mice fed the HFCD compared with the HFCD+ezetimibe group. Moreover, 100% of mice died in HFCD group vs 50% in HFCD+ezetimibe group after 1 year. Additionally, StARD1 overexpression induced by adenovirus, doubled the multiplicity of tumors and induced a parallel increase in expression of tumor markers when compared to animals injected with control empty adenovirus.
Conclusions: High cholesterol in liver promotes the growth and progression of HCC and ezetimibe reverses these effects. StARD1 overexpression increases HCC, likely by stimulating the trafficking of mitochondrial cholesterol.

P0231

EFFECT OF PERIFOSINE ALONE AND IN COMBINATION WITH SORAFENIB IN AN HrasG12V PLUS shp53 TRANSGENIC MOUSE MODEL OF HEPATOCELLULAR CARCINOMA GENERATED BY HYDRODYNAMIC INJECTION

M.N. Kim[1], S.W. Ro[1], Do Y. Kim[1], Da Y. Kim[1], J.H. Park[2], H.Y. Lim[3], K.-H. Han[1]. *[1]Department of Internal Medicine, [2]Department of Microbiology, Yonsei University College of Medicine, [3]Department of Internal Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, South*
E-mail: mnk2012@yuhs.ac

Background and Aims: Novel therapeutic strategies are needed to improve survival in patients with hepatocellular carcinoma (HCC). Perifosine has shown antitumor activity by inhibition of Akt phosphorylation in many advanced solid tumors. This study was to investigate the effect of perifosine alone and in combination with sorafenib in a HrasG12V plus short-hairpin RNA downregulating p53 (shp53) double transgenic mouse model of HCC.
Methods: The mouse model of HCC was generated by hydrodynamic injection of transgenes HrasG12V/shp53, and the mice were treated with perifosine with or without sorafenib to evaluate effects of drugs on tumor growth and survival. Tumor cell proliferation and tumor angiogenesis were evaluated by immunohistochemical analysis of Ki-67 and CD31, respectively. Tumor cell apoptosis was detected by using the terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling assay. Levels of key enzymes in the PI3K/Akt, Ras/Raf/MAPK, and caspase pathways were detetected by western blot analysis, and levels of vascular endothelial growth factor (VEGF) were determined by immunohistochemistry and western blot analysis.

Results: Treatment with perifosine for 5 weeks, alone and in combination with sorafenib, strongly inhibited tumor growth and increased survival. Perifosine inhibited HCC cell proliferation, induced apoptosis, and decreased tumor angiogenesis. Furthermore, its combination with sorafenib enhanced these effects. In addition, Akt phosphorylation was decreased by perifosine and further decreased by combination treatment. Although perifosine alone did not appear to activate the caspase pathway, combination treatment increased the cleavage of caspase-3, caspase-9, and poly (ADP-ribose) polymerase. Perifosine did not affect VEGF levels, as assessed by immunohistochemistry and western blot analysis.
Conclusions: Results of this in vivo study indicate that perifosine may be an effective drug for the treatment of HCC. Furthermore, their application in combination with sorafenib may have significant advantages compared with single-drug treatment in the treatment of HCC.

P0232
REDUCED TRANSCRIPTIONAL RESPONSIVENESS TOWARDS THE ANTI-CANCER DRUG IRINOTECAN IS MEDIATED BY A COMMON UGT1A HAPLOTYPE
S. Kalthoff[1], A. Winkler[1], C. Strassburg[1]. [1]*Universitätsklinikum Bonn, Medizinische Klinik I, Bonn, Germany*
E-mail: sandrakalthoff@hotmail.com

Background and Aims: A standard neoadjuvant therapy of colorectal cancer includes treatment with irinotecan. Its active metabolite SN-38 undergoes glucuronidation by different UDP-glucuronosyltransferases (UGT). A combination of several SNPs in the *UGT1A* genes (UGT1A1*28, UGT1A7*3) is associated with a higher risk for irinotecan toxicity including late diarrhea and leucopenia. To prevent unanticipated preoperative hepatotoxicity imposed by neoadjuvant chemotherapy, liver function including glucuronidation activity should represent an important consideration in therapeutic strategies. Aim of this study was therefore the analysis of irinotecan-mediated *UGT1A* gene regulation in presence and absence of *UGT1A* SNPs, as well as the expression of common *UGT1A* activating transcription factors (TF) [Aryl hydrocarbon receptor (AhR), NF-E2-related factor 2 (Nrf2)].
Methods: Humanized transgenic (htg)*UGT1A-WT* and *-SNP* (containing 10 common *UGT1A* SNPs) mice were treated with 25 mg/kg irinotecan for 4 days. RNA was isolated and mRNA expression was determined by TaqMan-PCR.
Results: In *htgUGT1A-WT* mice, irinotecan treatment led to the transcriptional upregulation of UGT1A1, UGT1A3, UGT1A4 and UGT1A9 mRNA in the liver (1.3–6 fold) and in the jejunum (2–10 fold). However, the highest irinotecan induced *UGT1A* upregulation was detected in the colon of *htgUGT1A-WT* mice (4–17 fold). In contrast, absolute *UGT1A* expression levels were reduced in *htgUGT1A-SNP* mice compared to *htgUGT1A-WT* mice. Analysis of the expression of TFs revealed that AhR expression was mainly induced in the liver, whereas Nrf2 expression was increased in the liver and in the intestine.
Conclusions: This is the first demonstration of *UGT1A* regulation by irinotecan. In contrast to the common assumption that the liver represents the most important organ for SN-38 glucuronidation, the considerable intestinal upregulation of *UGT1A* expression by irinotecan indicates that the intestine may be a significant location of SN-38 glucuronidation. Upregulation of AhR and Nrf2 by irinotecan indicates their direct role in *UGT1A* activation by irinotecan. The presence of *UGT1A* SNPs was associated with reduced *UGT1A* expression levels after irinotecan treatment in comparison to *htgUGT1A-WT* mice, which is a likely explanation for a higher risk for side effects in patients with *UGT1A* polymorphisms. Our data implicate that this effect should be considered as a risk factor for neoadjuvant therapies in patients with metastatic colorectal cancer and anticipated hepatic surgery.

P0233
MICRORNA-210 ENHANCES TUMOR ANGIOGENESIS BY TARGETING FGFRL1 IN HEPATOCELLULAR CARCINOMA
T. Xia[1], Yun Yang[2], G. Li[1], J. Zhang[2], Yuan Yang[2], Y. Wei[3], K. Lan[1], W. Zhou[2]. [1]*Institut Pasteur of Shanghai, Chinese Academy of Sciences,* [2]*Second Military Medical University, Shanghai, China;* [3]*Institut Pasteur, Paris, France*
E-mail: yu.wei@pasteur.fr

Background and Aims: Hypoxia is implicated in many aspects of tumor development and progression, especially for solid tumors like hepatocellular carcinoma (HCC). The master hypoxiamir miR-210 is upregulated in HCC tumor tissues, but its pathophysiological role and the relevance of the up-regulation to HCC has not been well established.
Methods: We analyzed miR-210 expression by qPCR in normal liver tissues, adjacent tumor tissues and hepatocellular carcinoma.
Results: We found that the expression level of miR-210 increases gradually from normal liver tissues to adjacent tumor tissues and to incipient and advanced tumor tissues. In HCC patients, high expression of miR-210 in tumor tissues associates with poor prognosis, on both overall survival ($P < 0.05$) and tumor free survival ($P < 0.05$). HCC tumors with high levels of miR-210 expression showed high scores of microvascular density by CD34 immunostaining. The pro-angiogenic role of miR-210 confirmed and evaluated through both *in vitro* and *in vivo* studies. Fibroblast growth factor receptor like 1 (FGFRL1) is a known direct target of miR-210. We demonstrate that extracellularly secreted FGFRL1 could attenuate the pro-angiogenic effects of fibroblast growth factor 2. By reducing FGFRL1, miR-210 might participate to cope with hypoxia stress during tumor genesis and development in HCC.
Conclusions: Our findings uncover a novel mechanism of hepatocarcinogenesis through enhancing angiogenesis by up-regulation of miR-210 in HCCs, which is correlated with poor prognosis, and open the perspective of targeting FGFRL1 for HCC drug development.

P0234
A TGF-BETA GENOMIC SIGNATURE IN INTRAHEPATIC CHOLANGIOCARCINOMA HIGHLIGHTS A NOVEL LONG NON CODING RNA LOCATED IN THE NUCLEAR PARASPECKLES OF TUMOR CHOLANGIOCYTES
A. Merdrignac[1], G. Angenard[1], D. Bergeat[2], A. Fautrel[1], B. Turlin[1], K. Boudjema[2], B. Clément[1], L. Sulpice[2], C. Coulouarn[1]. [1]*U991, INSERM,* [2]*Service de chirurgie hépatobiliaire et digestive, CHU de Rennes, RENNES, France*
E-mail: cedric.coulouarn@inserm.fr

Background and Aims: Intrahepatic cholangiocarcinoma (ICC) is the second most common type of primary cancer in the liver after hepatocellular carcinoma (HCC). ICC is an aggressive malignancy with a poor prognosis and limited therapeutic options. Recently, we reported that the overexpression of TGF-beta in the stroma of ICC correlates with a poor prognosis, suggesting that TGF-beta contributes to ICC progression. The aim of the present study is to investigate the role of TGF-beta and associated target genes, including long non coding RNA (lncRNA), in ICC.
Methods: Experiments were conducted in HuCCT1 and Huh28 ICC cell lines stimulated by TGF-beta. Gene expression profiling was done using pangenomic microarrays. The expression of relevant target genes was validated by RT-PCR. Cellular localization of lncRNA was determined by in situ hybridization in human ICC using tissue microarrays. Functional analysis was done by gain and loss of function experiments using expression plasmids and shRNA.
Results: We show that Huh28 cells display a high expression of mesenchymal markers (e.g. SNAI1, VIM) while epithelial markers (e.g. EPCAM, CDH1) are highly expressed in HuCCT1. In agreement with a mesenchymal phenotype, Huh28 cells exhibit a constitutive

activation of the TGF-beta pathway. Next, we established TGF-beta associated gene signatures in the two cell lines. Statistical analysis identifies 859 genes differentially expressed by TGF-beta ($p < 0.001$) in HuCCT1 and 491 genes in Huh28 cells, among those about 300 are in common. Interestingly, the signature includes lncRNA similarly deregulated in HuCCT1 and Huh28. The deregulation of known and new TGF-beta target genes is validated, including T-LINC-1, a lncRNA strongly up-regulated by TGF-beta. T-LINC-1 is induced by TGF-beta in ICC, HCC and hepatic stellate cells. TGF-beta inhibitors decrease the expression of T-LINC1 in Huh28 cells. Profiling of microdissected ICC shows that T-LINC-1 is up-regulated in tumor cholangiocytes and stromal cells. In situ hybridization reveals that T-LINC-1 localizes in the paraspeckles. Paraspeckles are subnuclear bodies critical to control of gene expression and acts as retention centers for specific RNA. Gain and loss of function experiments demonstrate that T-LINC-1 modulates the expression of NEAT1, another lncRNA required for paraspeckle structure.
Conclusions: Our study identifies a novel lncRNA induced by TGF-beta which may play a critical role in carcinogenesis by modulating paraspeckle activity in tumor cells.

PROTEIN N-TERMINAL ACETYLATION INHIBITION AS A NOVEL THERAPEUTIC TARGET FOR HEPATOCELLULAR CARCINOMA
D. D'Avola[1], L. Neri[2], M. Lasa[2], M. Iñarrairaegui[1], J.I. Herrero[1], J. Prieto[1,2], B. Sangro[1], R. Aldabe[2]. *[1]Liver Unit and Ciberehd, Clinica Universidad de Navarra, [2]Gene therapy and regulation of gene expression program, Centro de Investigación Medica Aplicada (CIMA), Pamplona, Spain*
E-mail: ddavola@unav.es

Background and Aims: The identification of new targets for systemic therapy in the treatment of hepatocellular carcinoma (HCC) is one of the main needs in HCC treatment. We have recently observed that hNatB enzyme catalyses N-*terminal acetylation* of 10% human proteome, being necessary for a proper activity of actin cytoskeleton, organelle with relevant implications in tumour development. Therefore, the aim of this study was to explore the therapeutic potential of NatB inhibition in HCC and its implication in HCC development and HCC patient prognosis.
Methods: hNatB expression was inhibited in HCC human cell lines, Huh7 and PLC/PRF/5, and the effects on cellular proliferation, signalling pathways and tumoral development were analysed in xenotransplant mouse model. Finally, hNatB subunits expression was analysed in paired tumor and non-tumoral samples from 31 HCC patients in BCLC A (74%) and B (26%) stages treated with liver resection or transplantation. The association of NATB expression and clinical, radiological and histological variables related to HCC prognosis was analysed. Chi-squared test was used for statistical analysis.
Results: hNatB expression inhibition resulted in the blockade of Huh7 and PLC/PRF/5 cell lines proliferation and in the impairment of their tumoral properties. This effect was associated with actin cytoskeleton disorganisation that results in YAP oncogene inactivation and in a reduced Epidermal Growth Factor (EGF)-mediated ERK activation. An overexpression of hNatB in tumor compared to non-tumor samples was observed in more than half of HCC patients (51%). Moreover, the overexpression of both NatB subunits was associated with microscopic vascular invasion ($p = 0.04$). No association between NatB overexpression and tumor stage, multinodularity or tumor differentiation was observed.
Conclusions: hNatB mediated protein N-terminal acetylation could be a new therapeutic target for the treatment of HCC and its overexpression could be related to more aggressive phenotype of HCC as it is associated with microvascular invasion.

P0236
ROLE OF YAP SIGNALLING DEREGULATION IN THE GENETIC SUSCEPTIBILITY TO HEPATOCARCINOGENESIS, AND STEMNESS AND AGGRESSIVITY OF LIVER CANCER
R.M. Pascale[1], G. Latte[1], R. Pola[1], L. Daino[1], M.A. Seddaiu[1], M.M. Simile[1], M.I. Demartis[1]. *[1]Dpt Clinical & Experimental Medicine. Div Experimental Pathology & Oncology, University, Sassari, Italy*
E-mail: patsper@uniss.it

Background and Aims: Recent observations suggest a contribution of YAP upregulation to hepatocellular carcinoma progression (HCC). We analyzed the connection of YAP deregulation with genetic susceptibility to hepatocarcinogenesis and HCC stemness and aggressivity.
Methods: HCC was induced in F344 and BN rats, genetically susceptible and resistant to hepatocarcinogenesis, respectively. Human HCCs with poorer prognosis (<3 years survival, after partial liver resection, HCCP) and HCCs with better outcome (>3 years survival; HCCB) were archival samples. Gene expression was evaluated by quantitative PCR and immunoblotting, and functional experiments were done with HepG2, Huh7, and Hep3B liver cell lines.
Results: Higher upregulation of Yap and of its target Ctgf, in F344 rat HCC than in BN HCC, was associated with highest increase in Yap-tyr357, p73 phosphorylation, and Caspase 3 cleavage in BN HCC. Upregulation of YAP, CTGF, 14–3-3 and YAP-14–3-3 complex, TEAD and YAP-TEAD complex in HCC reached highest values in HCCP. In contrast, YAP-ser127 decreased in HCC with lowest values in HCCP, and YAP-tyr357, p73 phosphorylation and Caspase 3 cleavage showed highest increase in HCCB. Stem cell markers NANOG, OCT3–4, and CD133 upregulation progressively increased from HCCB to HCCP and was significantly correlated to YAP and YAP-TEAD expression. Growth rate was 2.5–3 times lower, between 48 and 96 hours, in HepG2 s than in Huh7 and Hep3B cells. This was associated, at 48 hours, with lower YAP and NANOG, OCT3–4, and CD133 expression in HepG2 than in Huh7 and Hep3B cells. YAP downregulation by specific siRNA in Huh7 and HepG3 cells led to significant decrease in NANOG, OCT3–4, and CD133 expression. In contrast, sharp upregulation of stem cell markers was induced in HepG2 cells by forced *YAP* overexpression.
Conclusions: Our results indicate: (1) YAP signalling deregulation in HCC is under genetic control. (2) Genetic resistance to HCC is associated with highest phosphorylation of Yap at tyr357 and p73, and highest apoptosis. (3) YAP changes favoring the formation of YAP-14–3-3 and YAP-TEAD complexes, associated with cell survival, contribute to HCC aggressivity. In contrast, YAP changes favoring apoptosis, such as phosphorylation at tyr357, are associated with better HCC prognosis. (4) YAP upregulation favors HCC stemness and aggressivity.

HEPATOCELLULAR CARCINOMA: APPLIED GENOMICS TO DIAGNOSTIC AND PERSONALIZED THERAPY
S. Llerena[1,2], N. García[2], C. Rodriguez de Lope[1,2], L. Cereceda[2], L. Martin[1,2], C. Lopez[3], C. Cagigas[4], F. Castillo[4], A. Azueta[5], M.A. Piris[2,5], J.P. Vaqué[2], J. Crespo[1,2]. *[1]Hepatology Unit, Hospital Universitario Marqués de Valdecilla, [2]IDIVAL, [3]Oncology Unit, [4]General Surgery Unit, [5]Pathological, Hospital Universitario Marqués de Valdecilla, Santander, Spain*
E-mail: susanallerena@hotmail.com

Background and Aims: The application of targeted therapies as a result of precise molecular diagnosis of human cancer is now improving the clinical outcome of patients with melanoma (BRAF), breast (HER2) or lung cancer (EML-ALK) but not of those with hepatocellular carcinoma (HCC). From a genomic perspective, HCC is very heterogeneous with a low mutational recurrence and in advanced stages, sorafenib offers a suboptimal efficacy (OS =

11 months). We have decided to analyze specific mutational signatures to support precise molecular diagnostics with potential to guide the design of individualized targeted therapies.
Methods: *Selection of HepatoExoma:* Based on studying the NGS data already available for HCC, we have designed a targeted NGS platform (HepatoExoma) to study, in individual lesions, the somatic mutations detected among a selection of "actionable" genes potentially associated with inhibitory drugs. This can allow the characterization of specific microclonal dynamics and potentially guide the use of targeted therapies based on specific mutational signatures. For this, we have focused on studying the coding DNA of 114 genes using an enrichment library kit (HaloPlex, Agilent) compatible with ultrasequencing approaches.
Samples: (A) Commercial HCC cells with a known mutational profile (CCLE-Broad Institute). (B) Paired genomic DNA (normal vs tumoral) from HCC patient samples obtained from transplantation, resection or biopsy.
Results: *In silico:* We have confronted the genes included in our design to the WES data from 88 patients (Xiao Liu, 2013). We could detect alterations in 67% of the patients and up to 45.5% of these, with 2 "actionable" mutations that we can potentially associate to a targeted treatment using 2 drugs alone or in combination. HCC cell lines showed and average of 11 mutations with HepG2 (i.e.) being susceptible to targeted treatment using 4 drugs.
Experimental: (A) Biological and functional studies of specific targeted therapies for HCC cells. (B) Mutational data of 9 patients analyzed by HepatoExoma.
Conclusions: (1) The HepatoExoma allows the generation of data that can potentially guide a personalized therapy in 45.5% of HCC patients.
(2) Mutational data from preclinical HCC models allowed us to explore the effects of rationally designed targeted therapies with improved activity.
(3) In the near future, we will be able to test these therapies in murine xenografts or isolated hepatocyte from patients.

P0239
TUMORIGENIC POTENTIAL OF CANCER STEM CELLS (CSCS) ISOLATED FROM HUMAN CHOLANGIOCARCINOMA (CCA) SUBTYPES IN CIRRHOTIC MICROENVIRONMENT

E-mail: vincenzo.cardinale@uniroma1.it

Background and Aims: Cholangiocarcinomas (CCA) are comprised histologically of a mucin-secreting type, which can be intrahepatic (IHCCA) or perihilar (pCCA), and, of a mixed type located peripherally within the liver. We characterized cancer stem cells (CSCs) in CCA subtypes and evaluated their cancerogenic potential.
Methods: CSC markers (CD90, CD13, EpCAM, CD133, LGR5) were investigated in 25 human CCAs, in primary cultures and established cell lines. Tumorigenic potential was evaluated in vitro or in xenografted mice after subcutaneous or intrahepatic injection in normal and cirrhotic (CCL4) mice.
Results: CSCs comprise more than 30% of the tumor mass. While the CSC profile was similar between mucin-IHCCA and mucin-pCCA, CD13+ CSCs characterize the mixed-IHCCA while LGR5+ characterize the mucin-CCA subtypes. A significant percentage of neoplastic cells express epithelial–mesenchymal transition (EMT) markers (SNAIL, Twist), and co-express mesenchymal and epithelial markers. In primary cultures, EMT markers, mesenchymal markers (vimentin, CD90), and CD13 were largely more expressed than the "epithelial" markers (CD133, EpCAM and LGR5). In vitro, CSCs expressing "epithelial" markers formed a higher number of spheroids than CD13+ or CD90+ CSCs. In subcutaneous tumor xenografts, tumors dominated by stromal markers were formed primarily by CD90+ and CD13+ cells. By contrast, in intrahepatic xenografts, in the cirrhotic livers, tumors were dominated by epithelial traits resembling the original human CCAs.
Conclusions: CSCs were rich in human CCAs (>30%), implicating CCAs as stem cell based diseases. Different CSC subpopulations expressed EMT markers and co-expressed mesenchymal and epithelial markers, generating different types of cancers depending on the microenvironment. Remarkably, CSCs may reproduce the original human CCAs, when injected into cirrhotic livers.

PROTEOMIC ANALYSIS OF TISSUE INTERSTITIAL FLUID FOR IDENTIFICATION OF NOVEL SERUM CANDIDATE DIAGNOSTIC MARKER FOR HEPATOCELLULAR CARCINOMA

W. Sun[1], Z. Liu[1], L. Guo[2], B. Xing[3], J. Mu[4], L. Sun[1], H. Wei[1], X. Zhao[5], X. Qian[1], Y. Jiang[1], F. He[1,6]. *[1]State Key Laboratory of Proteomics, Beijing Proteome Research Center, Beijing Institute of Radiation Medicine, [2]AB SCIEX, [3]Beijing Cancer Hospital, 4302 Hospital of PLA, [5]Cancer Institute & Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, [6]Institutes of Biomedical Sciences Fudan University, Shanghai, China*
E-mail: sunway21cn@126.com

Background and Aims: Hepatocellular carcinoma (HCC) is the fifth most common malignant cancer in the world. The sensitivity of alpha-fetoprotein is still inadequate for clinical diagnosis of HCC and identification of new biomarkers is greatly needed.
Methods: Tissue interstitial fluid (TIF), as the liquid microenvironment of cancer cells, has been demonstrated as a promising material for biomarker discovery. In order to identify proteins highly expressed in HCC TIF for further validation, a proteomic technique named iTRAQ (isobaric tag for relative and absolute quantitation) was used to analyze paired tumor and nontumor TIF samples from 6 HBV-HCC patients.
Results: Totally, 241 up-regulated proteins (ratio tumor/nontumor ≥1.3, $p < 0.05$) and 288 down-regulated proteins in tumor TIF ($ratio_{tumor/nontumor} \leq -1.3$, $p < 0.05$) were identified. Proteins involved in lipid metabolism, cell cycle, cellular movement and cell morphology were up-regulated in HCC samples, while proteins involved in amino acid metabolism were down-regulated. Interestingly, we found the up-regulation of S100 family proteins and down-regulation of glutathion-s-transferase and leptin related proteins in tumor. One dramatically up-regulated protein S100A9 ($ratio_{tumor/nontumor}=19$) which plays a prominent role in the regulation of inflammatory processes and immune response was further validated by ELISA in sera from liver cirrhosis (LC, HCC high risk population) and HCC patients ($n = 47$ for each group). The level of this protein was significantly elevated in HCC sera (256 ± 167 ng/ml) compared with LC (112 ± 119 ng/ml). The area under the curve of this protein to distinguish HCC from LC was 0.83, with sensitivity of 91% and specificity of 66%.
Conclusions: Our result till now showed that S100A9 could be a candidate HCC biomarker for further validation in larger populations. And TIF was a promising material to identify candidate tumor biomarkers that could be detected in serum.

P0241

CD40/CD40LIGAND INTERACTION BETWEEN TUMOR LYSATE-PULSED DENDRITIC CELLS INDUCES A TH1-ENVIRONMENT AND ENHANCES THE CYTOTOXIC ACTIVITY OF IMMUNOLOGIC EFFECTOR CELLS TOWARDS HUMAN HEPATOCELLULAR CARCINOMA AND CHOLANGIOCELLULAR CARCINOMA CELLS

A. Vogt[1], R.M. Hillebrand[2], E. Raskopf[1], I.G. Schmidt-Wolf[2], C.P. Strassburg[1], M.A. Gonzalez-Carmona[1]. *[1]Department of Internal Medicine I, [2]Center for Integrated Oncology (CIO), University of Bonn, Bonn, Germany*
E-mail: Annabelle.Vogt@ukb.uni-bonn.de

Background and Aims: Dendritic cells (DC) are professional antigen presenting cells able to prime T-cells against tumor-associated antigens (TAA). The interaction of CD40 on DC and CD40L on effector cells is a potent co-stimulatory signal for an effective cellular immune response. In this study, the impact of CD40/CD40L-interactions between human DC on the induction of tumor-specific effector cells was analyzed towards human hepatocellular (HCC) and cholangiocellular (CCC) carcinoma cells *in vitro*.
Methods: Adenoviral vectors encoding human (h)CD40L were generated using the Adeno-Easy system. Peripheral blood lymphocytes were isolated from healthy donors by Ficoll density gradient-centrifugation to obtain DC and lymphocytes. DC were pulsed with tumor-lysates and transduced with Ad-hCD40L or Ad-Mock (control) on day 6. Expression of DC-maturation marker and cytokines were studied by flow cytometry and ELISA respectively. Lymphocytes were stimulated with CD3, IL-2, IFN-gamma and IL-1beta and co-cultured with DC. Ability to lyse HCC- (HepG2, Huh7 and CCL13) or CCC-cells (EGI-1 and Mz-ChA-2) was determined using a LDH (lactate-dehydrogenase)-based cytotoxicity assay. Apoptosis of tumor cells was studied by quantification of sub-G1-fraction by flow cytometry.
Results: Transduction with Ad-hCD40L induced a strong interaction between human DC due to the expression of hCD40L in more than 35% of DC. CD40/CD40L between the human DC induced a strong expression of Th1 cytokines, such as IL-12 and IFNgamma in DC-supernatant, as well as increased expression of CD83 (90%) and CCR7 (60%) on DC surface compared to Ad-Mock-transduced DC or non-transduced DC ($p < 0.05$). Moreover, specific lysis of human HCC- or CCC-cells was significantly ($p < 0.05$) higher, when effector cells were co-cultured with Ad-hCD40L-transduced DC than Ad-Mock-transduced or non-transduced DC. Interestingly, coculturing of tumor cells with the supernatant of hCD40L-expressing DC was able to induce a significant higher apoptosis in tumor cells.
Conclusions: Adenoviral-mediated expression of hCD40L is able to induce a strong CD40/CD40L-interaction between human DC. This interaction induces a Th1-environment increasing significantly the stimulatory capacity of TAA-pulsed DC and the apoptosis induction towards HCC- and CCC-cells. Thus, these results underline the potential of CD40/CD40L-interaction to improve the immunotherapy of TAA-pulsed DC towards HCC and CCC.

P0242

LIVER FIBROSIS PROMOTES HEPATOCARCINOMA GROWTH ACCORDING TO THE SEVERITY OF FIBROSIS IN AN ORTHOTOPIC TUMOR MODEL IN MOUSE

B. Delire[1], I. Leclercq[1], P. Stärkel[1,2]. *[1]Laboratory of Hepato-Gastroenterology, Université Catholique de Louvain, Institut de Recherche Expérimentale et Clinique, [2]Service d'hépato-gastroentérologie, Cliniques Universitaires St Luc, Université Catholique de Louvain, Brussels, Belgium*
E-mail: benedicte.delire@uclouvain.be

Background and Aims: HCC is associated in 90% of cases with cirrhosis. However, the fibrosis-dependent mechanisms of hepatocarcinogenesis remain poorly understood. MMP-2, -9 and Membrane-Type 1 (MT1)-MMP are endopeptidases that cleave the extracellular matrix and are related to HCC invasiveness. Our aim was to study the impact of fibrosis and its severity on HCC development and to evaluate the tumor expression of MMP-2, -9 and MT1-MMP according to the liver fibrosis status in an orthotopic transplantation model.
Methods: The HCC cell line Hepa 1–6 is syngenic with the C57Bl/6 mouse strain and is characterized by a constitutive expression of αFP. Hepa 1–6 cells (1×10^6) were injected into the liver by direct puncture in 3 groups of mice ($n = 10$/group): in non-fibrotic liver (normal liver group-NLG), in mild fibrotic liver (mild fibrosis group-MFG) and in severe fibrotic liver (severe fibrosis group-SFG). Mild and severe fibrosis were induced by CCl_4 injections for 2 and 7 weeks respectively. Mice were sacrificed 2 weeks post HCC cell injection. The liver was sliced and examined for the presence of tumor (nodule ≥1 mm). The tumor volume (TV) and the liver to body weight ratio (LW/BW) were used as parameters of tumor burden. A part of each tumor was used for histological analysis and the other for RNA preparation.
Results: A tumor nodule was observed in 60%, 80% and 100% of animals in the NLG, MFG and SFG respectively. The TV and the LW/BW were significantly higher in the MFG ($p = 0.05$ and $p = 0.04$) and in the SFG ($p = 0.03$ and $p = 0.02$) compared to the NLG. Both parameters were also higher in the SFG compared to the MFG ($p = 0.03$; $p = 0.04$). Compared to surrounding liver, αFP mRNA expression was high in all tumors, and significantly higher in SFG tumors compared to both MFG and NLG tumors ($p = 0.02$ and $p = 0.005$, respectively). Intra-tumor expression of MMP-2, -9 and MT1-MMP gradually and significantly increased with fibrosis severity at the time of tumor implantation (NLG < MFG < SFG). Furthermore, there was a positive and significant correlation between TV and LW/BW and the intra-tumor expression of all MMPs.
Conclusions: Our results demonstrate that liver fibrosis promotes HCC development in our model and suggest a link between the severity of fibrosis and the ability of liver cancer to develop. Moreover, we have shown an enhanced MMP-2, -9 and MT1-MMP expression in the tumors of the fibrosis group suggesting a role of the MMPs and matrix remodeling in the fibrosis-dependent promotion of HCC development.

P0243

ROLE OF S100A8/A9 IN CARCINOGEN-INDUCED HEPATOCELLULAR CARCINOMA ONSET AND DEVELOPMENT

A. De Ponti[1], D. Schneller[1], T. Pusterla[1], L. Wiechert[1], T. Longerich[2], A. Vogel[3], J. Hess[1], P. Angel[1]. *[1]Division Signal Transduction and Growth Control (A100), German Cancer Research Center (DKFZ), [2]Institute of Pathology, University Hospital Heidelberg, Heidelberg, [3]Department of Hepatology, Medical School Hannover, Hannover, Germany*
E-mail: d.schneller@dkfz.de

Background and Aims: S100A8 and S100A9 are calcium binding proteins which play a prominent role in the regulation of inflammatory processes. They predominantly form functional anti-parallel heterodimers (S100A8/A9), termed calprotectin. In the extracellular space they act as danger signals by bindung to different receptors such as RAGE (Receptor for Advanced Glycation-End products). Epidemiological studies show increased expression of S100A8 and S100A9 in human hepatocellular carcinoma (HCC), and a strong correlation of both proteins with poorly differentiated cancer. *In vitro* and *in vivo* results suggest a role of calprotectin in liver inflammation and damage, and a pro-tumorigenic function in HCC.
We already demonstrated that ablation of *Rage* impaired tumor development in the inflammation-driven *Mdr2*$^{-/-}$ model, where it reduced number and size of tumors and limited liver damage. On the contrary, in the cirrhosis-free diethylnitrosamine (DEN)

mouse model *Rage* depletion did not influence HCC development, emphasizing that RAGE is essential only in settings of chronic injury.
Absence of *S100a9* in the inflammation-driven *Mdr2*$^{-/-}$ model did not affect HCC development nor liver damage. To address the question if a different tumor microenvironment can influence the role played by S100A8/A9 in HCC onset and development, we investigated hepatocarcinogenesis in an inflammation-free context.
Methods: *S100a9*$^{-/-}$ mice were treated with the procarcinogen DEN, an alkylating agent that causes initial liver damage and promotes DNA-strand breaks, thus leading to HCC formation. Mice were scrificed at 6, 9 and 12 month of age in order to characterize the livers at premalignant and malignant stages.
Results: Lack of *S100a9* significantly reduced the size of tumors in the DEN model. This reduction in tumor size was associated with reduced tumor cell proliferation. Additionally, *S100a9*$^{-/-}$ mice exhibited a higher number of apoptotic cells.
Conclusions: In the *Mdr2*$^{-/-}$ model, the absence of an obvious phenotype due to *S100a9* ablation suggests that other molecules compensate for the lack of calprotectin in tumor development. Our results demonstrate that in contrast to HCC development preceded by chronic hepatitis, liver damage and fibrosis, S100A8/A9 affects hepatocarcinogenesis in an inflammation-free context, where compensatory mechanisms might be absent.

P0244
THIENO-TRIAZOLODIAZEPINES BLOCK HEPATOCARCINOMA PROGRESSION BY HSP-DEPENDENT KINOMA INHIBITION

E. Ceni[1], M. Tarocchi[1], S. Polvani[1], G. Marroncini[1], S. Tempesti[1], T. Mello[1], A. Galli[1]. [1]*Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy*
E-mail: mirko.tarocchi@unifi.it

Background and Aims: Hepatocellular carcinoma (HCC) is one of the most common malignancies worldwide. So far there is no effective chemotherapeutic treatment for HCC and the prognosis of advance stage remains poor. The thieno-triazolodiazepine are well known anti-inflammatory drugs that act as PAF-receptor antagonists. Recently an antineoplastic pleiotropic effect have been shown in hematologic tumors where treatment with two different thieno-triazolodiazepine WEB2086 and WEB2170 induces differentiation, growth arrest and apoptosis in leukemia cells. The effects of these drugs on solid tumors such as HCC remain untested.
Aim of this study was to investigate the anti-tumor efficacy of the thieno-triazolodiazepines in in vitro and in vivo models of HCC.
Methods: We tested the effect of WEBs treatment in several hepatoma cell lines evaluating proliferation, apoptosis, invasiveness, cell cycle, autophagy and senescence. We also studied the in vivo efficacy of these molecules in a HBV transgenic mouse model, that spontaneously develop hepatic tumors, and in nude mice injected subcutaneously with human HCC cells.
Results: WEBs were able to reduce the proliferation of cancer cells as assessed by thymidine incorporation and to eliminate the ability of these cells to form colonies in soft agar. This abrogation of anchorage dependent and independent cell growth was associated with cell cycle arrest, apoptosis, vitality reduction, and senescence induction. In addition, WEBs impair hepatoma cell migration and chemoinvasion. WEBs administration in HBV transgenic mice reduce the number and the dimension of tumors, and abrogated the levels of alpha-fetoprotein. Antitumorigenic effects in vivo were also confirmed in a xenograft model of HCC. A 2D-DIGE proteome study highlights that the WEB2086 inhibits the binding processes in particular inhibits protein binding of ATP and GTP and abrogation of this cellular function results kinoma inhibition. In addition 2D-DIGE analysis showed that WEBs down-regulate chaperone proteins such as hsp90 and hsp70 that are involved in protein refolding, an important mechanism in tumor cel resistence. The down-regulation of Hsp90 leads to failure of "client" protein refolding and mediates their degradation.
Conclusions: The thieno-triazolodiazepine are able to reduce HCC progression in human and murine HCC models blocking cancer cell proliferation and migration, and inducing apoptosis and senescence probably whit a mechanism that involve kinome inhibition.

P0245
THE IL-6/SIL6R AND STAT3 AXIS IS CRUCIAL FOR HEPATOPROTECTION AND SUPPRESSION OF LIVER CANCER IN FEMALE MICE WITH CHRONIC LIVER INJURY

J.H. Axelrod[1], T. Lanton[1], A. Shriki[1], A. Sonnenblick[2], R. Abramovitch[3], O. Pappo[4], A. Peled[1], S. Rose-John[5], E. Galun[1]. [1]*Goldyne Savad Institute of Gene Therapy,* [2]*Oncology,* [3]*Magnetic Resonance Imaging/Magnetic Resonance Spectroscopy Laboratory,* [4]*Pathology, Hadassah Hebrew University Hospital, Jerusalem, Israel;* [5]*Institut für Biochemie, Univ. of Kiel, Kiel, Germany*
E-mail: axelrod@hadassah.org.il

Background and Aims: Hepatocelluar carcinoma (HCC) commonly develops on a background of chronic hepatitis. Evidence from experimental animal models based on chemical-induced HCC associated with *acute* liver injury, suggests that the inflammatory cytokine, interleukin-6 (IL-6), is a crucial, gender-determined factor driving hepatocarcinogenesis. However, in *chronic* liver injury models, IL-6 is also known to be hepatoprotective. As such, its role in chronic hepatitis-associated liver cancer remains unresolved. We investigated the role of IL-6 and signal transducer and activator of transcription 3 (Stat3), one of the main mediators of IL-6 signal transduction, in liver cancer in multidrug resistant gene 2 (*Abcb4*) knockout mice (Mdr2$^{-/-}$), a physiologically relevant model of chronic hepatitis-associated HCC.
Methods: IL6 knockout mice (IL-6$^{-/-}$), and hepatocyte-targeted Stat3 knockout mice (Stat3$^{\Delta hep}$), were crossed into Mdr2$^{-/-}$ mice generating Mdr2$^{-/-}$IL6$^{-/-}$ and Mdr2$^{-/-}$Stat3$^{\Delta hep}$ mice, respectively. Additionally, a transgene encoding sgp130Fc – a selective inhibitor of IL-6 *trans*-signaling mediated by the soluble IL-6 receptor (sIL-6R) – was introduced into Mdr2$^{-/-}$ mice to generate Mdr2$^{-/-}$sgp130Fc mice. Female littermates were followed over the course of 16 months for analysis of hepatitis and tumor development.
Results: Mdr2$^{-/-}$IL6$^{-/-}$ developed increased liver injury and fibrosis, accompanied by reduced Stat3 phosphorylation, in comparison to Mdr2$^{-/-}$ controls. Ultimately, IL-6 deficiency strongly exacerbated tumor development in Mdr2$^{-/-}$ mice. Increased tumorigenesis correlated with a more pronounced inflammatory response, including increased neutrophil and macrophage infiltration to periductal regions, and notably increased dysplastic nodules. Likewise, Mdr2$^{-/-}$sgp130Fc mice displayed a similar phenotype of reduced Stat3 phosphorylation and increased liver injury. Mdr2$^{-/-}$sgp130Fc mice also eventually displayed significantly increased tumorigenesis associated with elevated levels of dysplastic nodules, but without a corresponding change in hepatic inflammation or fibrosis. Finally, hepatocyte-targeted Stat3 inactivation in the Mdr2$^{-/-}$Stat3$^{\Delta Hep}$ mice also resulted in significantly increased liver injury, more and larger dysplastic nodules in the liver parenchyma, and significantly increased tumorigenesis.
Conclusions: Our findings reveal that IL-6 signaling, mediated by sIL-6R and Stat3, promotes resistance to chronic hepatitis and liver cancer in female Mdr2$^{-/-}$ mice.

P0246

POTENT AKT/PKB INHIBITOR REDUCES AKT PHOSPHORYLATION AND TUMOR CELL GROWTH IN VITRO AND IN VIVO

K. Mäemets-Allas[1], J. Viil[1], V. Jaks[1]. [1]*Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia*
E-mail: kristina902@gmail.com

Background and Aims: The serine/threonine kinase AKT/PKB has a critical role in regulating cell growth by mediating signals from multiple growth factor receptors to a plethora of downstream targets that regulate cell survival, proliferation and apoptosis. Since AKT signaling is deregulated in a number of human malignancies it is an attractive anticancer drug target. Constitutively activating mutations in growth factor receptor genes are a common event in human cancers and result in elevated levels of AKT phosphorylation. Abnormal activation of the AKT pathway is a common event in cancers, most notably in liver, prostate, breast and colorectal carcinoma. Consequently, inhibiting/reducing AKT activity is considered to be an effective approach in anticancer therapy.
Methods: Protein complementation assay based on Renilla luciferase fragments was used to screen small molecule inhibitors from NCI Diversity Set. Reduction of AKT activity and effect on the AKT downstream targets was detected with Western Blot method. Inhibition of cell growth in vivo was confirmed by tumor xenograft model. Tumor xenografts were analysed by immunofluorescence.
Results: We have found a small molecule compound that could be a potent and selective inhibitor of Akt1 signaling pathway in tumor cells. Selected compound reduces Akt activity, inhibits the activity of AKT target proteins that are involved in regulating cell survival, proliferation and metabolism, reduces the growth of tumor cells in vitro and in vivo by increasing the differentiation status of cancer cells. Additional studies are required to elucidate the exact mechanism of Akt activity inhibition. The ability of the compound to reduce growth of human tumor xenografts in nude mice suggests its potential use as a anti-tumor agent and warrants for further research in this direction.
Conclusions: In conclusion, we have identified a potent inhibitor of AKT1-PDPK1 interaction that reduced the level of activated AKT in different experimental settings and shows a high potential to be used as a lead compound for desgning novel anti-tumor agents.

P0247

C1GALT1 IS OVEREXPRESSED IN CHOLANGIOCARCINOMA AND C1GALT1 KNOCKDOWN INHIBITS MALIGNANT BEHAVIORS OF CHOLANGIOCARCINOMA CELLS

M.-C. Huang[1], M.-J. Huang[1], Y.-M. Wu[2]. [1]*Graduate Institute of Anatomy and Cell Biology, National Taiwan University College of Medicine,* [2]*Department of Surgery, National Taiwan University Hospital, Taipei, Taiwan*
E-mail: mchuang@ntu.edu.tw

Background and Aims: Cholangiocarcinoma (CCA), arising primarily from the epithelial lining of bile ducts, is a highly lethal liver cancer. O-glycosylation is a common post translational modification of proteins. Beta-1,3-galactosyltransferase (C1GALT1) transfers galactose (Gal) to GalNAc-Ser/Thr (Tn antigen) to form Gal-GalNAc-Ser/Thr structure (T antigen). Tn and T antigens are often associated with tumor progression and altered expression of C1GALT1 has been found to regulate cancer behaviors. However, the expression and function of C1GALT1 in CCA has never been reported. The aim of this study is to investigate the expression of C1GALT1 in primary CCA tissues and the functional roles of C1GALT1 in CCA cells.
Methods: To analyze the expression of C1GALT1, immunohistochemical staining of C1GALT1 in tissue microarrays comprising CCA and normal bile ducts was performed. Knockdown of C1GALT1 with specific siRNAs was performed in CCA cell lines HUCCT1 and SNU1079. Cell viability was analyzed by MTT assay. Cell migration and invasion were analyzed by transwell migration and matrigel invasion assay, respectively.
Results: Our study shows that over 80% of CCA tissues exhibit significantly higher C1GALT1 expression levels than normal bile duct. Moreover, C1GALT1 knockdown significantly suppressed viability, migration, and invasion of CCA cells.
Conclusions: C1GALT1 is frequently up-regulated in CCA and the expression of C1GALT1 is able to regulate the malignant behaviors of CCA cells, suggesting that C1GALT1 is a potential target of therapeutic drug development.

H-1 PARVOVIRUS: A NEW THERAPEUTIC STRATEGY TARGETING HEPATOCELLULAR CARCINOMA

O. Morales[1], E. Boleslawski[2], D. Mrizak[3], M. Fenghour[1], J. Rommelaere[4], Y. deLaunoit[1], N. Delhem[1]. [1]*UMR 8161, CNRS,* [2]*Service de Chirurgie Digestive et Transplantations – Hôpital Huriez, CHRU de LILLE,* [3]*UMR 8161, CNRS UMR8161 IRCV team, Lille, France;* [4]*Tumor Virology, DKFZ, Heidelberg, Germany*
E-mail: olivier.morales@ibl.cnrs.fr

Background and Aims: Despite a diverse therapeutic arsenal, survival after treatment of hepatocellular carcinoma (HCC) remains mediocre. These discouraging results make it necessary and urgent to explore new therapeutic strategies. In this sense, the parvovirus H-1 (H-1 PV) is a small oncolytic virus that is capable of selectively destroying cancer cell lines. In this context, the aim of my project is to assess and validate the oncolytic and oncotropic properties of H-1 PV in HCC models to consider its use as an alternative to conventional treatments.
Methods: The oncolytic effect of H-1 PV was evaluated in vitro on a hepatocarcinoma cell line (HuH7) and ex vivo on human HCC explants from hepatectomy pieces and put into primary culture. The cells were infected with increasing amounts of H-1 PV (MOI 1.10 and 100). Cell viability was assessed by a qualitative (microscopy) and quantitative method (MTT). The expression of the viral marker NS1 was analyzed (Western blot) to validate specific H-1 PV lysis. The ability of tumor cells to produce the neo-virions was measured by viral titration (TCID50). These same experiments were used to test the susceptibility of hepatocytes, biliary cells and healthy intrahepatic fibroblasts regarding H-1 PV. Finally, the expression of genes encoding α-SMA and collagen I, III and IV were measured (RT-QPCR) in infected intrahepatic fibroblasts to assess the impact of the virus on the liver fibrogenesis.
Results: The results obtained show that HuH7 as well as tumor hepatocytes in primary cultures are susceptible to H-1 PV-induced oncolysis, with a decrease in cell viability that is dose-dependent and related to the expression of the viral protein NS1. Unlike HuH7, tumor hepatocytes do not produce neo-virions in the culture supernatants. Furthermore, no significant decrease in viability was observed in hepatocytes nor in intratumoral fibroblasts isolated from healthy livers. And, a similar result was obtained for the healthy biliary cells. In these three non-tumor cell types, no expression of the NS1 protein, and no neo-virions were detected. Finally, the analysis by RT-QPCR healthy intrahepatic fibroblasts infected with H-1 PV, shows a decrease in the expression of genes encoding proteins involved in hepatic fibrogenesis.
Conclusions: These experiments show for the first time that H-1 PV is capable of selectively destroying cells from human HCC while sparing healthy cells surrounding the tumor, suggesting new perspectives for HCC treatment.

P0250

EFFECT OF IRREVERSIBLE ELECTROPORATION (IRE) ON THE PORCINE LIVER: COMPARISON WITH RADIOFREQUENCY ABLATION

Y. Kobayashi[1], F. Moriyasu[1], K. Sugimoto[1], M. Ando[1], T. Sano[1], I. Nakamura[1], H. Oshiro[2]. *[1]Department of Gastroenterology and Hepatology, [2]Department of Pathology, Tokyo Medical University, Tokyo, Japan*
E-mail: ykobaya@tokyo-med.ac.jp

Background and Aims: Irreversible electroporation (IRE) is a promising, non-thermal ablation therapy for hepatocellular carcinoma, which, unlike radiofrequency thermal ablation (RFA), induces apoptosis through irreversible formation of nanoscale pores in the cell membrane with delivery of high-voltage electric current and is considered to improve safety in the vicinity of heat-sensitive blood vessel and bile duct. The aim of the present study is to clarify the acute pathological effect of IRE on the liver and also to compare with effect of RFA.
Methods: Three pigs underwent ultrasound-guided IRE and RFA of normal liver under general anesthesia and at laparotomy. A total of 9 IRE ablated areas and 3 RFA ablated areas were created. We examined histopathologic findings of ablated areas at 4 hours after therapy with immunohistochemical methods. The pathologic findings according to IRE ablation conditions were compared with findings of RFA.
Results: In IRE zones, various degree of congestion and hemorrhage, apoptotic change of hepatocytes, defluxion of portal endothelial cells and cholangitis were observed in hepatic lobules. With the increase in the total pulse number of IRE delivered, these pathological findings became remarkable. NADPH-diaphorase enzyme histochemistry performed in IRE zones demonstrated the stainability is very weak in the hepatic lobule, which reflecting defluxion of hepatocytes and reduced activity of viable hepatocytes in acute phase, while the stainability is lost in the central portion of RFA. Silver impregnation stain and collagen type 4 immunohistochemistry showed that reticular fibers and collagen fibers around the sinusoid remain well-preserved in IRE zones, on the other hand, those in RFA zones are very poorly stained. The vessels in IRE zones demonstrated a relatively intact configuration of positive smooth muscle cells for Caldesmon staining and endothelial cells for Factor 8 staining, with the minimal endothelial damage, while the vessels in RFA zones demonstrated a negative or weakened reaction. Bile duct epithelial cells showed a positive reaction for cytokeratin 7 staining in IRE zones with desquamated cells, while an entirely negative reaction in RFA zones, revealing protein denaturation.
Conclusions: Unlike RFA, IRE induces apoptosis of hepatocytes, endothelium of the blood vessels and mucosal membrane of the bile ducts, whereas preservation of sinusoidal framework and vascular structure may have the potential for liver regeneration.

P0251

HBx SENSITIZE HEPATOCELLULAR CARCINOMA CELLS TO LAPATINIB BY UP-REGULATING ErbB3

J.-Y. Chen[1]. *[1]The Ph.D. program for Cancer Biology and Drug Discovery, China Medical University, Taichung, Taiwan*
E-mail: yiakudo@hotmail.com

Background and Aims: Compelling evidence indicates epidermal growth factor receptor (EGFR/ErbB) family is critical for the tumor progression of hepatocellular carcinoma (HCC) cells, but EGFR/HER2 tyrosine kinase inhibitors (TKIs) showed less therapeutic benefits in unselected HCC patients in clinical trials. Notably, the activations of ErbB family and their downstream signaling pathways have been reported to be associated particularly with the poor prognosis of hepatitis B virus (HBV)-associated HCC, suggesting that HBV may modulate ErbB family signaling. HBV X (HBx) protein has been reported to regulate the cellular sensitivity to chemotherapy, but its roles in therapeutic efficacy of EGFR/HER2 TKIs remain unknown. In this study, we aim to investigate whether and how HBx affects the cellular sensitivity of HCC cells to EGFR/HER2 TKIs.
Methods: The viabilities of HCC cells and their HBx-overexpressing derivatives were analyzed by using MTT, cell counting, and colonogenic assay. The mRNA and protein expression of ErbB family were examined by reverse-transcription quantitative polymerase chain reaction (RT-qPCR) and Western blot analysis. The promoter activity of ErbB3 was determined by luciferase assay.
Results: We unexpectedly found that HBx overexpression renders HCC cell lines more sensitive rather than resistant to lapatinib but not sorafenib. We next investigated the protein and mRNA level of ErbB family and its downstream signaling pathway in HBx expressing cells and their parental cells. We found that ErbB3 was upregulated in HBx expressing cells. Furthermore, luciferase assay indicated that HBx enhanced ErbB3 expression through inducing ErbB3 promoter activity. Enhancing of ErbB3 expression not only sensitized HCC cell lines to Lapatinib but also switch oncogenic addition to ErbB3 signaling pathway. After silencing ErbB3 expression, the cell viability was decreased in HBx-overexpressing cells, further confirming that ErbB3 plays a critical role in HBx-expressing cells. Taken together, our data indicated that HBx and ErbB3 overexpression might be the biomarkers for predicting therapeutic efficacy of lapatinib treatment in HCC patients.
Conclusions: HBx overexpression enhanced the oncogenic addiction of HCC cells to the ErbB2/ErbB3/Akt signaling pathway, and thereby sensitizes HCC cells to lapatinib.

P0252

IDENTIFICATION OF THE APICAL SODIUM BILE SALT TRANSPORTER (ASBT) AS A NOVEL MOLECULAR TARGET TO ENHANCE THE SENSITIVITY OF CHOLANGIOCARCINOMA TO CHEMOTHERAPY

E. Lozano[1], R.I. Macias[1,2], M.J. Monte[1,2], O. Briz[1,2], F. Jimenez[1,2], S. Jimenez[1], B. Castaño[1], R. Al-Abdulla[1], F. Al-Aqil[1], A. Hernandez[3], J.M. Banales[2,4], M.A. Serrano[1,2], J.J. Marin[1,2]. *[1]Experimental Hepatology and Drug Targeting (HEVEFARM), University of Salamanca, IBSAL, SALAMANCA, [2]CIBERehd, Institute of Health Carlos III, Madrid, [3]Biochemistry and Molecular Biology, University of Salamanca, IBSAL, SALAMANCA, [4]Biodonostia Research Institute, University of Basque Country, San Sebastian, Spain*
E-mail: jjgmarin@usal.es

Background and Aims: The low sensitivity of cholangiocarcinoma (CCA) to available chemotherapy justifies the need of novel chemosensitizating strategies, for instance by enhancing drug uptake, which may be reduced in these tumors. Thus, the expression/function of the organic cation transporter OCT1, involved in the uptake of sorafenib, is markedly impaired in CCA. Bile acid derivatives had been previously investigated to target antitumor agents toward hepatocellular carcinoma. Decreased expression/function of bile acid uptake carriers, such as NTCP, in tumor cells may limit the usefulness of this possibility. The aim of this study was to revisit this pharmacological strategy for CCA, based on preliminary data indicating the expression the bile acid transporter ASBT in these tumors.
Methods: The ursodeoxycholic acid and cisplatin conjugate Bamet-UD2, which is transported by both OCT1 and ASBT, and has antiproliferative activity on tumor cells, but no toxic side-effect in rodents, was used as targeted drug in preclinical in vitro and in vivo models of CCA. Tumors were induced in rats by long-term (30 wk) thioacetamide administration.
Results: The expression by transfection or lentiviral infection of either ASBT or OCT1 enhanced the sensitivity of CCA cells to the anti-proliferative effect of Bamet-UD2, but not cisplatin. The

expression of both transporters in CCA was determined by RT-QPCR. The results confirmed a marked decrease of OCT1 expression in human and rat CCA. Interestingly, ASBT expression was preserved in both human and rat CCA. Moreover, human (TFK1) and rat (NT-92, REUSAL-C44, REUSAL-C49) CCA cells have a negligible expression of OCT1/Oct1 together with, although at different levels, maintained expression of ASBT/Asbt. In these cells, as well as in rat CCA in vivo, efficient uptake of bile acid was suggested by their ability to accumulate taurocholate and the fluorescent bile acid derivative CGamF. In nude mice implanted (s.c.) with tumors expressing ASBT, tumor growth was significantly inhibited by treatment with Bamet-UD2. As compared with cisplatin, the administration (i.p.) of Bamet-UD2 to rats with CCA resulted in an efficient liver uptake with lower exposure of extrahepatic tissues to the drug, which accounted for no sign of toxicity.

Conclusions: In CCA, the expression of OCT1 is markedly decreased as compared with healthy cholangiocytes, whereas that of ASBT is maintained, which suggests that this transporter may be useful for the targeting of cytostatic bile acid derivatives to CCA.

INHIBITION OF GLYCOLYSIS BY USING NANOLIPID BROMOPYRUVIC CHITOSAN CARRIER IS A PROMISING TOOL TO PREVENT HCC INVASIVENESS

N.A.N. Hanafy[1], M.L. De Giorgi[2], C. Nobile[1], G. Giannelli[3], A. Quarta[1], S. Leporatti[1]. *[1]NNL-Istituto Nanoscienze CNR, [2]Mathematics and Physics, University of Salento, Lecce, [3]Biomedical Science and Human Oncology, University of Bari, Bari, Italy*
E-mail: stefano.leporatti@nano.cnr.it

Background and Aims: An important issue in nanotechnology is that the passage in solid tumour cells will be limited for carriers which have smaller diameter than the range of cancerous cells junctions (100–600 nm). Thus, there is an urgent need to develop smart and efficient strategies tailoring size, shape, and specifically targeting to block one of glycolysis stage. In this way, folic acid (FA) as specific ligand for foliate receptor of cancer cells was conjugated with chitosan (CHI) which was attached with bovine serum albumin (BSA) as target of liver cells forming together (FA-CHI-BSA) to give rise to a specific carrier system. Our aim was to fabricate nano lipid carriers labelled by Rhodamine and covered by two layers: chitosan–bromopyruvic acid complex as one layer then conjugated by BSA-CHI-Folic acid as second layer.

Methods: Charge potential of lipid droplets and intensity of size distribution before and after sonication were investigated by photon correlation spectroscopy. Attachment of Bromopyruvic acid with chitosan was detected by infrared spectroscopy. Conjugation of folic acid and bovine serum albumin (BSA) with chitosan was also detected. Characterization of covering lipid droplets with chitosan–bromopyruvic acid was investigated by SEM, TEM and AFM before and after attachment. The effect of nano-lipid chitosan-BSA-FA encapsulated by bromopyruvic acid on the HCC growth was investigated upon time by crystal violet stain and MTT assay.

Results: Bromopyruvic acid was attached electrostatically by chitosan through amino groups. Molecular fingerprint of bromopyruvic acid, chitosan and complex was detected. Nano-lipid droplets labeled by Rhodamine were covered by chitosan-bromopyruvic acid complex under rotation for 5 min. Afterwards folic BSA-CHI-FA complex was added by completing time of rotation up to 15min. Fluorescence microscopy TRITC and FITC channels revealed successful labelling of lipid droplets covered by complex. Morphological change of HCC growth was shown clearly by crystal violet stain. MTT assay indicates that bromopyruvic acid encapsulated has strongly affected HCC growth. Tryplan blue shows significant increase of apoptotic cells number upon time.

Conclusions: Bromopyruvic acid has exhibited strong effect on HCC growth by blocking hexokinase II enzymes causing mitochondrial potential stress and reduction of ATP energy. Encapsulation of bromopyruvic acid in FA-BSA targeted nano-vehicle might offer protection of normal cell.

CCR5 EXPRESSED ACTIVATED BUT NOT RESTING REGULATORY T CELLS ACCUMULATED IN THE TUMOR SITE AND CORRELATED WITH STAGES OF HEPATOCELLULAR CARCINOMA

J. Mahalingam[1], W.-C. Lee[2], C.-C. Lin[1], W.-T. Chen[1], C.-H. Huang[1], W.-J. Jeng[1], I-S. Sheen[1], S.-M. Lin[1], C.-Y. Lin[3]. *[1]Gastroenterology and Hepatology, [2]General Surgery, Chang Gung Memorial Hospital, [3]Gastroenterology and Hepatology, Chang Gung Memorial Hospital, Taoyuan, Taiwan*
E-mail: chunyenlin@gmail.com

Background and Aims: Activated regulatory T cells (aTreg) could facilitate the progression of cancer had been demonstrated recently. However, the role of this activated Treg cells and possible underlying mechanisms had not been explored in patients with hepatoma.

Methods: Peripheral blood mononuclear cell (PBMC) from 54 patients with hepatoma and 21 health subjects were obtained. The immunophenotype and functional assays of Treg cells were measured by flow cytometry.

Results: The percentages of aTreg but not resting regulatory T cells significantly increased in peripheral blood and accumulated in the tumor parts in patients with hepatocellular carcinoma. These aTreg had higher expressions of Tumor necrosis factor-α receptor II, cytotoxic T-lymphocyte antigen-4, Ki67 and HLA-DR but very few effector cytokines like IL-2, IL-17A and IFN-g. In addition, an increased expression of CCR5 but not CCR4 on aTreg cells was found in the tumor sites when compared with peripheral blood, indicating CCR5 expressed aTreg cells would preferentially accumulated in the tumor microenvironment. Furthermore, the expression of CCL5, a chemokine for CCR5, increased significantly in tumor tissues as well. Finally, the frequencies of both aTreg and CCR5 expressed aTregs were well correlated with tumor stages of patients with hepatocellular carcinoma.

Conclusions: Activated but not naïve Treg cells increased peripherally and accumulated to the tumor microenvironment in patients with hepatoma. Furthermore, CCL5/CCR5 interaction might be the possible mechanisms for the migration of these aTreg cells into tumor site and be the possible target for the tumor immunotherapy.

P0255

DISRUPTION OF THE GP130 SIGNALING PATHWAY IN HEPATOCYTES ATTENUATES HEPATOCARCINOGENESIS

F.J. Cubero[1], M. Hatting[1], M. Spannbauer[1], J. Peng[1], M. Al Masaoudi[1], G. Sellge[1], Y.A. Nevzorova[2], N. Gassler[1], C. Liedtke[1], C. Trautwein[2]. *[1]Department of Internal Medicine III, University Hospital RWTH Aachen, [2]Department of Internal Medicine III, Department of Internal Medicine III, University Hospital Aachen, Aachen, Germany*
E-mail: fcubero@ukaachen.de

Background and Aims: Activation of gp130/IL-6/STAT3 signaling often correlates with tumorigenesis and poor prognosis in hepatocellular carcinoma (HCC) patients. A major disadvantage of global IL-6 anti-cancer therapy is the systemic elevations of IL-6, and new treatment options are needed. Thus, in the present study we aimed to investigate the role of gp130 in hepatocytes for the initiation and progression of HCC.

Methods: Female and male hepatocyte-specific gp130 knockout mice ($gp130^{\Delta hepa}$) and control animals ($gp130^{f/f}$) were treated with diethylnitrosamine (DEN). The role of gp130 for acute injury (0–144 h), tumor initiation (24 weeks) and progression (40 weeks) was analyzed.

Results: After acute DEN-induced injury, a reduction in periportal necrosis, dysplastic foci and in the inflammatory response as

reflected by decreased levels of IL-6, IL-11 and oncostatin M (OSM) were observed in gp130$^{\Delta hepa}$ mice. These results were supported by FACS analysis which showed decreased infiltration of polymorphonuclear leukocytes (PMN) and infiltrating monocytes. Loss of gp130 slightly attenuated HCC initiation 24 weeks after DEN treatment as evidenced by a trend towards less microscopic tumor nodules in gp130$^{\Delta hepa}$ compared to WT livers. In contrast, 40 weeks after DEN treatment, gp130$^{\Delta hepa}$ female and male mice displayed significantly smaller tumors and reduced tumor burden associated with decreased oxidative stress and DNA damage, indicating a role for hepatocyte-specific gp130 expression during HCC progression. Interestingly, while phosphorylation of STAT3 and Ser727 STAT3 was absent in gp130$^{\Delta hepa}$ livers, we found STAT5 activation and decreased pSMAD2/3, SMAD2 and TGFβ-dependent activity.
Conclusions: Our results suggest that gp130 deletion in hepatocytes plays a crucial role in DEN-induced HCC progression. Disruption of gp130 signaling resulted in STAT3 inhibition, increased STAT5 activation and diminished TGFb-dependent signaling. Hence, blocking gp130 in hepatocytes might be a therapeutic approach to inhibit progression of HCC.

P0256
INTERLEUKIN-8 LEVEL AS PREDICTIVE MARKER FOR TREATMENT RESPONSE AFTER TRANSARTERIAL CHEMOEMBOLIZATION IN HEPATOCELLULAR CARCINOMA

S.S. Kim[1], J.H. Park[1], S.W. Cho[1], J.H. Won[2], J.I. Bae[2], J.Y. Cheong[1], H.J. Cho[1]. *[1]Gastroenterology, [2]Radiology, Ajou University School of Medicine, Suwon, Korea, South*
E-mail: cocorico99@gmail.com

Background and Aims: Interleukin-8 (IL-8) is a multifunctional pro-inflammatory cytokine. Increased IL-8 level was reported to be associated with poor overall and disease-free survival in patients with hepatocellular carcinoma (HCC) after operation. We investigated the association of serum IL-8 levels and treatment response after transarterial chemoembolization (TACE) in patients with HCC.
Methods: A total of 119 patients with hepatitis B virus related HCC who underwent TACE were enrolled and followed up for TACE refractoriness and liver transplantation (LT)-free survival. Early TACE refractoriness was defined arbitrarily as TACE refractoriness within 12 months after the first TACE procedure. Pretreatment 11 serum cytokines levels (epidermal growth factor [EGF], fibroblast growth factor 2, granulocyte colony-stimulating factor [G-CSF], interferon-γ, IL-8, interleukin-12, interleukin-17A, interferon-γ-inducible protein-10, monocyte chemotactic protein-1, tumor necrosis factor-α and vascular endothelial growth factor) were analyzed using a Luminex 200 system (Millipore, Billerica, MA).
Results: During the mean follow-up period of 24.3 (1–79) months, 91 patients (76.5%) showed TACE refractoriness. Multivariate analyses showed that multiple tumor (Hazard ratio [HR], 2.37; 95% confidence interval [CI], 1.28–4.39; $P = 0.006$), large tumor size (HR, 2.36; 95% CI, 1.38–4.03, $P = 0.002$) and combination of AFP and IL-8 level (AFP >400 ng/ml or IL8 >32 pg/ml; HR, 1.72; 95% CI, 1.03–2.85, $P = 0.037$) are independent predictive factors for overall TACE refractoriness. Multiple tumor, large tumor size, high EGF level (>35 pg/ml; HR, 3.47; 95% CI, 1.01–11.96; $P = 0.049$), and low G-CSF level (<12.5 pg/ml; HR 6.25; 95% CI, 1.62–23.81; $P = 0.008$) were independent factors for prediction of early TACE refractoriness. High IL-8 levels were also associated with low probability of LT-free survival (HR, 1.68; 95% CI, 1.09–2.59, $P = 0.020$), together with multiple tumor number (HR, 4.43; 95% CI, 2.30–8.52, $P = 0.000$) and vascular invasion (HR, 2.24; 95% CI, 1.26–3.99, $P = 0.006$).
Conclusions: Pretreatment serum IL-8 levels are useful marker to predict overall TACE refractoriness and LT-free survival in patients with hepatitis B virus related HCC treated with TACE. Pretreatment serum EGF and G-CSF levels are also good markers for predict early TACE refractoriness in same patients.

P0257
LIPID PEROXIDES STIMULATE INTERLEUKIN-6 FORMATION FROM STELLATE CELLS BY AN OXIDATIVE STRESS-DEPENDENT MECHANISM

N. Rohr-Udilova[1], H. Hayden[1], M. Schmid[1], C. Österreicher[2], T. Claudel[1], M. Pinzani[3], R. Eferl[2], M. Trauner[1], M. Peck-Radosavljevic[1]. *[1]Gastroenterology and Hepatology, [2]Medical University of Vienna, Vienna, Austria; [3]University College of London, London, United Kingdom*
E-mail: nataliya.rohr-udilova@meduniwien.ac.at

Background and Aims: Lipid peroxides are intermediate oxidation products of unsaturated fatty acids formed under oxidative stress. Liver inflammation promotes oxidative stress which involves the tumorigenic factor interleukin-6 (IL-6). Perisinusoidal hepatic stellate cells play a key role in liver fibrosis with progression towards cirrhosis and hepatocellular carcinoma (HCC). We investigated the impact of lipid peroxides on IL-6 formation in stellate cells.
Methods: Human immortalized (LX-2) and primary human hepatic stellate cells were treated by various concentrations of native (LH) or peroxidized (LOOH) linoleic acid for different time periods with a maximal nontoxic effects at 20μM for 2 h. As a macrophage model, differentiated human monocytic THP-1 cells were used. Expression of IL-6 and C-reactive protein (CRP) was analysed by real-time RT-PCR and ELISA. Activation of IL-6 downstream targets Stat3 and p38 MAPK were investigated by western blotting.
Results: LOOH increased IL-6 expression and intracellular reactive oxygen species (ROS) in both immortalized and primary stellate cells. In particular, IL-6 increased from 2.07+0.66 pg/ml to 7.13+0.23 pg/ml in LX-2 cells ($p = 0.005$). In contrast, LOOH did not stimulate IL-6 in macrophages, whereas LPS was active in both cell types. Antioxidants N-acetylcystein and selenium as single agents or in combination inhibited the formation of ROS and LOOH-induced IL-6. PD169316, an inhibitor of p38 MAPK, prevented IL-6 upregulation by LOOH. Furthermore, when IL-6 containing supernatants from LOOH-treated LX-2 cells were applied to cultured human HCC-1.2 and HCC-3 cells, an IL-6 dependent phosphorylation of the transcription factor Stat3 as well as an increased expression of the downstream target CRP was observed. In particular, CRP mRNA and protein were increased in HCC-3 cells by 48+9%, $p = 0.0003$, and by 84+44%, $p = 0.013$, respectively.
Conclusions: These results suggest a novel mechanism of upregulation of pro-inflammatory IL-6 in stellate cells by lipid peroxides in a ROS-dependent way that can be inhibited by antioxidants.
This work was supported by Herzfeder'sche Familienstiftung.

TAUROURSODEOXYCHOLIC ACID DAMPENS ONCOGENIC APOPTOSIS INDUCED BY ENDOPLASMIC RETICULUM STRESS DURING HEPATOCARCINOGEN EXPOSURE

Y.-P. Vandewynckel[1], D. Laukens[1], L. Devisscher[1], A. Paridaens[1], E. Bogaerts[1], X. Verhelst[1], A. Van den Bussche[1], S. Raevens[1], C. Van Steenkiste[1], M. Van Troys[2], C. Ampe[2], B. Descamps[3], C. Vanhove[3,4], O. Govaere[5], L. Libbrecht[6], A. Geerts[1], H. Van Vlierberghe[1]. *[1]Department of Hepatology and Gastroenterology, [2]Department of Biochemistry, [3]Infinity imaging lab, [4]GROUP-ID Consortium, Ghent University, Ghent, [5]Translational Cell and Tissue Research, Department of Imaging and Pathology, University of Leuven, Leuven, [6]Department of Pathology, Ghent University, Ghent, Belgium*
E-mail: yvespaul.vandewynckel@ugent.be

Background and Aims: Hepatocellular carcinoma (HCC) is characterized by accumulation of unfolded proteins in the endoplasmic reticulum (ER) which activates the unfolded protein response (UPR). However, the role of ER stress in tumour initiation

and progression remains a contentious topic. To determine the impact of ER stress, we applied tauroursodeoxycholic acid (TUDCA), a cytoprotective bile acid with chaperone properties reducing ER stress.
Methods: The effect of TUDCA on hepatic tumour burden, apoptosis, ER stress, autophagy, oxidative stress and inflammation was assessed in the diethylnitrosamine-induced orthotopic mouse model for HCC in a preventive and therapeutic setting. The effect on MTT metabolic activity and BrdU incorporation was investigated *in vitro* and the effect on tumour progression was assessed in a HepG2 xenograft model.
Results: Administration of TUDCA in a preventive setting reduced the carcinogen-induced elevation of aspartate and alanine aminotransferase levels and apoptosis of hepatocytes and, surprisingly, also the tumour burden. TUDCA markedly reduced the phosphorylation of eukaryotic initiation factor 2α, the expression of the pro-apoptotic C/EBP homologous protein (CHOP) and caspase-12 activation in the DEN-treated livers, suggesting that TUDCA suppressed terminal UPR signalling. Although no significant effects were observed on oxidative stress or autophagic flux, TUDCA alleviated hepatic inflammation associated with repeated carcinogen exposure. Furthermore, TUDCA dose dependently enhanced the cellular MTT metabolic activity, but not the cell proliferation rate *in vitro*. Importantly, administration of TUDCA in a therapeutic setting after tumour development did not affect the growth of orthotopic tumours or HepG2 xenografts.
Conclusions: These findings indicate that TUDCA attenuates hepatocarcinogenesis by suppression of carcinogen-induced ER stress-mediated cell death and inflammation without stimulation of tumour progression. Therefore, the chemical chaperone TUDCA could represent a novel chemopreventive agent for HCC.

TRANSENDOTHELIAL MIGRATION DEPENDS ON TRANSFORMING GROWTH FACTOR BETA IN HEPATOCELLULAR CARCINOMA PROGRESSION

P. Koudelkova[1], G. Weber[1], S. Dooley[2], V. Costina[3], P. Findeisen[3], W. Mikulits[1]. *[1]Department of Medicine I, Institut for Cancer Research, Medical University Vienna (MUV), Austria, Vienna, Austria; [2]Section Molecular Hepatology Department of Medicine II, [3]Department of Clinical Chemistry, Faculty of Medicine in Mannheim at Heidelberg University, Mannheim, Germany*
E-mail: petra.koudelkova@meduniwien.ac.at

Background and Aims: Transendothelial migration of malignant hepatocytes into blood vessels represents a hallmark of hepatocellular carcinoma (HCC) progression. Overcoming of endothelial barrier is necessary for the entry into and exit from the circulation, termed intra- and extravasation. Yet, both mechanisms are poorly understood due to lack of appropriate study tools. We established a model of transendothelial migration by employing malignant hepatocytes, which have undergone epithelial to mesenchymal transition (EMT) dependent on transforming growth factor (TGF)-β and liver sinusoidal endothelial cells. The aim was to study the molecular mechanisms of transendothelial migration of EMT-transformed hepatocytes through hepatic sinusoidal blood endothelial barriers.
Methods: Murine liver sinusoidal endothelial cells (mLSECs) were isolated by liver perfusion from $p19^{ARF-/-}$ mice. Genomic stability of LSECs was examined by flow cytometry and their functional properties were assessed by tube formation and response to anti-angiogenic drugs. Integrity and polarity of endothelial cell layers were determined by transendothelial electrical resistance and confocal immunofluorescence analysis, respectively. Proteome profiling using stable isotope labeling with amino acids (SILAC) and mass spectrometry was performed to analyze real-time changes in protein expression during transendothelial migration.
Results: Lack of $p19^{ARF}$ allows immortalization of genetically stable LSECs expressing the endothelial markers VEGFR-2, VE-cadherin and CD146. LSECs show VEGF-induced tube formation and apoptosis after administration of the VEGFR inhibitors sorafenib or sunitinib. In addition, LSECs grow to compact monolayer with functional cell junctions including cell polarity. To study transendothelial migration, SILAC-labeled EMT-transformed hepatocytes were allowed to cross the layer of LSECs that were seeded on the bottom of collagen coated Transwell inserts. Expression of SILAC labeled proteins derived from either post-EMT hepatocytes and from SILAC-labeled LSECs was profiled in kinetics of endothelial transmigration in the presence and absence of TGF-β. Candidate regulatory proteins were further validated for their functional impact in endothelial transmigration.
Conclusions: We established a novel cellular model to accurately analyze the intravasation of EMT-transformed hepatocytes through the liver sinusoidal blood endothelium in a TGF-β dependent fashion.

E-mail: izubiete@cicbiogune.es

Background and Aims: The liver kinase B1 (LKB1) is usually described as a tumor suppressor gene in a variety of tissues and is known to act as an upstream activator of AMP-activated protein kinase (AMPK), a central metabolic sensor. Surprisingly, recent evidence has underscored the role of LKB1 upregulation in advanced hepatocellular carcinoma as well as the therapeutic potential of LKB1 silencing in liver tumors. However, the controversial role of LKB1 in hepatocarcinogenesis initiation remains to be unequivocally identified.
Methods: Gene array, metabolomics profiling approaches were used on mice livers and hepatoma cells overexpressing LKB1. Western blot and qPCR analysis were also used to further investigate the effect of LKB1 overexpression.
Results: LKB1 overexpression accounts for deregulated cell proliferation and an overall malignancy-related phenotype with induction of carcinogenesis hallmarks. Under these conditions, LKB1 induces Ras guanyl-releasing protein 3 (RasGRP3) transcriptional upregulation, activating both the Ras/ERK and the mammalian target of Rapamycin (mTOR) pathways. LKB1-mediated Ras activation induces the elevation of Cyclin D1 levels, a master cell cycle regulator. Furthermore, induced mTOR activity promotes glycolysis and expression of pyruvate kinase muscle 2 expression in association with histone 3 phosphorylation and acetylation, which are essential for the induction of proliferation markers such as Cyclin D1. Interestingly, LKB1 overexpression is not associated with AMPK activation, suggesting a LKB1/AMPK uncoupling due to their cellular delocalization.
Conclusions: We provide strong evidence that LKB1 in the liver not only plays a role in liver cancer progression but is also an oncogenic driver and therefore a potential early diagnosis marker as well as a therapeutic target.

A GLOBAL RISK GENE SCORE PREDICTS EARLY AND LATE TUMOR RECURRENCE AFTER RESECTION OF HEPATOCELLULAR CARCINOMA

J. Dekervel[1,2], D. Popovic[3], H. van Malenstein[1,2], P. Windmolders[2], L. Libbrecht[4], A. Bulle[2], B. De Moor[3], E. Van Cutsem[5], F. Nevens[1,2], C. Verslype[1,2,5], J. van Pelt[2]. *[1]Department of Hepatology, University Hospitals Leuven, [2]Department of Clinical and Experimental Medicine, [3]Department of Electrical Engineering (ESAT), KU Leuven, Leuven, [4]Department of Pathology, University Hospital Ghent, Ghent, [5]Department of Digestive Oncology, University Hospitals Leuven, Leuven, Belgium*
E-mail: jeroen.dekervel@med.kuleuven.be

Background and Aims: Patients undergoing treatment with curative intent for hepatocellular carcinoma (HCC) remain at high risk for tumor recurrence by the emergence of intrahepatic metastasis ("early recurrence") or the formation of new lesions ("late recurrence"). We aimed to develop and validate a gene expression signature that could predict this risk.
Methods: HepG2 liver cancer cells made resistant to sorafenib during several months were used as a model for hepatocyte dedifferentiation and aggressive tumor biology. The differential expressed genes between this cell line and its non-resistant parental lineage were determined using an Affymetrix microarray platform. To form a score, the number of genes was subsequently downsized by assessing the performance of each one in published microarray data sets of HCC samples (GSE25097, GSE9843) and samples of non-tumoral surrounding liver (GSE40873). This resulted in a 7 gene score (Global Risk Score, GRS) which was validated in two independent data sets (LEC cohort, GSE1898/GSE4024, n = 67 and NCI cohort, GSE14520, n = 247) using a tumor- and liver-specific cut-off for high and low GRS.

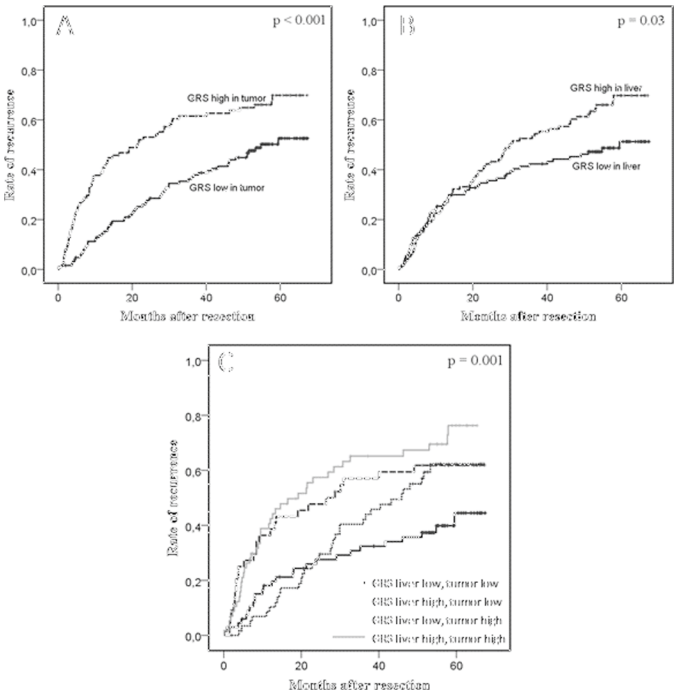

Figure 1. Performance of the Global Risk Score in the NCI cohort (n = 247).

Results: The GRS, when assessed in tumor tissue of patients treated with resection, identified patients at low and high recurrence risk at 3 years in the LEC (68±10% vs 35±7%, p = 0.03) and NCI (62±5% vs 37±4%, p < 0.001, Figure 1A) cohort. Moreover, assessment of the GRS in non-cancerous surrounding liver tissue of the NCI patients revealed that, starting at about 19 months after resection, the score was correlated with the formation of new lesions in the cirrhotic liver (Figure 1B). Taken together, based on the tumor and liver score value, the GRS identified 4 patient groups with differences in recurrence rates and time patterns of recurrence (Figure 1C). Multivariable analysis by Cox regression showed that GRS group was a significant predictor of recurrence, independent from BCLC stage (p = 0.007).
Conclusions: We present the first gene score validated in both HCC tissue and surrounding liver based on an in vitro model. By identifying aggressive tumor biology as well as tumorigenic potential of the underlying liver disease, the Global Risk Score allows calculating a prognostic estimate for an individual patient facilitating therapeutic decisions.

INHIBITION OF REGULATORY T CELLS USING THE FOXP3-INHIBITORY PEPTIDE P60 IMPROVES ANTITUMOURAL EFFECT OF A VACCINATION WITH mAFP-EXPRESSING DC IN SUBCUTANEOUS AND ORTHOTOPIC MURINE HCC MODEL

J. Waysczak[1], A. Vogt[1], N. Casares[2,3], J.J. Lasarte[2,3], J. Prieto[2,3], I. Schmidt-Wolf[4], C.P. Strassburg[1], M.A. Gonzalez-Carmona[1]. *[1]Department of Internal Medicine I, University of Bonn, Bonn, Germany; [2]Liver Unit, Clínica Universitaria, [3]CIMA and Centro de Investigación Biomédica en Red de enfermedades Hepáticas y Digestivas (CIBERehd), University Navarra, Pamplona, Spain; [4]Center for Integrated Oncology (CIO), University of Bonn, Bonn, Germany*
E-mail: s4juways@uni-bonn.de

Background and Aims: Dendritic cells (DC) are professional antigen-presenting cells able to prime T-cell responses against tumour-associated antigens such as alpha-fetoprotein (AFP). However, the antitumoural effect of DC vaccination in therapy of hepatocellular carcinoma (HCC) is limited by the immunosuppressive tumour environment. Immunosuppressive regulatory T-cells (Treg) are increased in tumour milieu and peripheral blood of patients with HCC. The aim of this study was to analyse whether a functional inhibition of Treg improves the antitumoural effect of a vaccination with murine (m) AFP-expressing DC in a subcutaneaous (s.c.) and an orthotopic murine HCC model.
Methods: DC were gained from bone marrow of C3H mice and transduced on day 6 with a mAFP-encoding adenovirus (Ad-mAFP). For tumour induction, 10^6 or 10^5 mAFP positive Hepa129 cells were injected s.c. into the right flank or into the left liver lobe of C3H mice respectively. On days 9 and 15 after s.c. or on day 3 and 6 after orthotopic tumour induction 10^6 Ad-mAFP-transduced or Ad-Mock-transduced DC were s.c. inoculated. In addition, mice were treated with a daily intraperitoneal (i.p.) injection of 100 μg of the FOXP3-inhibitory peptide P60 or the control peptide P301.
Results: A monotherapy with the FOXP3-inhibitory peptide P60 or with a vaccination using Ad-mAFP-transduced DC had no positive effect on the outcome of tumour-bearing mice (p > 0.05). In contrast, the combination of P60 and vaccination with mAFP-expressing DC lead to a significant tumour inhibition and prolonged survival in s.c. and orthotopic AFP-positive HCC model. Interestingly, the synergistic antitumoural effect of the combined therapy was stronger in the orthotopic HCC model (p = 0.0056). On day 21, 90% of the tumour bearing mice treated with P60 and mAFP-expressing DC and only 14% of the untreated mice with orthotopic HCC had survived. Even one week later, 40% of the therapy group still lived while all of the untreated mice had died.
Conclusions: We showed that the functional inhibition of Treg using the FOXP3-inhibitory peptide P60 or a vaccination with mAFP-expressing DC alone has no antitumoural effect towards HCC *in vivo*. However, P60 in combination with Ad-mAFP-transduced DC synergistically decelerates tumour growth improving the outcome of HCC-bearing mice. Thus, these results emphasize the potential

of the specific inhibition of Treg using P60 to enhance the antitumoural effect of DC vaccination in the therapy of HCC.

P0263
CONSEQUENCES OF β-CATENIN PATHWAY ACTIVATION ON MOUSE HEPATIC METABOLISM

N. Senni[1], A. Gougelet[1], C. Sartor[1], C. Perret[1], S. Colnot[1], P. Bossard[1].
[1]*Institut Cochin Inserm U1016, Paris, France*
E-mail: nadia.senni@inserm.fr

Background and Aims: Hepatocellular carcinoma (HCC) are the 3rd cause of cancer-related death in the world. 20 to 40% of HCC are caused by activating mutations in the CTNNB1 gene coding for β-catenin. They are poorly "proliferative", well differentiated and display a specific metabolic phenotype: indeed these tumors are cholestatic and never steatosic. Currently, tumor metabolism is a potential target in the treatment of cancer. The aim of this study was to determine the metabolic alterations leading to this distinctive metabolic phenotype in hepatic tumors where β-catenin is over-activated
Methods: We use the inducible liver-specific APC KO mouse models TTR-Cre-Apclox/lox. We either activate constitutively β-catenin in the whole hepatic lobule to mimic a "preneoplasic" situation or we abnormally activate β-catenin in few hepatocytes that will then generate tumors after 6 months. Using these two approaches we analyze metabolic fluxes to determine the carbon fate from different potential substrate in order to identify the source of energy and cellular components of β-catenin activated hepatocytes or tumors.
Results: Our results reveal that an abnormal activation of β-catenin in hepatocytes leads to an increase in fatty acids β-oxidation with a decrease in triglycerides synthesis which may explain the lack of steatosis. This has to be seen in connection with the loss of fat mass in our "preneoplasic" model that indicates an increase in lipid reserve utilization. Regarding tumor metabolism, Warburg effect, an aerobic glycolysis, is often described as many tumors use glucose as a preferential substrate. Here we show that there is no increase in the utilization of glucose in β-catenin activated hepatocytes but a rerouting of its carbons towards ribose synthesis instead of glycolysis or mitochondrial oxidation. Moreover the mouse β-catenin tumors are negative in PET-scan FDG and metabolic flux analyses revealed that they oxidize fatty acids much more efficiently than the adjacent normal tissue.
Conclusions: Our results show that an abnormal activation of the β-catenin pathway in hepatocytes leads to a reorientation of liver metabolism. Hepatocytes and tumors then use fatty acids as the main energy source and glucose is rerouted into the pentose phosphate pathway.

REDIRECTING ADENOVIRUS-SPECIFIC T CELLS BY A TUMOR-SPECIFIC T CELL RECEPTOR FOR THERAPY OF HEPATOCELLULAR CARCINOMA

C.I. Ureche[1], E. Guerlevik[1], N. Woller[1], B. Fleischmann-Mundt[1], A. Kloos[1], M.P. Manns[1], S. Kubicka[1], F. Kuehnel[1]. [1]*Clinic for Gastroenterology, Hepatology, and Endocrinology, Hannover Medical School, Hannover, Germany*
E-mail: ureche.cristina@mh-hannover.de

Background and Aims: Hepatocellular carcinoma is highly resistant to conventional therapies and need alternative treatments. Oncolytic viruses are promising tools for the treatment for solid tumors but unfortunately trigger strong T cell immune responses against the applied virus.
Here, we wanted to investigate whether antiviral cytotoxic T lymphocytes triggered by oncolytic virotherapy can be redirected with a tumor specific TCR for therapy of HCC in an immunocompetent C57BL/6 mouse model.
Methods: First, virus-specific T cells were induced by intraperitoneal challenge with oncolytic Adenovirus in Thy1.1 mice and splenocytes were used to generate bispecific T cells by lentiviral transfer of the OT-1 receptor in adenovirus-specific T cells. Resulting bispecific T cells were adoptively transferred into Thy1.2 recipient mice bearing HCC tumors expressing OVA minimum epitopes. Prior to adoptive transfer, mice were preconditioned with Cyclophosphamid and Treosulfan to achieve lymphoreduction.
Results: To obtain a suitable HCC cell line for a syngeneic tumor model we used the transposon system. We hydrodynamically injected an oncogenic transposon coding for KRasG12V/myrAkt1 and a transposon for MHC class I and II minimum epitopes of OVA, SB13, and Cre recombinase in p53fl/fl mice. FACS analyses on isolated tumor clones showed that the cell line LV13531 constitutively expressed MHC class I which can be further triggered by IFN-gamma. The cell line was used for inoculation of subcutaneous tumors. After adoptive transfer of bispecific T cells, tracking lentiviral encoded GFP and CD8 by FACS analysis, proved successful establishment of transduced CD8 T cells in blood, spleen and tumor tissue. Finally we demonstrated that, compared with naïve and immunized mock-transduced cohorts, the group which received Ad/OT-1 specific T cells showed significantly improved regression and long-term survival.
Conclusions: Our findings suggest that virus-specific T cells induced by oncolytic virotherapy can be successfully redirected with a tumor specific TCR to address therapy-resistant HCC.

E-mail: imartinez@clinic.cat

Background and Aims: Hepatocellular carcinoma (HCC) is the 16th absolute cause of death world-wide and accounts for 90% of all liver cancers. IGF-Insulin signaling has a relevant role in HCC pathogenesis and elucidation of its key molecular drivers is important to overcome the poor therapeutic results obtained so far by inhibiting this pathway. Since IGF2 ligand have been shown to be overexpressed in HCC, we aimed (1) to explore the oncogenic potential of IGF2 in genetically modified animal models (GEMM), (2) to elucidate the oncogenic mechanism of IGF2 through the receptors IGF1R and IR, and (3) to determine the antitumoral efficacy of molecular therapies against this target.
Methods: A GEMM overexpressing IGF2 in the liver was generated using hydrodynamic tail vein injection. A cohort of 228 human HCCs was characterized analyzing gene expression, exomic mutations, DNA copy number and methylation status with a focus on the IGF-Insulin pathway. Activation of IGF2 promoters and expression of isoforms A and B from IR were additionally assessed by qRT-PCR. Therapeutic potential of the monoclonal antibody BI836845 (Boehringer Ingelheim), selective for IGF ligands, was studied in

HCC cell lines by analyzing cell viability, proliferation and pathway activation.
Results: Only mice overexpressing IGF2 showed increased number/size of tumors and significantly reduced survival ($p = 0.02$) when compared to control mice. In humans, 15% (31/207) of patients in our cohort showed IGF2 overexpression (FC >2), being hypomethylation of fetal promoters the main cause in 87% of cases (21/54 vs 7/171, $p < 0.0001$). Patients with high levels of IGF2 showed significant association with stem-cell signatures. In addition, 40% of the HCCs overexpressed the IR-A (which has a pro-proliferative input, in contrast with the pro-metabolic input caused by IR-B). In cell lines with increased levels of IGF2 and IR-A, selective IGF-ligands blockade with BI836845 significantly reduced cell viability and proliferation (30%, $p = 0.002$), inhibiting IGF-Insulin pathway activation, and without interfering with insulin metabolic effect.
Conclusions: Overexpression of IGF2 has a relevant role in the process of hepatocarcinogenesis through activation of IGF1R and IR-A in a subgroup of HCC patients. These results provide the rationale that favors therapeutic strategies based on monoclonal antibodies against IGF ligands, in front of tyrosine kinase inhibitors, to selectively block the pathway.

ADENO-ASSOCIATED VIRUS 2 (AAV2) INDUCES RECURRENT INSERTIONAL MUTAGENESIS IN HUMAN HEPATOCELLULAR CARCINOMAS

J.C. Nault[1], S. Datta[1], A. Franconi[1], S. Imbeaud[1], M. Mallet[1], G. Couchy[1], E. Letouzé[1], C. Pilati[1], B. Verret[1], J.F. Blanc[2], C. Balabaud[3], J. Calderaro[4], A. Laurent[5], M. Lextexier[6], P. Bioulac-Sage[7], F. Calvo[8], J. Zucman-Rossi[1]. *[1]Inserm U1162, Paris, [2]Liver unit, CHU Bordeaux, [3]INSERM U1053, Bordeaux, [4]Department of pathology, Henri Mondor Hospital, [5]Department of hepatobiliary surgery, Henri Mondor Hospital, Creteil, [6]Integragen, Evry, [7]Department of pathology, CHU Bordeaux, Bordeaux, [8]INCA, Boulogne, France*
E-mail: naultjc@gmail.com

Background and Aims: Hepatocellular carcinomas (HCC) are related to various etiologies including hepatitis B and hepatitis C virus infection, alcohol intake, obesity, hemochromatosis. Additional risk factors remain to be identified particularly in HCC developed on non-fibrotic liver. We identified a fragment of Adeno-Associated Virus type 2 (AAV2, a defective DNA virus considered as non-pathogenic) inserted in an HCC genome and this result prompted us to screen a large series of HCC samples.
Methods: We screened 150 HCC and matched non-tumor liver samples for AAV2 sequences using PCR and next generation sequencing. Expression of the genes targeted by viral integration was quantified and the functional consequences of AAV2 integration within TERT promoter was analyzed in 3 HCC cell lines using luciferase assay.
Results: Among the 150 tumors, we identified 7 cases (5%) with a clonal AAV2 insertion whereas no clonal insertion was found in the corresponding non-tumor liver tissues. In the first HCC tumor, we identified a 208 base pairs insertion of an AAV2 fragment within the TERT (coding for the telomerase reverse transcriptase) promoter. In HCC cell lines, we demonstrated that this AAV2 insertion resulted in an increased TERT promoter activity. We next identified 6 additional clonal somatic integrations of AAV2, all occurred within known cancer driver genes, CCNA2 (4 cases), CCNE1 or TNFSF10 leading to over-expression of the targeted gene without generating chimeric viral-endogeneous functional fusion transcripts. In CCNA2 (coding for cyclin A2), the four integration sites were identified within intron 2 and AAV2 insertion ranged from 219 to 1,975 bp occurring in both orientations. In CCNE1 (coding for cyclin E1), we identified a 368 bp AAV2 integration within intron 4. In the remaining case, AAV2 integration occurred in the 3′ UTR of TNSFS10 (coding for the receptor TRAIL), 244 bp after the stop codon. In 6 out of the 7 tumors, the inserted AAV2 included the 3′ inverse tandem region. Strikingly, almost all the tumors were developed on non-fibrotic liver (6 out of 7 cases, $p < 0.05$) without known risk factor (5 out of 7, $p < 0.05$), thus suggesting a particular pathogenic role of AAV2 in this subset of patients.
Conclusions: Infection by AAV2, that is very frequent in the general population (around 30–60% of individuals), is involved in the pathogenesis of rare human HCC by recurrent somatic integration in cancer driver genes challenging its safety as a vector for gene therapy.

P0267
RAS AND P-ERK IN METABOLIC SYNDROME ASSOCIATED HEPATOCELLULAR CARCINOMA (HCC)

A. Whitehead[1], L. Ogle[1], G.L. Patman[1], G. Anwar[2], D.G. Tiniakos[3], Q.M. Anstee[3], H.L. Reeves[1,4], on behalf of FLIP investigators (FP7/2007–2013) Health-F2-2009-241762. *[1]Northern Institute for Cancer Research, University of Newcastle Upon Tyne, [2]Liver Unit, Newcastle-upon-Tyne Hospitals NHS Foundation Trust, [3]Institute of Cellular Medicine, University of Newcastle Upon Tyne, [4]Hepatopancreatobiliary MDT, Newcastle-upon-Tyne Hospitals NHS Foundation Trust, Newcastle-upon-Tyne, United Kingdom*
E-mail: h.l.reeves@ncl.ac.uk

Background and Aims: HCC mortality associated with the metabolic syndrome (MetS) is rising, often in the absence of liver cirrhosis. We reported an animal model in which C3H/He mice with impaired glucose tolerance, fed the American lifestyle (ALIOS) diet, develop NASH, fibrosis and HCC at 1 year. While activated Ras/MAPK signalling is often key in murine carcinogenesis, increased p-ERK is reported in just 2.5–10% of HBV/HCV associated human HCC. We have assessed this pathway in our animal model and in MetS HCC.
Methods: H&E sections, DNA, RNA and protein from paired murine tumour and non-tumour (NT) livers were compared. p-ERK was with western blot in mice and immunohistochemistry in paraffin embedded needle biopsies from 20 MetS HCC patients without any other contributing liver disease. *KRAS* mutations in plasma DNA were explored using a MALDI-TOF platform.
Results: Murine development of large HCC (6–15 mm, with nuclear atypia and loss of reticulin) was associated with histologically confirmed NASH in ALIOS fed mice. Marked microvesicular steatosis, ballooning and inflammation were common in the tumours, which were classed as steatohepatitic HCC (SH-HCC). AFP and glypican-3 were up-regulated over 100 fold, with iNOS (1.22 ± 0.31 vs. 14.25 ± 5.23; $p = 0.001$) and TNFα (0.63 ± 0.08 vs 1.66 ± 0.54, $p = 0.007$) also elevated in tumours. *H-ras* mutation at codon 61 was present in 5/20 (25%) of HCC, while p-ERK was up-regulated relative to paired NT in all cases (5.5 ± 0.6 vs 99.8 ± 26.0, $p = 0.004$). In 20 biopsied MetS HCC patients, 35% had cirrhosis and 80% had NAFLD. Three (15%) HCC had minimal (<5%) p-ERK positive nuclei assessed by immunohistochemistry and digital quantification (Aperio Imagescope). Of 17 HCC with >10% nuclei positive for p-ERK, in 6 (30%) this was in excess of 50% nuclei (none cirrhotic, all diabetic, BMI median 24.8). In 11 (55%) with SH-HCC, p-ERK was classed as moderate (10–35% nuclei; 8 cirrhotic; 9 diabetic; BMI median 32.0). Plasma DNA *KRAS* mutations in codon 12 were detected in 2 patients.
Conclusions: Alteration of the Ras/MAPK pathway was evident in 85% of metS associated Human HCC, including marked p-ERK elevation in 30% (actually 50% of non-cirrhotic cases). A further 55% of HCC had moderately elevated p-ERK, in association with SH-HCC features. *KRAS* mutations in circulating plasma DNA were detected in 10%. The C3H/He ALIOS model will be useful for studying Ras/MAPK in the pathogenesis of these tumours. Treatments targeting this pathway may be particularly relevant for patients with MetS associated HCC.

P0268

ACCUMULATION OF DELETERIOUS PASSENGER MUTATIONS DURING LIVER INJURY PROGRESSION TO HEPATOCELLULAR CARCINOMA

M. Budzinska[1,2], F. Luciani[2], N. Shackel[1,3], T. Tu[1]. *[1]Liver Injury and Cancer, Centenary Institute, [2]Inflammation and Infection Research Centre, The University of New South Wales, [3]Australian National Liver Transplantation Unit, Royal Prince Alfred Hospital, Sydney, Australia*
E-mail: m.budzinska@centenary.org.au

Background and Aims: Hepatocellular carcinoma (HCC) is associated with genetic alterations in several driver genes. However, no single driver mutation is necessary or sufficient for carcinogenesis. The vast majority of mutations unique to the patients, known as passenger mutations, have been so far ignored. Some passenger mutations are deleterious and could act as markers for disease progression. A previous study has shown that deleterious passenger mutations (DPMs) occur more frequently in tumour tissue compared to surrounding non-tumour tissue. The accumulation of DPMs was hypothesised to be due to: (1) that DPMs occur more frequently than driver mutations; and (2) the accumulated DPMs eventually offset the survival advantage conferred by driver mutations. Therefore, we aim to detect DPMs in liver disease progression and hypothesise that DPMs accumulate in hepatocytes in precancerous liver disease leading up to HCC.
Methods: We have performed whole exome sequencing of pre-cancerous liver tissues: 12 patients with limited level of liver injury and 6 HCV-positive patients with liver cirrhosis. We have also analysed publically available paired HCC and surrounding non-tumour datasets. To compare different data we only analysed mutations that occurred in protein-coding genes, filtered out probable germline mutations and normalised the analysis to only exonic variants detected. Poly-Phen2 was employed to predict impact of variants on protein function.
Results: We have found that HCC genomes contain significantly more DPMs compared to paired non-tumour tissue (33.1 vs 30.3% total exonic variants respectively, $p < 0.001$ by paired two-tailed t-test). Comparison with non-cirrhotic and cirrhotic tissues showed significantly fewer DPMs (19.9 and 21.7% respectively) compared to tumour and non-tumour tissues. Moreover, we observed a significantly more DPMs in non-tumour tissue as the number of putative driver genes with damaging mutations increases (24.1, 31.7, 34.8% for 0, 1, ≥2 drivers respectively). DPMs were evenly distributed across the genome and the majority were unique for each patient, suggesting they are truly passenger mutations.
Conclusions: We showed that DPMs accumulate in precancerous tissues leading up to HCC. Moreover, precancerous alterations were found in non-tumour tissue, despite being used in prior studies as normal paired controls. We are currently sequencing larger patient cohorts with precancerous states to develop marker regions that predict HCC risk.

P0269

THE INSULINE-LIKE GROWTH FACTOR 2 (IGF2) MRNA BINDING PROTEIN (IMP) P62 PROMOTES CIRRHOSIS-LINKED HEPATOCARCINOGENESIS

S.M. Kessler[1], B. Czepukojc[1], K. Engel[1], N. Van Hul[2], J. Haybaeck[3], I. Leclercq[2], A.K. Kiemer[1]. *[1]Pharmaceutical Biology, Saarland University, Saarbruecken, Germany; [2]Laboratory of Hepato-Gastroenterology, Institut de Recherche Expérimentale et Clinique, Université Catholique de Louvain, Brussels, Belgium; [3]Institute of Pathology, Medical University of Graz, Graz, Austria*
E-mail: s.kessler@mx.uni-saarland.de

Background and Aims: The insulin-like growth factor 2 (*IGF2*) mRNA binding protein (IMP2) p62 was shown to accelerate progression of NASH to a disease stage with fibrosis (Simon et al. *Gut*, 2014). Aim of our study was to test the hypothesis that p62 promotes fibrosis progression towards malignancy.
Methods: NASH was induced by feeding either a methionine-choline deficient (MCD) or a control diet in wild-type or *p62* transgenic mice for 2 and 4 weeks. Carcinogenesis was induced by diethylnitrosamine (DEN, 5 mg/BW *i.p.*) given either after or prior to the onset of MCD feeding (up to 21 weeks). Tissues were histologically analyzed by HE and Sirius red staining. mRNA and protein levels were investigated by real-time RT-PCR and immunohistochemistry, respectively.
Results: On normal chow *p62* transgenic animals showed elevated expression of *E-cadherin*, an epithelial marker overexpressed in liver progenitor cells (LPC). In MCD-induced NASH a strong ductular reaction and LPC proliferation was observed in *p62* transgenic mice. Gene expression of laminin, an extracellular matrix (ECM) component supporting LPC proliferation, increased in MCD-fed *p62* transgenic animals. Expression of hyaluronic acid receptor was not altered. Expression analysis revealed that *p62* transgenic mice have specifically increased *Krt19* expression. *Sox9*, another biliary marker of the ductal plate, was induced in both genotypes upon MCD feeding. Immunohistochemical characterization rvealed small nests of LPC as well as bile duct-like formations. LPC proliferation was surrounded by an ECM layer and directed into the lobule by ECM deposition ahead of the LPC.
When carcinogenesis was induced by injection of DEN after the onset of MCD feeding, all animals died within 10 weeks or had to be sacrificed; survival was significantly reduced in *p62* transgenic animals ($p = 0.0056$). Administration of DEN before the onset of MCD feeding (21 weeks) induced macroscopically visible hyperplastic nodules preferentially in *p62* transgenic mice ($p = 0.0019$). Sirius red staining confirmed cirrhotic changes solely in the livers of *p62* transgenic animals. Interestingly, *p62* transgenic mice overexpressed the hepatocellular carcinoma (HCC) marker alpha-fetoprotein (AFP) mostly in hepatocytes and rarely in LPC suggesting carcinogenic changes in the cirrhotic tissue.
Conclusions: p62 promotes a progression of fibrosis towards cirrhosis and thus promotes hepatocarcinogenesis.

P0270

SERPINB3 AND YAP INTERPLAY INCREASES MYC ONCOGENIC ACTIVITY

C. Turato[1], S. Cannito[2], D. Simonato[1], V. Gianmarco[1], L. Terrin[1], S. Quarta[1], A. Biasiolo[1], M. Ruvoletto[1], S. Fasolato[3], G. Zanus[3], U. Cillo[3], A. Gatta[1], M. Parola[2], P. Pontisso[1]. *[1]Dept. of Medicine, University of Padova, Padova, [2]Dept. of Clinical and Biological Sciences, Unit of Experimental Medicine and Interuniversity Center for Liver Pathophysiology, University of Torino, Torino, [3]Dept. Surgical, Oncological and Gastroenterological Sciences, University of Padova, Padova, Italy*
E-mail: cristianturato@gmail.com

Background and Aims: SerpinB3 has been recently described as an early marker of liver carcinogenesis, but the potential mechanistic role of this serpin in tumour development is still poorly understood. Myc is one of the most important oncogenes in human cancer. Somatic amplification and overexpression of Myc often correlate with more advanced and aggressive tumour forms, supporting its involvement in carcinogenesis. Yes-associated protein (Yap), the main effector of the Hyppo pathway, is a central regulator of proliferation and self-renewal of normal and cancer stem cells. This molecule, found up-regulated in hepatocellular carcinoma (HCC), has been described also to increase Myc expression.
The present study has been designed in order to investigate whether SerpinB3 may functionally modulate Myc in different experimental models and in human HCC specimens.
Methods: Expression of Myc, Yap and its target genes was evaluated in relation to SerpinB3 expression in HCC specimens from 67

patients obtained at the time of surgical resection, in C57BL/6 mice transgenic for human SerpinB3. In addition, mRNA quantification and Western Blot analysis was performed in HepG2 and Huh7 cells stably transfected with plasmid vectors carrying the SerpinB3 gene. Moreover the inhibitory effect of SerpinB3 on calpain was assessed by means of the calpain activity assay.

Results: A positive correlation between Myc and SerpinB3 expression was observed at transcription and protein level in HCC specimens, where Myc oncogene was found predominantly in the nucleus of cancer cells overexpressing SerpinB3. Myc expression was significantly and mechanistically up-regulated by SerpinB3 through calpain and Hyppo-dependent molecular mechanisms. Recombinant SerpinB3 protein was indeed capable to inhibit the activity of calpain in vitro, likely reducing its ability to cleave Myc in its non-oncogenic Myc-nick cytoplasmic form. Furthermore, SerpinB3 indirectly increased the transcription of Myc through the induction of Yap pathway, as documented by a remarkable Yap nuclear translocation and up-regulation of Yap target genes in transgenic mice and in hepatoma cells overexpressing human SerpinB3.

Conclusions: Data from the present study provide evidence that SerpinB3 can improve the production of Myc oncogene through direct and indirect mechanisms that include the inhibition of generation of its cytoplasmic form and the activation of Yap pathway.

P0271

EFFECTS OF FXR AGONIST PX20606 ON TUMOUR FORMATION IN ANIMAL MODELS OF NON-ALCOHOLIC FATTY LIVER DISEASE

A. Whitehead[1], G.L. Patman[1], U. Deuschle[2], C.P. Day[3], C. Kremoser[2], D.G. Tiniakos[3], Q.M. Anstee[3], H.L. Reeves[1], on behalf of FLIP investigators (FP7/2007–2013) Health-F2–2009–241762. *[1]Northern Institute for Cancer Research, University of Newcastle Upon Tyne, Newcastle-upon-Tyne, United Kingdom; [2]Research Office, Phenex Pharmaceuticals, Heidelberg, Germany; [3]Institute of Cellular Medicine, University of Newcastle Upon Tyne, Newcastle-upon-Tyne, United Kingdom*

E-mail: h.l.reeves@ncl.ac.uk

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is an increasingly common cause of cirrhosis and hepatocellular carcinoma (HCC). FXR receptor agonists have shown promise, reducing steatosis, inflammation and fibrosis. We explored the effects of the FXR receptor agonist PX20606 on tumour formation in two murine models of NAFLD.

Methods: C57BL/6 mice fed high-fat diet (HFD) plus 1% cholesterol received 0, 1, 3 or 10 mg/kg PX20606 in food for 12–18 weeks (n = 17, 7, 8, 17 respectively). In a longer term study, C3H/He mice (Harlan), which develop obesity, fatty liver and HCC with age, were fed American lifestyle (ALIOS, n = 24) or control diet (n = 23) from 8 until 48 weeks of age. Parallel groups received PX20606 1 mg/kg (n = 24) or 5 mg/kg (n = 16) for the final 24 weeks.

Results: In C57BL/6 mice at 12–16 weeks, plasma cholesterol and liver triglycerides were suppressed by PX20606, with no significant changes in ALT. Surface liver tumours (2–3 mm) were evident after 18 weeks of PX20606 treatment in 9%, with no significant difference between groups (Table 1A). In C3H/He mice at 48 weeks, PX20606 lowered the total cholesterol/HDL and TG levels (Table 1). While all C3H/He mice developed NAFLD with age, ALIOS diet markedly exacerbated this, with increased steatosis, ballooning, lobular inflammation, fibrosis and with a greater number and size of HCC (Table 1B). PX20606 modestly reduced the histological severity of NAFLD in ALIOS fed animals, but had no impact on tumour number or size. Unexpectedly, on the control diet, the severity of hepatitis, as well as tumour number and size increased stepwise with PX20606 dose (Table 1B). In these animals, tumour development was strongly associated with liver weight (Spearman 0.425, p = 0.005) and hepatocellular ballooning (Spearman 0.491, p = 0.001).

Table 1A. C57BL/6 mice (12–16 weeks) fed HFD with or without FXR agonist PX20606

PX20606	0 mg	1 mg	3 mg	10 mg	p (10 mg to 0 mg)
Number of mice	17	7	8	17	
HCC mean	0.23±0.11	0.14±0.14	0	0.18±0.10	0.531
Liver (g)	3.30±0.93	2.71±1.04	3.08±0.64	2.90±0.60	0.118
ALT	90.41±43.31	65.00±32.98	59.12±31.62	81.88±56.67	0.625
Total CH	277.71±58.22	129.00±45.64	138.13±43.03	81.76±29.33	0.000
Liver TG (μg/mg)	123.01±14.58	101.05±2.36	108.18±4.21	43.80±13.72	0.000

Conclusions: Treatment with FXR agonist PX20606 strongly affected lipids in C57BL/6 and modestly affected lipids and NASH in C3H/He, but did not reduce HCC risk in either animal model of NAFLD. In 18 weeks C57BL6 HFD mice or 48 weeks C3H/He ALIOS mice, there were no significant differences in HCC incidence associated with PX20606 treatment. However, in 48 weeks control diet C3H/He mice with background mild NAFLD, HCC risk increased stepwise with PX20606 dose, associated with increased liver weight and hepatocellular ballooning. These data may not be an FXR-agonist class effect and could reflect a rodent or strain-specific mechanism. However, studies assessing similar agents as long-term treatments in humans should consider HCC risk.

Table 1B (abstract P0271). C3H/He mice (48 weeks) fed control or ALIOS diet, with or without FXR agonist PX20606

	Control diet				ALIOS diet				p 6 groups (KW)
PX20606	0 mg	1 mg	5 mg	p	0 mg	1 mg	5 mg	p

LONG-TERM INHIBITION OF EGFR IN HUMAN CHOLANGIOCARCINOMA CELLS LEADS TO THE INDUCTION OF AN EPITHELIAL TO MESENCHYMAL TRANSITION PROGRAM AND ACTIVATION OF INSULIN/INSULIN GROWTH FACTOR 1 RECEPTORS

J. Vaquero[1,2], A. Clapéron[1,2], M. Mergey[1,2], C. Desbois-Mouthon[1,2], F. Praz[1,2], L. Fouassier[1,2]. *[1]INSERM, UMR_S 938, Centre de Recherche Saint-Antoine, F-75012, Paris, France; [2]Sorbonne Universités, UPMC Univ Paris 06, UMR_S 938, Centre de Recherche Saint-Antoine F-75012, Paris, France*
E-mail: javiervr84@hotmail.com

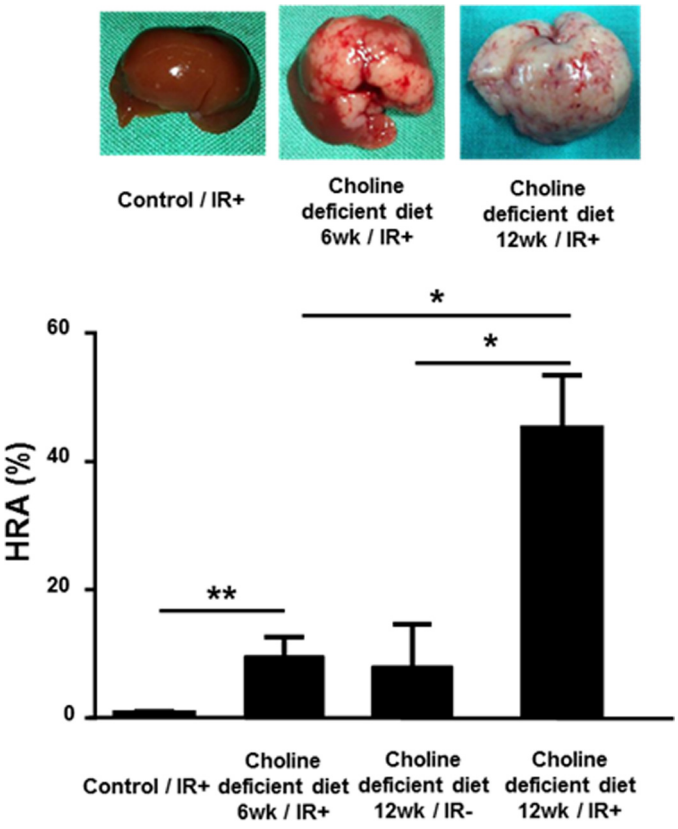
Background and Aims: Cholangiocarcinoma (CCA) is a liver cancer with poor prognosis due to local invasion and metastasis. Epidermal growth factor receptor (EGFR) is overexpressed in CCA tumors and plays a major role in CCA progression. Thus, EGFR has been envisaged as molecular target for CCA therapy. However, clinical trials using anti-EGFR such as the small-molecule tyrosine kinase inhibitor (TKI) erlotinib did not provide a therapeutic benefit in patients with CCA, suggesting resistance to anti-EGFR therapies. This study was designed to unravel the underlying cellular and molecular mechanisms involved in acquired resistance to anti-EGFR in CCA.
Methods: Cell pools resistant to erlotinib were obtained by treating four human CCA cell lines (HuCCT1, SK-ChA-1, EGI-I and Mz-ChA-1) with increasing concentrations of erlotinib (0–20 μM) for a long period of time (6–9 months). Cell viability was determined by MTT assay. Epithelial to mesenchymal transition (EMT) was investigated by examining the expression of epithelial and mesenchymal markers by RT-qPCR, western blot and immunofluorescence. Signaling pathways were analyzed by phosphoprotein arrays, immunoprecipitation and western blot.
Results: The four erlotinib-treated CCA cell lines showed reduced sensitivity to TKI toxicity compared to their parental counterparts. Long-term treatment with erlotinib induced CCA cells scattering, which was accompanied by a disruption of the adherens junctions as attested by the internalization and/or decreased expression of E-cadherin, as well as dephosphorylation and nuclear translocation of β-catenin. In pools with acquired resistance to erlotinib, the expression of EMT-transcription factors (SNAIL, SLUG and ZEB-1) and mesenchymal markers (*i.e.* N-cadherin and α-SMA) was induced. Additionally, the expression of cancer stem cell (CSC) markers (*i.e.* CD117, CD133 and ABCG2) was also up-regulated in erlotinib-resistant cells. In these cells, all members belonging to the ERBB family (ERBB1/EGFR, ERBB2, ERBB3 and ERBB4) were inhibited. In contrast, insulin/insulin growth factor 1 receptors (IR/IGF1R) were activated and IGF2, a ligand for IR/IGF1R, was overexpressed in resistant cells compared to untreated cells.
Conclusions: The establishment of an EMT program with the acquisition of CSC phenotype, and the activation of the IGF signaling axis could contribute to the resistance of CCA cells to erlotinib.

P0273

ISCHEMIC PRECONDITIONING OF INJURED STEATOTIC LIVERS REDUCES HEPATOCELLULAR CARCINOMA RECURRENCE

L.A. Orci[1], S. Lacotte[2], C. De Vito[3], G. Oldani[1], P. Morel[1], L. Crowe[4], C. Toso[1]. *[1]Division of abdominal and transplantation surgery, Hepato-pancreato-bliliary centre, Department of Surgery, [2]Department of Surgery, [3]Department of Clinical Pathology, [4]Department of Radiology, Geneva University Hospitals and Faculty of medicine, University of Geneva, Geneva, Switzerland*
E-mail: lorenzo.orci@hcuge.ch

Background and Aims: Although livers with parenchymal abnormalities poorly tolerate ischemic damage, there is limited data as to whether the susceptibility of steatotic livers to ischemia-reperfusion (IR) injury also impacts on cancer recurrence.
Methods: Wild type C57BL/6 mice were fed with a choline-deficient (CD) diet for 6 and 12 week, or standard chow. Hepatic IR injury and ischemic preconditioning were achieved by clamping the liver blood inflow. Hepa 1–6 hepatocellular carcinoma (HCC) cells were inoculated through the spleen. After three weeks, tumor burden, serum alpha fetoprotein and cancer cell aggressiveness were compared among groups.
Results: Hepatocellular damage and inflammatory genes (*Il6, Tnf-α, Hif-1α, E-selectin*) expression were significantly exacerbated after IR injury in severely steatotic mice. Compared to control livers or those with minimal steatosis, livers exposed to prolonged CD diet developed larger tumor nodules, and exhibited higher serum AFP levels. Non-ischemic lobes of steatosis/IR+ mice were not protected from IR-mediated accelerated tumor overgrowth. This remote effect was linked to a promotion of the aggressiveness of HCC cells exposed *in vitro* to the serum of steatosis/IR+ mice. Importantly, the tumor burden of livers undergoing ischemic preconditioning before IR was reduced to the level of non-ischemic steatotic controls.
Conclusions: Steatotic livers poorly tolerate IR injury, contributing to more severe HCC recurrence patterns in mice with increasing degree of fatty liver infiltration. IR mitigation by performing ischemic preconditioning results in reduced tumor load and serum AFP. In addition to *in situ* effects, the IR-related susceptibility of steatotic livers impacts on remote cancer cell aggressiveness.



P0274

LIVER TUMOR INCIDENCE IS DEPENDENT ON SEX AND TELOMERASE STATUS IN TRP53 KNOCKOUT MICE

M. Svinarenko[1], S.-F. Katz[1], T. Seufferlein[1], P. Schirmacher[2], A. Lechel[1]. *[1]Internal Medicine I, Ulm University Hospital, Ulm, [2]Institute of Pathology, University Hospital, Heidelberg, Germany*
E-mail: michael.svinarenko@uni-ulm.de

Background and Aims: Key features of human liver cancer are telomere shortening, dysregulation of the p53-signaling pathway and chromosomal instability. Defects in the p53-signaling pathway

are frequently associated with increase in stem cell features, mixed differentiation and poor prognosis. In this study we analyze the cooperation between telomere dysfunction and p53 loss in a humanized mouse model.
Methods: We crossed telomerase knockout mice (Terc$^{-/-}$) with a conditional Trp53 mouse and a liver-specific AlfpCRE mouse (CRE expression under the albumin-alphafetoprotein-enhancer-promoter) to induce a liver-specific deletion of the Trp53 gene during embryogenesis. We crossed Terc$^{-/-}$ mice up to the third generation (G3 Terc$^{-/-}$) for the generation of short telomeres. At this step we intercrossed G3 Terc$^{-/-}$ with Terc$^{+/-}$ mice. Through this mating strategy we produced Trp53 knockout mice lacking telomerase (AlfpCre, Trp53Δ/Δ, iG4 Terc$^{-/-}$) and mice with reactivated telomerase (AlfpCre, Trp53Δ/Δ, iF1 Terc$^{+/-}$). We compared these mice with Trp53 knockout mice with long telomeres and active telomerase (AlfpCre, Trp53Δ/Δ, Terc$^{+/+}$).
Results: Mice of all three cohorts developed liver cancer with an incidence of up to 80% showing a mixed tumor differentiation of hepatocellular carcinoma and cholangiocellular carcinoma (HCC-CC). Tumor formation frequently occurs in male mice. The tumor incidence was slightly increased in male mice with short telomeres and lack of telomerase. Liver tumor formation in female mice was a rare event at the age of 12–14 month but increases in females with short telomeres and telomerase reactivation (AlfpCre, Trp53Δ/Δ, iF1 Terc$^{+/-}$: 6 out of 11; AlfpCre, Trp53Δ/Δ, iG4 Terc$^{-/-}$: 2 out of 18; AlfpCre, Trp53Δ/Δ, Terc$^{+/+}$: 2 out of 12).
Conclusions: Overall this study shows that Trp53 deletion frequently results in liver tumor formation in male mice, whereas incidence of tumor formation in female mice depends on telomere length and telomerase status. The arising liver tumors show an increase in stem cell features.

PDGFRA-MEDIATED LAMININ B1 DEPOSITION INDUCES INVASION IN HUMAN HEPATOCELLULAR CARCINOMA
O. Govaere[1], M. Petz[2], J. Wouters[1], Y.-P. Vandewynckel[3], A. Ceulemans[1], B. Topal[4], C. Verslype[5], H. Van Vlierberghe[3], F. Nevens[6], W. Mikulits[2], T. Roskams[1]. *[1]Department of Imaging and Pathology, KU Leuven and University Hospitals Leuven, Leuven, Belgium; [2]Department of Medicine I, Institute of Cancer Research, Medical University of Vienna, Vienna, Austria; [3]Department of Hepatology & Gastroenterology, Ghent University, Ghent, [4]Department of Abdominal Surgery, [5]Department of Hepatology, KU Leuven and University Hospitals Leuven, [6]Department of Hepatology, KULeuven, Leuven, Belgium*
E-mail: olivier.govaere@med.kuleuven.be

Background and Aims: Platelet-derived growth factor receptor α (PDGFRA) has been associated with the progression of hepatocellular carcinoma (HCC), although the exact underlying mechanism of PDGFRA still remains unclear.
Methods: Clinicopathological value of PDGFRA was assessed in a Caucasian cohort of 136 HCC patients (resection or explant specimens) with different underlying aetiologies; the predictive value was evaluated in an independent series of 46 pre-operative needle biopsies with a follow-up of 5 years. Activation or inhibition of PDGFRA (using recombinant PDGFA/B or Crenolanib respectively) and alteration of downstream target laminin B1 (LAMB1) and its receptor integrin B1 (ITGB1) (by laminin-1 coating, shRNAs or targeted antibodies) was performed in the SNU423 and HepG2 HCC cell lines. Functional readout was done using invasion and invadopodia assays, and mouse xenograft models.
Results: In the cohort of surgical specimens PDGFRA expression was found in 66% of the samples and was significantly correlated with metastasis ($p < 0.001$), microvascular invasion ($p < 0.001$) and increased tumour size ($p < 0.05$), and was especially found in the invasive front. In the cohort of needle biopsies, PDGFRA was significantly linked with poor overall survival ($p < 0.05$). In vitro activation of PDGFRA enhanced LAMB1 expression through the LA/SSB cascade and promoted invasion and invadopodia formation, whereas inhibition of PDGFRA by Crenolanib had the opposite effect. Antibodies targeting laminin-1 or ITGB1 receptor reduced the invasive potential and altered the expression of genes involved in cytoskeleton remodelling (e.g. KRT19, ANXA3). Similar results were obtained by inhibiting Rho-associated, coiled-coil containing protein kinase 2. Moreover, knockdown of LAMB1 diminished the metastatic potential in vivo.
Conclusions: PDGFRA-LAMB1 pathway plays an important role in the invasion of HCCs and is a promising therapeutic target.

HIF2-ALPHA NEDDYLATION AS A SELECTIVE SERPINB3-DEPENDENT MECHANISM LEADING TO ITS INCREASE
S. Cannito[1], G. Villano[2], C. Turato[2], E. Morello[1], C. Paternostro[1], S. Quarta[2], S. Colombatto[3], F. Lopitz-Otsoa[4], M.L. Martinez-Chantar[4], P. Pontisso[2], M. Parola[1]. *[1]Dept. Clinical and Biological Sciences, University of Torino, Torino, [2]Dept. of Medicine, University of Padova, Padova, [3]Dept. of Oncology, University of Torino, Torino, Italy; [4]Dept. of Metabolomics, Centro de Ivestigation Biomedica en Red de Enfermedades Hepaticas y Digestivas, Technology Park of Bizkaia, Bizkaia, Spain*
E-mail: stefania.cannito@unito.it

Background and Aims: SerpinB3 is a cysteine-proteases inhibitor overexpressed in hepatocellular carcinoma (HCC). In previous studies SerpinB3 has been reported to be up-regulated by hypoxia through a redox- and HIF2α-dependent mechanism. Our preliminary results suggested to act as a paracrine mediator able to induce stabilization and increased nuclear translocation of HIF2α and up-regulation of HIF2α-related genes in liver cancer cells such as CXCR4, c-Myc and CyclinD1. The ubiquitin-like molecule, NEDD8, is a key regulator of cell growth, viability and malignant transformation. Neddylation promotes timely stabilization of proteins with essential regulatory roles in an extensive variety of biological processes. It has been reported that the overexpression of global neddylation is associated with clinical HCC and it's poorest prognosis. In the present study we have investigated selective HIF2α neddylation stabilization in a serpinB3 dependent mechanism providing the advantage that this regulation has in liver cancer.
Methods: The cross-talk between SerpinB3 and HIF2α has been investigated by taking advantage of morphological, molecular and cell biology techniques in the following experimental models: (i) control HepG2 exposed to recombinant SerpinB3 (rSerpinB3); (ii) HepG2 stably transfected to overexpress SerpinB3 (HepG2/SB3); (iii) transgenic mice overexpressing SerpinB3 in the liver.
Results: Immunohistochemistry performed on liver sections from SerpinB3 transgenic mice show an impressive level of nuclear staining for HIF2α and exposure of HepG2 to rSerpinB3 results in increased nuclear levels of HIF2α. Different experimental approaches (normoxic conditions) revealed that in relation to the action of SerpinB3: (i) increased protein levels of HIF2α are unrelated to its increased transcription; (ii) increased HIF2α protein levels are unrelated to an inhibition of overall proteasome activity by SerpinB3; (iii) overexpression of SerpinB3 lead to an increase in the level of neddylated proteins and of levels of NEDD8 activating enzyme 1 (NAE-1); (iv) the use of a specific inhibitor of NAE-1 selectively reduces HIF2α levels.
Conclusions: SerpinB3 can affect the behaviour of target cells by increasing protein levels of HIF2α, followed by its nuclear translocation and induced transcription of target genes, by inducing HIF2α selective neddylation and consequent stabilization which is independent on hypoxia.

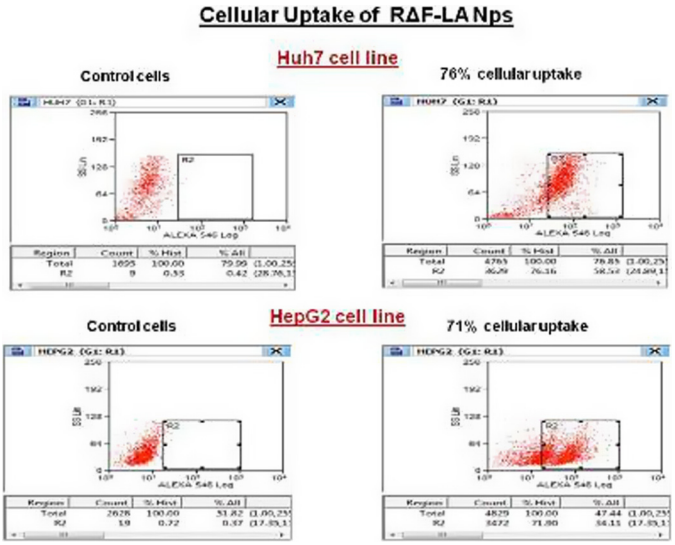
ENHANCED AND EFFECTIVE DELIVERY OF MICRORNA BY USING LIGAND MODIFIED SELF ASSEMBLED CATIONIC DIPEPTIDE NANOPARTICLES IN HEPATOCELLULAR CARCINOMA (HCC)

A. Varshney[1], J.J. Panda[2], A.K. Singh[1], S.B. Rooge[1], S. Biswas[1], S.K. Sarin[3], V.S. Chauhan[4]. *[1]Department of Research, Institute of Liver & Biliary Sciences, New Delhi, [2]Institute of Nano Science and Technology, Mohali, [3]Department of Hepatology & Research, Institute of Liver & Biliary Sciences, [4]International Centre for Genetic Engineering and Biotechnology, New Delhi, India*
E-mail: virander@icgeb.res.in

Background and Aims: HCC is a primary liver tumor with high mortality. Systemic and locoregional chemotherapy have limited role due to toxicity and low uptake of chemotherapeutic agents in HCC. RNA interference holds potential as a new therapeutic approach. However, safe and efficient nanovectors for delivery of microRNA (miRNA) are few. We aimed to create a novel vehicle to restore dysregulated gene expression in liver tumor cells by miR-199a-3p delivery. Self-assembled arginine dehydrophenylalanine-lactobionic acid nanoparticles (RΔF-LA Nps) are biodegradable, stable to proteases, non-toxic and tunable structures for targeted delivery. For selective targeting of Nps to tumor cells, we introduced ligand (LA) that can actively interact with the asialoglycoprotein receptors overexpressed on liver tumor cell surface.
Methods: Dipeptide (RΔF) was synthesized by solution phase method and LA conjugated RΔF Nps were prepared, then complexed with miRNA by electrostatic interactions. Biophysical characterizations were done by particle size analysis, zeta potential, transmission electron microscopy, electrophoretic mobility measurements, and florescence microscopy. Therapeutic efficacy was evaluated in liver tumor cell lines like HepG2 and Huh7 using MTT assay, flow cytometry, RT-PCR, wound healing/cell migration assay.
Results: We observed that the RΔF-LA Nps were spherical in morphology with mean size of 320±40 nm, zeta potential of +0.91mV±0.3mV, stable in serum, RNAse and had miRNA encapsulation efficiency of 70±4.3%. The RΔF-LA Nps were non-cytotoxic with cellular uptake of 76±2.5% in Huh7 and 71±1.7% in HepG2 cell line, significantly higher as compared to RΔF Nps. RΔF-LA Nps efficiently entered and delivered miR-199a-3p in Huh7 cell line with 10 fold increase in mature miR-199a-3p expression and a 35% decrease in CMET ($p < 0.03$), a target of miR-199a-3p. MTT assay revealed that selective reduction in Huh7 cell proliferation was 41% ($P < 0.02$). Over expression of miR-199a-3p in tumor cell lines resulted in decrease of 42±1.8% gap closure in cell migration was measured by ImageJ software and increase in apoptotic level detected by Annexin V and propidium iodide based flow cytometry analysis.



Conclusions: In this study, RΔF-LA Nps were developed and showed high affinity towards liver cancer cell lines. In vitro studies demonstrated the successful delivery of miRNA, resulted in significant inhibition in cell proliferation and migration. RΔF-LA Nps showed great promise as a selective anticancer agent against HCC.

HEPATIC STEATOSIS AND HIGH CIRCULATING FREE FATTY ACID LEVELS PROMOTE GROWTH AND INVASIVENESS OF HEPATOCELLULAR CARCINOMA

A. Koch[1], C. Dorn[1], W. Thasler[2], M. Müller[1], A. Bosserhoff[3], C. Hellerbrand[1]. *[1]University Hospital Regensburg, Regensburg, [2]Ludwig-Maximilians-University Munich, Munich, [3]University of Erlangen, Erlangen, Germany*
E-mail: claus.hellerbrand@ukr.de

Background and Aims: The metabolic syndrome and hepatic steatosis are independent risk factors for HCC development and progression but the underlying mechanisms are incompletely understood. Here, we aimed to investigate the influence of high free fatty acid levels and hepatic steatosis on HCC progression.
Methods: Murine HCC cells were implanted into the liver of control mice or mice fed with a high-fat diet (HFD) causing significant hepatic steatosis. Subsequently, feeding was continued with control diet or HFD for 14 days. Furthermore, different human HCC-cell lines (Hep3B, PLC, Huh7) were incubated with conditioned medium (CM) of steatotic primary human hepatocytes (PHH) or different doses of free fatty acids (FFA).
Results: Tumors grown in steatotic livers were significantly larger, showed increased mitotic activity, revealed a more invasive growth and higher expression of matrix metalloproteases (MMPs) compared to tumors formed in normal liver tissue. Under the feeding conditions used, the HFD did not cause activation of hepatic stellate cells (HSC) in the non-tumorous liver parenchyma. However, there was a significant increase of HSC activation in tumors grown in steatotic livers compared to tumors of the control group as shown by α-SMA mRNA and immunohistochemical analysis. This is critical because we and others have shown before that activated HSC promote tumorigenicity of HCC cells. Furthermore, HCC cells incubated with CM of steatotic hepatocytes caused a significant increase of proliferation as compared to HCC cells treated with CM from control PHHs. Moreover, we addition of FFA to the cell culture medium of HCC cells caused a dose dependent induction of cellular lipid accumulation, which was in line with observation that also in vivo HCCs grown in mice fed with the HFD revealed higher triglyceride levels compared to HCCs in control livers. Noteworthy, steatotic HCC cells showed enhanced migratory activity in Boyden Chamber assays and higher expression of MMPs compared to HCC control cells.
Conclusions: Different mechanisms promote HCC growth in steatotic livers. Once, lipid accumulation in hepatocytes causes secretion of factors promoting tumor growth. Furthermore, desmoplastic reaction is enhanced in HCC in steatotic tissues and systemic metabolic changes associated with the metabolic syndrome such as hyperlipidemia seem to directly affect HCC cells offering a further option for HCC prevention and treatment.

SLC25A11 PROMOTES CELL PROLIFERATION IN HEPATOCELLULAR CARCINOMA SPHEROIDS AND ORTHOTOPIC TUMOR GROWTH

A. Baulies[1,2], D. Robles[2], D. Babu Uthaya Kumar[3], K. Machida[3], H. Tsukamoto[4,5], C. García-Ruiz[1,2,6], J.C. Fernández-Checa[1,2,6]. *[1]Liver Unit, Hospital Clinic Barcelona, IDIBAPS, CIBERehd, Universitat de Barcelona, [2]Cell Death and Proliferation, Instituto de Investigaciones Biomedicas de Barcelona, CSIC, Barcelona, Spain; [3]Southern California Research Center for ALPD and Cirrhosis and Department of Molecular Microbiology and Immunology, Keck School of Medicine of the University of Southern California, [4]Southern California Research Center for ALPD and Cirrhosis and Department of Pathology, Keck School of Medicine of the University of Southern California, [5]Department of Veterans Affairs Greater Los Angeles Healthcare System, [6]USC Research Center for Liver Diseases, Los Angeles, United States*
E-mail: abaulies@gmail.com

Background and Aims: Hepatocellular carcinoma (HCC) is the most common form of liver cancer and a leading cause of cancer-related deaths in the world. Cancer cells exhibit increased mitochondrial cholesterol (mChol), which contributes to apoptosis and chemotherapy resistance by impairing mitochondrial outer membrane permeabilization. However, hepatocellular mChol accumulation promotes steatohepatitis due to mitochondrial GSH (mGSH) depletion determined by defective GSH import by the 2-oxoglutarate carrier (SLC25A11). Hence, the purpose of our study was to characterize the status of mGSH in HCC and to explore the role of SLC2511 in HCC spheroid formation and i*n vivo* liver tumorigenesis.
Methods: Hep3B cells were cultured in monolayers or in 3D spheroids using PolyHEMA-coated plates with or without SLC25A11 silencing by siRNA. Hep3B monolayers were subject to hypoxia ($1\%O_2$) to examine the impact on reactive oxygen species (ROS) and cell death. Spheroids growth and size was monitored during 6 days with or without GSH ethyl ester (GSHee). Immunohistochemical analyses of PCNA, KI67 and pimonidazole (PIMO) were performed in collected spheroids at day 7. Tumor initiating stem cells (TICs) were stably transfected with two silencing vectors targeting SCL25A11 and injected in the parenchyma of the left liver lobe of immunodeficient mice (NOG mice). Animals were sacrificed three weeks later and tumor growth was analyzed in all animals.
Results: SLC25A11 silencing in Hep3B monolayers depleted mGSH by 50–60%, resulting in hypoxia-induced ROS overgeneration (2 fold) and sensitization to hypoxia-induced cell death (70%). Moreover, Hep3B spheroids growth was reduced upon SLC25A11 silencing by 50–60% compared to control spheroids. The effect of SLC25A11 silencing on spheroids growth was reversed by mGSH replenishment with GSHee treatment, while GSHee *per se* increased size in control spheroids. Core spheroids cells stained with PIMO and Ki-67 and PCNA positive cells were reduced in siRNA SLC25A11-treated spheroids compared to siRNA scrambed-treated spheroids. SCL25A11 silencing in TICs also caused reduced cell number and proliferation without effect in cell size. Moreover, in vivo tumor size and multiplicity were reduced in mice injected with stably genetic SLC25A11 silenced TICs.
Conclusions: SLC24A11 silencing in Hep3B-3D spheroids and TICs orthotopic tumor model reduced tumor growth *in vitro* and *in vivo*, suggesting that targeting this mitochondrial carrier may be of potential relevance in HCC.

EFFECT OF EXTRACELLULAR MATRIX ON CANCER STEM CELLS

F. Heindryckx[1], D. Rauer[1], E. Bogaerts[2], P. Gerwins[1], H. Van Vlierberghe[3]. *[1]Medical Cell Biology, Uppsala University, Uppsala, Sweden; [2]Gastroenterology–Hepatology, Ghent University Hospital, [3]Gastroenterology–Hepatology, Uppsala University, Ghent, Belgium*
E-mail: fempie@gmail.com

Background and Aims: Activated hepatic stellate cells are responsible for the excessive deposition of extracellular matrix (ECM) in chronically damaged livers. ECM proteins as well as their proteolytic fragments have been implicated in playing a crucial role in tumor growth, metastasis, and tumor neo-angiogenesis. Whereas some of the molecules in the tumor microenvironment have an effect on vasculature, others have a direct effect on the tumor cells, altering their behavior and phenotypic properties. An interesting feature is the increasing evidence that the ECM is an essential component of the stem cell niche and that it can directly regulate stem cell differentiation. However, the molecular details of how this is achieved have only just started to emerge. Our aim is to investigate the direct effect of ECM on hepatocellular carcinoma (HCC), mainly focusing on cancer stem cell (CSC) properties, migration and proliferation.
Methods: Human immortalized hepatic stellate cells (LX2) were stimulated with TGF-beta and/or the fibrin degradation product Fragment E (FnE) for 48 hrs. Medium from these cells was collected and used for subsequent stimulation of the human hepatoma cell line HepG2. HepG2 cells were grown on plates coated with ECM proteins, including collagen, fibrinogen, fibrin, FnE and fibrinogen-like-protein 1. Cells were harvested after 48 hrs and RNA was isolated for subsequent qPCR analysis on CSC markers. Scratch wound assays were performed to assess migration. Inhibitors of collagen-synthesis and integrin-signaling were used to study the involvement of collagen.
Results: FnE and TGFβ lead to a 2-fold increased expression of smooth muscle actin and collagen in HSC, compared to TGFβ alone. Stimulating HepG2 cells with medium from these HSC caused a significant increase of CSC-markers, and increased migration in the condition where TGFβ and FnE were used together to stimulate the HSC. This effect was diminished when a collagen-synthesis inhibitor was added to the HSC during stimulation with TGFβ and FnE, suggesting that perhaps the increased collagen production by activated HSC could be a key influence on tumor behavior. Growing HCC cells on collagen-coated plates also increased expression of CSC-markers prominin-1 and CK19. Other ECM proteins did not have this effect.
Conclusions: Fibrin fragment E can stimulate HSC to secrete factors which cause cancer cells to de-differentiate towards a more CSC-phenotype, associated with more aggressive tumours.

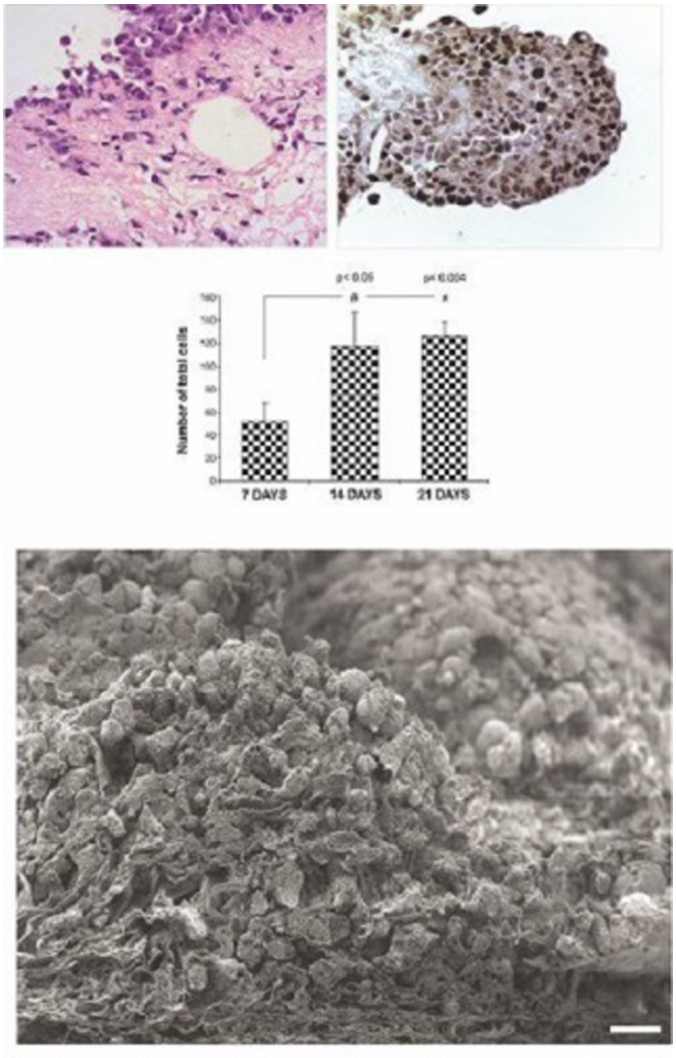
E-mail: giuseppe.mazza.12@ucl.ac.uk

Background and Aims: It is generally well recognised that animal models are poor surrogates for understanding the pathophysiology of liver disease, and generally unrepresentative when it comes to studying liver fibrosis, cancer and drug metabolism. The ideal

model would use human liver, or a biologically relevant 3D in vitro model of human liver cells grown on an extracellular matrix (ECM) derived from healthy liver tissue.
The aim of this study was to develop a rapid protocol for the decellularisation of small samples of human liver and demonstrate repopulation with cultured human liver cell lines, namely hepatocarcinoma (HepG2), metastatic adenocarcinoma (SK-Hep-1) and hepatic stellate (LX2) cells.
Methods: Liver tissue cubes (5×5×5 mm, i.e. 0.125 cm^3) were dissected from human livers unsuitable for transplantation. The decellularisation of the human liver cubes was completed within 3 hours of incubation and agitation in our decellularization medium (1. deionized water, 2. detergents and 3. enzymes [trypsin]), and following optimization of pre-existing protocols for animal tissues. The decellularization efficiency was determined by immunohistochemistry for ECM components and residual DNA, scanning electron microscopy, as well as DNA and ECM protein quantification. The liver cube scaffolds were seeded and repopulated by HepG2, SK-Hep-1 and LX2 for up to 21 days.



Results: This innovative protocol resulted in liver cube scaffolds with a preserved 3D structure and ECM composition, while DNA and cellular residues were successfully removed. Human liver scaffolds were progressively repopulated for up to 21 days with LX2, SK-Hep-1 and HepG2 cells which showed remarkable viability, motility and proliferation associated with remodelling effects on the surrounding ECM. Notably, the expression of some genes and proteins involved in liver fibrosis and cancer was different between the 2D and the 3D system.
Conclusions: This is the first report describing an efficient protocol to completely decellularize human liver cubes. The decellularization protocol was rapid and maintained the natural 3D structure and ECM composition and organisation. This is a key advance in the development of 3D technologies for the study of human liver fibrosis and cancer.

Sansom[6], N. Valeri[1], C. Braconi[1]. *[1]Institute of Cancer Research, Sutton, United Kingdom; [2]ARC-NET Research Centre, University of Verona, Verona, Italy; [3]Institute of Cancer Sciences, University of Glasgow, Glasgow, United Kingdom; [4]University of Bellinzona, Bellinzona, [5]Institute of Pathology, University of Basel, Basel, Switzerland; [6]Beatson Institute of Cancer Research, Glasgow, United Kingdom; [7]Aging Research Centre, University of Chieti, Chieti, Italy; [8]School of Biosciences, University of Cardiff, Cardiff, [9]MRC Centre for Inflammation Research, University of Edinburgh, Edinburgh, United Kingdom; [10]University of Ferrara, Ferrara, Italy; [11]Transplant Center, Mayo Clinic, Jacksonville, United States*
E-mail: IoHong.Cheong@icr.ac.uk

Background and Aims: Transcribed-Ultraconserved-Regions (T-UCR) are long ncRNAs which are conserved across the species and are involved in carcinogenesis. Here we look at T-UCRs downstream of Wnt/β-catenin pathway in HCC.
Methods: $APC^{fl/fl}$ mice developed Wnt/β-catenin dependent hepatocarcinoma (HCC). Expression of T-UCR was assessed by microarray, qtPCR, and In Situ Hybridization. Mutations of CTNNB1-exon3 were analysed by direct-sequencing. Cell viability was assessed by Alamar Blue, apoptosis by Caspase3/7GLO.
Results: We profiled T-UCR expression in the liver of $APC^{fl/fl}$ and $APC^{+/+}$ mice. Over-expression of uc.158− could differentiate Wnt/β-catenin dependent HCC from normal liver and from β-catenin negative DEN-induced HCC. RACE showed uc.158− is transcribed as an independent antisense ncRNA. uc.158− was over-expressed in human HepG2 vs Huh7 cells and in Hepatic Stem Cells vs normal hepatocytes, in line with the activation of the Wnt pathway. In vitro modulation of β-catenin resulted in alteration of uc.158− expression in human HCC cell lines. uc.158− expression was increased in CTNNB1-mutated compared to non-mutated human HCCs, and in human HCC with nuclear localization of β-catenin. LNA-mediated inhibition of uc.158− reduced anchorage cell growth by 60% (probe1) and 70% (probe3) at 72 hrs in HepG2 cells. HepG2 3D-spheroid formation was reduced to 34% and 40% after silencing of uc.158− with probe 1 and 3 respectively. Inhibition of uc.158− also reduced spheroid-based cell migration. FACS analysis showed no changes in the phases of cell cycle, but for an increased number of cells in the subG0-G1 phase after uc.158 silencing. Inhibition of uc.158 increased cleavage of caspase3/7, but did not affect cytotoxicity. Computational analyses identified binding sites (ddG score <10) for 14 miRNAs (conserved across species) within the uc.158− miRNA profile in the $APC^{fl/fl}$ and $APC^{+/+}$ mice showed 10 of these miRNAs being down-regulated in HCC compared to controls, suggesting that uc.158− may act as a competing endogenous RNA. Amongst these, miR-193b, miR-346 and miR-615 were increased after silencing of uc.158− in HepG2 cells. miR-193b expression was reduced in HepG2 compared to Huh7. Enforced expression of uc.158− in Huh-7 cells reduced expression of miR-

193b. Data from literature confirm reduced expression of miR-193b in human HCC.
Conclusions: We showed that uc.158− is activated by Wnt/β-catenin pathway in HCC and drives HCC growth. Thus it may represent a promising target for the development of novel therapeutics.

P0283
ADENOSINE MONOPHOSPHATE ACTIVATED KINASE (AMPK) IN CANCER AND HUMAN HEPATIC STELLATE CELL CROSSTALK
K. Schölzel[1], L. Longato[1], H. Hummels[1], B. Davidson[2], K. Moore[1], M. Pinzani[1], K. Rombouts[1]. [1]*Institute for Liver and Digestive Health, University College London,* [2]*Division of Surgery, Royal Free London Foundation Trust, London, United Kingdom*
E-mail: katrin.schoelzel.13@ucl.ac.uk

Background and Aims: Human hepatic stellate cells (HSC) are important in fibrosis associated with hepatocellular carcinoma (HCC) progression. In addition, it has been demonstrated that HCC modifies HSC behaviour. Hence, tumour-stromal interactions are considered as a potential target for anti-cancer and anti-fibrogenic therapy. Adenosine monophosphate-activated kinase (AMPK) and liver kinase B1 (LKB1) have a critical function in energy homeostasis regulation in HCC. However, little is known about the effects of AMPK-related HCC metabolic alterations on the microenvironment, particularly activated HSC. In this study, we utilized primary HSC and HCC cell lines to systematically analyse the role AMPK/LKB1 on tumour-stromal crosstalk in vitro.
Methods: Conditioned media (CM) of HepG2 and PLC/PRF/5 HCC cells were harvested after 48 hrs of incubation in serum-free medium. Primary HSC were treated with CM from either cell lines for 24 hrs. Measured endpoints included proliferation (BrdU incorporation), metabolic activity (MTS assay), and gene and protein expression. To assess the role of AMPK, the above responses at 24 hrs were evaluated in presence of AICAR (1mM), an AMPK agonist.
Results: Conditioned media from HepG2 and PLC/PRF/5 had differential effects on HSCs proliferation and AMPK activation status. While HepG2-CM stimulated HSC proliferation and induced AMPK-Ser485-phosphorylation, PLC/PRF/5 CM had no effect on HSCs proliferation while inducing AMPKThr172/LKB1 phosphorylation. These experiments suggest that the AMPK phosphorylation status in HSCs correlates with their proliferation rates and the presence of a soluble "factor" in the supernatant of HCC cells able to induce significant effects on hHSC proliferation. Differential size-fractionation centrifugation identified a factor of <10kDa with inhibitory effects and a factor of >30kDa that stimulates HSC proliferation. The effect of both HCC conditioned media on HSC proliferation was prevented by the AMPK agonist AICAR, which induced the phosphorylation of AMPK-Thr172 and LKB1. Lastly, HepG2- and PLC/PRF/5-CM modified HSC gene expression of several profibrogenic and proinflammatory genes. These effects were further altered in the presence of AICAR.
Conclusions: Our results suggest a complex crosstalk between HCC and HSC during liver cancer development. Understanding the dual mechanisms mediated by multisite phosphorylations by which AMPK is regulated could allow identifying new targets to inhibit both cancer development and the accompanying stromal reaction.

P0284
TYPE 2 DIABETES PROMOTES HEPATOCARCINOGENESIS BY INHIBITING THE INDUCTION OF SENESCENCE AFTER DNA DAMAGE
M. Lu[1], N. Hüser[1], D. Hartmann[1], H. Friess[1], J. Kleeff[1], Y. Sunami[1]. [1]*Department of General Surgery, Klinikum rechts der Isar, Technical University Munich, Munich, Germany*
E-mail: luleiice@163.com

Background and Aims: Diabetes and cancer are both serious and growing health problems worldwide. A number of clinical studies have demonstrated a positive correlation between type 2 diabetes and an increased cancer risk including hepatocellular carcinoma (HCC). The mechanism by which type 2 diabetes promotes hepatocarcinogenesis is largely unknown. FoxO3, a Forkhead-box transcription factor family member, is known to be a master regulator in the insulin signalling pathway and plays a critical role in glucose metabolism. Activation of FoxO3 leads to glucose production and resistance to insulin in hepatocytes. The aim of our study was to investigate the underlying mechanism of type 2 diabetes-enhanced tumorigenesis.
Methods: In order to test this hypothesis, we investigated a mouse model expressing a constitutively active form of FoxO3 (FoxO3CA) in mouse hepatocytes, which show hyperglycemia, hyperinsulinemia, impaired glucose tolerance and insulin resistance. Potential signalling mechanisms in the frame of type 2 diabetes-associated tumorigenesis were investigated using several human HCC cell lines, such as HepG2 and HuH7.
Results: Activation of hepatic FoxO3 signalling led not only to insulin resistance and type 2 diabetic characteristics, but we also observed histomorphological alterations, such as the induction of hepatic dysplasia. Hepatocytes expressing FoxO3CA were found to become relatively atrophic, exhibiting a histological similarity to so-called small cell dysplasia or small cell changes (SCC) which have been observed in livers from patients of pre-cancerous stage. Moreover, we observed intensively hypertrophic hepatocytes (Large cell changes = LCC), which obviously lost FoxO3 expression and apparently showed an activation of the p53-p21 senescence pathway. In contrast, in SCC areas severe DNA damage and expression of several HCC markers could be detected, which could not be seen in LCC. Furthermore, we observed that status of FoxO3 activity and p21 expression in HepG2 and HuH7 cells was consistent to what we observed in the mouse model.
Conclusions: Hepatic FoxO3 over-expression mimicking type 2 diabetes seems to promote hepatocarcinogenesis, presumably due to the inhibition of senescence signalling after DNA damage. These findings are of major relevance with regards to type 2 diabetes-induced cancers.

E-mail: rsonntag@ukaachen.de

Background and Aims: E-type cyclins (CcnE1, CcnE2) are regulatory subunits of Cyclin-dependent kinase 2 (Cdk2) and control the

transition of quiescent cells into the cell cycle. Surprisingly, single genetic deletion of CcnE1, CcnE2 or Cdk2 does not inhibit cell proliferation during embryonic development or liver regeneration. In the present study we evaluated if E-type cyclins may have a specific role for hepatocarcinogenesis.
Methods: We used mice with constitutive deletion of Cyclin E1 (CcnE1$^{-/-}$) or Cyclin E2 (CcnE2$^{-/-}$) and conditional knockout mice with hepatocyte-specific inactivation of Cdk2 (Cdk2$^{\Delta hepa}$), respectively. To induce hepatocellular carcinoma (HCC), mice were treated with a single dose of Diethylnitrosamine (DEN) at the age of two weeks and analysed for tumor initiation and progression after 24 and 40 weeks.
Results: 24 weeks after DEN treatment 40% of wildtyp (WT) and CcnE2$^{-/-}$ mice developed few small tumor nodules, whereas 100% of CcnE1$^{-/-}$ mice revealed normal liver morphology lacking visible tumor nodules. At the age of 40 weeks, 100% of DEN-treated WT and CcnE2$^{-/-}$ mice developed HCC. In sharp contrast, HCC incidence in CcnE1$^{-/-}$ animals was only 50%, and the overall number of tumor nodules was tenfold reduced in comparison to WT and CcnE2$^{-/-}$ mice. Ablation of CcnE1 also protected from HCC in transgenic mice with hepatic over-expression of the proto-oncogene c-*myc*. Interestingly, Cdk2$^{\Delta hepa}$ mice and Cdk2$^{\Delta hepa}$CcnE2$^{-/-}$ double mutants were also strongly protected from DEN-mediated hepatocarcinogenesis. We next isolated primary, CcnE1-floxed hepatoma cells from DEN-treated CcnE1$^{f/f}$ mice and inactivated CcnE1 *in vitro* using EGFP-labeled, cre-expressing adenoviruses. Confocal live cell imaging revealed that acute CcnE1 inhibition in transformed hepatoma cells effectively results in apoptosis within 72 hours. In addition, CcnE1-depleted hepatoma cells showed strong activation of caspase-3, and de-regulation of S-phase and cytokinesis related genes and proteins, respectively.
Conclusions: Our data demonstrate that CcnE1 – but not its homologue CcnE2 – is essential for proliferation and survival of immortalized hepatoma cells *in vivo* and *in vitro*. This requirement of CcnE1 seems to be dependent on the availability of Cdk2. We hypothesize that hepatoma cells get addicted to high CcnE1 expression levels during the transformation process. Thus, acute inhibition of CcnE1 during HCC progression could be a novel therapeutic option.

C-MET SIGNALING CONTRIBUTES TO CARCINOGENESIS OF CHOLANGIOCARCINOMA AND IS BLOCKED BY LY2801653, A SMALL MOLECULE INHIBITOR

S. Barat[1], P. Bozko[1], X. Chen[1], T. Scholta[1], F. Hanert[1], J. Götze[1], N. Malek[1], L. Wilkens[2], R. Plentz[1]. [1]*Medical Clinic I, UKT, Tübingen,* [2]*Pathology, Nordstadt Krankenhaus, Hannover, Germany*
E-mail: ruben.plentz@med.uni-tuebingen.de

Background and Aims: The incidence and mortality rate of cholangiocarcinomas (CCC) are increasing worldwide and they represent the second most common primary hepatobiliary cancer. Currently, the combination of Gemcitabine and Cisplatin is the standard chemotherapeutic regimen for patients undergoing first line treatment. Further improvements in the treatment of CCC, especially targeted therapies are still needed to overcome this deadly disease. c-MET signaling is important for a variety of normal cellular function, but aberrant expression plays also a major role in carcinogenesis in many human cancer diseases. The role of c-Met in the carcinogenesis of CCC remains still unclear. In this study we investigated the effects of LY2801653, a small-molecule inhibitor with potent activity against MET kinase, in human CCC cell lines (TFK-1, SZ-1) and *in vivo* using a Xenograft mouse model.
Methods: We analyzed the effect of LY2801653 by testing different dosages on CCC growth and epithelial plasticity by using WST-1 assay, wound healing assay, invasion assay, colony formation assay, apoptosis assay, senenscence assay, Western Blot, Immunohistochemistry and in vivo CCC tumor growth by using an intra- and extrahepatic Xenograft model.
Results: c-MET was expressed in 72% of analyzed intra- and extrahepatic human CCC tissues and in TFK-1, SZ-1 cell lines. MET inhibition was achieved by blocking phosphorylation of MET with LY2801653 and subsequent down regulation of downstream targets like p-Erk, p-AKT and RAC1 which are associated with important cell regulatory functions. LY2801653 treatment mainly induced senescence and partially apoptosis as the key mechanisms for cell death. Treatment showed in Xenograft models potent anti-tumor activity with a decrease of cell proliferation and increased cleavage of PARP and expression of P21.
Conclusions: Our data demonstrates that c-MET signaling is important for CCC carcinogenesis and that LY2801653 treatment is a potential, effective alternative strategy to treat CCC.

P0287
LIVER-SPECIFIC EXPRESSION OF HBs-Ag LEADS TO A SHIFT OF TUMOR DIFFERENTIATION IN Trp53-DELETED LIVER TUMORS

S.-F. Katz[1], U. Tharehalli[1], M. Svinarenko[1], P. Schirmacher[2], T. Seufferlein[1], A. Lechel[1]. [1]*Internal Medicine I, Ulm University Hospital, Ulm,* [2]*Institute of Pathology, University Hospital, Heidelberg, Germany*
E-mail: sarah-fee.katz@uni-ulm.de

Background and Aims: Around 50% of all human hepatocellular carcinomas are associated with a chronic HBV infection. Furthermore, up to 70% of HCC are characterized by defects in the p53-signaling pathway. The loss of p53 is often characterized with a mixed tumor differentiation and a stem cell gene expression pattern which is associated with a poor prognosis. It is unknown how HBV infection and p53 loss affects tumor differentiation and gene expression profiles.
Methods: For the induction of liver tumors, we crossed a conditional Trp53 mouse with an Alb-HBs mouse (HBs-Ag under the albumin-promoter) and a liver-specific AlfpCRE mouse (CRE expression under the albumin-alphafetoprotein-enhancer-promoter) to induce a liver-specific deletion of the Trp53 gene during embryogenesis and a chronic liver damage by the HBs-Ag. Moreover, we compared these mice with single Trp53 deleted mice without HBs-Ag expression.
Results: Tumor incidence in mice with liver-specific Trp53 deletion was significant lower (32.4%) compared to mice with Trp53 deletion and chronic liver damage (100%) at an age of 12–14 months. In mice without chronic liver damage, 79.7% of the tumors showed mixed differentiation with hepatocellular carcinoma as well as cholangiocellular carcinoma (HCC-CC), and 10.9% showed only hepatocellular carcinoma (HCC). This mixed tumor differentiation decreased to 30% HCC-CC in mice with chronic liver damage by HBs-Ag. The expression of HBs-Ag results in a shift of tumor differentiation towards HCC (70%). Tumors with a mixed differentiation exhibit an increased expression of stem cell markers (CD90, CD133, Sox9).
Conclusions: Our study shows that Trp53 deletion alone leads to liver tumor formation with a mixed differentiation with stem cell features. The addition of a chronic liver damage by HBs-Ag leads to a partial shift towards hepatocellular carcinoma.

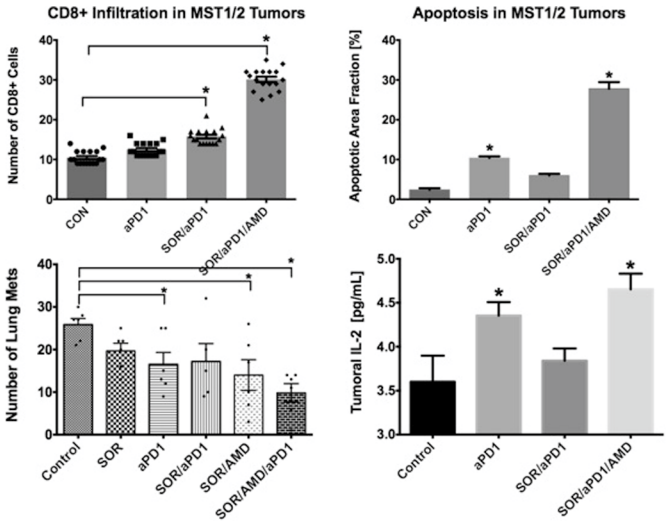
CXCR4 INHIBITION REVERTS IMMUNOSUPPRESSIVE TUMOR MICROENVIRONMENT AND FACILITATES ANTI-PD-1 IMMUNOTHERAPY IN SORAFENIB-TREATED HEPATOCELLULAR CARCINOMA

T. Reiberger[1], C. Yunching[2], R.R. Ramjiawan[3], R.R. Ng[3], T. Hato[3], Y. Huang[3], E.C. Unan[3], T.P. Reddy[3], C. Fan[3], P. Huang[3], N. Bardeesy[4], A.X. Zhu[4], R.K. Jain[3], D.G. Duda[3]. *[1]Internal Medicine III, Div. of Gastroenterology & Hepatology, Medical University of Vienna, Vienna, Austria; [2]National Tsing Hua University, Institute of Biomedical Engineering, Hsinchu, Taiwan; [3]Radiation Oncology, Steele Laboratory of Tumor Biology, [4]Medicine, Cancer Center, MGH and Harvard Medical School, Boston, United States*
E-mail: thomas.reiberger@meduniwien.ac.at

Background and Aims: Sorafenib – a broad tyrosine kinase inhibitor – is the only approved systemic therapy for advanced hepatocellular carcinoma (HCC), but provides limited survival benefits. We have shown in mouse models that after sorafenib treatment, intratumoral hypoxia is increased and may fuel evasive resistance.
Methods: Two sophisticated HCC models with and without underlying cirrhosis were used: the orhtotocpic HCA1 tumor implantation in C3H mice and the GEM model of YAP1-driven HCC in MST1/2 knockout mice. Fibrosis was induced by iterative CCl_4 administration. The growth of intrahepatic HCCs was evaluated by high-frequency ultrasound imaging. Treatment regimens were started when tumor size reached 3×3 mm (14 mm^3): Sorafenib (50 mg/kg/day gavage), CXCR4 inhibitor AMD3100 (10 mg/kg, s.c. by osmotic minipump), antibody against murine PD-1 (100 μg every 3 days, i.p.).



Results: Using orthotopic HCC models, we now show that increased hypoxia after sorafenib treatment induces an immunosuppressive tumor microenvironment characterized by increased intratumoral expression of the immune checkpoint inhibitor programmed death-ligand 1 (PD-L1) and accumulation of T-regulatory cells and M2-type macrophages. The recruitment of these cells was mediated by hypoxia-induced upregulation of stromal cell-derived 1 alpha (SDF1α). Inhibition of the SDF1α receptor (C-X-C receptor type 4/CXCR4) using AMD3100 prevented the immunosuppressive reprogramming of the microenvironment after sorafenib treatment, inhibited tumor growth, reduced lung metastasis, and improved survival. However, combination of AMD3100 and sorafenib did not increase cytotoxic CD8+ T-lymphocyte infiltration. Moreover, *in vivo* antibody blockade of the PD-L1 receptor PD-1 showed anti-tumor effects in treatment-naïve tumors, and additional anti-tumor activity when combined with sorafenib and AMD3100, but not when combined with sorafenib only.
Conclusions: Anti-PD-1 treatment seems to boost immune response in HCC tumors. However, when used with sorafenib – concomitant targeting of the hypoxic and immunosuppressive microenvironment with agents such as CXCR4 inhibitors may be required.

P0289

EVOLUTION ANALYSIS BY DEEP SEQUENCING REVEALED HIGH IMPACT OF THE MITOCHONDRIAL GENOME IN HEPATOCELLULAR CARCINOMA INITIATION AND PROGRESSION

W. Amer[1], A. Quass[1], U. Drebber[1], H. Eischeid[1], U. Koitzsch[1], A. Arens[2], C. Vollbrecht[1], R. Büttner[1], M. Odenthal[1]. *[1]Pathology Institute, Cologne, [2]QIAGEN, Hilden, Germany*
E-mail: wata.amer@uk-koeln.de

Background and Aims: Hepatocellular carcinoma (HCC) is highly malignant tumor, prone to multicentric occurrence (nodule-in-nodule pattern) and triggered by a wide variety of genetic alterations. Herein, we aimed to study the occurrence of disease related mitochondrial mutations variants by a comprehensive ultra-deep sequencing approach as a novel tool for hepatocellular cancer follow-up and prognosis.
Methods: Macrodissected 48 HCC nodules, representing different tumor grades, and adjacent non-cancerous tissues from ten patients were investigated. One hundred-eight primer sets spanning the whole mtDNA were designed and automatic single PCR set-up was established using the Biomek robotic system. Target enriched libraries of mtDNA was sequenced by means of the MiSeq platform and data analysis was performed by the CLC Cancer Research Workbench.
Results: The mitochondrial (mt) genome is highly susceptible to DNA alterations due to the lack of protective histones and a limited repair system. Here, we are using mt-variations as a way of focal cancer barcoding and tracking. Whole mt-genome analysis revealed high frequency of variants in the D-Loop region and the MT-CYB gene. In particular, in HCC nodules of non-cirrhotic origin a wide spectrum of mt-variants with high frequency were identified. However, highly frequent mt-variants occur not only in HCC nodules but also in peri-tumorous parenchymal foci raising the possibility that mtDNA mutations might precede nuclear alterations and play a role in the pre-tumor machinery. Furthermore, the occurrence of identical mt-variants in different nodules of one liver sample indicates the monoclonal HCC origin. Most notably, the increasing numbers of mt-variants as well as the increasing frequency of a particular mt-hot-spot mutation refer to the progression of the HCC dedifferentiation.
Conclusions: In conclusion, screening of mitochondrial genome by ultra-deep sequencing is a reliable and useful molecular tool to identify pre-tumorous nodules with high transformation potential and to illustrate tumor clonality and history. Early appearance and high frequency of mt-hot spot mutations associated with HCC development and nuclear genomic alterations provide novel insights in cancer diagnostics and therapeutic approaches.

PLACENTAL GROWTH FACTOR INHIBITION MODULATES THE INTERPLAY BETWEEN HYPOXIA AND THE UNFOLDED PROTEIN RESPONSE IN HEPATOCELLULAR CARCINOMA

Y.-P. Vandewynckel[1], D. Laukens[1], L. Devisscher[1], A. Paridaens[1], E. Bogaerts[1], X. Verhelst[1], A. Van den Bussche[1], S. Raevens[1], C. Van Steenkiste[1], B. Jonckx[2], L. Libbrecht[3], A. Geerts[1], P. Carmeliet[4,5], H. Van Vlierberghe[1]. *[1]Department of Hepatology and Gastroenterology, Ghent University, Ghent, [2]ThromboGenics NV, ThromboGenics NV, Heverlee, [3]Department of Pathology, Ghent University, Ghent, [4]Laboratory of Angiogenesis and Neurovascular link, Vesalius Research Center, KU Leuven, [5]Laboratory of Angiogenesis and Neurovascular link, Vesalius Research Center, VIB, Leuven, Belgium*
E-mail: yvespaul.vandewynckel@ugent.be

Background and Aims: Hepatocellular carcinoma (HCC) is the second leading cause of cancer-related mortality worldwide. We previously showed that inhibition of Placental growth factor (PlGF) exerts antitumour effects and induces vessel normalization in HCC, possibly reducing hypoxia. However, the exact mechanism of PlGF inhibition in HCC remains unclear. Since hypoxia signalling and the unfolded protein response (UPR) have been implicated in tumour progression, we assessed the interaction between PlGF and these tumoural adaptation processes.
Methods: PlGF knockout mice and monoclonal anti-PlGF antibodies were used in a diethylnitrosamine-induced mouse model for HCC to investigate the effect of PlGF inhibition on UPR activation and tumour hypoxia. In addition, we examined the interaction between the UPR, hypoxia and PlGF expression in human HCC cell lines.
Results: Both genetic and pharmacological inhibition of PlGF significantly reduced diethylnitrosamine-induced chaperone levels ($p < 0.05$) and the activation of the PKR-like endoplasmic reticulum kinase (PERK) pathway of the UPR ($p < 0.01$). Also tumour hypoxia was attenuated by both, as shown by reduced pimonidazole staining in the tumour nodules ($p < 0.05$). Interestingly, hypoxia markedly activated the PERK pathway in human HCC cells ($p < 0.01$), suggesting PlGF inhibition may diminish PERK activation by improved oxygen delivery via vessel normalization. Finally, we found that both hypoxia and two chemical inducers of endoplasmic reticulum stress, tunicamycin and thapsigargin, increased the expression of PlGF in HCC cells ($p < 0.01$), predominantly via the inositol-requiring enzyme 1 (IRE1) pathway of the UPR.
Conclusions: These findings indicate that PlGF inhibition reduces UPR activation by tempering hypoxia in experimental HCC and that the UPR, in turn, is able to induce PlGF expression, suggesting the existence of a feedback mechanism of hypoxia-mediated UPR which stimulates PlGF-mediated angiogenesis.

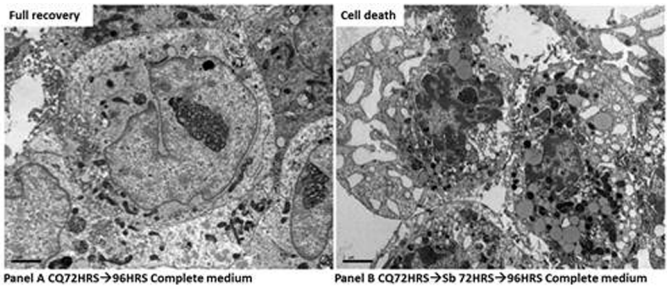
THE ONCOSTATIC ACTION OF SORAFENIB ON LIVER CANCER CELLS IS CHANGED TO AN ONCOLYTIC EFFECT FOLLOWING PRE-TREATMENT WITH CHLOROQUINE: DEMONSTRATION OF SYNERGY BETWEEN CHLOROQUINE AND SORAFENIB AS A POTENTIAL NOVEL APPROACH TO TREATMENT OF HCC

F. De Chiara[1], R.C. Montella[1], F. Andreola[1], R. Jalan[1]. *[1]Institute of Liver and Digestive Health, University College London, London, United Kingdom*
E-mail: francesco.chiara@ucl.ac.uk

Background and Aims: Sorafenib (Sb), a multikinase inhibitor is the elective treatment for patients with advanced HCC. Currently no preventive strategies or cost-effective treatment option(s) for HCC are available. Chloriquine (CQ) has been implicated as a chemosensitizer when used in combination with anti-cancer drugs. The aim of this study is to determine if pretreatment with CQ potentiates the efficacy of Sorafenib admistered in subpharmacological doses.
Methods: Response to CQ and Sb, alone and in combination, was tested in Huh7 and HepG2 cells as follows: (i) untreated; (ii),(iii) CQ (15 μM), Sb (3 μM) 96 h treatment (IC50) followed by 96 h recovery, respectively; (iv) CQ 72 h treatment followed by Sb 24–72 h treatment and 96 h recovery. Cell response was evaluated by MTS assay, electron microscopy (EM) and cell cycle analysis (FACS analysis).
Results: CQ treatment had an oncostatic effect on HCC by causing an impaired cytoplasmic compartmentalisation resulting in G2 cell cycle arrest. Both mitochondria and nuclei preserved their structure/functions. When CQ was removed, the cells were capable to fully overcome the CQ-induced oncostasis by restoring their ultrastructure (Figure, Panel A), cell cycle, and growth rate. Low doses of Sb alone caused a transient reduction in cell growth with no ultrastructural changes. Interestingly, when Sb was added to CQ-damaged cells, their ability to recover was completely eliminated and autophagic cell death induced (Figure, Panel B).
Conclusions: CQ-treatment alone had a transient oncostatic effect on HCC cells. Nevertheless, when low doses of Sb were administered to CQ-sensitised cells, an oncolytic effect on HCC cells associated with autophagic cell death was achieved. Altogether, these data underscore the synergy between CQ and Sb as a potentially novel approach to the treatment of HCC.



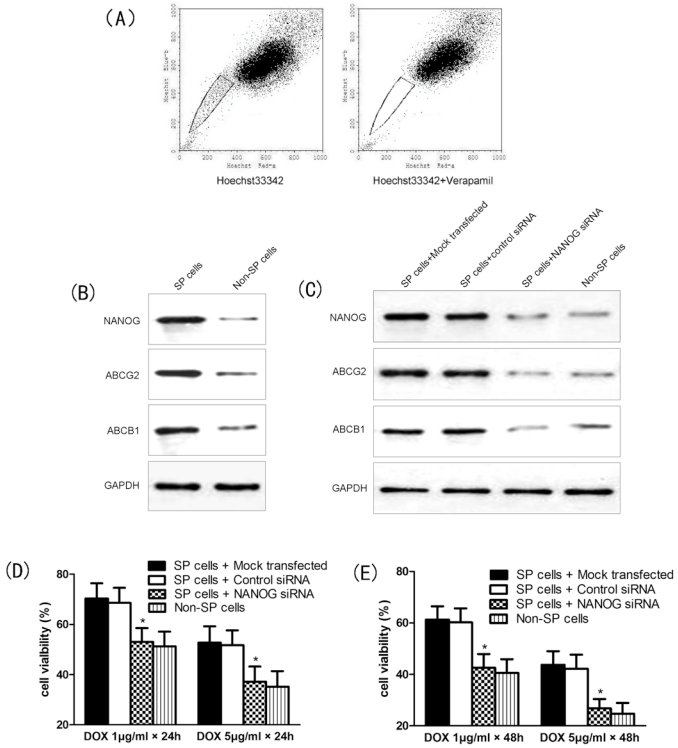
P0292

KNOCKDOWN OF NANOG REVERSES THE CHEMORESISTANCE TO DOXORUBICIN IN LIVER CANCER STEM-LIKE CELLS BY REDUCING ABCB1 AND ABCG2 EXPRESSION

J. Zhou[1], R. Chen[1], X. Deng[1]. *[1]Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China*
E-mail: jiajiazh2004@126.com

Background and Aims: Chemoresistance of cancer cells is one of the major reasons for the failure of liver cancer chemotherapy in clinic. Cancer stem cells (CSCs) are regarded as the origin of tumors, which are resistant to current chemotherapies. NANOG is one of the most important core markers of CSCs in maintaining the self-renewal and pluripotency. However, the association between NANOG and chemoresistance in CSCs remains uncertain. The aim of this study was to investigate whether NANOG inhibition sensitizes human liver CSCs to doxorubicin treatment.
Methods: Liver cancer stem like cells were purified from liver cancer cells Hep3B by side population (SP) analysis. siRNA was employed to inhibit NANOG expression in SP cells and chemosensitivity to doxorubicin as well as expression of NANOG, ABCB1 (MDR1, P-gp) and ABCG2 (BCRP1) were analyzed by CCK8 method and Western blot, respectively.
Results: SP cells were detected in liver cancer cells Hep3B (Figure A). NANOG, as well as ABCB1 and ABCG2, are overexpressed in SP cells compared with Non-SP cells (Figure B). Meanwhile, NANOG siRNAs efficiently decreased the expression of NANOG at both mRNA and protein levels (Figure C). Knockdown of NANOG resulted in enhanced chemosensitivity to doxorubicin (Figures D,E) and reduced expression of ABCB1 and ABCG2 in SP cells (Figure C).
Conclusions: Our findings suggest that knockdown of NANOG may reverse the chemoresistance of liver CSCs to doxorubicin by

reducing ABCB1 and ABCG2 expression. Thus NANOG can prove to be a novel potential therapeutic target for liver cancer treatment.



P0293

TARGETING GLUCOSYLCERAMIDE SYNTHASE INCREASES SORAFENIB EFFICACY AND EVADES SORAFENIB RESISTANCE IN HCC MODELS

M. Stefanovic[1], A. Tutusaus[1], C. Barcena[1], G.A. Martinez-Nieto[1], M. Marí[1], C. Garcia-Ruiz[1], J.C. Fernandez-Checa[1], A. Morales[1].

E-mail: amorales@clinic.ub.es

Background and Aims: Multikinase inhibitor sorafenib has limited efficacy in the treatment of advanced hepatocellular carcinoma (HCC) due to primary and acquired drug-resistance mechanisms. Ceramide participates in chemotherapeutic cytotoxicity and the induction of the ceramide-modifying enzyme glucosylceramide synthase (GCS) is common in cancer resistance.
Methods: Hepatoma cell lines (HepsG2 and Hep3B) with sorafenib sensitive or with sorafenib resistance were selected after long term exposure to sorafenib (0 to 5 μM). GCS reduction was accomplished genetically by RNA interference and pharmacologically via inhibitor administration (PDMP). Western blots in total, cytosolic and mitochondrial extracts and qPCRs were performed after sorafenib exposure. ROS production, mitochondrial membrane permeabilization, caspase activity and ATP measurements were analyzed in sorafenib-treated hepatoma cells. Subcutaneous tumors, sensitive or with sorafenib resistance, were analyzed after injection of HepG2 cells on the flanks of nude mice
Results: Ceramide metabolism is activated in hepatoma cells after short-time exposure to sorafenib, principally by increased expression of the ceramide degrading enzyme GCS. Hep3B and HepG2 cells treated with GCS inhibitor (PDMP) or transfected with siRNAs against GCS exhibit higher sorafenib-induced cell death. The mechanism of sensitization is autophagy- and caspase-independent, but caused via mitochondria after energetic collapse as detected by cytochrome c release and ATP depletion. GCS targeting, genetically and pharmacology, is also effective in resensitizing sorafenib-resistant hepatoma cells after long-term exposure (12 months) to the drug. In vivo, administration of GCS inhibitor (PDMP), in combination with sorafenib, reduced tumor growth of HepG2 cells after subcutaneous injection in nude mice, compared with sorafenib treatment alone. Moreover, GCS inhibition concomitant with sorafenib administration was also effective in reducing sorafenib-resistant tumors in mice.
Conclusions: GCS reduction increases the cytotoxic accumulation of ceramide in sorafenib-treated hepatoma cells via mitochondrial-dependent cell death and improves sorafenib efficacy in HCC models, both in sorafenib sensitive and resistant hepatoma cells. Strategies aimed to increase ceramide toxicity, particularly through GCS inhibition, may increase sorafenib effectiveness in HCC management.

ONCOGENESIS: A POTENTIAL "OFF-TARGET" EFFECT OF RADIOFREQUENCY ABLATION

N. Rozenblum[1], E. Zeira[1], V. Scaiewicz[2], B. Bulvik[1], S. Gourevitch[1], E. Galun[1], N.S. Goldberg[1,3,4]. *[1]The Goldyne Saved Institute for Gene Therapy, Hadassah Hebrew University Medical Center, [2]Institute for Drug Research, School of Pharmacy, Faculty of Medicine, The Hebrew University of Jerusalem, [3]Department of Radiology, Hadassah Hebrew University Medical Center, Jerusalem, Israel; [4]Laboratory for Minimally Invasive Tumor Therapies, Department of Radiology, Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, United States*
E-mail: nir.rozenblum@mail.huji.ac.il

Background and Aims: Hepatocellular carcinoma (HCC) is the 2nd most common cause of worldwide cancer-related mortality. Radiofrequency ablation (RFA) treatment for HCC, facilitates thermal injury and thus cell death via coagulation necrosis to the tumor through electromagnetic energy deposition. The 5 years survival rate of patients treated with RFA remains approximately 50% with 70–81% new tumor recurrence. Our aim is determine the tumorigenic mechanism of HCC RFA.
Methods: Nine months old MDR2 KO female mice that have dysplastic nodules underwent either RFA (tip temperatures of 70±1°C for 5 min [ablating approximately 5.5% liver volume]), or a 35% partial hepatectomy (PHx), or a sham operation (n = 7, in each group) and followed for survival studies. In order to evaluate the potential tumorigenic effect of RFA, additional untreated (n = 12) or RFA treated (n = 12) MDR2 KO littermates were sacrificed 7 days and 1 month post the operation, and lesions greater than 3 mm in diameter were counted. In order to inhibit umorigenesis, MDR2 KO mice were treated with a c-met inhibitor or DMSO (n = 7, each) post RFA and were sacrificed 1 month post treatment.
Results: Both RFA and PHx mice survived significantly less than the sham operated mice ($p = 0.03$). Six months post treatment, only 68% of the mice that underwent RFA or PHx survived in comparison to the sham operation in which 100% of the mice were still alive. Moreover, one month post RFA, RF treated mice had and average of 1.66 dysplastic nodules compared to 0.636 in the controls ($p = 0.016$), with no significant differences noted 7 days post ablation. These lesions were observed in 83.3% of the mice that underwent RFA in comparison to 50% of the control mice ($p = 0.002$). Seven days post ablation, massive accumulation of activated myofibroblasts was observed at the border zone of the coagulation necrosis area, with increased Ki67 positive hepatocytes staining both in the ablated as well as in the untreated lobes ($p = 0.003$ and $p = 0.02$ respectively). Treatment with PHA 665752, a c-met inhibitor, post RFA diminished the tumorigenic effect of RFA in comparison to the control (tumor load: $p = 0.001$, tumor volume: $p = 0.02$).
Conclusions: RFA in an inflamed liver encounters a pro-tumorigenic effect per-se. This effect is mediated by c-met. Combining RFA and

a c-met inhibition may decrease tumor recurrence and increase survival in RFA treated HCC patients.

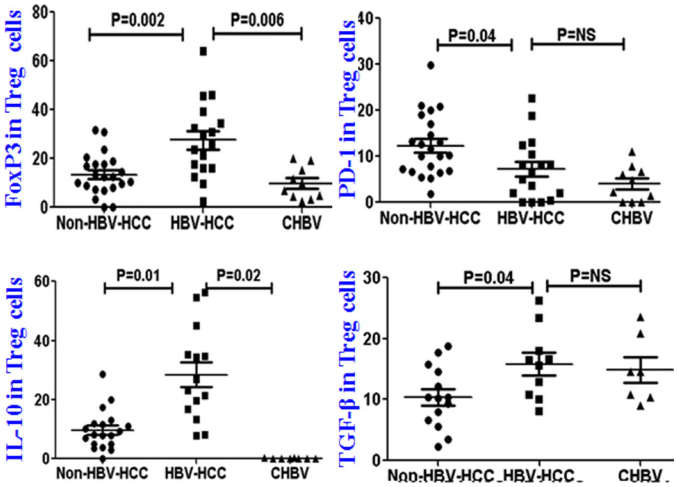
CD4+CD25+CD127LOW REGULATORY T CELLS PLAY PREDOMINANT ANTI-TUMOR SUPPRESSIVE ROLE IN HEPATITIS B VIRUS ASSOCIATED HEPATOCELLULAR CARCINOMA

S. Sharma[1], R. Khosla[1], P. David[1], A. Rastogi[2], A.K. Vyas[1], A. Bhardwaj[3], A. Sahney[3], R. Maiwall[3], G. Ramakrishna[1], S.K. Sarin[3], N. Trehanpati[1]. *[1]Research, [2]Pathology, [3]Hepatology, Institute of liver and biliary sciences, New Delhi, India*
E-mail: trehanpati@gmail.com

Background and Aims: Hepatocellular carcinoma (HCC) is the second leading cause of cancer death worldwide and hepatitis B is one of the common causes. T regulatory cells (Tregs) are strong immunomodulators and are likely to play major role in HCC development. We hypothesize that HBV infection expands Treg mediated immunosuppression creating ideal microenvironment for oncogenic transformations. Therefore, we investigated T regulatory cells CD4+CD25+CD127^{low} and their regulation by TGF-β, IL-10 and PD1 in patients with HBV related HCC (HBV-HCC) vs. non-HBV-HCC.
Methods: HBV-HCC (n = 17), non-HBV-HCC (n = 22; NASH =16, alcohol related=6) and Chronic hepatitis B infection (CHBV; n = 10) patients were recruited for study. Whole blood immunophenotyping was done by multicolor flow cytometry. Functionality of isolated CD4+CD25+CD127low Treg was assessed by *in vitro* suppression assay. Expression of FoxP3, IL-10, PD-1, TGF-β and Notch in Tregs and liver explants was analyzed by flow cytometry, immuno-histochemistry (IHC) and qRT-PCR.
Results: Total lymphocyte count and CD8+Tcells were significantly lower in HBV-HCC compared to Non-HBV-HCC (p = 0.04 and p = 0.04) and CHBV (p = 0.003 and p = 0.05). Foxp3 expression in CD4+CD25+^{hi} CD127^{low} was significantly increased in HBV-HCC compared to Non-HBV-HCC and CHBV patients (P = 0.002, P = 0.006). In *in vitro* suppression assay Tregs isolated from HBV-HCC showed increased suppressive ability and secretion of immunosuppressive cytokines IL-10 and TGF-β compared to Non-HBV-HCC (P = 0.01 and P = 0.04) and CHBV (P = 0.02 and P=NS). PD1 expression in CD4+CD25+^{hi} was significantly decreased in the HBV-HCC than non-HBV-HCC and CHBV (P = 0.04 and P=NS). In HBV-HCC, α fetoprotein (AFP) levels were significantly high (median 941, range 2–575736.6) than Non-HBV-HCC (median 13.5, range 2–18,900). In HBV-HCC Foxp3 expression in CD4+ CD127^{low}CD25+^{hi} was significantly correlated with both, high (>1000 ng/ml, r = 0.914, P = 0.000) and low (<1000 ng/ml, r = 0.857, P = 0.014) AFP levels. Reduced PD1 expression in HBV-HCC also had negative correlation with FOXP3 in CD4+CD25+^{hi} CD127^{low} (r = −0.78, p = 0.04).



Conclusions: Our results demonstrates that CD4+ CD25+^{hi} Tregs from HBV-HCC patients have decreased expression of PD-1, resulting in higher IL-10 and TGF-β secretion. Increased suppressive ability of Tregs in HBV related HCC confers increased anti-tumor suppressive response than in non HBV-HCC. Modulation of T-regs and PD1 may serve as useful therapeutic targets.

eNOS POLYMORPHISMS IN RELATION TO OUTCOME IN ADVANCED HCC PATIENTS RECEIVING SORAFENIB

A. Caadei Gardini[1], M. Scartozzi[2], L. Faloppi[3], G. Marisi[1], P. Ulivi[1], E. Scarpi[1], G. Luca Frassineti[1]. *[1]IRST-IRCCS, Meldola, [2]Università Cagliari, Cagliari, [3]Università ancona, Ancona, Italy*
E-mail: casadeigardini@gmail.com

Background and Aims: Cancer cells adapt to hypoxic microenvironment through the activation of many molecules, including endothelial nitric oxide synthase (eNOS). Sorafenib, by blocking the vascular endothelial growth factor receptors (VEGFRs), induces an inhibition of eNOS activitywith a consequent decrease of the production of nitric oxide (NO). NO is associated with an increase of tumor angiogenesis, tumor invasion and metastasis formation. In our study we analysed the role ofeNOS polymorphisms in relation to clinical outcome in patients with hepatocellular carcinoma treated with sorafenib.
Methods: From a database of 257 patients diagnosed with hepatocellular carcinoma from 2004 to 2014, we selected 54 patients who received sorafenib. Peripheral blood samples or FFPE tumor tissues were available for DNA extraction and genotyping analysis. Three eNOS polymorphisms (eNOS +894 G/T, eNOS VNTR 27bp 4a/b, eNOS −786 C/T) were analyzed by direct sequencing or Real Time PCR method. We analyzed 21 patients for the VNTR 4a/b polymorphism and 32 patients for −786 C/T polymorphism. All the candidate genotypes were evaluated to identify a potential correlation with overall survival (OS) (log-rank test).
Results: With regard to eNOS VNTR it was observed that patients carrying the b allele (5 repetitions of 27bp) both in homozygosity (4bb) and in heterozygosity (4ab) were associated with a better OS. The variants 4aa (4 repeats of 27bp in homozygosity), 4ab and 4bb, were associated with a median OS of 5.7, 13.9 and 23.6 months, respectively (p = 0.016). For *eNOS* −786 the presence of the T allele both in homozygosity (TT) and in heterozygosity (TC) was associated with a statistically significant longer OS with respect to patients with CC genotype (15.6 versus 13.9 months, respectively, p = 0.031). No correlations were observed in relation to PFS (p = 0.494).
Conclusions: eNOS VNTR and eNOS −786 could represent prognostic markers in patients with advanced hepatocellular carcinoma treated with sorafenib.

P0297

THE TRANSFORMING GROWTH FACTOR-BETA (TGF-β) GOVERNS HUMAN LIVER TUMOR CELL PLASTICITY

A. Malfettone[1], J. Fernando[1], P. Koudelkova[2], J. Soukupova[1], E. Bertran[1], À. Fabra[1], M. Grubinger[2], B. Rani[3], G. Giannelli[3], W. Mikulits[2], I. Fabregat[1,4]. *[1]Bellvitge Biomedical Research Institute (IDIBELL), L'Hospitalet, Barcelona, Spain; [2]Institute of Cancer Research, Medical University of Vienna, Vienna, Austria; [3]Department of Biomedical Sciences and Human Oncology, University of Bari, Medical School, Bari, Italy; [4]School of Medicine, University of Barcelona, Barcelona, Spain*
E-mail: amalfettone@idibell.cat

Background and Aims: Transforming Growth Factor-beta (TGF-β) acts as a tumor suppressor in initial stages of hepatocarcinogenesis. However, tumour cells acquire mechanisms to overcome TGF-β suppressor effects and respond to it undergoing epithelial–

mesenchymal transition (EMT). In some tumour cells a link exists between EMT and the expression of stem cell markers. Aim of this study was to analyze if autocrine activation of the TGF-β pathway in hepatocellular carcinoma (HCC) cells may control the expression of Cancer Stem Cell (CSC) markers concomitant with the acquisition of mesenchymal properties.

Methods: Different HCC cell lines with different autocrine expression of TGF-β and epithelial–mesenchymal phenotypes were analysed. TGF-β Receptor I (TβRI) expression was stably silenced by shRNA. EMT and SC marker expression was analyzed by Flow Cytometry, Immunofluorescence and Real-Time PCR. Sphere-forming and colony-formation assays were performed to explore the biological properties of liver CSCs.

Results: Epithelial liver tumour cells expressed EpCAM and CD133, whereas mesenchymal-like cells expressed CD44. Cancellation of the TβRI in Hep3B (with a mixed epithelial–mesenchymal phenotype) prevented the TGF-β-induced EMT, but also induced a mesenchymal–epithelial transition (MET). Relevantly, TβRI knock-down decreased the basal expression of EpCAM and CD133 and reduced the formation of liver spheroids and number of clones. The TβRI knock-down in HLE and HLF (mesenchymal-like cells) decreased significantly the expression of the Snail family genes, but unexpectedly did not produce a full MET. Nevertheless, TβRI knock-down decreased expression of CD44, which correlated with a lower ability to form liver spheroids and clones. Interestingly, chronic treatment of Hep3B cells with TGF-β induced progressive down-regulation of EpCAM and CD133 and up-regulation of CD44, concomitant with the appearance of a mesenchymal phenotype. Furthermore, these cells formed liver spheres and colonies more efficiently.

Conclusions: TGF-β not only modulates the EMT phenotype of HCC cells, but also the expression of CSC genes, although it is not clear yet the cross-talk among both processes. A mesenchymal phenotype and CD44 expression are associated with poor prognosis in HCC. Results of this study further support that activation of the TGF-β pathway may be considered a therapeutic target in HCC.

GLUCOSE TRANSPORTER ISOFORM 1 (GLUT1) EXPRESSION DETERMINES HEPATIC METASTASIS OF MELANOMA CELLS

A. Koch[1], S.A. Lang[1], P. Wild[2], A. Bosserhoff[3], C. Hellerbrand[1].
[1]University Hospital Regensburg, Regensburg, Germany; [2]University Hospital Zurich, Zurich, Switzerland; [3]University of Erlangen, Erlangen, Germany
E-mail: claus.hellerbrand@ukr.de

Background and Aims: The facilitative glucose transporter isoform 1 (GLUT1) is the key rate-limiting factor in glucose transport into cancer cells, and we have previously shown that GLUT1 is a tumor-promotor in hepatocellular carcinoma, while its expression is at the detection limit in normal hepatocytes.

The aim of this study was to analyze whether GLUT1 expression and a high capacity for glucose uptake, respectively, are general pro-cancerogenic factors in the liver.

Methods: We used malignant melanoma as a model-tumor, which is known to preferentially metastasize to the liver.

Results: Similar as observed in HCC, GLUT1 expression was enhanced in melanoma cell lines compared to primary melanocytes, as well as in melanoma compared to naevi. Immunohistochemical analysis of a tissue micro array consisting of 140 human melanoma tissues showed that GLUT1 expression was significantly enhanced in metastasis compared to primary tumors. GLUT1 expression in primary tumors correlated with tumor staging, and most importantly, with progression- and overall-survival. To determine the role of GLUT1 in melanoma metastasis, GLUT1 expression was suppressed in the murine melanoma cell line B16 (i) by stable transfection with shRNA and (ii) by using the selective GLUT1-Inhibitor WZB117. GLUT1 suppression caused decreased anaerobic glycolysis and lactate secretion, and inhibited proliferation and migration of B16 cells. Moreover, GLUT1 suppression lowered apoptosis resistance of melanoma cells. Next, B16 cell clones with and without GLUT1 suppression were subjected to an established model of hepatic metastasis, in which tumor cells were injected into the spleen of syngeneic mice, from where they metastasize into the liver *via* the portal circulation. GLUT1 suppressed cells formed significantly less metastases and hepatic metastases derived from GLUT1 suppressed B16 cells revealed less immune-cell infiltration and more apoptosis as assessed by CD3-immunohistochemistry and TUNEL staining.

Conclusions: Our data promote the hypothesis that high glucose levels in the portal circulation and the liver, and the capacity to utilize those, respectively, promote hepatic metastasis. Our data indicate enhanced apoptosis resistance of tumor cells and known immunomodulatory effects of lactate as potential underlying mechanisms of this phenomenon. GLUT1, which is almost selectively expressed in malignant cells but not in healthy liver or other non-malignant tissues, appears as an attractive therapeutic target for hepatic metastasis.

P0299

SORAFENIB EFFECT ON MITOCHONDRIAL FUNCTION PROVIDES A TARGET FOR INCREASING HCC THERAPY EFFICACY

A. Tutusaus[1], M. Stefanovic[1], J.C. Fernandez-Checa[1], M. Marí[1], A. Morales[1]. *[1]IIBB-CSIC/Hospital Clinic-IDIBAPS-CIBEREHD, Barcelona, Spain*
E-mail: amorales@clinic.ub.es

Background and Aims: Multikinase inhibitor sorafenib has limited efficacy in the treatment of advanced hepatocellular carcinoma (HCC). Novel therapies, in combination with sorafenib or in monotherapy, are demanded to increase drug efficacy in HCC treatment. The lack of positive results from other drugs, underscores the importance of identifying weaknesses in HCC biology that current approaches have not recognized. A mitochondrial effect of sorafenib has been previously reported, although its participation in sorafenib toxicity and HCC therapy has drawn little attention.

Methods: Hepatoma cell lines (HepG2 and Hep3B) were treated with sorafenib and Bcl2-inhibitors. Western blots in total, cytosolic and mitochondrial extracts and qPCRs were performed after sorafenib exposure. ROS production, mitochondrial membrane permeabilization, caspase activity and ATP measurements were analyzed in sorafenib-treated hepatoma cells. Tumor growth was determined after subcutaneous injection of HepG2 cells on the flanks of nude mice.

Results: Sorafenib induces a rapid decline in mitochondrial membrane potential, with production of reactive oxygen species (ROS) and reduction in the levels of the antiapoptotic Bcl-2-family protein MCL-1. However, cytochrome c release from mitochondria and/or ATP depletion after sorafenib exposure were not observed during hours, suggesting modest mitochondrial contribution in cell death. Bcl-2 levels, that play an important role in mitochondrial dependent cell death, were not affected by sorafenib, so we decided to evaluate the effect of several Bcl-2 inhibitors (HA-14, ABT-263, ABT-767 and AT-101) on sorafenib toxicity in hepatoma cells. Among them, ABT-263 (Navitoclax) a potent inhibitor of Bcl-xL and Bcl-2 now in Phase II clinical trials for leukemia and solid tumors, was the drug that exhibited higher capacity to potentiate sorafenib effects on Hep3B and HepG2 cells. ABT-263 co-administration with sorafenib induced quick release of cytochrome c and enhanced caspase-3 activity. Moreover, *in vivo* administration of ABT-263 combined with sorafenib greatly potentiated sorafenib effects,

decreasing subcutaneous tumor growth of HepG2 cells in nude mice.
Conclusions: Sorafenib alone is unable of inducing mitochondrial dependent death but provokes mitochondrial vulnerability that allows Bcl-2 inhibitor ABT-263 to sensitize hepatoma cells to sorafenib treatment. Navitoclax increases sorafenib efficacy and Bcl-2 inhibitors should be taken into account in HCC management.

P0300
DICHOTOMY OF TRANSFORMING GROWTH FACTOR-β SIGNALING IN HEPATOCELLULAR CARCINOMA PROGRESSION

C. Haider[1], M. Grubinger[1], W. Mikulits[1]. [1]*Department of Medicine I, Division: Institute of Cancer Research, Comprehensive Cancer Center Vienna, Medical University of Vienna, Vienna, Austria*
E-mail: christine.haider@meduniwien.ac.at

Background and Aims: Transforming growth factor (TGF)-β is a ubiquitously expressed cytokine with fundamental roles in various aspects of cell physiology. In carcinogenesis, TGF-β signaling plays a dual role. While it suppresses the proliferation of epithelial cells and adenoma cells at early stages by inducing growth arrest and apoptosis, it triggers epithelial to mesenchymal transition (EMT) and gain of metastatic abilities at later stages of carcinoma development. The molecular mechanisms underlying this 'TGF-β-switch' are only beginning to be unravelled. To mimic the pathophysiological situation as closely as possible, we exposed the cells to TGFβ long-term. Through this approach we aimed to identify those cooperating factors and signaling pathways that cause HCC cells to interpret the TGF-β signal in a tumor progressive way.
Methods: *In vitro* comparison of migratory behaviour of various HCC cell lines treated long-term (>10 days) with TGF-β. Analysis of regulatory networks and target genes underlying the TGF-β treatment.
Results: HCC cell lines that have undergone EMT secrete TGF-β and show elevated levels of Smad2/3 phosphorylation indicating an autocrine regulatory feedback loop. Inhibition of TGF-β by LY2109 abrogates autocrine stimulation and diminishes the migratory potential of mesenchymal HCC cells. Silencing of either TGF-βR1 or Smad4 indicated the importance of canonical TGF-β/Smad signaling HCC cell migration. Short-term treatment of cells with TGF-β could not improve migratory abilities. Interestingly, long-term TGF-β treatment revealed crucial differences between mesenchymal HCC cell lines. While HLF cells showed an increase in migration when treated with TGF-β for more than 10 days, SNU449 displayed a dramatic reduction in migration. However, both cell lines displayed no modulation in Smad phosphorylation, indicating a change in the utilization of TGF-β signaling in long-term treated SNU449 cells.
Conclusions: EMT-transformed HCC cells establish an autocrine TGF-β loop which stimulates migration. However, TGF-β cannot add up to the autocrine loop but causes a different, even opposing reaction, over time. Interpretation of long-term TGF-β signaling, which mimics the patient's situation more closely, depends on duration and intensity and is controlled by co-acting factors and signaling pathways.

TARGETING OF MIR-518D REDUCES CHEMORESISTANCE IN HEPATOCELLULAR CARCINOMA CELL LINES

D. Fernández-Ramos[1], P. Fernández-Tussy[1], M.J. Perugorria[2], J.M. Bañales[2], O. Briz[3], E. Herráez[3], J.J. García Marín[3], J.M. Mato[1], M.L. Martínez-Chantar[1]. [1]*Metabolomics, CIC bioGUNE, Derio,* [2]*Liver and Gastrointestinal Diseases, Biodonostia Research Institute, Donostia University Hospital, University of the Basque Country (UPV-EHU), CIBERehd, IKERBASQUE, Donostia,* [3]*Laboratory of Experimental Hepatology and Drug Targeting (HEVEFARM), IBSAL, University of Salamanca, Salamanca, Spain*
E-mail: dfernandez.ciberehd@cicbiogune.es

Background and Aims: Glycine N-methyltransferase (GNMT) catalyzes the conversion of S-adenosylmethionine (SAM) to glycine generating S-adenosylhomocysteine and sarcosine. This enzyme is highly abundant in the adult liver, and its expression has been observed downregulated or completely blocked in liver and prostate tumors, in most cell lines and in some preneoplasic lesions. The transient expression of the protein in cancer cell lines induces apoptosis.
MicroRNAs (miRNAs) are small noncoding RNAs that selectively target mRNAs leading to a translational repression or mRNA degradation. The dysregulation of specific miRNAs leads to chemoresistance in different cancers and correction of these miRNAs can sensitize cancerous cells to chemotherapy.
In this study we found a miRNA (miR-518d) that reduces GNMT level providing chemoresistance to a variety of cancer cell lines.
Methods: The candidate miRNAs regulating GNMT expression were found by in silico analysis (Targetscan and EMBL-microcosm). After this, the expression of candidate miRNAs was tested by real-time PCR in metastatic and hepatocellular carcinoma human samples, and in tumoral cell lines with different chemoresistance level. Finally, the resistance to doxorubicin and sorafenib treatments was assessed in tumoral cell lines after overexpressing or silencing the miRNA.
Results: Two miRNAs (miR-873 and miR-518d) were found to regulate GNMT expression. The analysis of both miRNAs in metastatic and hepatocellular carcinoma human samples found a miR-518d elevated in comparison with healthy samples.
miR-518d and GNMT levels were measured in sensitive and chemoresistant cell lines. It showed a correlation in which the drug-resistant cell lines presented higher amount of miR-518d and lower GNMT.
Finally, the overexpression of miR-518d in HuH7 hepatoma cell line increased the resistance to doxorubicin, whereas the inhibition of the miRNA in BCLC3 hepatoma cell line sensitized it to doxorubicin and sorafenib.
Conclusions: miRNA-518d is increased in tumoral samples and hepatoma cell lines, reducing GNMT expression. The expression of this miRNA correlates with the chemoresistance, and its inhibition sensitizes the hepatoma cell lines to treatment with drugs such as doxorubicin and sorafenib. The selective modulation of this microRNA can be important to improve the response to chemotherapies, sensitizing the tumors to the specific drugs.

P0302
CONSTITUTIVE GP130 ACTIVATION ACCELERATES TRANSFORMATION OF PROLIFERATING HUMAN HEPATOCYTES VIA INCREASED LEVELS OF OXIDATIVE STRESS

I. Gil-Ibanez[1], D. Heim[1], J. Herden[1], A.C. Parplys[1], K. Borgmann[1], D. Schmidt-Arras[2], A.W. Lohse[1], S. Rose-John[2], H. Wege[1].
[1]*University Medical Center Hamburg-Eppendorf, Hamburg,*
[2]*Christian-Albrechts-Universität zu Kiel, Kiel, Germany*
E-mail: i.gil-ibanez@uke.de

Background and Aims: Presently, a prominent hypothesis states that pro-inflammatory signaling pathways (IL-6) and reactive

oxygen species (ROS) promote hepatocyte transformation during the course of chronic hepatitis. In order to elucidate the driving oncogenic mechanisms, we activated the IL-6 signal transducer glycoprotein 130 (gp130) in untransformed hTERT-immortalized human fetal hepatocytes (FH-hTERT) and challenged the cells with ROS.

Methods: We generated FH-hTERT clones with stable expression of a ligand-independent constitutively active gp130 construct (L-gp130). Following phenotype characterization, we treated FH-hTERT/L-gp130 clones with H_2O_2 after glutathione depletion with BSO. ROS levels were measured (Carboxy-H_2DCFDA) and DNA-double strand breaks (DSB) were determined by immunofluorescent staining for γ-H2AX and Rad51. We assessed the expression of DNA-damage and antioxidant response genes by qRT-PCR. Proliferation was monitored by BrdU incorporation, and anchorage-independent growth was scored in soft agar. Finally, to compare ligand-independent with ligand-dependent IL-6 signaling, we activated IL-6 transsignaling with the designer cytokine Hyper-IL-6 and recapitulated the experiments.

Results: Constitutive gp130 activation alone was not sufficient to induce full malignant transformation. However, challenge with H_2O_2/BSO resulted in 2- to 3-fold higher ROS levels and up to 5-fold more DSB in FH-hTERT/L-gp130 clones in comparison to parental cells. Despite higher ROS levels, FH-hTERT/L-gp130 clones survived and even displayed an enhanced proliferation following treatment with H_2O_2/BSO, and developed colony growth capabilities in soft agar with a frequency of up to 20 colonies per 5,000 seeded (FH-hTERT with/without treatment no colonies, FH-hTERT/L-gp130 clones without treatment no colonies). As possible mechanism, we detected a decreased expression of antioxidant genes, like GPX3 and APOE, and absence of p21 upregulation. In contrast to FH-hTERT/L-gp130 clones, FH-hTERT incubated with Hyper-IL-6 did not demonstrate increased ROS levels and, as observed in control cells, proliferation was diminished in response to oxidative stress.

Conclusions: In contrast to Hyper-IL-6 stimulation, ligand-independent constitutive activation of gp130 resulted in an enhanced cell cycle turnover despite increased levels of ROS and DSB. Increased ROS levels in hepatocytes might be a consequence of an altered gp130-mediated oxidative stress response.

P0303

HEPATITIS C VIRUS CORE PROTEIN INCREASES OCT4 EXPRESSION AND PROMOTES CELL CYCLE PROGRESSION IN HEPATOCELLULAR CARCINOMA

J. Zhou[1], R. Chen[1], X. Deng[1]. [1]*Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China*
E-mail: jiajiazh2004@126.com

Background and Aims: Hepatitis C virus (HCV) core protein plays an important role in the development of hepatocellular carcinoma. OCT4, a homeodomain transcription factor of the POU family, is critically involved in the self-renewal of undifferentiated embryonic stem cells. Abnormal expression of OCT4 has been detected in several human solid tumors. However, relationship between HCV core and OCT4 remains uncertain. The aim of this study was to investigate the role of HCV core in regulating OCT4 expression and its role in tumorigenesis of hepatocellular carcinoma.

Methods: HepG2 stable cell lines were established by transfection with pcDNA-core. HCV core siRNAs were employed to knockdown of HCV core expression. OCT4 expression was analyzed by qRT-PCR and Western blot. Proliferation and cell cycle of HepG2 cells, transfected with OCT4 siRNAs, were assessed using CCK8 assay and flow cytometry.

Results: The results showed that HCV core efficiently up-regulated OCT4 expression (Fig. A). The expression levels of OCT4 at both mRNA and protein were markedly increased in HepG2 cells with HCV core transfection. Meanwhile, HCV core-increased OCT4 expression was attenuated by RNA interference-mediated knockdown of HCV core (Fig. B). In addition, HCV core-increased OCT4 expression resulted in enhanced cell proliferation and cell cycle progression. Inhibition of OCT4 reduced the CCND1 expression and induced G0/G1 cell cycle arrest in hepatocellular carcinoma cells (Fig. C,D).

Conclusions: Our findings suggest that HCV core protein can increase OCT4 expression and promote cell cycle progression, and also provides a new insight into the mechanism of hepatocarcinogenesis by HCV infection.

Background and Aims: Three-dimensional *in vitro* tumor models are needed to obtain more information about drug behavior in tumors. The aim of this study is to establish a new model for hepatocellular carcinoma (HCC) using decellularized rat livers.

Methods: After generating acellular rat liver matrix, characterization was performed in terms of morphology, ultrastructure and biochemistry. HepG2 liver cancer cells were perfused via the portal vein and placed in a bioreactor for 10 days. Histology was performed to analyze cell distribution within the scaffolds. Function and tumor-related gene expression were examined by polymerase chain

reaction (PCR), immunohistochemistry and western blot. Albumin secretion by cells grown within scaffolds, monolayer culture and on Matrigel was chekced by ELISA. We also evaluated the function of HepG2 cells grown on scaffolds in the presence of a well-known anti-cancer drug; methotrexate, to investigate the potential application of our system for drug screening.

Results: Histological and scanning electron microscopy examinations of decellularized scaffold revealed total removal of the cytoplasmic and nuclear materials. Perfusion of decellularized liver by fluroscent dextran showed the preservation of the vascular tree in scaffolds. Biochemical analysis showed the presence of a negligible amount of DNA and preserving of the important extracellular matrix components such as collagen, elastin and glycosaminoglycans. HepG2 cells grew well on the scaffolds. PCR, immunohistochemical examination and western blotting showed the ability of HepG2 cell grown within scaffolds to maintain their function and tumorgenicity at significantly higher levels than cells grown on two-dimensional (2-D) dishes or spheroids on Matrigel. Unlike the 2-D cultures, albumin secretion and alpha-fetoprotein expression in three-dimensional cultures were less susceptible to lower concentrations of the drug. Cells grown in scaffolds seemed to respond to the drug in an analogous manner to its known activity *in vivo*.

Conclusions: In summary, using HepG2-reseeded scaffolds as *in vitro* 3-D cancer models provided a superior 3-D cell culture environment for tumor studies and will enable researchers to evaluate and predict the efficacy of new anti-cancer drugs.

P0305
HOXA13 EXPRESSION IS ASSOCIATED TO WORST PROGNOSIS IN HCC AND MODULATES HCC-DERIVED CELLS RESPONSE TO SORAFENIB IN VITRO

L. Quagliata[1], C. Quintavalle[1], V. Perrina[1], M. Matter[1], C. Cillo[1], L. Terracciano[1]. [1]*Institute of Pathology, University Hospital Basel, Basel, Switzerland*
E-mail: luca.quagliata@usb.ch

Background and Aims: Despite significant advances in HCC diagnosis and management, for advanced stages no therapeutic options exist beside Sorafenib. Recently, using human liver biopsies, we showed that HOXA13 expression in HCC correlates with poor survival and metastasis presence. In addition, we observed that HOXA13 expression increases HCC cells proliferation *in vitro*. Here we seek to confirm our data on a larger cohort of samples and to investigate whether HOXA13 could modulate cells' Sorafenib response.

Methods: A liver TMA (tissue microarray) comprises a total of n = 305 specimens, n = 82 normal liver tissues, n = 108 cirrhotic patients and n = 115 HCCs, has been stained for HOXA13, CK-7, CK-19, E-Cad. Protein levels have been correlated with patients'clinical data. *In vitro* experiments to stably modulate HOXA13 expression (gain and loss of function) have been performed using the HCC derived cell lines: Hep-G2, SNU449 and PLC5. Subsequently, cells have been treated with Sorafenib and cell cycle analysis, proliferation, migration and drug responce have been tested.

Results: HOXA13 is altered in 41% of HCC tested samples, thus confirming our previous results obtained using iver biopsies. In addition, high HOXA13 levels are associated with poorer outcome and higher grading (Edmondson and BCLC). Increased HOXA13 expression is linked with stem progenitor markers, CK-7 and CK19. Furthermore, high HOXA13 expression is coupled with diminished levels of E-Cad, providing a molecular basis for its association with metastasis in HCC. Finally, *in vitro* experiments demonstrate that HOXA13 overexpression results in higher resistance to Sorafenib exposure. Conversely, HOXA13 downregulation sensitize HCC cells to Sorafenib.

Conclusions: Here we show that HOXA13 IHC-based protein levels can reliably predict HCC outcome and correlates with a number of tumour features (e.g. grade). Thus the usage of HOXA13 as a marker for HCC aggressiveness deserves further investigations. In addition, our *in vitro* data concerning HOXA13 modulation of Sorafenib response prompt us to validate this finding *in vivo* using HCC samples.

IMPAIRMENT OF AUTOPHAGY IN THE EARLY STAGES OF HEPATOCARCINOGENESIS

M.A. Kowalik[1], A. Perra[1], L. Falasca[2], M. Piacentini[3], G.M. Ledda-Columbano[1], A. Columbano[1]. Spallanzani',* [3]*Department of Biology, University of Rome 'Tor Vergata', Rome, Italy*
E-mail: mkowalik@tiscali.it

Background and Aims: Hepatocellular carcinoma (HCC), the third leading cause of cancer-related mortality worldwide, represents a major health problem. Recent studies highlight the importance of autophagy, a catabolic process by which cells remove protein aggregates and damaged organelles, in hepatocarcinogenesis. Autophagy dysfunction is also associated with neurodegeneration, aging and autoimmune disorders, however, its role in carcinogenesis remains complex, dependent on cancer stage and still controversial. Therefore, the aim of this study was to investigate the role of autophagy in the early stages of HCC development.

Methods: The Resistant-Hepatocyte (R-H) rat model [1], which offers the possibility to identify distinct lesions (preneoplastic nodules, early and fully advanced HCCs) at well-defined timings, was used. Autophagy was investigated by immunohistochemistry, electron microscopy and qRT-PCR.

Results: First of all, the expression of different autophagy markers (Ambra1, p62, Becn1, VpS34, UVRAG) was investigated in preneoplastic nodules. The results indicate that while the mRNA levels of Ambra1, p62, Becn1, Ulk1, Atg5 and Atg12 were not increased in the preneoplastic lesions, immunohistochemistry analysis demonstrated a marked accumulation of all analyzed proteins in preneoplastic nodules when compared with the surrounding tissue, suggesting impairment of the autophagic process. The results of electron microscopy analysis confirmed the autophagy blockage, as demonstrated not only by the lack of autophagic vacuoles but also by the presence of strongly altered, swollen and unremoved mitochondria. Recent studies [2] reported that p62 interacts with the Nrf2-binding site on Keap1, resulting in stabilization of Nrf2 followed by transcriptional activation of its target genes. Accordingly, p62 accumulation in preneoplastic nodules was associated with a significant induction of NQO1, GCLC and GSTA4 (Nrf2 target genes). Finally, the expression levels of miRNA-224, a miR whose expression is inversely correlated with autophagy [3], was about 100-fold higher in preneoplastic nodules when compared to the surrounding tissue.

Conclusions: These results strongly suggest that autophagy results impaired in the early stages of hepatocarcinogenesis induced by R-H model and its modulation may represent a promising therapeutic target in HCC.

E-mail: rordf@unileon.es

Background and Aims: Hepatocellular carcinoma is the five most common malignancy worldwide. Autophagy is a process that targets internal or damaged organelles and misfolded proteins to lysosomal degradation for the purpose of maintaining homeostasis during stress, although this process also contributes to cell death in several situations. On the other hand, ceramides have emerged as important effectors in the regulation of the autophagic pathway, mediating the cross talk between apoptosis and autophagy. Melatonin induces anti-apoptotic, anti-angiogenic and anti-invasiveness effects on HepG2 cells. However, it is unknown how autophagy affects cell death induced by melatonin. The aim of this study was to explore the effects of melatonin on autophagy and cell death mechanisms in HepG2 cells.
Methods: Autophagy was evaluated in HepG2 cells by Western blot of LC3 and p62 and confocal microscopy of LC3 and LAMP2. Autophagy flux was assessed using 50 μM chloroquine and 100 nM bafilomicyn. Ceramide levels were measured by HPLC, and acid sphingomyelinase (ASMase) activity using a fluorescent sphingomyelin analog. mRNA levels were assessed by RT-PCR and cell viability by MTT.
Results: Melatonin administration (1–2 mM) induced a transient autophagic response characterized by LC3II increased expression and p62 degradation, as well as LC3II and LAMP2 colocalization, which reached a maximum at 8 hours and disappeared at 24 h. Poly-ADP-ribose-polymerase (PARP) cleavage and BAX protein levels increased while cell viability was reduced from 24 h to 48 h of treatment. ATG5-silenced HepG2 cells were more susceptible to melatonin induced-cell death than non-silenced cells, and showed a significantly increased cleavage of PARP. Melatonin was able to enhance ceramide levels, serine palmitoyltransferase (SPT) and acid sphingomyelinase (ASMase) expression, and ASMase activity after 4 h of administration. SPT inhibition (5 μM myriocin) prevented melatonin induced autophagy and there was an impaired autophagy flux in response to the ASMase inhibitor imipramine (20 μM).
Conclusions: Melatonin induces in HepG2 cells an early and transient autophagic response that is prevented by ceramide inhibitors. Furthermore, suppression of autophagy by ATG5 silencing makes cells more susceptible to melatonin-induced apoptosis. Our findings support a protective effect of autophagy, partially regulated by ceramides, on melatonin-induced apoptosis, and suggest that autophagy suppression may strengthen the proapoptotic effect of melatonin in liver cancer

GENOME-WIDE HIGH-THROUGHPUT SCREENING OF TGF-BETA RELATED BIOMARKERS IN HCC CELLS

Y. Cao[1], R. Agarwal[2], F. Dituri[1], B. Rani[1], P. Winter[2], G. Giannelli[1].
[1]*Biomedical Sciences and Human Oncology, University of Bari, Bari, Italy;* [2]*GenXPro GmbH, Frankfurt am Main, Germany*
E-mail: yuan.cao@uniba.it

Background and Aims: The small molecule kinase inhibitor, LY2157299, targeting the TGF-β receptor I (RI), blocks invasion and migration of HCC cells in vitro and is currently being evaluated in clinical trials, where it shows promising anti-tumor effects in HCC patients. Aim of the study is to identify new biomarkers to assess the drug's efficiency.
Methods: The mRNA and smallRNA transcriptomes of an HCC cell line treated with TGF-beta and LY2157299, used both alone and in combination, were investigated using Next-Generation Sequencing (NGS)-based Massive Analysis of cDNA Ends (MACE) and smallRNA seq, respectively. For functional assignment of differentially expressed genes, Gene Ontology enrichment analysis was performed. Differential expression of selected TGF-β-responsive transcripts and microRNAs that were reverted by LY2157299 to the level of the untreated controls were evaluated by Quantitative Real-time (qRT-) PCR. The same assays were used to analyse the expression of the respective mRNAs and miRNAs in HCC patients.
Results: Six mRNA transcripts were selected as significantly up-regulated by TGF-β and down-regulated by LY2157299. Some of these transcripts, such as *PMEPA1*, are highly expressed also in other cancers, being targets for therapeutic drugs. Others, such as *SKIL* and *Snai1,* are involved in the TGF-β/SMAD pathway and evoke tumor progression in HCC. We also detected, for the first time, that the *C4orf26* transcript was significantly up-regulated by TGF-β in our cell line. We further identified three novel microRNAs, namely miR-27a-5p, miR-1248 and miR-1973, that were up-regulated by TGF-β and responded to LY2157299 treatment. miR-27a regulates lipid metabolism and cell proliferation during hepatic stellate cell (HSC) activation, affecting the expression of 1267 proteins. However, nothing is known about the relation of these miRNAs to TGF-β signaling. In HCC patients, *ANGPTL4*, *SNAI1*, *SKIL* and *PMEPA1* mRNAs are strongly expressed in tissue specimens, and the last three are also significantly correlated with TGF-b1 mRNA levels.
Conclusions: We identified at least one novel mRNA and 3 novel miRNAs that have not previously been related to TGF-β signaling and may be important for TGF-β-related oncogenicity. Further in vivo studies are needed to investigate their role in HCC progression and also as biomarkers for companion diagnostics of LY2157299 treatment in HCC patients.

GENE EXPRESSION PROFILING OF HEPATOCELLULAR CARCINOMA BIOPSIES REVEALS THREE MOLECULAR CLASSES WITH DISTINCT CLINICAL AND BIOLOGICAL PROPERTIES

Z. Makowska[1], T. Boldanova[1], D. Adametz[1], L. Quagliata[1], J.E. Vogt[1], M.T. Dill[1], M.S. Matter[1], V. Roth[1], L. Terracciano[1], M.H. Heim[1].
[1]*University of Basel, Basel, Switzerland*
E-mail: zuzanna.makowska@unibas.ch

Background and Aims: Hepatocellular carcinoma (HCC) is a heterogeneous disease, and despite considerable research efforts, no molecular classification of HCC has been introduced in clinical practice. The existing molecular classification systems were established using resected tumors, which introduces a selection bias towards patients without liver cirrhosis and with early stage HCCs. So far, these classification systems have not been validated in liver biopsy specimens from tumors diagnosed at intermediate and late stages.
Methods: We generated and analyzed expression profiles of 60 HCC biopsies from an unselected patient population representing all tumor stages.
Results: Unbiased clustering identified 3 HCC classes. Class membership correlated with survival, tumor size, and with Edmondson and BCLC stage. Most biopsy specimens could be assigned to the classes of published classification systems, demonstrating that gene expression profiles obtained from patients with early stage disease are preserved in all stages of HCC. When a reference set of healthy liver samples was integrated in the analysis, we observed that the differentially regulated genes

up- or down-regulated in a given class relative to other classes were actually dysregulated in the same direction in all HCCs, with quantitative rather than qualitative differences between the molecular subclasses. With the exception of a subset of samples with a definitive β-catenin gene signature, biological pathway analysis could not identify class specific pathways reflecting the activation of distinct oncogenic programs.
Conclusions: Our results suggest that gene expression profiling of HCC biopsies has limited potential to direct therapies that target specific driver pathways, but can identify subgroups of patients with different prognosis.

P0310
FAK/EZH2 FUNCTIONAL INTERACTION IS CRUCIAL FOR HCC DEVELOPMENT AND PROGRESSION BOTH IN VIVO AND IN VITRO

D. Gnani[1], S. Ceccarelli[1], S. Artuso[2], C. De Stefanis[1], N. Panera[1], A. Crudele[1], V. Nobili[3], C. Leonetti[2], A. Alisi[1]. *[1]Liver research unit, Bambino Gesù children's hospital, [2]Experimental Preclinical Laboratory, Regina Elena National Cancer Institute, [3]Hepato-metabolic disease unit, Bambino Gesù children's hospital, Rome, Italy*
E-mail: daniela.gnani@yahoo.it

Background and Aims: Hepatocellular carcinoma (HCC) is the fifth most common cancer worldwide and the incidence is rising across most of the world. During the multi-step process of HCC pathogenesis, the activation/inactivation of several epigenetic mechanisms, mainly those regulating proliferation/apoptosis and migration, may play a major role. Focal Adhesion Kinase (FAK) is a non-receptor tyrosine kinase involved in the regulation of many cellular processes such as proliferation, adhesion, invasion or cell survival. FAK over-expression and activation, often occurs during neoplastic transformation including HCC development, even though its role during hepatocarcinogenesis remains unclear. The aim of the present study was to investigate the effect of FAK silencing in an *in vivo* HCC xenograft NOD/SCID mouse model and in an *in vitro* model of HCC.
Methods: We established HepG2Luc-siCTRL or HepG2Luc-siFAK cells that were intrahepatically injected in NOD/SCID mice to analyze *in vivo* tumorigenicity or used to study the role of FAK on HepG2 cell homeostasis. BrdU incorporation, cell proliferation and soft agar assays were performed to assess the effect of FAK silencing on cell tumorigenic ability. Real-Time PCR, Western Blotting and immunofluorescence assays were also carried out to study the expression and the activity of FAK and EZH2 in FAK depleted cells.
Results: Xenograft experiments showed a range of 30–60% reduction on the tumor mass derived from HepG2Luc-siFAK injection with respect to that observed in HepG2Luc-siCTRL cells. In HCC from silenced HepG2 clones the expression of FAK and PCNA was drastically down-regulated. Furthermore, FAK-silenced HepG2 cells showed a statistically significant downsized *in vitro* proliferation and invasion rates. The silencing of FAK also induced a reduction of major pathways regulating hepatocellular homeostasis. Interestingly, a down-regulation of EZH2 at the transcript level was observed in FAK-silenced cells together with a decreased nuclear EZH2 and a reduced expression of the 3meH3k27. We also reported an increased expression of the EZH2-targeted mir-200b compared to control cells.
Conclusions: In conclusion our results showed that FAK silencing can counteract the invasive and high proliferative cancer phenotype in HCC. Moreover, the silencing critically affect the activity of EZH2 suggesting a potential interaction between FAK and EZH2. However, further studies are needed to shed light on FAK and EZH2 molecular cross-talk.

P0311
BALB/C AND C57/BL6 MICE EXHIBIT DIFFERENCES IN THEIR SUSCEPTIBILITY AND ANTI-TUMOR RESPONSE TO B16F10 MELANOMA LIVER METASTASIS

F. Foerster[1,2], S. Strobl[1], L. Kaps[1], S.-Y. Weng[1], Y.O. Kim[1], M. Bros[3], M. Diken[4], S. Boegel[4], J. Castle[4], E. Bockamp[1], D. Schuppan[1,5]. *[1]Institute of Translational Immunology and Research Centre for Immunotherapy, [2]First Department of Medicine, [3]Department of Dermatology, [4]TRON – translational oncology gGmbH, University Medical Center Mainz, Mainz, Germany; [5]Division of Gastroenterology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States*
E-mail: friedrich.foerster@unimedizin-mainz.de

Background and Aims: While progress has been made in increasing survival rates in neoplasms detected at early stages, the prognosis of metastasized tumors remains dismal. Liver metastases in particular are survival-limiting in a broad range of malignancies. Therefore, a better understanding of the mechanisms that underlie (liver) metastasis is essential for improving cancer patients' outcome. The B16F10 melanoma cell line is a well described cancer cell line with high metastatic potential that has been successfully used for human anti-cancer drug development. Since the B16F10 cell line has very low expression of MHC class I molecules, it is predestined for studying the innate anti-tumor immune response.
Methods: We administered B16F10 cells stably transfected with a luciferase-expressing lentivirus via intrasplenic injection to induce liver metastasis in two different strains of wild-type mice. Bioluminescence was recorded 7 and 14 days after injection using an IVIS in vivo imaging system. 2 weeks after injection, mice were sacrificed and their metastatic burden measured. Liver probes were analysed with regard to immune cell populations and markers of M1-/M2-polarization by FACS, RT-qPCR and IHC. Whole transcriptome sequencing was performed on selected samples and their differential gene expression analysed.
Results: Within 2 weeks, mice developed severe metastatic disease. Notably, the allogeneic mouse strain (Balb/c) was more susceptible to B16F10 liver metastasis than the syngeneic strain (C57/Bl6). Metastasized livers showed a pattern of predominantly innate immunity with macrophages representing the major immune cell population. Interestingly, Balb/c mice exhibited a pattern of M1-, while C57/Bl6 mice showed a pattern of M2-macrophage polarization. Complete RNA sequencing of metastasized liver samples demonstrated that interferon-γ and its downstream pathway (which is usually associated with an anti-tumor response) was significantly overexpressed in Balb/c mice, whereas the Tgf-beta pathway (which is considered immunosuppressive) was significantly upregulated in C57/Bl6 mice.
Conclusions: The B16F10 melanoma liver metastasis model allows to study the innate immune response to invading cancer cells in the liver. The two wild-type mouse strains, Balb/c and C57/Bl6, appear to differ dramatically in their immunological anti-tumor responses, which is currently further explored to better define therapeutic targets related to innate immunity.

PRECLINICAL EVALUATION OF DEXTRAN-BASED THERAPEUTIC NANOPARTICLES FOR HEPATIC DRUG DELIVERY

F. Foerster[1,2], L. Kaps[1], A. Brose[1], S. Strobl[1], D. Bamberger[3], M. Diken[4], A. Tüttenberg[5], P. Wich[3], D. Schuppan[1,6]. *[1]Institute of Translational Immunology and Research Centre for Immunotherapy, [2]First Department of Medicine, University Medical Center Mainz, [3]Institute of Pharmacy and Biochemistry, University of Mainz, [4]TRON – translational oncology gGmbH, [5]Department of Dermatology, University Medical Center Mainz, Mainz, Germany; [6]Division of Gastroenterology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States*
E-mail: friedrich.foerster@unimedizin-mainz.de

Background and Aims: Nanoparticles bear great potential for a broad range of clinical applications. In particular, nanoparticles may be used for targeted therapies in which the active substance is specifically delivered to the desired organ, tissue or cell population increasing its therapeutic efficacy while reducing its side effects. A few examples of such therapeutic nanoparticles are already routinely used in the clinic today, e.g. liposomal amphotericin B (Ambisome®) and pegylated liposomal doxorubicin (Caelyx®). We aimed to explore novel therapeutic nanoparticles targeting the (innate) immune system for the treatment of inflammatory/fibrotic liver disease or primary/metastatic liver cancer using dextran-based nanoparticles designed for liver specific drug delivery.
Methods: Dextran nanoparticles measuring 100 to 150 nm were synthesized using a mini-emulsion technique from dextran, a polysaccharide of glucose naturally found in bacteria. Particles were loaded with (near infrared) fluorescent dyes, siRNA or small molecules. In vitro, uptake of nanoparticles in different cell types was documented by laser scanning microscopy and measured by FACS. Cell viability was quantified using the CellTiter-Glo® assay. In vivo, nanoparticles were administered to wild-type mice via retroorbital injection and their biodistribution was recorded using an IVIS in vivo imaging system. Following repeated treatments serum parameters were analysed to detect relevant toxicities. Samples from treated mice were studied by FACS, immunofluorescence and RT-qPCR
Results: In vitro, nanoparticles were readily taken up by endothelial cells, hepatocytes and macrophages with no clear preference for a specific cell type. Viability of cells was not decreased after incubation with the particles. Nanoparticles loaded with paclitaxel showed similar cytotoxicity as conventional paclitaxel. In vivo and ex vivo, nanoparticles were largely distributed to the liver (70–80%) and the lungs (10–20%) with irrelevant distribution to other organs (including the spleen). Following repeated particle injections, serum parameters indicated a lack of overt in vivo toxicity. After a single treatment, a large portion of liver macrophages (70%) had taken up the nanoparticles.
Conclusions: Dextran-based nanoparticles of defined size are multifunctional liver specific drug carriers, which lack toxic side effects and bear great potential for clinical applications targeting liver macrophages.

P0313

CORRELATION BETWEEN VEGF AND VEGF-R POLYMORPHISMS, TOXICITY AND CLINICAL OUTCOME IN HCC PATIENTS RECEIVING SORAFENIB

L. Faloppi[1], M. Bianconi[1], G. Svegliati Baroni[2], A. Casadei Gardini[3], N. Silvestris[4], G. Masi[5], P. Ulivi[3], C. Vivaldi[5], R. Giampieri[1], M. Del Prete[1], A. Benedetti[2], M. Scartozzi[6], S. Cascinu[1]. *[1]Department Medical Oncology, [2]Clinica di Gastroenterologia, Università politecnica delle Marche, AOU Ospedali Riuniti, Ancona, [3]Medical Oncology Unit, IRCCS-IRST, Meldola, [4]IRCCS Ospedale Oncologico Giovanni Paolo II, Bari, [5]Medical Oncology Unit, Università di Pisa, Pisa, [6]Department Medical Oncology, Università di Cagliari, Cagliari, Italy*
E-mail: lucafaloppi@gmail.com

Background and Aims: The introduction of sorafenib for the treatment of advanced HCC radically changed patients' clinical outcome. However response to treatment as well as toxicity are still largely unpredictable in the single patient. We previously reported that VEGF and VEGFR polymorphisms may have a predictive and prognostic role in this setting, but little is known about the possible correlation with toxicity. The aim of our study was to evaluate whether VEGF and VEGFR genotyping was able to correlate with toxicity in HCC patients receiving sorafenib.
Methods: 73 histological samples of HCC patients receiving sorafenib were tested for VEGF-A, VEGF-C and VEGFR-1, 2, 3 single nucleotide polymorphisms (SNPs). Patients time to progression (TTP), overall survival (OS) and toxicities were analysed.
Results: VEGF-A rs833061 T>C, rs699947 C>A and rs2010963 C>G polymorphisms were statistically significant associated with any grade global (respectively: $p = 0.031$; $p = 0.018$; $p = 0.003$) and cutaneous toxicities (respectively: $p = 0.043$; $p = 0.019$; $p = 0.025$). Furthermore patients with any grade global and cutaneous toxicities showed a better progression free survival and overall survival (global toxicity PFS: 7.0 vs 5.0 months, $p = 0.016$; OS: 26.8 vs 13.0 months, $p = 0.023$) (cutaneous toxicity PFS: 7.6 vs 5.1 months, $p = 0.033$; OS: 22.7 vs 13.3 months, $p = 0.014$).
Conclusions: In our analysis patients with polymorphism T at rs833061, C at rs699947 and C at rs2010963 showed a higher rate of toxicities and, accordingly to our previous report, this correlates with a better PFS and OS. Analysis of VEGF and its receptor genes polymorphisms represents a clinical tool to identify patients with favourable response to sorafenib presumably related to a more efficient control of tumour growth. The occurrence of toxicity could be an interesting clinical surrogate during sorafenib treatment and may help clinicians in a more cautious and aware management of HCC patients.

P0314

PSEUDOGENE INTS6P1 REGULATES ITS COGNATE GENE INTS6 THROUGH COMPETITIVE BINDING OF MIR-17-5P IN HEPATOCELLULAR CARCINOMA

M. Vedean[1], Iuliu Hatieganu Translational Hepatology Working Group. *[1]Medicine, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj Napoca, Romania*
E-mail: madalina.vedean@yahoo.com

Background and Aims: Through complex regulation of messenger RNA (mRNA), non-coding RNA species play key roles in the pathogenesis of hepatocellular cancer (HCC). Pseudogenes are non-protein coding transcripts that display high homology with, and may act through the regulation of, their cognate protein-coding genes. However, the roles played by pseudogenes in the pathogenesis of HCC are still incompletely elucidated.
Methods: The unbiased arrays were performed to determine a putative tumor suppressive regulatory circuit composed of integrator complex subunit 6 (INTS6), integrator complex subunit 6 pseudogene 1 (INTS6P1) and miR-17-5p in HCC. A large cohort study of HCC and matched normal liver tissues is to verify the

array data. The miR-17-5p gain and loss of function were conducted to study the mediator role of miR-17-5p between INTS6 and INTS6P1. The miR-17-5p binding site in INTS6 and INTS6P1 was confirmed by luciferase assays. Functional studies included growth curves, cell death, and migration assays. In vivo studies included electroporation in a xenograft model of HCC.
Results: The large cohort study finds that INTS6 and INTS6P1 are down-regulated in a coordinated fashion in HCC. The function studies indicate that INTS6 is a novel tumor suppressor in HCC. Furthermore, mechanistic experiments indicate that the pseudogene of INTS6, namely INTS6P1, also acts as a tumor suppressor in HCC, through competition for oncomiR-17-5p.
Conclusions: Our findings demonstrate INTS6P1 and INTS6 are part of the same competitive tumor suppressor network that includes oncomiR-17-5p. This regulatory circuit reveals novel insights into the underlying mechanisms of hepatocarcinogenesis.

P0315
INCREASED AEROBIC GLYCOLYSIS IS ASSOCIATED WITH POOR OUTCOME AND SUPPRESSION OF APOPTOSIS IN HUMAN LIVER CIRRHOSIS AND HCC

V. Iansante[1], P.M. Choy[1], S. Chokshi[2], R. Williams[1], R.A. Anders[3], C. Bubici[4], S. Papa[1]. *[1]Cell signaling and Cancer Laboratory, [2]Viral Hepatitis Laboratory, Institute of Heptaology, Foundation for Liver Research, London, United Kingdom; [3]Division of Gastrointestinal and Liver Pathology, The Johns Hopkins University School of Medicine, Baltimore, United States; [4]Division of Biosciences, Brunel University, London, United Kingdom*
E-mail: s.papa@researchinliver.org.uk

Background and Aims: Pro-inflammatory signalling in the liver promotes the appearance of a metabolic phenotype that involves the transition from mitochondrial respiration to aerobic glycolysis. It was demonstrated that this metabolic shift occurs during the transition from healthy and early stage of liver injury (NAFLD/NASH, ALD) to late stage of disease (i.e. cirrhosis), and further escalates during HCC development [1,2]. This metabolic signature enables dividing cells to satisfy anabolic and energetic needs for biomass production and to suppress apoptotic signalling, which is consistent with increased compensatory hepatic cell proliferation typical of cirrhotic and HCC livers. However other studies in contrast have suggested that hepatocytes are unable to sustain glycolysis during late stage of chronic liver disease [3].
Methods: We used unbiased gene expression analyses of microarray datasets to investigate the expression of glycolytic genes in cirrhotic and HCC livers and correlated their expression with patient outcome. Furthermore, by using a combination of *in vitro* and *in vivo* analyses we have characterized the abilities of a novel anti-apoptotic gene to regulate aerobic glycolysis in liver cirrhosis and HCC.
Results: mRNA profiling showed significantly higher expression of glycolytic transcripts in cirrhotic and HCC livers compared to normal quiescent livers ($P < 0.05$). Up regulation of *Glut1*, *Hk1*, *Hk2*, *G6PI*, and PFKL was seen in HCC livers compared to their adjacent non-tumor tissues ($P < 0.001$). Notably, expression of enzymes regulating mitochondrial activity (Pdha, Pdk) was unchanged between non-tumor tissues and late stage of HCC. Moreover, up regulation of a novel anti-apoptotic gene positively correlated with increased expression of glycolytic transcripts in a group of cirrhotic patients prospectively classified as poor prognosis based on HCC development, and promotes the aerobic glycolysis of hepatoma cells.
Conclusions: In summary, our findings delineate a putative link between aerobic glycolysis and suppression of apoptosis that is an important part of the progression of cirrhosis to HCC. The identification of the mechanism regulating this link may lead to design new therapeutic strategies for human liver disease.

DESPITE REPRESSING IGF-1R, MIR-181A HALTS THE TUMOR-SUPPRESSOR ACTIVITY OF DECORIN BY ENHANCING TUMOR PROGRESSION IN HEPATOCELLULAR CARCINOMA

R.A. Assal[1], H.M. El Tayebi[1], K.A. Hosny[2], G. Esmat[3], A.I. Abdelaziz[1]. *[1]The Molecular Pathology Research Group, Department of Pharmacology and Toxicology, Faculty of Pharmacy and Biotechnology, German University in Cairo, [2]Department of General Surgery, Faculty of Medicine, Cairo University, [3]Department of Endemic Medicine and Hepatology, Cairo University, Cairo, Egypt*
E-mail: reem.amr@guc.edu.eg

Background and Aims: Decorin (DCN) is a tumor suppressor stromal-specific proteoglycan, and a modulator of several tyrosine-kinase receptors including insulin-like growth factor receptor 1 (IGF-1R). Thus, it was intriguing to study the effect of manipulating the expression of DCN in hepatocellular carcinoma (HCC) and consequently its effect on the oncogenic IGF-1R. Our preliminary in silico analysis predicted miR-181a to target DCN 3′ UTR with high score. The regulation of DCN by miRNAs was never investigated in HCC before. Hence we aimed at exploring this obscure relationship and its impact on IGF-1R.
Methods: Huh-7 HCC cell lines were cultured and transfected with miR-181a mimics, anti-miR-181a, and siRNAs against DCN. This was followed by total RNA extraction, reverse transcription to cDNA, and quantification with Real-time PCR. Viability and proliferation analysis were performed using MTT and BrdU assays. Unpaired t test and Pearson statistical methods were used. Data was considered statistically significant with $p < 0.05$ using GraphPad 5.0 software.
Results: Mimicking miR-181a in Huh-7 cells resulted in a significant down-regulation in DCN mRNA expression. Similarly, miR-181a mimics resulted in a concomitant significant down-regulation of IGF-1R mRNA expression. A direct correlation was observed between DCN and IGF-1R mRNAs' expression in mimicked cells. On the other hand, miR-181a was inversely correlated with both DCN and IGF-1R in miR-181a mimicked cells. Functional characterization of miR-181a in Huh-7 cells revealed induction in cellular viability and proliferation upon forcing the expression of miR-181a. Similarly, knocking down DCN gene using specific siRNAs induced Huh-7 cellular viability and proliferation.
Conclusions: The tumor suppressor activity of DCN is halted by the oncomiR miR-181a in HCC, which was observed in decreased DCN expression by miR-181a mimics. This was further proved by the induced cellular viability and proliferation by miR-181a and DCN siRNAs. On the other hand, the decrease in IGF-1R by oncomiR miR-181a remains unexplained but may be due to the direct targeting with miR-181a as predicted by our in silico analysis. Thus it can be concluded that miR-181a has a role in the interplay between DCN and IGF-1R and hence on HCC progression. These findings display a novel molecular mechanism of DCN regulation in HCC, and decreasing miR-181a levels might be a strategy for the enhancement of the tumor suppressor effects of DCN.

DOWN-REGULATION OF Hao2 IS ASSOCIATED WITH THE ONSET AND DEVELOPMENT OF HEPATOCELLULAR CARCINOMA IN RODENTS

S. Mattu[1], A. Perra[1], S. Menegon[2], M.A. Kowalik[1], A. Petrelli[2], G.M. Ledda-Columbano[1], S. Giordano[2], A. Columbano[1]. [1]*Biomedical Sciences, University of Cagliari, Cagliari,* [2]*Oncology, University of Turin, Turin, Italy*
E-mail: mattu.sandra@yahoo.it

Background and Aims: L-2-Hydroxy acid oxidases are flavin mononucleotide (FMN)-dependent peroxisomal enzymes, which are responsible for the oxidation of a number of l-2-hydroxy acids to ketoacids at the expense of molecular oxygen, resulting in the formation of hydrogen peroxide. Its role in cancer, if any, is still unknown. The aim of this work was to investigate the expression of Hao2 in early and advanced neoplastic lesions.
Methods: qRT-PCR and western blot analysis were performed in (i) HCCs developed in mice exposed to repeated injections of the CAR ligand TCPOBOP, with or without a single administration of diethylnitrosamine (DENA); (ii) pre- and neoplastic lesions generated by the rat Resistant Hepatocyte model (RH); (iii) several human hepatoma cells.
Results: We found a strong down-regulation of Hao2 in HCCs induced in mouse liver by DENA + TCPOBOP or by TCPOBOP alone. To establish whether Hao2 down regulation occurs early in HCC development, we moved to the rat RH model of hepatocarcinogenesis which allows the identification of very early preneoplastic lesions. Using this model, we found that both mRNA and protein expression of Hao2 were profoundly down-regulated in early preneoplastic lesions. Down regulation of Hao2 was maintained all throughout the process (early and advanced HCCs). An almost undetectable Hao2 expression was observed also in 5 different human hepatoma cell lines. Interestingly, down-regulation of Hao2 was associated with miRNA-183 and miR-223, which are predicted to target Hao2 mRNA.
Conclusions: These results describe, for the first time, the dysregulation of a metabolic gene whose expression is severely impaired in HCC generated in two different species and by different etiological agents. They also demonstrate that dysregulation of Hao2 is a very early event in the development of HCC, and suggest that Hao2 expression is under the control of two miRNAs overexpressed in all the stages of hepatocarcinogenesis.

E-mail: wata.amer@uk-koeln.de

Background and Aims: Point mutations and small insertions/deletions (indels) in tumor relevant genes have been identified and proposed as new indicators in hepatocellular carcinoma prognosis. Next generation sequencing (NGS) technologies provide the simultaneous analysis of genomic mutations in numerous target regions with high sensitivity. In the present study, based on data by whole exome analysis, a hotspot targeted multiplex PCR approach was combined with ultra deep sequencing and applied to hepatocellular carcinoma representing different grade of progression.
Methods: 72 HCC nodules of different etiology and grades were macrodissected and DNA extracted. At least 3000 genomic copies were amplified by multiplex PCR using primer sets targeting a wide panel of hotspot cancer genes. 394 amplicons of each sample were generated and sequenced by means of the MiSeq platform (Illumina). Conventional Sanger sequencing served as a reference technology. Alignment and variant calling was performed using the CLC Cancer Workbench software (CLC Bio, QIAGEN).
Results: Each macrodissected HCC nodule was sequenced by more than one million reads covering each targeted hotspot locus between approximately 400 and 2,000 reads. Variants were detected in exons of HNF1a, PTEN, retinoblastoma, Axin1, CTNNB1, CDH1, SMAD4 and APC. Variants of ARID2, and ARID1A were affected in high frequency by mutations. Interestingly, different nodules of one liver biopsy showed mostly but not always similar variant pattern, but in different extent as we expected from histological classification of the hepatocellular dedifferentiation.
Conclusions: We established a fast pipeline of mutation analysis of a tumor specific, hotspot gene panel covering diagnostic relevant loci of HCC by 500–2000 reads. For prognostic and therapy relevant data interpretation numerous nodules should be sequenced to get a representative mutation status for further clincial treatments.

P0319

IDENTIFICATION OF MOLECULAR ALTERATIONS INDUCED BY TARGETING METABOLISM IN HEPATOCELLULAR CARCINOMA

Z.C.F. Nwosu[1], J. Moreno-Càceres[2], C. Meyer[1], S. Dooley[1].
[1]*Department of Medicine II, Section Molecular Hepatology, University Hospital Mannheim, University of Heidelberg, Mannheim, Germany;* [2]*Institut d'Investigació Biomèdica de Bellvitge (IDIBELL), L'Hospitalet de Llobregat, Barcelona, Spain*
E-mail: zeribe.nwosu@medma.uni-heidelberg.de

Background and Aims: Cancer cells significantly rely on energy-rich substrates, e.g. glucose, for survival, proliferation and invasiveness. However, studies suggest that tumours can evade cell death by switching metabolic pathways or substrates when challenged by microenvironmental insults. Identification of regulators of these metabolic alterations will potentially guide targeted cancer therapy with an attendant improved prognosis. In this study, we aimed to identify signalling and genomic changes in hepatocellular carcinoma (HCC) following treatment with anti-metabolic drugs.
Methods: A panel of HCC cells, representative of early and advanced stages, were treated with anti-metabolic drugs, including 2 deoxy glucose (2-DG), metformin and also transforming growth factor beta 1 (TGF-β1). Functional effects were evaluated by cell proliferation, ATP production, clonogenicity, migration, caspase-3 assay and flow cytometry. Signalling alterations were studied using immunoblotting techniques and differential gene expression was analysed by quantitative real-time PCR of selected potential target genes. The target genes were predicted by in silico analyses of microarray datasets available in public domains.
Results: We find that HCC models harbour divergent metabolic portraits, and show varying degree of sensitivity to metabolism targeting drugs. Accordingly, HCC cells with epithelial phenotype (e.g. HUH7) were more responsive to metformin, and mesenchymal-like cell types (e.g. HLE) to 2-DG. In combination, both drugs significantly reduced proliferation, ATP production, colony formation and absolute cell count in HLE and HUH7, with >3 fold induction of caspase-3 in HLE cells. Further analyses implicated pro-survival pathways: while ERK1/2 phosphorylation was detected in both cell types, only HUH7 had obvious loss of pERK1/2 upon combinatorial treatment. Increased phospho-AKT was also observed only in HUH7 cells. This was, however, contrary to TGF-β induced cell death in HUH7 in which total AKT but not pAKT was increased. Finally, CAV1, implicated in tumour progression was strongly downregulated in HLE by 2-DG treatment, while other genes involved in metabolic alterations, e.g. SLC16A1, were differentially regulated upon targeting metabolism.
Conclusions: We report that divergent stage-dependent molecular alterations are consequent upon targeting metabolism in HCC. A mechanistic study of implicated genes and signalling pathways could help in defining optimal therapeutic options for patients with various HCC grades.

P0320

TARGETING TGF-BETA I WITH THE TRANSFORMING GROWTH FACTOR RECEPTOR TYPE I KINASE INHIBITOR, LY2157299, MODULATES STEMNESS-RELATED BIOMARKERS IN HEPATOCELLULAR CARCINOMA

B. Rani[1], F. Dituri[1], Y. Cao[1], U. Engström[2], L. Lupo[3], S. Dooley[4], A. Moustakas[5], G. Giannelli[1]. *[1]Department of Biomedical Sciences and Human Oncology, University of Bari, Bari, Italy; [2]Biomedical Center, Ludwig Institute for Cancer Research, Science for Life Laboratory, Uppsala, Sweden; [3]Department of Emergency and Organ Transplantation, University of Bari, Bari, Italy; [4]Molecular Hepatology-Alcohol associated diseases, Department of medicine II, Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany; [5]Department of Medical Biochemistry and Microbiology, and Ludwig Institute for Cancer Research, Science for Life Laboratory, Box 581 Biomedical Center, Uppsala, Sweden*
E-mail: bhavna.rani@uniba.it

Background and Aims: The stemness of Hepatocellular Carcinoma (HCC) is likely implicated in cancer heterogeneity, recurrence and therapy resistance. Aim of this study is to investigate the effects of TGF-beta and its type I receptor kinase inhibitor, LY2157299, on stemness-related biomarkers.
Methods: We investigated, by qRT-PCR and flow cytometry, the expression levels of EpCAM, CD133, CD13, Keratin-19 (CK-19), CD44, CD-133 and CD90 in early and late TGF-beta signature cells, after 48 hours of treatment with TGF-beta or LY2157299, respectively. Human tissue samples from patients who underwent surgery were cultured for 48 hours in the presence of LY2157299 and processed by qRT-PCR.
Results: In the early TGF-beta signature cells, the stem cell biomarkers EpCAM, CD44, CD90, CD133 and CK-19 were less expressed than in the late TGF-beta signature cells. However, TGF-beta stimulation upregulates their expression in early TGF-β signature cells, while LY2157299 downregulates their expression in late TGF-β signature cells. Consistently with the mRNA data, at the protein level TGF-beta treatment increases, whereas LY2157299 decreases, the expression of EPCAM, CD133 and CK-19 in early TGF-beta cell lines. Interestingly, the early TGF-beta signature cells do not express CD90 at basal level nor after TGF-beta treatment. However, downstream TGF-beta signalling molecules (Fibronectin, MAPK) are activated in these cell lines, indicating that TGF-beta signalling is switched on. In the late TGF-beta signature cell lines, the stimulation of TGF-beta increases the expression of CD-90 as well as activating *MAPK* and Fibronectin. In ex-vivo experiments, the CD-90 and CK-19 results paralleled those observed in HCC cell lines treated with LY2157299. A higher expression of EPCAM, AFP, CD44 and CD90 indicated an aggressive tumor pattern.
Conclusions: Inhibition of the TGF-beta pathway leads to a modulation of stemness-related biomarkers in HCC cell lines and in human HCC tissue samples.

INCREASED ANTI-TUMOR EFFECT OF VITAMIN D AFTER CYP24A1 INHIBITION ON HCC CELL LINES

H.N.A. Jozilan[1], P. Horvath[1], J.P. Kosa[1], P. Lakatos[1], D. Nemeth[1], J. Wölfling[2], D. Kovacs[2], B. Bodnar[2], P. Matyus[3], E. Horvath[1], I. Kovalszky[4], F. Szalay[1]. *[1]1st Department of Internal Medicine, Semmelweis University, Budapest, [2]Department of Organic Chemistry, University of Szeged, Szeged, [3]Department of Organic Chemistry, [4]1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary*
E-mail: jozilanhasan@gmail.com

Background and Aims: 24-hydroxylase (CYP24A1) is the main inactivating enzyme of 1alpha,25-dihydroxyvitamin D3 (1,25-D3). The anti-tumor effect of 1,25-D3 is well documented. Increased expression of CYP24A1 mRNA after vitamin-D3 administration has been shown in hepatocellular carcinoma (HCC) cell lines. We investigated the change of antiproliferative effect of 1,25-D3 after administration of CYP24A1 inhibitors.
Methods: 1,25-D3 and 16 newly synthetized tetralone compounds as CYP24A1 inhibitors were simultaneously added to the HepG2 and Hep3B human HCC cell lines. Cell proliferation was measured by bromodeoxyuridine (BrdU colorimetric) incorporation and the cytotoxicity by lactate dehydrogenase (LDH) detection in the cell culture supernatant. The CYP24A1 mRNA expression was measured by real time reverse transcription-polymerase chain reaction (RT-PCR).
Results: The CYP24A1 expression reached the peak value at 8 hours after 1,25-D3 administration and returned to the almost initial range at 16 hours in HepG2 cells. There was no measurable CYP24A1 expression in Hep3B cell line. Only two inhibitor compounds (KD-35 and BB-8) out of 16 reduced significantly the cell proliferation in the presence of 1,25-D3 in HepG2 cell line compared to the control cells. In Hep3B cells there was no significant change in proliferation. The cell proliferation reduction was 53% in the presence of BB-8 and 30% with of KD-35 after 32 hours incubation with 100 nmol/L 1,25-D3 and 5 μmol/L CYP24A1 inhibitors compared to the control cells treated only with 1,23-D3 (100 nmol/L). Neither BB-8 nor KD-35 alone or co-administered with 1,25-D3 had direct cytotoxic effect based on the LDH levels.
Conclusions: Our novel data show increased antitumor effect of 1,25-D3 on human HCC cell line after co-administration with CYP24A1 inhibitors. The BB-8 showed the highest inhibitory potential on CYP24A1 in HepG2 cells. The use of CYP24A1 inhibitors might decrease the dose of 1,25-D3 in the antitumor treatment in the future.

P0322

GLYPICAN-3 PROMOTES HEPATOCELLULAR CARCINOMA PROGRESSION AND METASTASIS BY ACTIVATION OF THE ERK SIGNALING PATHWAY

Y. Wu[1], H. Liu[1], H. Weng[2], X. Zhang[1], P. Li[1], C. Fan[1], B. Li[1], P. Dong[1], L. Li[1], S. Dooley[2], H. Ding[1]. *[1]Department of Gastroenterology and Hepatology, Beijing You'an Hospital affiliated with Capital Medical University, Beijing, China; [2]Molecular Hepatology, University Medical Center Mannheim, Mannheim, Germany*
E-mail: dinghuiguo@medmail.com.cn

Background and Aims: Glypican-3 (GPC3), a membrane-associated heparan sulfate proteoglycan, is frequently up-regulated in hepatocellular carcinoma (HCC). However, how GPC3 contributes to progress of HCC is largely unclear. The present study investigated the association between GPC3 expression and HCC clinicopathological characteristics, and particularly focused on the role and underlying mechanisms of GPC3 in HCC epithelial–mesenchymal transition (EMT).
Methods: Expression of GPC3 in paired liver tissues (tumor versus non-tumor) was examined in 45 patients with HCC by quantitative real-time PCR, immunohistochemistry, and western blotting, respectively. Correlations between GPC3 expression, clinicopathogenical features and EMT-related biomarkers were analyzed in these patients. In vitro, the effects of GPC3 on cell migration, invasion and EMT were investigated in 3 HCC cell lines (HepG2, Hep3B and Huh 7) by scratch, transwell assays and Western blot analyses.
Results: In comparison with surrounding non-tumor tissue, remarkably elevated expression of GPC3 demonstrated in HCC tumor tissues. The tissue expression of GPC3 was increased during HCC progression from BCLC stage A or B to stage C. The enhanced levels of GPC3 in HCC tumor tissues were tightly correlated to expression of the EMT-associated proteins and tumor vascular invasion. Moreover, patients with GPC3-high expression in tumor tissues displayed significantly shorter survival time than those with GPC3-low expression ($P = 0.041$). Consistent with the findings in patients, HepG2 cells, which expressed high levels of GPC3, showed stronger capacity of migration and significant EMT-like changes when compared to those HCC cells with low levels of GPC3, e.g., Hep3B

and Huh7. Furthermore, administration with exogenous GPC3 in HCC cells activated extracellular signal-regulated kinase (ERK) and significantly enhanced cell migration and invasion. These behaviors were significantly inhibited by an ERK inhibitor, PD98059.
Conclusions: GCP3 contributes to HCC progression and metastasis through impacting EMT of cancer cells. The effects of GCP3 are associated with ERK activation.

P0323
LDH SERUM LEVELS AS PROGNOSTIC AND PREDICTIVE FACTOR IN ADVANCED BILIARY TRACT CANCER PATIENTS TREATED WITH FIRST LINE CHEMOTHERAPY

L. Faloppi[1], M. Del Prete[1], M. Bianconi[1], D. Santini[2], N. Silvestris[3], A. Casadei Gardini[4], O. Brunetti[3], R. Giampieri[1], M. Scartozzi[5], S. Cascinu[1]. *[1]Università Politecnica delle Marche, AOU Ospedali Riuniti, Ancona, [2]Campus Biomedico, Roma, [3]IRCCS Ospedale Oncologico Giovanni Paolo II, Bari, [4]IRCCS IRST, Meldola, [5]Università di Cagliari, Cagliari, Italy*
E-mail: lucafaloppi@gmail.com

Background and Aims: Previous data suggested that LDH serum levels may be associated with tumour hypoxia and VEGFA and VEGFR-1 over-expression. LDH may then represent an indirect marker of activated tumour neo-angiogenesis and worse prognosis in many tumour types. In our analysis, we analyzed the role of LDH serum levels in predicting clinical outcome for biliary tract cancer patients treated with first-line cisplatin and gemcitabine chemotherapy, to individuate a potentially reliable and easy to use marker for patients stratification.
Methods: 71 advanced biliary tract cancer patients treated with cisplatin and gemcitabine in first-line chemotherapy were available for our analysis. For all patients, LDH values were collected within one month before treatment beginning. We chose the laboratory cut-off (Upper Normal Rate, UNR) as LDH cut-off value (450 U/l) and then we divided the patients into two groups (A and B, below and above the UNR respectively). Survival distribution was estimated by the Kaplan–Meier method. Disease control rate (DCR) was assessed with chi-square test. A significant level of 0.05 was chosen to assess the statistical significance.
Results: Patients in group A (46 patients) and B (25 patients) proved homogeneous for all clinical characteristics analyzed. Median progression free survival (PFS) was 3.97 months and 1.8 months respectively in group A (patients with LDH level below the UNR) and in group B (patients with LDH level above the UNR), $p = 0.0064$ (HR = 2.07, 95% CI: 1.07–3.99). Median overall survival (OS) was 9.24 months and 2.55 months in group A and B respectively, $p < 0.0001$ (HR = 2.93; 95% CI: 1.37–6.27). DCR was 65% in group A vs. 21% in group B ($p = 0.004$).
Conclusions: Our observations seem to suggest a prognostic role of LDH in biliary tract cancer patients. Our findings showing an improved PFS and DCR in patients with low LDH serum levels also suggest a possible predictive role in patients treated with a cisplatin and gemcitabine regimen as first-line chemotherapy. After further confirmation in larger trial, these results may be relevant for a better patients stratification and selection.

P0324
EpCAM CLEAVED EXTRACELLULAR DOMAIN HAS PROFOUND EFFECT ON HUMAN PROGENITOR CELL LINE HepaRG, BUT BARELY EFFECTS HEPATOCARCINOMA CELL LINE HepG2

N. Fekete-Drimusz[1], R. Gutierrez Jauregui[1], M.P. Manns[1,2], M. Bock[1,2]. *[1]Clinic of Gastroenterology, Hepatology und Endocrinology, REBIRTH-AG "Hepatic Cell Therapy – Patient Liver Stem Cells", Medizinische Hochschule Hannover, [2]TTU Hepatitis, Deutsches Zentrum für Infektionsforschung, Hannover, Germany*
E-mail: Fekete.Nora@mh-hannover.de

Background and Aims: EpCAM has long been established as an important marker of liver cancer cells and a prognostic predictor. Its signalling activities in cancer development have been studied in some detail, exposing an ambiguous role in tumour cell proliferation and metastasis, but little is known about the profile of EpCAM-responsive cells. EpCAM anchored to the cell membrane mediates homophilic adhesion interactions and cell-to-cell signalling. The extracellular domain of EpCAM (EpEx) can also be cleaved off by various proteolytic enzymes, releasing a molecule with proposed cytokine-like functions. We set out to study the effect of EpEx on human hepatic progenitor and tumour cell lines.
Methods: cDNA encoding EpEX (243 aa) together with the signal peptide for secretion was obtained via RT-PCR from the human hepatocarcinoma cell line Huh7.5 and together with EGFP as a marker gene, cloned into the mammalian expression vector pCDNA3.1. HEK-293T cells were transfected with the vector. After verification of EpEx-secretion, the EpEx expressing cells were cocultured with the human hepatic progenitor cell line HepaRG, or the human hepatocarcinoma cell line HepG2. Following a 10 day long incubation protocol their gene expression profile was compared to cells co-cultured with EGFP-only expressing HEK-293Ts.
An RT-qPCR panel of more than 120 transcripts indicative for liver cell differentiation and maturation status was employed in the experiment analysis.
Results: In HepaRG cells, the expression of the transcription factor Onecut and the receptor Notch 3 have been greatly upregulated (50- and 10-fold, respectively), while members of the Wnt/β-catenin pathway for instance were not affected. Cytokeratins 7 and 14 also showed a 15–18 fold increase in expression, and elevated levels of SALL4, SOX17, TAT, CD34, Gys2, Patched1, Notch1 and GGT were observed. On the other hand, EpEx effects on HepG2 cells were not significant.
Conclusions: While both the HepG2 and HepaRG cell lines are EpCAM positive themselves to a similar extent, only the latter is responsive to EpEx signalling. The mechanisms of the responses observed need to be further elucidated, but are likely to be connected to the progenitor specific characteristics of HepaRGs. Amongst other findings to be presented, the results hint towards a possible cross talk between EpEx and the Notch cascade.

Liver tumors: b. Clinical (epidemiology, diagnosis)

EVERY 3-MONTH SURVEILLANCE IS SUPERIOR TO SEMIANNUAL SURVEILLANCE FOR THE SURVIVAL OF PATIENTS WITH HEPATOCELLULAR CARCINOMA AFTER HEPATECTOMY: A 10-YEAR OBSERVATIONAL STUDY

M. Lee[1], S. Oh[2], Y.Y. Cho[1], J.-J. Yoo[1], Y. Cho[1], D.H. Lee[1], E.J. Cho[1], J.-H. Lee[1], S.J. Yu[1], N.-J. Yi[3], K.-W. Lee[3], J.-H. Yoon[1], K.-S. Suh[3], H.-S. Lee[1], Y.J. Kim[1]. *[1]Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, [2]Department of Biostatistics, Seoul Metropolitan Government Seoul National University Boramae Medical Center, [3]Department of Surgery, Seoul National University College of Medicine, Seoul, Korea, South*
E-mail: yoonjun@snu.ac.kr

Background and Aims: The current guidelines recommend the surveillance of patients treated with curative hepatectomy for hepatocellular carcinoma (HCC) recurrence, based on liver computed tomography (CT) repetition at 3 month intervals. Since there is no compelling evidence of superiority of the stringent program, this study aimed at comparing survival rates between

patients treated with hepatectomy for very early or early stage HCC in Barcelona Clinic Liver Cancer (BCLC) stage on every 3-month and semiannual surveillance.

Methods: This retrospective study included 456 prospectively registered consecutive patients treated with hepatectomy for HCC. Patients were divided into two groups according to surveillance intervals; 307 patients submitted to every 3-month (Group 1) and 35 patients to semiannual surveillance (Group 2). Patients without recurrence in 2 years after hepatectomy were divided into two surveillance groups; 88 patients in every 3-month (Group 3) and 114 patients who underwent every 3-month surveillance until 2 years and changed to semiannual surveillance after 2 years (Group 4). The survival rates comparing each group were analyzed using inverse probability weighting according to liver cirrhosis or HCC risk factors. The results were presented as corrected for the lead time bias. Univariate and multivariate analyses were performed to identify risk factors for recurrence.

Results: The median follow-up duration was 30, 53, 40, and 72 months in Group 1, 2, 3, and 4, respectively. The survival rates in Group 1 was significantly higher than those in Group 2; hazard ratio of 1.83 ($P < 0.01$). In patients without HCC recurrence in 2 years, the survival rates in Group 3 were not significantly different from those in Group 4 ($P = 0.12$). Alpha-fetoprotein (AFP) and microvascular invasion (MVI) were independent prognostic factors for HCC recurrence in 2 years. Patients with high AFP level (≥50) and/or MVI showed poorer prognosis than those with low AFP level (<50) and no MVI in Group 1 and 2 ($P < 0.05$).

Conclusions: Every 3-month surveillance improves the survival of patients treated with hepatectomy for HCC in BCLC stage 0 or A as compared to the semiannual program. However, there were no benefits of every 3-month surveillance over semiannual surveillance after 2 years in patients without HCC recurrence in 2 years after treatment. Posthepatectomy surveillance CT schedules may be optimized according to risk stratification for recurrence to reduce the frequency of CT scans without compromising surveillance benefits.

HEPATOCELLULAR CARCINOMA (HCC) IN HCV-PATIENTS WITH OR WITHOUT HIV-COINFECTION. SIMILAR SURVIVAL IN A NATIONWIDE STUDY

N. Goutté[1], P. Sogni[2], N. Bendersky[3], B. Falissard[4], O. Farges[1].
[1]Hepatology – hepatobiliary surgery, Beaujon Hospital – Paris VII University – INSERM U773, Clichy, [2]Hepatology, Cochin Hospital – Paris Descartes University, Paris, [3]Medical Informatics, Beaujon Hospital – Paris VII University, Clichy, [4]Biostatistique, University Paris-Sud, INSERM U669, Paris, France
E-mail: nathalie.goutte@bjn.aphp.fr

Background and Aims: HCV end-stage liver diseases including liver decompensation (LD) and HCC represent the first cause of mortality in coinfected HIV-HCV patients. Published data on the influence of HIV on the prognosis of HCC are controversial. The aim of this study was to address this issue in an all-inclusive, nationwide analysis, taking into account potential confounders.

Methods: The 2007 to 2012 National French health care databases were screened to identify all hospital admission that included a diagnostic code of HCC and HCV. Incident cases of HCC were selected by defining the entry point as a first admission in 2009. Demographic data, associated conditions, underlying liver disease, as well as the type, location and annual HCC-caseload of the hospital were retrieved. Treatments were stratified into curative (transplantation, surgical resection, trans-dermal ablation), palliative or others. The characteristics and survival of HIV+ and HIV− HCV-patients with HCC were compared.

Results: Between 2009–2012, 5,067 incident-cases of HCC in HCV-patients were identified including 268 (5.3%) in HIV+ patients. HIV+ patients were significantly younger (51.9±6.5 vs. 63.9±12.8 years), had fewer comorbidities (diabetes, obesity, arterial hypertension) and more frequently co-étiologies associated with HCV. The frequency of LD and metastatic form at diagnosis were similar. The type of treatment received was not different and curative treatment was realized in 35.4%. HIV+ patients were more frequently followed in high-volume structures and in teaching hospitals, and significant geographic regional differences were observed. In multivariate analysis, only age, co-etiologies and geographic region remained significant. The crude survival was not different in HIV+ and HIV− patients (15.2 [9.4–22.4] vs. 18.0 months [16.5–19.3]) and was influenced by age, the presence of cirrhosis and LD at diagnosis, the presence of co-morbidities (diabetes, arterial hypertension), the hospital case-load and the type of treatment. After adjusting for confounders, the survival remained not different in HIV+ and HIV− patients (16.3 [11.6–22.4] vs. 18.4 months [17.4–19.2]).

Conclusions: In this nationwide study of HCC in HCV-patients, the adjusted survival is not different in HIV+ and HIV− patients. Despite of a relatively high rate of curative treatment, the prognosis remains poor and underlines the need for early anti-HCV treatment in both HIV+ and HIV− patients

P0327

ANALYSIS OF HEPATIC PROGENITOR CELL MARKER POSITIVE HEPATOCELLULAR CARCINOMA AND THEIR PROGNOSTIC SIGNIFICANCE

A. Tsuchiya[1], Y. Kojima[1], S. Seino[1], Y. Watanabe[1], M. Nomoto[1], S.J. Forbes[2], S. Terai[1]. *[1]Niigata University, Department of Gastroenterology and Hepatology, Niigata, Japan; [2]The University of Edinburgh, Edinburgh, United Kingdom*
E-mail: atsunori@med.niigata-u.ac.jp

Background and Aims: Much attention has been paid to hepatic progenitor cell (HPC) marker-positive hepatocellular carcinoma (HCC) as a marker of poor prognosis of patients with HCC. Cytokeratin19 (CK19), neural cell adhesion molecule (NCAM), and epithelial cell adhesion molecule (EpCAM) are known HPC markers on HCC. However, the relationship between each HCC marker, the

characteristics of each marker, and the relationship between HPC marker-positive HCC and serum levels of previously reported tumor markers such as AFP, as well as the frequency of fucosylated-AFP (AFP-L3) and des-γ-carboxy prothrombin (DCP) remain unclear. In this study, we analyzed 202 HCC nodules to elucidate the prognostic significance of each HPC marker-positive HCC.

Methods: Surgically removed HCC were stained for CK19, NCAM and EpCAM. Expression of each HPC marker was considered positive if more than 5% of tumor cells were stained. The frequency of each marker single-, double-, and triple-positive HCC, the recurrence free survival (RFS), and overall survival (OS) were calculated and the relationship between these serum markers and HPC marker-positive cells was analyzed.

Results: The frequency of each HPC marker-positive HCC was as follows: $CK19^+NCAM^-EpCAM^-$ (6 cases, 3.0%), $CK19^-NCAM^+EpCAM^-$ (11 cases, 5.4%), $CK19^-NCAM^-EpCAM^+$ (15 cases, 7.4%), $CK19^+NCAM^+EpCAM^-$ (1 case, 0.5%), $CK19^+NCAM^-EpCAM^+$ (8 cases, 4%), $CK19^-NCAM^+EpCAM^+$ (2 cases, 1.0%), $CK19^+NCAM^+EpCAM^+$ (1 case, 0.5%), and $CK19^-NCAM^-EpCAM^-$ (158 cases, 78.2%). CK19 and EpCAM are often co-expressed, this double-positive group showed particularly high serum levels of AFP and AFP-L3. In contrast, $NCAM^+$ HCC differed from CK19 and EpCAM HCC and showed relatively low serum levels of AFP and AFP-L3, and relatively high serum levels of DCP. No significant difference in the RFS between each marker-positive HCC was observed. However, the OS did differ significantly: EpCAM has poorest prognosis, followed by NCAM and CK19 has the best prognosis. Importantly, CK19 single-positive HCCs exhibited significantly better prognosis than CK19 and EpCAM double-positive HCCs, indicating that EpCAM-positive cells in the CK19-positive HCC population plays a major role in the poor prognosis of $CK19^+$ HCC.

Conclusions: EpCAM is a better predictor of prognosis than CK19. NCAM is a strong indicator of poor prognosis and marked different populations to CK19 and EpCAM. We consider that EpCAM and NCAM, in addition to serum levels of tumor markers, are useful in predicting the prognosis of HCC patients.

E-mail: pierre.nahon@jvr.aphp.fr

Background and Aims: The objective was to prospectively assess the benefits of sustained viral response (SVR) on the incidence of primary liver cancer (PLC) in French patients with compensated HCV cirrhosis and to describe their characteristics.

Methods: Patients with the following inclusion criteria were included in 35 French centres: (a) biopsy-proven HCV cirrhosis; (b) Child–Pugh A; (c) absence of previous liver complications. Patients were prospectively followed-up every 6 months.

Results: A total of 1323 patients were enrolled between March 2006 and June 2012 [age 55, men 63.5%, Genotype 1: 62%, 2: 5%, 3: 14%, 4: 8%, MD: 11%]. At end-point in January 2014 (median follow-up of 43 months), SVR was observed in 458 (34.6%) patients after at least one interferon-based regimen. PLC was diagnosed in 141 [136 hepatocellular carcinoma (HCC) and 5 cholangiocarcinomas]. SVR was an independent factor associated with a decreased incidence of HCC (Cumulative incidence, CumI 5 years: 5.1% vs 20%, HR = 0.35 [0.20–0.62], $P < 0.001$). In patients with SVR, 18 HCC were diagnosed. At diagnosis, as compared to patients without SVR, the rate of HCC within Milan criteria was higher in SVR patients (88.9% vs 81.1%, $P = 0.7$), median serum AFP level was lower (4 ng/mL [3–7.4] vs 20 [9.7–101], $P < 0.0001$), and the rate of first-line curative treatment was higher (83% vs 77%, $P = 0.7$). The last imaging examination was performed 5.9 [5.4–6.6] months before HCC diagnosis in the SVR group, compared to 6.7 [5.7–8.1] ($P = 0.07$) in the non-SVR group. In multivariate analysis in SVR patients, only lower PT <80% (HR = 4.97 [1.93–12.84], $P = 0.001$) and higher GGT levels >ULN (HR = 4.30 [1.24–14.90, $P = 0.006$) were independent HCC risk factors, while in non SVR patients HCC predictors were age >50, past excessive alcohol intake, higher GGT levels and lower platelet count. The overall mortality was lower in SVR patients (CumI 5 years 3.8% vs 15.3%, log-rank <0.0001). Among the 16 deaths recorded in SVR patients, progression of HCC (13.3%) was the fourth cause of death after end-stage liver disease (33.3%), extra-hepatic cancers (26.7%) and other extra-hepatic diseases including bacterial infection (25%).

Conclusions: A four-fold reduction in HCC incidence is observed in patients with HCV compensated cirrhosis achieving SVR. HCC developed after SVR could be less advanced at diagnosis than tumours occurring in the absence of SVR, even if this result needs confirmation.

THE ITA.LI.CA STAGING SYSTEM FOR PATIENTS WITH HEPATOCELLULAR CARCINOMA: A MULTICENTER COHORT STUDY

F. Farinati[1], A. Vitale[2], F. Trevisani[3], T.-L. Huo[4], Y.-H. Lee[4], U. Cillo[2], ITA.LI.CA. study group. *[1]Divisione di Gastroenterologia, Università di Padova, [2]Dipartimento di Chirurgia Generale e Trapianto d'Organo, Unità di Chirurgia Epatobiliare e Trapianti Epatici, Università di Padova, Padova, [3]Department of Medical and Surgical Sciences, Division of Semeiotics, Alma Mater Studiorum – University of Bologna, Bologna, Italy; [4]National Yang-Ming University, Taipei, Taiwan*
E-mail: alessandro.vitale@unipd.it

Background and Aims: The Barcelona Clinic Liver Cancer (BCLC) classification stratifies patients with hepatocellular carcinoma (HCC) in different evolutionary stages. While it showed to help treatment allocation especially in the context of clinical trials, its prognostic ability to stratify HCC patient survival still remains controversial when compared to that of other systems (HKLC, MESIAH, CLIP, JIS). The aim of this study is to develop and validate a new staging system for HCC patients taking as a reference the original BCLC evolutionary stages but focused in optimizing individual patient survival prediction.
Methods: The ITA.LI.CA (Italian Liver Cancer) database (n = 5183, period 1986–2012) was divided in training (n = 3628, 70%) and validation (n = 1555, 30%) cohorts. A further cohort of 2651 HCC patients from Taiwan was used for external validation. We defined the ITA.LI.CA Tumor Status (TS) using BCLC stages (0, A, B, C) but adding 3 intermediate B sub-stages (based on TNM and HKLC staging): B1 = single >5 cm or 2–3 nodules 3–5 cm; B2 = 2–3 nodules >5 cm or >3 nodules ≤5 cm; B3 = >3 nodules >5 cm or presence of intrahepatic macrovascular invasion. TS was then included in a multivariate survival model together with Child–Pugh Score (CPS) and ECOG performance status (PS), and a novel ITA.LI.CA prognostic staging was developed. Discrimination and calibration of the new prognostic model was internally and externally validated and compared with that of other staging systems.

Variables	0n	An		B1n		B2n		B3n		Cn
Diameter(cm)	< 2	≤ 3	≤ 5	3-5	> 5	3-5	> 5	> 5	Any	Any
N° nodules	1	2-3	1	2-3	1	> 3	2-3	> 3	Any	Any
Vascular invasion or metastases	no	no	no	no	no	no	no	no	Intrahep.	Extrahep./ Meta

n score based on PS and CPS

0: PS 0 and CPS 5 → best possible HCC therapy

1: PS 1 - 2 or CPS 6 -7 → relative controindication to HCC therapy

≥ 2: PS 1-2 and CPS 6-7 or PS > 2 or CPS> 7 → absolute contraindication to HCC therapy

Figure: The ITA.LI.CA staging system for HCC patients.

Results: The ITA.LI.CA staging system was based on the following stages: 0n, An, B1n, B2n, B3n, Cn, where capital letters defined TS stages indicating potential for treatment as in BCLC (from radical to palliative therapies), while n defined an additional score (0/1 = eligible for HCC therapy; 2/>2 = contraindication to therapy) based on CPS and PST indicating treatment feasibility. Discrimination ability of the ITA.LI.CA staging system was higher than that of the other systems in the training, internal, and external validation cohorts. The concordance (c)-statistics for this model in training, internal and external validation cohorts were respectively 0.72, 0.71, and 0.78, and they were superior to that for BCLC (0.65, 0.64, and 0.73), CLIP (0.69, 0.68, and 0.75), JIS (0.67, 0.67, and 0.70), MESIAH (0.69, 0.69, and 0.77), and HKLC (0.68, 0.68, and 0.75).

Conclusions: We developed a novel ITA.LI.CA staging system, easy to apply in clinical practice, and with a strong prognostic impact in two large western and eastern populations.

COST-EFFECTIVENESS ANALYSIS OF HEPATOCELLULAR CARCINOMA SURVEILLANCE IN PATIENTS WITH HEPATITIS C RELATED CIRRHOSIS AFTER SUSTAINED VIROLOGICAL RESPONSE

H. Farhang Zangneh[1], W.W. Wong[2], B. Sander[3], C.M. Bell[4], K. Mumtaz[5], M. Kowgier[1], A.J. Van Der Meer[6], S.P. Cleary[7], K. Chan[4], J.J. Feld[1]. *[1]University of Toronto, Toronto Centre for Liver Diseases, [2]THETA Collaborative, [3]Institute of Health Policy, Management & Evaluation, [4]Department of Medicine, University of Toronto, Toronto, Canada; [5]Wexner Medical Center, Ohio State University, Ohio, United States; [6]Erasmus MC University Medical Center, Rotterdam, Netherlands; [7]Department of General Surgery, University of Toronto, Toronto, Canada*
E-mail: hooman.f.zangneh@mail.utoronto.ca

Background and Aims: Hepatitis C virus (HCV) causes hepatocellular carcinoma (HCC) in patients with cirrhosis. New therapies eradicating HCV-infection lead to sustained virological response (SVR). Screening for HCC in cirrhosis patients, as recommended by guidelines, is cost-effective. However, since SVR substantially decreases the risk for HCC, cost-effectiveness of screening for HCC in these patients is unknown. Therefore, our objective is to evaluate cost-effectiveness of biannual ultrasound (US) HCC surveillance in HCV-related cirrhosis patients post-SVR.
Methods: We designed a Markov state transition model to simulate the natural history of HCV post-SVR. A lifetime time horizon was used in a cohort of 50-year-old cirrhosis patients post-SVR to evaluate biannual US screening and management of HCC by screen-all vs. screen-none strategies. Based on AASLD guidelines, tumors detected by US were confirmed by additional dynamic imaging techniques. Parameter values including probabilities, utilities and costs were obtained from the literature and if not available, experts' opinions were sought. Costs were in CAN$, health outcomes were measured as quality adjusted life years (QALYs) and both were discounted at 5%. Sensitivity analyses were conducted to assess parameter uncertainty.
Results: With 0.5% HCC annual incidence rate in the model population, biannual US screening offered a gain of 0.096 QALYs vs. no screening through early tumor detection and proper management. Liver-related mortality was decreased by about 20%. The calculated costs were $41,475 in screen-all and $27,625 in screen-none strategies, resulting in an incremental cost-effectiveness ratio of 149,590/QALY. Sensitivity analysis on model variables demonstrated that the results are most sensitive to annual discount rate, HCC incidence rate, asymptomatic HCC to symptomatic tumor transition probability and also utility and cost of living without HCC. Probabilistic sensitivity analysis showed that with $50,000/QALY as willingness to pay threshold, in 98% of cases the screen all strategy would not be cost-effective. This trend starts to reverse if the threshold is $150,000/QALY and over.
Conclusions: We found that with 0.5% HCC incidence in HCV-related cirrhosis patients post-SVR and the cost-effectiveness threshold of $50,000/QALY, this strategy would not be cost-effective. However, we need to find better ways to identify patients with high risk for HCC post-SVR because HCC surveillance for all patients with cirrhosis is likely not cost effective.

P0331

THE 'GALAD SCORE' FOR SEROLOGICAL DETECTION OF HEPATOCELLULAR CARCINOMA: INTERNATIONAL VALIDATION AND ASSESSMENT OF THE INFLUENCE OF TUMOUR SIZE AND AETIOLOGY ON MODEL UTILITY

Gerken[6], J. Schlaak[7], H.L. Reeves[8,9], P. Johnson[10]. *[1]Department of Molecular and Clinical Cancer Medicine, University of Liverpool, Liverpool, United Kingdom; [2]Department of Gastroenterology and Hepatology, Ogaki Municipal Hospital, Gifu, Japan; [3]Wako Life Sciences, Inc, Mountain View, United States; [4]Clinic of Gastroenterology, Hepatology and Endocrinology, Hannover Medical High School, Hannover, [5]Division of Gastroenterology and Hepatology, University Hospital Leipzig, Leipzig, [6]Department of Gastroenterology and Hepatology, University Hospital Essen, Essen, [7]Department of Gastroenterology and Hepatology, Evangelisches Krankenhaus Duisburg-Nord, Duisburg, Germany; [8]Northern Institute for Cancer Research, [9]The Hepatopancreatobiliary Multidisciplinary Team, Newcastle upon Tyne NHS Foundation Trust, The Freeman Hospital, Newcastle upon Tyne, [10]The Clatterbridge Cancer Centre NHS Foundation Trust, Wirral, United Kingdom*
E-mail: sarah.berhane@liverpool.ac.uk

Background and Aims: A statistical model that uses objective measures to estimate the likelihood that hepatocellular carcinoma (HCC) is present in patients with chronic liver disease (CLD) has recently been developed. This model, GALAD, uses Gender, Age and the serological tumor markers AFP-L3, AFP and DCP. It has the potential to be used in the screening/surveillance setting, has not been validated in an international setting.

Methods: Cohorts comprising 4476 patients from Japan (1514 HCCs and 2962 CLDs) and 1086 from Germany (238 HCCs and 848 CLDs) were recruited. In each case sera and related clinical features were collected by investigators independent of the laboratory in which the biomarker assays were performed and the group performing the statistical analysis. We also included, for reference, the original UK cohort on which the model was developed (394 HCCs and 439 CLDs). We assessed the change in sensitivity, specificity and area under the ROC curve (AUROC) when the new model was compared to the conventional approach to using these biomarkers in the Japanese screening program (Table). We also assessed the impact of tumour size and aetiology on model performance.

Table: Sensitivity, specificity, and area under the curve (AUROC) for the biomarkers and the GALAD model

	Cut-off [a]	Sensitivity (%)	Specificity (%)	AUROC
Japan				
AFP	20 ng/mL	51.3	97.3	0.89
AFP-L3	7%	41.2	91.8	0.75
DCP	0.48 ng/mL	57.3	97.4	0.84
AFP + AFP-L3 + DCP	Same as above	79.3	88.3	0.84
GALAD Model	−1.55	82.2	87.6	0.93
Germany				
AFP	20 ng/mL	57.6	93.2	0.87
AFP-L3	7%	70.2	79.0	0.83
DCP	0.48 ng/mL	88.2	67.1	0.87
AFP + AFP-L3 + DCP	Same as above	94.5	56.1	0.75
GALAD Model	−0.63	86.6	89.0	0.95
United Kingdom				
AFP	20 ng/mL	60.7	96.4	0.88
AFP-L3	7%	75.4	73.5	0.84
DCP	0.48 ng/mL	94.0	63.7	0.90
AFP + AFP-L3 + DCP	Same as above	99.2	50.0	0.75
GALAD Model	−0.63	91.6	89.7	0.97

[a] Cut-off points for three biomarkers were based on the guideline of the Japan Society of Hepatology and our previous studies.

Results: In the Japanese and German cohorts, AUROC was 0.93 and 0.95 respectively, both almost identical to the results in the UK series (0.97). The model showed better diagnostic accuracy than when the biomarkers were used individually (Table). Additionally the model utility increased slightly in larger tumours (≥5 cm) with an AUROC of 0.98, 0.97 and 0.98 in the Japanese, German and UK cohorts respectively. Aetiology had no impact on model performance in the UK and German cohorts.

Conclusions: The GALAD model for serological diagnosis of HCC has been validated by application to large patient cohorts from Germany and Japan.

P0332

GENE ALTERATIONS IN TERT PROMOTER, CTNNB1, AND TP53 ARE CLOSELY ASSOCIATED WITH DEVELOPMENT AND PROGNOSIS OF HEPATOCELLULAR CARCINOMA: COMPREHENSIVE ANALYSES BY NEXT GENERATION SEQUENCING TECHNOLOGY

Y. Asahina[1,2], F. Kawai-Kitahata[1], S. Kaneko[1], H. Nagata[1], F. Goto[1], S. Otani[1], M. Taniguchi[1], M. Murakawa[1], S. Nitta[1], T. Watanabe[1], M. Tasaka-Fujita[1], Y. Nishimura-Sakurai[1], Y. Itsui[1], M. Nakagawa[1], S. Azuma[1], S. Kakinuma[1,2], S. Tanaka[3], M. Tanabe[3], N. Enomoto[4], M. Watanabe[1]. *[1]Gastroenterology and Hepatology, [2]Department of Liver Disease Control, [3]Hepato-Biliary-Pancreatic Surgery, Tokyo Medical and Dental University, Tokyo, [4]First Department of Internal Medicine, Yamanashi University, Chuo-shi, Japan*
E-mail: asahina.gast@tmd.ac.jp

Background and Aims: Genetic alterations in specific genes lead to disruption of cellular pathways and are thought to be critical events in the hepatocarcinogenesis and progression of hepatocellular carcinoma (HCC). However, such genetic alterations responsible for tumor development and progression are still unclear. To identify genetic alterations associated with hepatocarcinogenesis and prognosis of HCC, we comprehensively investigated genetic alterations in paired HCC and surrounding non-HCC tissues using next generation deep sequencing technology.

Methods: The exacted DNA from 104 patients was amplified by multiplexed polymerase chain reaction (PCR) targeting 50 cancer-related genes containing 2790 mutational hotspots. The mutations were analyzed using a semiconductor-based DNA sequencer. Alignment to the hg19 human reference genome and variant calling was carried out, and nucleotide variants that were detected in tumors and absent in corresponding non-tumor tissue were determined as somatic mutations. We also investigated TERT promoter mutation at 2 hot spots through direct sequencing. Association between gene mutation and data on clinical outcomes were analyzed.

Results: The mean coverage depth was 2088 per sample. We found that TERT, TP53, CTNNB1, PTEN, CDKN2A, HRAS, PIK3CA, STK11, GNAS were mutated in 68 (65%), 37 (36%), 31 (35%), 2 (2%), 2 (2%), 1 (1%), 1 (1%), 1 (1%), 1 (1%) of the total 104 HCCs, respectively, and 92 (88%) of 104 HCCs had mutations either in TERT promoter, CTNNB1 or TP53. HBV integration was found in 93% (25/27) of HBsAg positive HCC by deep sequencing. TERT promoter mutations were associated with older age ($p = 0.017$), presence of hepatitis C virus infection ($p = 0.0026$) and absence of hepatitis B virus infection ($p < 0.0001$). TP53 mutations were found in hepatitis B virus infection ($p = 0.0002$) and absence of hepatitis C virus infection ($p = 0.0014$). CTNNB1 mutations were associated with absence of hepatitis B virus infection ($p = 0.010$). Moreover, TERT promoter mutation was significantly associated with shorter DFS ($p = 0.006$) and poor overall survival ($p = 0.048$).

Conclusions: Gene alterations in TERT promoter, CTNNB1, and TP53 are closely associated with HCC development, and mutation in TERT promoter is related to poor prognosis. These results are useful for diagnosis and predicting outcomes for patients with HCC.

P0333

AN EPIDEMIOLOGICAL ASSOCIATION BETWEEN THE TRENDS OF NUCLEOSIDE ANALOGUE PRESCRIPTION AND LIVER CANCER INCIDENCE FROM 1999 TO 2012 IN HONG KONG, CHINA

W.-K. Seto[1], E.H.Y. Lau[2], J.T. Wu[2], I.F.-N. Hung[1], W.K. Leung[1], J. Fung[1], C.-L. Lai[1], M.-F. Yuen[1]. [1]*Medicine,* [2]*School of Public Health, The University of Hong Kong, Hong Kong, Hong Kong, China*
E-mail: wkseto@hku.hk

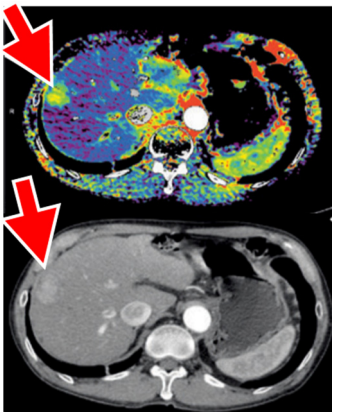
Background and Aims: More than 85% of hepatocellular carcinoma (HCC) in Hong Kong, China is associated with chronic hepatitis B (CHB) infection. Nucleoside analogue therapy for CHB was introduced to Hong Kong since 1999. We determined whether there was a positive effect on the population incidence of liver cancer by the introduction of nucleoside analogue therapy up to 2012.
Methods: We obtained nucleoside analogue (lamivudine, adefovir, telbivudine, entecavir and tenofovir) prescription data (1999–2012) from the electronic health record system of the Hospital Authority, Hong Kong, which provides >90% of secondary and tertiary care to the Hong Kong population. We excluded prescriptions with concomitant anti-HIV medications. Liver cancer data from 1990 to 2012 was obtained from the population-based Hong Kong Cancer Registry. Using Poisson piecewise regression analysis, we compared rate trends of liver cancer incidence from the period of 1990 to 1998 with the period of 1999 to 2012.
Results: Nucleoside analogue prescription patient headcount increased from 329 prescriptions in 1999 to 5,942 prescriptions in 2006, then to 26,411 prescriptions in 2012. The increase rate of 1999–2006 and 2006–2012 were 802 and 3,411 prescriptions per year respectively ($p < 0.001$). Age-standardized incidence of liver cancer, using World Health Organization standard population 2000 as reference, dropped from 22.4 per 100,000 persons in 1998 to 15.4 per 100,000 persons in 2012. After adjusting for the change in local CHB prevalence over the study period, there was a decline in the age-adjusted liver cancer incidence for all patients (2.7%, $p < 0.001$, 95% CI 1.4–4.0%), male patients (3.5%, $p = 0.009$, 95% CI 1.1–5.9%) and female patients (2.0%, $p < 0.001$, 95% CI 1.1–2.9%). When analyzing specific age groups, the decline in liver cancer incidence was most significant among patients aged 50–59 years (male: 15.8%, $p = 0.006$, 95% CI 5.7–25.9%, female: 7.1%, $p = 0.001$, 95% 3.4–10.9%), and patients aged 30–39 years (male: 3.8%, $p = 0.008$, 95% CI 1.3–6.4%; female: 1.3%, $p = 0.004$, 95% CI 1.1–2.1%).
Conclusions: From this interim analysis, we demonstrated an ecological association of nucleoside analogue prescription with the incidence of liver cancer in a CHB-prevalent region, providing epidemiological evidence that nucleoside analogue therapy for CHB could reduce the risk of HCC. Further analysis will be performed for liver cancer mortality and for more a detailed comparison of different time periods.

P0334

COMPUTER-TOMOGRAPHY (CT) WITH MAPPING OF THE ARTERIAL ENHANCEMENT FRACTION (AEF) FOR SCREENING OF HEPATOCELLULAR CARCINOMA (HCC) IN PATIENTS WITH END-STAGE LIVER CIRRHOSIS

A. Christe[1], L. Ebner[1], J. Heverhagen[1], A. Huber[1]. [1]*Radiology, Hospital and University of Bern, Inselspital, Bern, Switzerland*
E-mail: andreas.christe@hotmail.com

Background and Aims: CT imaging with arterial enhancement fraction (AEF) uses a tri-phasic CT image acquisition (unenhanced, arterial, portal venous phase) to generate color coded CT-perfusion images. The purpose of this study was to investigate if the use of the AEF imaging would supersede the acquisition of a fourth contrast phase (equilibrium phase) and thus allow a 25% reduction of radiation dose.
Methods: 55 patients who underwent liver transplantation between 2010 and 2013 and who had a CT scan acquired in four contrast phases (unenhanced, arterial, portal venous and equilibrium phase) on a Siemens Somatom Sensation 64 were included: 35 patients with 108 histologically proven HCC lesions, as well as 20 patients without HCC lesions. 47 lesions were already treated by prior TACE. AEF was calculated using the syngo.via workstation (Siemens, Erlangen, Germany): AEF = $[(HU_A - HU_U)/(HU_P - HU_U)] \times 100$, where HU is the attenuation, A the arterial phase, P the portal phase, and U the unenhanced scan. A total of 6 radiologists read the tri-phasic grayscale images in conjunction with the color AEF-maps. For the second read-out, three readers looked at the CT images with four contrast phases and three readers only at three contrast phases (without equilibrium phase).
Results: The JAFROC analysis showed a significant difference of the figures of merit (θ) between the tri-phasic read-out without ($\theta = 0.718$) and with the AEF-maps ($\theta = 0.750$, $p = 0.0007$). Diagnostic performance with four-phases ($\theta = 0.775$) was significantly better than with tri-phases ($\theta = 0.718$) without using the AEF-map ($p = 0.0018$), but not different from the tri-phasic CT with the AEF-maps ($\theta = 0.750$, $p = 0.3053$). Sensitivity of tri-phasic CT was 36.4% (95% CI: 32.5–40.5%) and PPV was 76.5% (95% CI: 71.0–81.4%). With the AEF-maps sensitivity and PPV increased to 49.7% (95% CI: 45.6–53.9%) and 83.4% (95% CI: 79.0–87.1%), respectively.
Lesions with and without prior TACE treatment were detected with a sensitivity of 31.9% and 42.3% without the use of the AEF map and with a sensitivity of 48.4% and 51.6% with the AEF map. A normalized AEF cut-off value of 70% for small lesions (<1 cm) and 60% for larger lesions (≥1 cm) leads to highest HCC-accuracy.
Conclusions: In HCC CT-screening the fourth equilibrium phase could be replaced by the calculated AEF-maps. This allows a 25% reduction of radiation dose, which is relevant for patient undergoing repetitive HCC-screening.



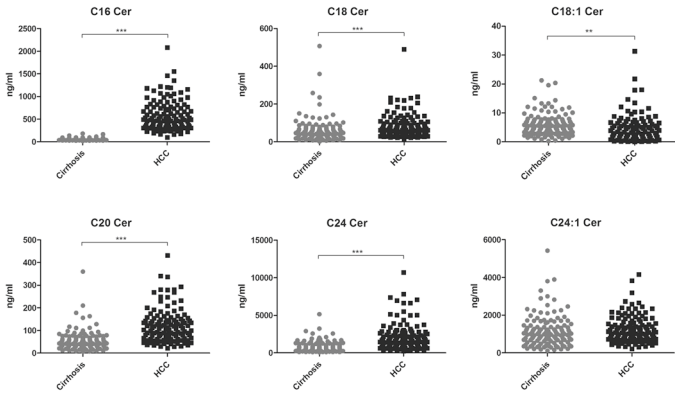
P0335

SERUM LONG CHAIN CERAMIDES, SPHINGOSINE AND SPHINGOSINE-1-PHOSPHATE AS NOVEL DIAGNOSTIC MARKERS IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

G. Grammatikos[1], N. Schoell[1], N. Ferreiros[2], D. Bon[3], E. Herrmann[3], H. Farnik[1], S. Zeuzem[1], B. Kronenberger[1], O. Waidmann[1], J. Pfeilschifter[4]. [1]*Medizinische Klinik 1,* [2]*Pharmazentrum Frankfurt, Institut für klinische Pharmakologie,* [3]*Institute of Biostatistics and Mathematical Modelling,* [4]*Pharmazentrum Frankfurt, Institut für Allgemeine Pharmakologie und Toxikologie, Johann Wolfgang Goethe University Frankfurt, Frankfurt am Main, Germany*
E-mail: georgios.grammatikos@kgu.de

Background and Aims: We have recently shown that major alterations of serum sphingolipid metabolites in patients with chronic liver disease associate significantly with the stage of liver fibrosis in corresponding patients. Aim of the current study is to assess the serum sphingolipidomic profile of patients with HCC as

compared to liver cirrhosis und thus identify novel diagnostic tools potentially applicable in the clinical setting.
Methods: We assessed via mass spectrometry serum concentrations of sphingolipid metabolites in a series of 122 patients with HCC compared to an age- and sex-matched series of 127 patients with liver cirrhosis.
Results: We observed a highly significant upregulation of long and very long chain ceramides (C16-C24) in patients with HCC as compared to patients with liver cirrhosis ($p < 0.001$). Accordingly, dihydro-ceramides, synthetic precursors of ceramides and notably sphingosine, sphingosine-1-phosphate (S1P) and dihydro-S1P were upregulated in HCC as well as compared to liver cirrhosis ($p < 0.001$). Especially the diagnostic accuracy of C16-ceramide and S1P, assessed by receiver operating curve (ROC) analysis, showed a higher area under the curve (AUC) value as compared to α-fetoprotein (AFP), which constitutes the only available serologic biomarker of HCC so far (0.999 and 0.985 versus 0.823, $p < 0.001$ respectively).
Conclusions: Serum levels of long chain ceramides, sphingosine and S1P show a significant upregulation in patients with HCC as compared to patients with liver cirrhosis. Particularly C16ceramide and S1P may serve as novel diagnostic tools for the early identification of HCC in patients with liver cirrhosis.



P0336
IMPACT OF GENETIC VARIANTS OF TUMOR NECROSIS FACTOR LOCUS ON HEPATOCELLULAR CARCINOMA SURVIVAL
J.-F. Tsai[1], Z.-Y. Lin[1], S.-C. Chen[1], W.-L. Chuang[1], M.-L. Yu[1], C.-Y. Dai[1].
[1]*Department of Internal Medicine, Kaohsiung Medical University (KMU) Hospital, KMU, Kaohsiung, Taiwan*
E-mail: jftsai@cc.kmu.edu.tw

Background and Aims: Genetic epidemiology indicates that cytokine polymorphisms related to cancer prognosis. This study aimed to assess the effect of polymorphisms of tumor necrosis factor (*TNF*) locus on survival in hepatocellular carcinoma (HCC).
Methods: Two hundred consecutive newly diagnostic cirrhotic patients with HCC were enrolled. Polymorphisms of *TNFα* −308, and *lymphotoxin (LT)* α +252 were genotyped by the polymerase chain reaction with direct sequencing or restriction fragmented length polymorphism. Kaplain-Meier method with log-rank test was used for univariate analysis of survival analysis. Cox proportional hazard regression meodel was used for multivariate analysis to assess independent factors related to survival.
Results: The frequency distribution of the genotypes of *TNFα* −308 and *LTα* +252 were [G/G (73.5%), G/A (26.5%) and A/A (0%)] and [A/A (34.5%), A/G (36.5%) and G/G (29.0%)], respectively. The variant genotypes (*TNFα* G/A and/or *LTα* G/G) were biomarkers for poor cumulative survival in patients with HCC (Kaplan–Meier method with log-rank test, $P = 0.0001$). The cumulative survival in patients with both variant genotypes (median, 0.62 year; 95% CI, 0.22–1.03 years; n = 33) was shorter than that in those without (median, 3.81 year; 95% CI, 3.09–4.52 year; n = 123, $P = 0.0001$) or those with either variant genotype [*TNF* 308 G/A, median, 2.48 (95% CI, 1.61–3.36) years, n = 19, $P = 0.01$; *LTα* G/G, median, 1.63 (95% CI, 1.48–1.71) years, n = 25, $P = 0.01$]. However, there was no significant difference in the cumulative survivals between patients with either variant genotype. Multivariate analysis with the Cox proportional hazard model indicated that the variant *TNFα* −308 G/A genotype [hazard ratio (HR), 2.55; 95% CI, 1.65–3.9 years] and *LTα* +252 G/G genotype (HR, 2.40; 95% CI, 1.54–3.74 years) were independent factors for poor HCC survival.
Conclusions: The variant genotypes *TNFa* −308 G/A and *LTα* +252 G/G were biomarkers for poor HCC survival.

P0337
A POLYMORPHISM IN IFNL3 IS AN INDEPENDENT RISK FACTOR FOR DEVELOPMENT OF HEPATOCELLULAR CARCINOMA AFTER TREATMENT OF HCV INFECTION
K.-C. Chang[1], P.-L. Tseng[1], H.-C. Hung[1], M.-T. Lin[1], T.-H. Hu[1].

E-mail: ux2551207@yahoo.com.tw

Background and Aims: Polymorphism of the *IL28B* gene may predict the therapeutic response and outcome of chronic hepatitis C virus (HCV) infection. However, the impact of *IL28B* polymorphism on the development of hepatocellular carcinoma (HCC) after antiviral treatment remains controversial.
Methods: We retrospectively analyzed tissues from 1118 histologically proven HCV patients after peg-IFN/RBV therapies from 2000 to 2009 for *IL28B* polymorphism (rs12979860).
Results: The frequency of the *IL28B* rs12979860 CC, CT, and TT genotypes in chronic HCV patients was 86.4%, 13.2%, and 0.3%, respectively. The duration of follow-up ranged from 12–159 months, with a median of 60 months. At the end of follow-up, 108/1118 (9.66%) patients developed HCC. The *IL28B* CT/TT genotype was positively correlated with high baseline AFP levels (≥20 ng/mL), advanced fibrosis stage, diabetes (DM), and failure to attain sustained virologic response (SVR; all $P < 0.05$). Multivariate Cox regression analysis showed that age ≥60 y, low platelet count ($<15 \times 10^9$ cells/L), AFP ≥20 ng/mL, advanced fibrosis stage, DM, non-SVR and the *IL28B* CT/TT genotype were significant risk factors for HCC development ($P < 0.05$). Subset analysis revealed that age, platelet count, AFP levels, and fibrosis stage were risk factors for patients with SVR. The impact of *IL28B* was not significant although HCC occurred in SVR patients with the CT/TT genotype. In contrast, for patients without SVR, only fibrosis stage and the *IL28B* CT/TT genotype (HR: 1.80, 95% CI: 1.06–3.07, $P = 0.030$) were independent risk factors for HCC development.
Conclusions: The CT/TT *IL28B* polymorphism was associated with HCV-related HCC development, especially for patients without SVR after antiviral therapy.

P0338
SURVIVAL POST SORAFENIB IN HEPATOCELLULAR CARCINOMA: ARE AFP NON-SECRETORS A DISTINCT SUB-GROUP?
M. Afshar[1], H. Clarke[1], A. Jackson-Wilding[2], A. Ahmed[2], Y.T. Ma[1,2,3], P. Punia[1,3]. [1]*Oncology, Queen Elizabeth Hospital Birmingham,* [2]*Medical School,* [3]*School of cancer Sciences, University of Birmingham, Birmingham, United Kingdom*
E-mail: mehranafshar@yahoo.com

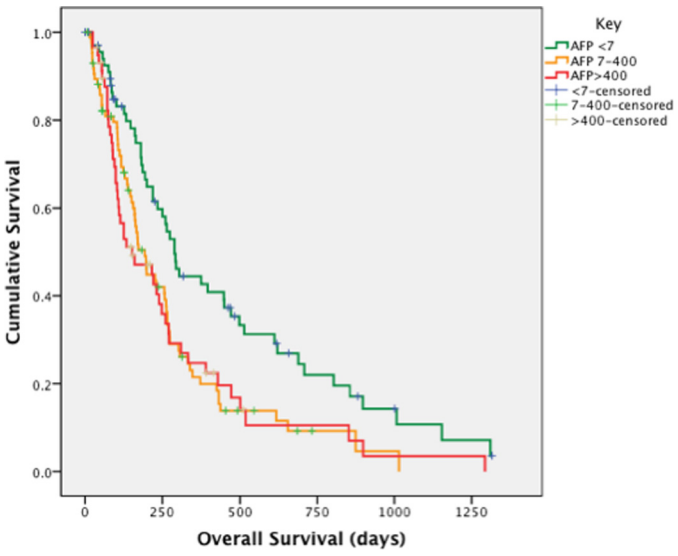
Background and Aims: Alfa fetoprotein (AFP) is the most commonly used marker for hepatocellular cancer (HCC), the serum concentration of which is elevated in about 70% of patients. An increase in AFP concentration up to 400 ng/ml has been reported in 10–15% of cases of acute and chronic hepatitis and liver cirrhosis, thus a level above 400 ng/ml in a high risk patient is generally accepted as diagnostic of HCC. Studies have shown that the higher

the AFP, the poorer the prognosis, but no good evidence in the literature exists on the minority of patients with HCC who do not secrete AFP. Our aim was to analyse this sub-group of patients from a cohort with advanced HCC treated with Sorafenib, and assess survival outcomes.

Methods: Consecutive patients with a confirmed diagnosis of HCC as per AASLD criteria, treated with Sorafenib at Queen Elizabeth Hospital Birmingham UK, between April 2009 and March 2014 were included in the analysis. We took our local reference range of <7 ng/ml as defining AFP non-secretory HCC. Electronic patient records were reviewed and variables including demographics, laboratory results, radiological data and survival outcomes were collected. Cox regression analysis was used to assess hazard ratios, and Kaplan–Meier methods were used for survival analysis.

Results: 217 patients were included in the analysis, consisting of 173 (79.7%) males and 44 (20.2%) females. The median age was 66 years (range 17–88) and 74 (34.1%) patients had received either RFA or TACE prior to Sorafenib. Median overall survival (OS) post Sorafenib was 7.2m (95% CI: 5.5–8.8m) and median progression free survival (PFS) was 4.8m (95% CI: 3.8–5.8m). 69 patients (32%) had AFP non-secretory HCC in this cohort. The median OS for the non-secretors was 9.5m (95% CI: 8.0–11.0) and for the secretor group it was 5.5m (95% CI: 4.0–7.1). The hazard ratio for survival when comparing these two groups was 1.78 (p = 0.0014). When analyzing survival in the secretor subgroup group with AFP between 7–400 ng/ml, little difference was noted between them and the group with APF >400 ng/ml (HR: 1.02, p = 0.89). The Kaplan–Meier curve presented shows the separation of survival curves for the 3 groups.

Conclusions: There is very little published in the literature about the AFP non-secretor HCC sub-group. Our data shows that this sub-group has better prognosis compared to patients with AFP secretory HCC. We believe that this data is important for clinicians and patients for prognostication and decision making.



P0340

CLINICAL PATTERNS OF HEPATOCELLULAR CARCINOMA (HCC) IN NON ALCOHOLIC FATTY LIVER DISEASE (NAFLD): A MULTICENTER CASE–CONTROL STUDY

F. Piscaglia[1], G. Svegliati Baroni[2], A. Barchetti[3], A. Pecorelli[1], S. Marinelli[1], C. Tiribelli[3], S. Bellentani[3], HCC-NAFLD Italian Study (full list exceeds available space) Bolondi L, Zoli M, Trevisani F, Malagotti D, Bugianesi E, Vanni E, Mezzabotta L, Cabibbo G, Petta S, Fracanzani A, Fargion S, Marra F, Fani B, Sacco R, Morisco F, Caporaso F, Guarino M, et al.. *[1]Dpt of Medical and Surgical Sciences, University of Bologna, Uni of Internal Medicine, University of Bologna, Bologna, [2]Gastroenterology, University of Ancona, Ancona, [3]Liver Research Center, Science Park – Basovizza Campus, Trieste, Italy*
E-mail: fabio.piscaglia@unibo.it

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) represents the hepatic manifestation of metabolic syndrome; its incidence is growing rapidly and can progress to hepatocellular carcinoma (HCC). Only scant clinical information on HCC in NAFLD is available.

The aim of the study was to assess the clinical features of patients with NAFLD-related HCC (NAFLD-HCC), and to compare them to those having HCV-related HCC.

Methods: The study is a multicenter observational case-control study. 756 patients with either NAFLD (145) or HCV-related chronic liver disease (611) have been enrolled in Secondary Care Italian Centers. Survival was modeled according to clinical parameters, lead time bias and propensity analysis.

Results: As compared to HCV, HCC in patients with NAFLD were less often male (61% vs 79%), had a higher BMI (29.1 vs 27.6) and metabolic syndrom components, had similar Child–Pugh score (5.6 vs 5.8), had a larger tumor volume (diameter largest nodule 4.1 vs 3.3 cm), more often showed an infiltrative pattern (15.4% vs 4.0%) and detection outside specific surveillance (52.4% vs 36.7%). Survival was significantly shorter (p = 0.017) in patients with NAFLD-HCC: namely 25.5 months (95% CI 21.9–29.1) in the NAFLD patients and 33.7 months (95% CI 31.9–35.4) in the HCV patients. This difference remained significant even after adjustment for lead time bias in surveilled patients. Cirrhosis was present in only about 50% of NAFLD-HCC patients. To understand the intrinsic aggressiveness of HCC and to eliminate possible confounders, a propensity score analysis was carried out considering age, gender, Child–Pugh score, largest tumor size, leading to 64 patients in each group. In this case, the difference in mean survival between the two groups (n= was no longer statistically significant, being 30.2 months (95% CI 25.3–35.2) in patients with NAFLD-HCC and 36.9 (95% CI 32.6–41.1) in patients with HCV-related HCC liver-related disease (p = 0.330).

Conclusions: NAFLD-HCC rises in the absence of cirrhosis in about 50% of the cases, and it is detected at a later tumor stage than in HCV-infected patients. Future research should identify patients with NAFLD who require surveillance in order to offer them the most timely and effective treatment.

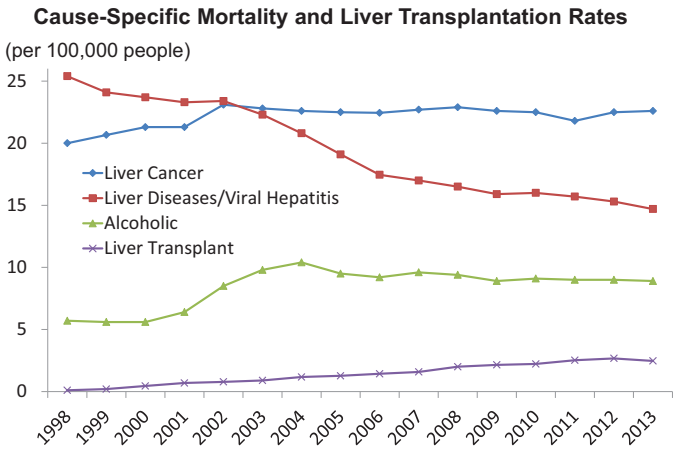
P0341

DECREASING MORTALITY BY LIVER DISEASES BUT INCREASING INCIDENCE OF AND MORTALITY BY HEPATOCELLULAR CARCINOMA IN A HEPATITIS B VIRUS ENDEMIC AREA: NATIONWIDE WHOLE POPULATION DATA ANALYSES

Y.-S. Lim[1], Y. Chang[2], J. An[1], N. Kim[3]. *[1]Gastroenterology, [2]Radiology, [3]Convergence Medicine, Radiology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, South*
E-mail: limys@amc.seoul.kr

Background and Aims: The annual mortality rate by chronic liver diseases and hepatocellular carcinoma (HCC) that are associated with hepatitis B and C has been shown to be reduced by antiviral treatments. However, the prolonged life-expectancy of patients

with chronic viral hepatitis may increase the cumulative incidence and mortality rates by HCC.
Methods: Data on incidence rates of HCC were obtained from the Korea Central Cancer Registry, which compiles nationwide data on all newly diagnosed cancers. Data on cause-specific mortality were obtained from the Korean national death registry (Statistics Korea).
Results: The mean age at death by liver diseases and HCC significantly increased between 1998 and 2013 (56.3 years vs 64.8 years; $\beta = 0.65$, $p < 0.001$ and 60.0 years vs 63.9 years; $\beta = 0.30$, $p < 0.001$, respectively). Between 1998 and 2013, the mortality rate by liver diseases and viral hepatitis significantly decreased (25.4/100,000 people vs 14.7/100,000 people; $\beta = -0.77$, $p < 0.001$). The incidence rate of and mortality rate by HCC significantly increased during the same period (28.2/100,000 people vs 32.9/100,000 people; $\beta = 0.45$, $p < 0.001$ and 20.0/100,000 people vs 22.6/100,000 people; $\beta = 0.11$, $p = 0.01$). The trends in mortality rates by liver diseases and HCC were consistently observed after adjusting for alcoholic disease and liver transplantation.
Conclusions: During recent 15 years when the antiviral treatments for hepatitis B and C have been introduced, life-expectancy of patients with chronic liver disease has increased in a hepatitis B virus endemic area, which may be associated with the increasing nationwide incidence and mortality rates by HCC. There results suggest that HCC is becoming the main cause of death in patients with chronic viral hepatitis.



P0342
CANCER STEM CELLS AND VASCULOGENIC MIMICRY IN HEPATITIS C VIRUS-RELATED HEPATOCELLULAR CARCINOMA: RELATION TO TUMOR PROGRESSION

H. El Aggan[1], L. Younis[2], E. Hassona[1], M. Sharaan[3], W. Youssef[1].
[1]Departmet of Medicine (Hepatobiliary Unit), [2]Department of Pathology, [3]Department of Surgery, Faculty of Medicine, University of Alexandria, Alexandria, Egypt
E-mail: hodaelaggan@yahoo.com

Background and Aims: Accumulating evidence suggests that cancer stem cells (CSCs) play an important role in tumorigenicity and may be involved in tumor vascularization by forming non-endothelial vascular channels described as vasculogenic mimicry (VM). The aim of the present work was to study the expression of Epithelial cell adhesion molecule (EpCAM), a marker for CSCs and VM in HCV-related HCC in relation to tumor progression.
Methods: Twenty-five patients with HCV-related cirrhosis and HCC were enrolled in the study. The severity of liver disease was assessed according to Child–Pugh classification and the Model for End Stage Liver Disease (MELD) score. Tumor stage was classified according to the Barcelona Clinic Liver Cancer (BCLC) staging system and the Cancer of the Liver Italian Program (CLIP). Histological tumor grading was performed according to the Edmondson and Steiner and the adjacent non-neoplastic liver tissue was examined to assess METAVIR histological activity grade and stage. Immunohistochemical analysis was done in HCCs and adjacent non-neoplastic liver tissues using anti-human antibodies against EpCAM, alpha fetoprotein (AFP), hepatocyte for identification of VM and CD105 to quantify microvessel density (CD105-MVD).
Results: Positive immunostaining for EpCAM (>5% of cells) was demonstrated in 11 (44.0%) HCV-related HCCs while EpCAM expression in the adjacent non-neoplastic liver tissues was observed mainly in proliferating bile ductules in the portal tracts and/or in periportal hepatocytes. Vasculogenic mimicry was identified in 15 (60.0%) of HCC samples but in none of the adjacent non-neoplastic liver tissues. The cells lining the VM channels showed positive immunostaining for EpCAM. Compared with $EpCAM^-$ HCC patients, $EpCAM^+$ HCC patients showed significantly higher Child–Pugh class ($P = 0.036$), tumor size ($P = 0.006$), CLIP stage ($P = 0.004$) and histological grade ($P = 0.001$), AFP expression ($P = 0.024$) and VM formation ($P = 0.006$). Positive correlations were found between VM formation and tumor size ($P = 0.018$), CLIP stage ($P = 0.020$) and histological grade ($P = 0.025$). No significant correlations were found between EPCAM expression or VM formation with CD105-MVD.
Conclusions: EpCAM positivity may identify a subpopulation of HCCs originated from CSCs with aggressive biological behavior and may be involved in tumor vascularization through VM formation. Targeting CSCs as well as VM may be pivotal therapeutic options in the treatment of HCC.

P0343
THE PATTERN OF ALPHA-FETOPROTEIN LEVEL HAS GREATER DIAGNOSTIC VALUE COMPARED TO ISOLATED VALUES IN PREDICTING THE PRESENCE OF HEPATOCELLULAR CARCINOMA

A. Vasudevan[1], J. Lubel[1,2], N. Denyar[1], K. Nalankilli[1], A. Jackson[1], J. Greenhalgh[2], C. Scanlon[2]. *[1]Department of Gastroenterology, Eastern Health, [2]Eastern Health Clinical School, Monash University, Melbourne, Victoria, Australia*
E-mail: abhinav.vasudevan@gmail.com

Background and Aims: It has been suggested that a very high serum alpha-fetoprotein (AFP) level in patients with chronic liver disease is diagnostic of hepatocellular carcinoma (HCC), however there is little data exploring other causes of such elevated AFP levels. In addition, there is limited data exploring the pattern of AFP elevation and its diagnostic utility in HCC.
Aims:
1. To determine the causes of an elevated AFP in a hospital setting
2. To determine the predictive value of an AFP greater than 100 μg/L, 400 μg/L and 1000 μg/L for diagnosing hepatocellular carcinoma (HCC)
3. To evaluate the diagnostic utility of the pattern of AFP change

Methods: All AFP values of 20 μg/L or greater were determined from the Eastern Health Pathology database from the 1st of January 2008 to the 1st of January 2013. Pregnant females and children were excluded. Electronic patient records were searched to determine the cause of the elevated AFP and peak AFP. Patients with at least three AFP readings over at least a three month interval were further analysed graphically and divided into one of four patterns; increasing, decreasing, fluctuating or stable.
Results: 195 patients were identified as having at least one AFP value of at least 20 μg/L, of which 22 (11%) were excluded (21 due to pregnancy and 1 due to infancy). 61 (35%) of the raised levels were attributed to HCC with other causes including hepatitis C (24%), hepatitis B (23%), germ cell tumours (9%), gastrointestinal (GI) malignancy (3%) and metastatic malignancy of unknown primary (3%). There were 81, 44 and 13 patients with a peak AFP of greater than 100 μg/L, 400 μg/L and 1000 μg/L, respectively, and these gave positive predictive values of 0.48 [95% confidence interval (CI)

0.37–0.59], 0.64 (95% CI 0.48–0.77) and 0.62 (95% CI 0.32–0.85), respectively, for the diagnosis of HCC. Other causes of an AFP greater than 400 included germ cell tumours (16%), GI malignancy (7%), hepatitis B (5%) and hepatitis C (5%). 67 patients had at least 3 AFP readings. An increasing pattern of AFP yielded a sensitivity of 0.55 (95% CI 0.36–0.74), a specificity of 0.85 (95% CI 0.48–0.79) for HCC. Hepatitis C (19%) and germ cell tumours (10%) were the only other causes of an increasing pattern of AFP.

Conclusions: An AFP of greater than 400 μg/L suggests a malignant process but is not specific for hepatocellular carcinoma. An increasing pattern of AFP in the absence of a germ cell tumour or hepatitis C is highly suggestive of hepatocellular carcinoma and warrants further investigation.

P0344

STREAMLINING HEPATOCELLULAR CARCINOMA SURVEILLANCE TO IMPROVE ITS PERFORMANCE: THE HEPATOMA AND COMPENSATED CIRRHOTIC FOLLOW-UP (HACC-FOL) PILOT PROGRAMME

O. Cullen[1], D. Ekanayake[2], M. Fenech[1], K. Beckman[1], B. Leggett[1], R. Skoien[1,2]. *[1]Department of Gastroenterology and Hepatology, Royal Brisbane and Women's Hospital, [2]School of Medicine, The University of Queensland, Brisbane, Australia*
E-mail: rskoien@hotmail.com

Background and Aims: The incidence of hepatocellular carcinoma (HCC) is increasing and patient outcomes depend critically on early diagnosis through surveillance of at-risk patients. The effectiveness of surveillance is adversely affected by patient, physician and administrative factors. We aimed to study whether a streamlined, nurse-led model of HCC surveillance could be implemented to improve outcomes.

Methods: Patients undergoing standard of care (SOC) HCC surveillance (6-monthly US +/− AFP measurement and specialist outpatient follow-up of results) were identified. A new model of care (the HACC-FOL programme) was piloted between July 2013 and June 2014. This comprised a prospectively implemented nurse-led telephone clinic, with a reminder sent to patients prior to their US and follow-up telephone call within 5 working days of surveillance investigations to assess patient symptoms and relay results. Informed consent was obtained in all cases and patients were returned to SOC follow-up after 1 cycle of surveillance. A staff hepatologist was immediately consulted regarding new symptoms or abnormal results, and appropriate diagnostic imaging was expedited if a lesion was detected on surveillance US. Patients completed satisfaction surveys at the start and end of the programme. Results were compared with those of SOC surveillance in the same patients over a 2 year period immediately before implementation of the HACC-FOL pilot.

Results: 130 patients were enrolled in the HACC-FOL pilot programme. In the 2 year period prior to its implementation, there were 26 episodes of failure to attend (FTA) surveillance US or follow-up appointments compared with only 3 FTA under the HACC-FOL programme. Six new lesions were detected requiring contrast imaging. Features of the SOC model "annoyed" or "distressed" patients, such as having to return to clinic for results (23%), excessive waiting times to see the doctor in clinic (13%) and not knowing results for weeks (14%). Patient satisfaction with the HACC-FOL programme was very high with improvements in perceived reporting of results, access to treatment and overall satisfaction.

Conclusions: The pilot HACC-FOL programme represents a streamlined, low-cost, nurse-led telephone clinic that improves clinical productivity and efficiency, reduces costs associated with FTA, and specifically addresses patient factors that may contribute to non-compliance. This innovative model represents an important initiative in an era of increasing mortality due the rising incidence of HCC.

P0345

THE ROLE OF CYTOKINES AND SEROMARKERS IN PREDICTING HCC RECURRENCE AFTER RADIOFREQUENCY ABLATION – INTERIM REPORT

W.-J. Jeng[1,2], W.-T. Chen[2,3], C.-C. Lin[1], C.-H. Huang[1], W. Teng[1], Y.-C. Chen[1], C.-W. Hsu[1], C.-Y. Lin[1,2], S.-M. Lin[1,2]. *[1]Department of Gastroenterology and Hepatology, Division of Hepatology, Chang Gung Memorial Hospital, Linkou, [2]College of Medicine, Chang Gung University, [3]Division of Hepatology, Department of Gastroenterology and Hepatology, Chang Gung Memorial Hospital, Linkou, Taipei, Taiwan*
E-mail: rachel.jeng@gmail.com

Background and Aims: Hepatocellular carcinoma (HCC) is one of the most common malignancies in the world. High recurrence rate after curative therapy may result in poor survival. Seromarkers such as VEGF, IGF-1 and cytokines including IL-γ, IL-5, IL-6, IL12, IP-10, fractalkine were found to be correlated with the outcome of HCC after therapies. The aim of the study is to investigate the prognostic role of seromarkers and cytokines in patients with HCC after radiofrequency ablation (RFA) with complete ablation.

Methods: This prospective study enrolls patients with HCC received RFA with complete ablation in our department. Patients were followed up every 3 months post treatment. The baseline liver biochemistry, age, gender, cirrhosis, etiology of HCC, viral load, history of anti-viral therapy, and baseline tumor parameters, as well as serum IL-γ, IL-5, IL-6, IL12, IP-10, fractalkine, VEGF and IGF-1 level were analyzed. Serum samples were stored at −80°C and tested by enzyme-linked immunosorbent assay (ELISA) (Quantikine Human IGF-1 and VEGF ELISA Kits; R&D Systems, Minneapolis, MN). Statistic analysis is done by SPSS 19. Independent student T test will be applied for normal distributed continuous variable while Mann–Whitney U test for non-normal distributed continuous variable analysis. Chi-square test will be used for categorical variable. AUROC was done for the goodness of the predictors.

Results: A total of 62 patients were recruited with a mean age of 69.4 year and 58.1% were male. HBV was detected in 34% while HCV as 53.2% of 62 patients. The median tumor size was 2.5 cm. 75.8% of HCC were TMN stage I while the rest were stage II. Only 26 (41.9%) of the 62 patients completed follow-up over 180 days, and 9 (34.6%) of 26 patients with additional intrahepatic HCC recurrence within 1 year. Those with higher IL-6 level tend to have high risk of recurrence (P = 0.021). The AUROC of IL-6 was 0.77 (95% CI: 0.571–0.969, P = 0.03). Moreover, if tumor size ≥3 cm, higher VEGF (AUROC: 0.833, 95% CI 0.635–1, P = 0.021) was more predictive than IL-6 (AUROC: 0.728, 95% CI 0.479–0.073, P = 0.117).

Conclusions: IL-6 is a pretreatment predictor for HCC with 1-year recurrence post RFA regardless of size while VEGF is more predictive of 1-year recurrence in HCC ≥3 cm. Further validation is necessary for the relative small sample size of this pilot study.

P0346

MULTICENTER ANALYSIS OF SOLUBLE Axl REVEALS DIAGNOSTIC VALUE FOR VERY EARLY STAGE HEPATOCELLULAR CARCINOMA

E-mail: wolfgang.mikulits@meduniwien.ac.at

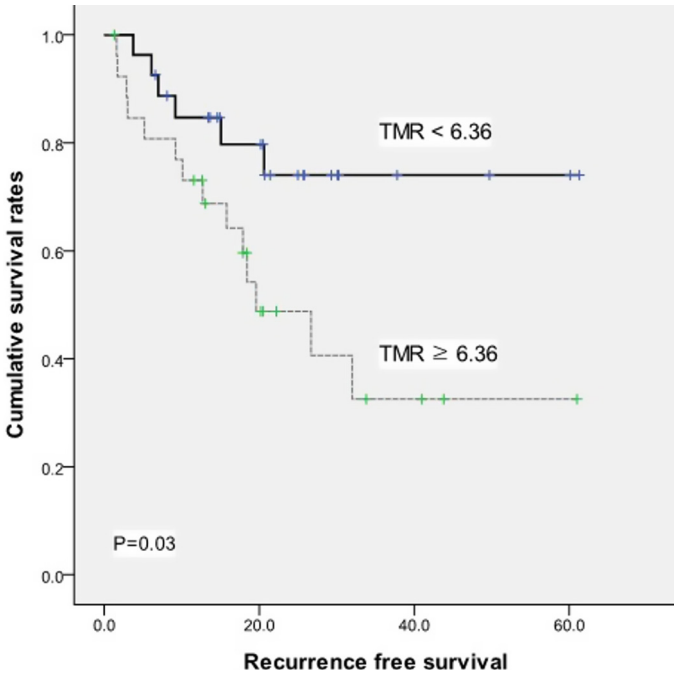
Background and Aims: If diagnosed at early stages, patients with hepatocellular carcinoma (HCC) can receive curative therapies, whereas therapeutic options at later stages are very limited. Here we addressed the potential of soluble Axl (sAxl) as a biomarker of early HCC.
Methods: Levels of sAxl were analyzed by enzyme-linked immunosorbent assay in 548 serum samples from centers in Europe and China.
Results: Serum concentrations of sAxl were significantly increased in HCC (18.575 ng/mL) as compared to healthy (13.388 ng/mL) or cirrhotic (12.169 ng/mL) controls. Receiver operating characteristic curve analysis of sAxl in very early stage HCC patients (BCLC 0) showed an area under the curve (AUC) of 0.848, with a sensitivity of 76.9% and a specificity of 69.2%. α-Fetoprotein (AFP)-negative HCC patients displayed an AUC of 0.803, with sensitivity and specificity of 73% and 70.8%. Combination of sAxl and AFP improved diagnostic accuracy to 0.936 in very early HCC patients and to 0.937 in all HCC. Differential diagnosis of very early HCC versus liver cirrhosis showed a combined performance for sAxl and AFP of 0.901 with a sensitivity of 88.5% and a specificity of 76.7%. Furthermore, sAxl levels failed to be elevated in primary ovarian, colorectal and breast carcinomas as well as in secondary hepatic malignancies derived from colon.
Conclusions: sAxl outperforms AFP in detecting very early HCC as compared to healthy or cirrhotic controls and shows high diagnostic accuracy for AFP-negative patients. sAxl is specific for HCC and suggested as a biomarker for routine clinical use.

P0347

CORRELATION OF VARIOUS METABOLIC PARAMETERS OF ^{18}F-FDG PET WITH HISTOLOGIC FEATURES AND RECURRENCE OF HCC

Y.-H. Baek[1], S.-Y. Han[1], S.-L. Lee[1], Y.-J. Jeong[2], J.-S. Jeong[3].
[1]Department of Internal Medicine, [2]Department of Nuclear Medicine, [3]Department of Pathology, Dong-A University College of Medicine, Busan, Korea, South
E-mail: p100100@dau.ac.kr

Background and Aims: Hepatocellular carcinoma (HCC) recurrence is observed in up to 70–80% of patients despite a curative treatment. Microvascular invasion (MVI) and poor differentiation are strong risk factors for recurrence, but these cannot be known preoperatively. The aim of this study was to investigate the correlation of ^{18}F-FDG PET with MVI and differentiation, and predictive role of tumor-to-background ratio of PET for recurrence in HCC.
Methods: Fifty-four patients including 45 males and 9 females had ^{18}F-FDG PET/CT study before surgical resection for HCC between December 2008 and December 2012. We analyzed the predictive role of clinicopathological features and metabolic parameters of ^{18}F-FDG PET/CT for recurrence of HCC. All 18F-FDG PET/CT scans were performed using a Discovery 710 PET/CT scanner (General Electric Medical System, Milwaukee, USA). Maximal standardized uptake value (SUVmax), tumor-to-nontumor ratio (TNR), tumor-to-muscle ratio (TMR) and tumor-to-blood ratio (TBR) were tested as metabolic index of ^{18}F-FDG PET.
Results: The mean follow-up duration was 31.48 months and postoperative recurrence developed in 20 (37%) patients. Twenty-seven patients (50%) had increased uptake in PET before surgical resection and 14 (51.9%) of them experienced the recurrence. Increased uptake in PET and TMR were associated with microvascular invasion (MVI) ($p = 0.04$, $p = 0.005$) and histologic differentiation ($p = 0.018$, $p = 0.002$). The median values of SUVmax, TNR, TMR and TBR were 3.22, 1.66, 6.36 and 2.24, respectively. Patients were classified into low and high groups using the mean values as cutoffs.
Patients were stratified and analyzed by univariate analysis using age, sex, tumor size, number, Child–Pugh classification, preoperative serum AFP, preoperative serum PIVKA-II, operative type, surgical resection margin, differentiation, capsule formation, septal formation, MVI, surgical resection margin, and SUVmax, TNR, TMR and TBR for metabolic parameters of PET. MVI was the only independent predictive factor for recurrence in multivariate analysis although TMR ≥6.36 showed a favorable result despite no statistical significance ($p = 0.061$). The cumulative recurrence-free survival (RFS) rates at 12 and 24 months were 79.7% and 74% in patients with TMR <6.36 and 64.2% and 32.5% in patients with TMR ≥6.36 ($p = 0.03$).
Conclusions: Increased 18F-FDG uptake of HCC, especially high TMR might be correlated with MVI and poor differentiation, and tends to have a risk for recurrence in HCC.



P0348

CAN HISTOLOGIC GRADE BE PREDICTED IN HEPATOCELLULAR CARCINOMA PATIENTS USING ENHANCEMENT DEGREE OF Gd-EOB-DTPA-ENHANCED MAGNETIC RESONANCE IMAGES? A PROSPECTIVE COHORT STUDY

Y.-J. Jin[1], S.G. Cho[2], J.M. Kim[3], J.-W. Lee[1]. [1]*Internal Medicine,* [2]*Radiology,* [3]*Pathology, Inha University Hospital, Inha University School of Medicine, Incheon, Korea, South*
E-mail: jyj412@hanmail.net

Background and Aims: Gd-EOB-DTPA (Primovist) is a liver-specific contrast agent, and Primovist-enhanced magnetic resonance images (MRI) has become clinically useful tool for diagnosis of small hepatocellular carcinoma (HCC). Several previous retrospective studies have tried to evaluate the association of histological grading with enhancement of HCC using MRI. In this study, we intended to evaluate whether histologic grade of HCC can be predicted using enhancement degree of Primovist-enhanced MRI in a prospective cohort with surgical resection for HCC.
Methods: A total of 71 patients who underwent surgical resection for HCC at our institution between January 2012 and March 2014 were prospectively enrolled. Primovist-enhanced MRI was performed in all patients before surgery. Signal intensities of HCC and peri-HCC areas were measured by using a region of interest. The relative intensity ratios of HCC lesion to the surrounding non-HCC area on unenhanced images (pre-contrast ratio) and those on hepatobiliary phase images (post-contrast ratio) were calculated.
Results: Of the 71 patients, Edmondson-Steiner grades I, II, III, and IV were observed in 5 (7%), 35 (49.3%), 28 (39.4%), and 3 (4.2%), respectively. Based on the Edmondson-Steiner grades I, II, III, and IV, mean pre-contrast ratios were 0.776, 0.773, 0.798, and 0.799, respectively, and mean post-contrast ratios were 0.673, 0.594, 0.599, and 0.597, respectively. These ratios showed no significant differentiation between each Edmondson-Steiner grade (each P-value >0.05).
Conclusions: Despite the liver-specific contrast agent of Gd-EOB-DTPA, enhancement degree of Primovist-enhanced MRI cannot provide useful information for prediction of histologic grade of HCC. Hasty decision on the differentiation of HCC based on the enhancement pattern of Primovist-enhanced MRI needs to be avoided.

P0349

sFRP-4, A POTENTIAL NOVEL SERUM MARKER FOR HEPATITIS B VIRUS-RELATED HEPATOCELLULAR CARCINOMA

C. Xu[1], X. Zeng[1], Y. Wang[1]. [1]*Infectious diseases, Southwest hospital, Chongqing, China*
E-mail: wangyuming357@163.com

Background and Aims: To explore the diagnostic value of secreted frizzled related protein 4 (sFRP-4) in patients with hepatitis B virus (HBV)-related hepatocellular carcinoma.
Methods: Serum samples of 272 patients with chronic HBV infection [142 with hepatocellular carcinoma (HCC), 130 with chronic hepatitis B (CHB)] and 33 healthy controls were collected and divided into 2 sets. Meanwhile, 60 tissue specimens obtained from 30 HCC patients (30 specimens in foci, other 30 were precancerous tissues) were analyzed. Human antibody arrays were used for preliminary screening for serum markers in 15 patients (8 HCCs, 7 CHBs). Latent markers selected by human antibody arrays were assessed in 305 serum samples and 60 tissue specimens.
Results: Human antibody assays indicated that serum sFRP-4 levels were significant higher in HCC patients than in CHB patients ($P < 0.05$), and serum sFRP-4 levels were also significant higher in HCCs than in non-HCCs in test set [79.7 (54.3, 117.3) vs 41.3 (35.9, 56.2), $P < 0.001$] and validation set [89.0 (63.6, 131.1) vs 39.0 (28.9, 54.5), $P < 0.001$]. The area under the Receive Operating Characteristic curves (AUCs) were comparable between alpha-fetoprotein (AFP) and sFRP-4 [test set: 0.847, 95% confidence interval (CI): 0.788–0.906, vs 0.857, 95% CI: 0.796–0.918, $P > 0.05$; validation set: 0.868, 95% CI: 0.800–0.936, vs 0.0.889, 95% CI: 0.837–0.942, $P > 0.05$]. In the test set, sFRP-4 (sensitivity 94.4%, specificity 60.5% at 46.37 ng/ml) combined AFP (sensitivity 75%, specificity 84.9% at 11.3 ng/ml) resulted in a better performance with a sensitivity of 79.2% and specificity of 95.3%, and AUC of the two combination increased to 0.941 (95% CI: 0.908–0.975), similar results were seen in the validation group. Expression of sFRP-4 was higher in precancerous tissues than in focal lesions (22/30, 73.3%), there was no significant difference between precancerous tissues and focal lesions in the rest patients (8/30, 26.7%).
Conclusions: sFRP-4 is comparable to AFP for the diagnosis of HCC in CHB patients, their combination analysis can improve the diagnostic value.

P0350

KOREAN VERSION OF A MODEL TO ESTIMATE SURVIVAL IN AMBULATORY PATIENTS WITH HEPATOCELLULAR CARCINOMA (K-MESIAH)

B.H. Nam[1], J.-W. Park[2], S.-H. Jeong[3], S.S. Lee[3], A. Yu[1], B.H. Kim[2], W.R. Kim[4]. [1]*Biometric Research Branch,* [2]*Center for Live Cancer, National Cancer Center, Korea, Goyang,* [3]*Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Korea, South;* [4]*Division of Gastroenterology and Hepatology, Stanford University, Stanford, United States*
E-mail: jwpark@ncc.re.kr

Background and Aims: A model to estimate survival in ambulatory hepatocellular carcinoma patients (MESIAH) is useful for estimating patient prognosis but needs improvement for Korean patients, most of whom have a hepatitis B virus. We aimed to modify the MESIAH for better prognostication through enhancing calibration for Korean patient population (K-MESIAH).
Methods: Utilizing a cohort of 1,969 hepatocellular carcinoma (HCC) patients from the National Cancer Center of Korea between 2004 and 2009, a survival prediction model was developed using the Cox proportional hazards model. The model's performance was evaluated using C-statistical and χ^2-statistical analyses. External validation was performed using an independent cohort of 328 patients from the Seoul National University Bundang Hospital.
Results: To develop the K-MESIAH, etiology was added to the original risk factors (age, Model for Endstage Liver Disease, albumin, size of the largest nodule, number of tumor nodules, vascular invasion, metastasis, and alpha fetoprotein) in the MESIAH. From the internal validation study, the C-statistics and χ^2-statistics for one-, three-, and five-years of survival were 0.83 (95% Confidence Interval: 0.82–0.85), 49.07; 0.81 (95% Confidence Interval: 0.79–0.82), 28.95; and 0.80 (95% Confidence Interval: 0.79–0.81), 20.93, respectively. The K-MESIAH also showed a high prediction ability for the external validation cohort.
Conclusions: A survival prediction model for Korean HCC patients was developed and validated to have a high level of performance. This K-MESIAH may be more useful in clinical practice and personalized care in a hepatitis B virus endemic area.

P0351

HIGHLY SENSITIVE α-FETOPROTEIN, *Lens culinaris* AGGLUTININ-REACTIVE FRACTION OF α-FETOPROTEIN AND DES-γ-CARBOXY PROTHROMBIN FOR HEPATOCELLULAR CARCINOMA DETECTION IN AN ITALIAN COHORT

M.L. Abate[1], G.P. Caviglia[1], E. Petrini[2], S. Gaia[2], P. Carucci[2], A. Smedile[2]. [1]*Lab. of Liver Physiopathology, Dept. Medical Sciences, University of Turin,* [2]*Dept. Gastroenterology and Hepatology, Città della Salute e della Scienza Hospital, Turin, Italy*
E-mail: caviglia.giampi@libero.it

Background and Aims: Hepatocellular carcinoma (HCC) is a common complication in patients with chronic liver disease (CLD),

and particularly in those with cirrhosis. Currently, diagnosis and surveillance is mainly based on imaging-methods. However, recent technical improvements in the analytical methods of measuring α-fetoprotein (AFP), *Lens culinaris* agglutinin-reactive fraction of AFP (AFP-L3) and des-γ-carboxy prothrombin (DCP) employing an advanced microfluidics-based separation technology have been developed.

The aim of this study was to evaluate the diagnostic accuracy of α-fetoprotein (AFP), *Lens culinaris* agglutinin-reactive fraction of AFP (AFP-L3) and des-γ-carboxy prothrombin (DCP) alone and in combination, and to apply a recently proposed model (GALAD) that combines gender, age, AFP, AFP-L3 and DCP for the diagnosis of HCC in an Italian cohort.

Methods: A total of 98 patients [44 CLD patients without HCC (23M, 21F; mean age 53.2±13.4 years, 80% HBV-related) and 54 patients with HCC (45M, 9F; 69.5±9.8 years, 70% HCV-related)] were evaluated for AFP, AFP-L3 and DCP levels using highly sensitive assay on the μTASWako™ i30 auto-analyzer. Areas under the curve (AUC), sensitivity (Se), specificity (Sp) were calculated and compared to assess diagnostic performance of HCC markers and GALAD model.

Results: AFP, AFP-L3 and DCP values were significantly elevated in HCC compared to CLD patients [median AFP 13.4 (2.4–5785) ng/mL and 2.3 (1–25) ng/mL, p < 0.0001; median AFP-L3 5.9 (1–81.6) % and 1 (1–15.1) %, p < 0.0001; median DCP 1.13 (0.1–87.49) ng/mL and 0.265 (0.1–1.45) ng/mL, p < 0.0001; in HCC and CLD respectively]. AFP showed an AUC of 0.891 (cut-off 5.3 ng/mL, Se=0.81, Sp=0.86; 79.4% of patients correctly classified), AFP-L3 an AUC of 0.867 (cut-off 1%, Se=0.845, Sp=0.89; 84.5% of patients correctly classified) and DCP an AUC of 0.870 (cut-off 0.4 ng/mL, Se=0.78, Sp=0.91; 79.6% of patients correctly classified). The combination of the 3 markers resulted in AUC=0.947 (Se=0.94, Sp=0.86; 87.6% of patients correctly classified), whereas GALAD model showed AUC=0.976 (Se=0.96, Sp=0.84; 89.8% of patients correctly classified). Differences between AUC values and corresponding statistical significance are reported in Table 1.

Conclusions: Our data confirm the high analytical performance of the μTASWakoTM i30 tests for AFP, AFP-L3 and DCP quantitation. Moreover, the combination of these biomarkers and the use of GALAD model is superior to a single biomarker in HCC detection.

Table 1. AUC values comparison between AFP, AFP-L3, DCP, alone and in combination, and GALAD model

	DCP	AFP-L3	AFP + DCP + AFP-L3	GALAD model
AFP	ΔAUC = 0.024, p = 0.611	ΔAUC = 0.024, p = 0.551	ΔAUC = 0.056, p = 0.063	ΔAUC = 0.085, p = 0.011
DCP	/	ΔAUC = 0.003, p = 0.996	ΔAUC = 0.080, p = 0.002	ΔAUC = 0.106, p = 0.001
AFP-L3	/	/	ΔAUC = 0.080, p = 0.022	ΔAUC = 0.109, p = 0.002
AFP + DCP +AFP-L3	/	/	/	ΔAUC = 0.029, p = 0.028

Abbreviations: AFP, α-fetoprotein; AFP-L3, *Lens culinaris* agglutinin-reactive fraction of AFP; AUC, area under the curve; DCP, des-γ-carboxy prothrombin.

P0352
NEUTROPHIL LYMPHOCYTE RATIO (NLR) AT DIAGNOSIS IS A PREDICTOR FOR SURVIVAL IN PATIENTS RECEIVING SORAFENIB FOR ADVANCED HEPATOCELLULAR CARCINOMA (HCC): A LARGE UK COHORT

M. Afshar[1], H. Clarke[2], A. Jackson-Wilding[3], A. Ahmed[3], Y.T. Ma[4], P. Punia[1]. *[1]Oncology, Queen Elizabeth Hospital Birmingham, Bimringham, [2]Oncology, Queen Elizabeth Hospital Birmingham, Birmingham, [3]Medical School, [4]School of Cancer Sciences, University of Birmingham, Bimringham, United Kingdom*
E-mail: mehranafshar@yahoo.com

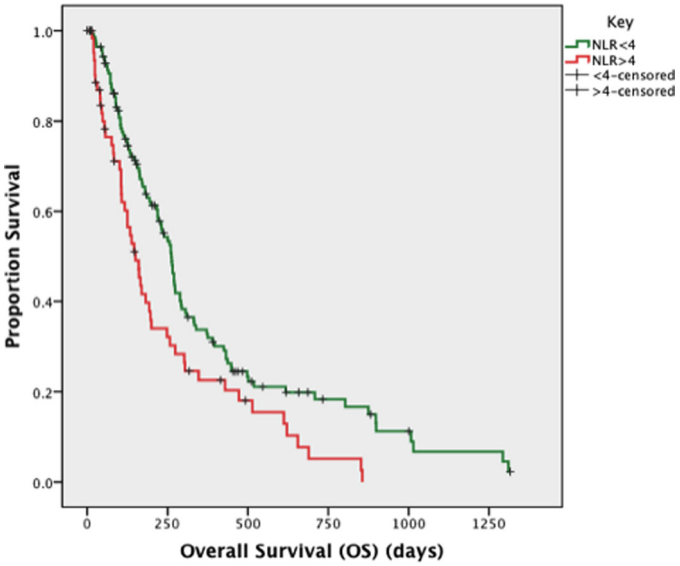
Background and Aims: Sorafenib is the current standard of care for patients with advanced or metastatic hepatocellular carcinoma. A body of evidence exists for the wide heterogeneity of response to sorafenib, but robust prognosticators in this setting are lacking. Neutrophil lymphocyte ratio (NLR) is a marker of systemic inflammation, and high NLR has been associated with poor response post TACE and RFA treatment, and with recurrence post transplantation. A small analysis on a Chinese population showed an NLR of >4 to be associated with poorer outcomes with sorafenib. Our aim was to perform a retrospective review of patients treated at a large academic cancer centre in the UK to assess the possible correlation between NLR and response to sorafenib.

Methods: All patients with a confirmed diagnosis of HCC, either by biopsy or radiologically as per AASLD criteria, who were treated with sorafenib at our centre between April 2009 and March 2014 were included in this analysis. Electronic patient records were reviewed and variables including demographics, hematological and biochemical laboratory results, radiological data and survival outcomes were collected. Cox regression analysis was used to assess hazard ratios, and Kaplan–Meier methods were used for survival analysis.

Results: 234 patients were included in the initial notes review. 17 were excluded at first review for unconfirmed diagnosis of HCC, or not having received sorafenib. The remaining 217 patients consisted of 173 (80%) males and 44 (20%) females. The median age was 66 years (range: 17–88) and 74 (34%) patients had received either RFA or TACE prior to sorafenib. Median overall survival (OS) post sorafenib was 7.2 mo (95% CI: 5.5–8.8 mo) and median progression free survival (PFS) was 4.8 mo (95% CI: 3.8–5.8 mo). Patients separated into 2 groups based on NLR of ≤4 or >4.0 derived diverging Kaplan–Meier curves for OS.

The median OS in those with NLR ≤4.0 was 8.6 mo (95% CI: 7.6–9.6 mo) and in those with NLR >4.0 it was 4.9 mo (95% CI: 3.5–6.3 mo). Corrected for AFP and the Child–Pugh score, patients with an NLR >4.0 had a 48% increased hazard of death than those with NLR ≤4.0 (HR 1.48, p = 0.041). The median PFS in those with NLR ≤4.0 was 5.5 mo (95% CI: 4.4–6.5 mo) and in those with NLR >4.0 was 3.4 mo (95% CI: 2.1–4.6 mo). The hazard ratio for progression between the two groups was 1.51 (p = 0.02).

Conclusions: NLR at diagnosis is a significant predictor for OS and PFS from initiation of sorafenib. We are currently undertaking validation of these findings utilizing an external dataset.



P0353
PROTEIN BIOMARKERS REACTIVE WITH HCC SERA SERVE AS A SIGNATURE FOR HEPATOCELLULAR CARCINOMA (HCC)

N.S. Reau[1], M. Bissonnette[1], S. Forrester[2], D. Schabacker[2], T. Barder[3], D. Jensen[1]. [1]*University of Chicago,* [2]*Argonne,* [3]*Eprogen, Chicago, United States*
E-mail: nreau@medicine.bsd.uchicago.edu

Background and Aims: HCC is a known consequence of cirrhosis. Early recognition affords curative options, whereas delayed diagnosis has a poor prognosis. Despite current guidelines, many present with HCC at a non-curative stage. While biomarkers have been evaluated for screening and diagnosis, current biomarkers remain insensitive. A humoral response directed against oncoproteins or other aberrantly expressed proteins, has been documented in several malignancies. This immune response to neoantigen exposure might serve as a protein fingerprint for early and specific diagnosis.
Aim: Determine if an autoantibody signature exists to identify patients with HCC using patient's serum and established HCC cell lines as the reference
Methods: 40 patients with HCC (confirmed by histology or established radiologic features) were prospectively recruited from liver clinic. Sera were compared to 40 cancer-free patients with liver disease (LD) and 40 healthy controls (HC). Huh7 and HepG2 liver cancer cells were cultured, harvested and lysed. Proteins were extracted and separated by chromatofocusing. Fractions were further separated by non-porous silica according to hydrophobicity, collected in 96-well plates and deposited onto nitrocellulose slides generating protein microarrays. Arrays were hybridized with subject sera followed by fluorescently labeled goat anti-human IgG and scanned using a microarray scanner. Single-channel intensities of spots were determined. Replicated arrays were averaged and differences between cancer and normal serum were determined by non-parametric Wilcoxon rank-sum test p-value threshold 0.05. Quintile normalization was compared to averaged non-normalized data to detect consistent signals in HCC sera that were absent in LD sera and HC. Signal minimum of >1000 was accepted to eliminate low signal intensity. Prediction Analysis for Microarrays (PAM) was utilized for prediction analysis and validated with random forest.

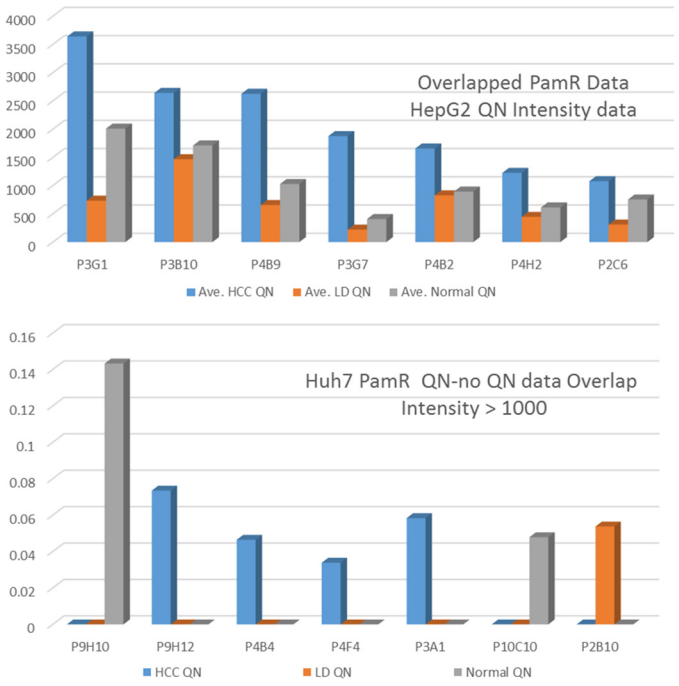


Figure 1.

Figure 2.

Results: Using the HepG2 cell line, 7 high-titer protein fractions were identified as potential markers to discriminate HCC from LD/HC (Figure 1). Similarly using Huh7 cell line, 2 high titer protein fractions were identified as potential markers (Figure 2). Mass spectrometry analysis is underway to identify potential reactive proteins.
Conclusions: Several candidate autoantibody biomarkers were identified using protein microarrays. These proteins will be further characterized and studied for their classification power using a larger sample set.

P0355
THE EVALUATION OF AN AUTOMATED RECALL PROGRAMME FOR SURVEILLANCE LIVER ULTRASOUND IN PATIENTS AT INCREASED RISK OF HEPATOCELLULAR CARCINOMA

C. Farrell[1], T.J. Cross[2], A. Halpen[3], P.D. Richardson[2], P. Healey[1], J. Barr[2], N. Ladep[4], O. Noorullah[2,4], R.P. Sturgess[4], L. Boland[2,4], N. Stern[4], D. Palmer[5], M.G. Lombard[2], E. Joekes[1], The Liverpool Liver Cancer Group. [1]*Department of Radiology,* [2]*Department of Gastroenterology and Hepatology, The Royal Liverpool Hospital,* [3]*Department of Radiology, The Royal Liverpool Hospital Department of Hepatology,* [4]*Department of Hepatobiliary medicine, Aintree University hospital,* [5]*The University of Liverpool, Liverpool and Clatterbridge Cancer Centre, Liverpool, United Kingdom*
E-mail: tjscross@hotmail.com

Background and Aims: Hepatocellular carcinoma is the fifth commonest cause of cancer death worldwide. The disease is often detected late when curative treatment is no longer possible. AASLD and EASL recommend six-monthly liver ultrasound in cirrhotic patients. The implementation of this is usually ad hoc from liver clinics, with risk of poor adherence.
Aims: To evaluate a radiology led, automated recall programme for HCC surveillance.
Methods: A single centre, retrospective cohort study of patients enrolled in the HCC surveillance programme at the Royal Liverpool Hospital from September 2009 to May 2013. All patients with cirrhosis Childs A-B, were included and hepatitis B patients with a family history of HCC. Patient demographics, cancer stage and cirrhosis etiology were recorded. Targeted liver ultrasounds were performed and rebooked for 6 months by administrative staff. The authors reviewed what happened to the cohort of patients.
Results: 6725 patients were identified. 804 patients were identified in the surveillance programme. Mean age 55 years (IQR 46–63 years), 497 male (62%). Aetiology: ALD 308 (38%), hepatitis C 154 (19%), hepatitis B 113 (13%), NASH 78 (10%), PBC 37 (5%), AIH 33 (4%), haemochromatosis 22 (3%), mixed 38 (5%). A total of

2366 scans were performed, for 100% adherence 3495 scans should have been done. 368 (46%) patients had complete surveillance, 182 (23%) did not attend 1 appointment. 81 (10%) patients had a USS suspicious for HCC. Of these 38 underwent CT, 56 had MRI, 2 contrast ultrasound and 14 both CT and MRI. 31 patients were diagnosed with HCC (3.9%), 19/31 (61%) were within Milan criteria, compared to the overall regional data 82/400 (21%), $p < 0.0001$, OR 0.49 (0.31–0.76). 9 patients had radiological curative disease, 9 were assessed for liver transplant. 4 patients were delisted for disease progression, two patients were not listed due to comorbidities, two were managed by ablation, and one patient was transplanted. 1 had a liver resection, 7 patients had ablations with curative intent. Of the other 10 patients, 6 were deemed too frail for any treatment, 3 had significant co-existent malignancies and 1 died of sepsis.

Conclusions: Patients in an automated USS surveillance programme had HCC detected at an earlier stage, but those receiving curative treatment were low. Adherence to surveillance was poor. A prospective randomized trial assessing the benefit, cost, and potential harm of surveillance is needed.

P0356

CIRCULATING FREE TUMOUR DNA CONCENTRATION IS A MORE USEFUL DIAGNOSTIC MARKER THAN TP53 MUTATION DETECTION IN HBV-RELATED HCC IN WEST AFRICAN PATIENTS

S. Knapp[1], J. Howell[1], Y. Sherwani[1], M. Shariff[1], L. Karanfilian[1], N. Ladep[1], E. Okeke[2], S. Taylor-Robinson[1], M. Thursz[1]. *[1]Hepatology, Imperial College, London, London, United Kingdom; [2]Medicine, Jos University Teaching Hospital, Jos, Nigeria*
E-mail: manukascarlet@yahoo.com

Background and Aims: Hepatitis B and aflatoxin-related hepatocellular carcinoma (HCC) is common in West Africa, but access to HCC diagnostics such as CT and MRI are limited. This study evaluates circulating free tumour DNA (cfDNA) and aflatoxin-mediated TP53 249Ser gene mutation measurement in blood for HCC diagnosis.

Methods: 66 Nigerians had liver disease evaluation including liver ultrasound and blood tests. HCC was diagnosed by α-fetoprotein >400 IU/mL and characteristic findings on ultrasound or histology. CfDNA was isolated from 250 μL of plasma using QiaAmp circulating DNA kit (Qiagen). Plasma cfDNA was quantified with real time PCR using TaqMan TP53 249Ser Mutation detection assay (Invitrogen) and TP53 Reference assay, performed on a StepOnePlus instrument (Invitrogen).

Results: 26 patients had HCC (39%), 11 had HBV cirrhosis (17%), 11 chronic hepatitis B (17%) and 22 were healthy controls (33%). There were no significant clinical differences between groups on multivariate analysis. All HCC patients had stage IV disease. cfDNA concentrations were higher in HCC cases compared with controls (median cfDNA concentration 0.383 ng/μL, IQR 0.166–1.453 in HCC; 0.090 ng/μL, IQR IQR 0.044–0.239 in controls, $p = 0.0003$). ROC analysis of cfDNA concentration showed AUC = 0.766 for HCC diagnosis. Combining cfDNA concentration and α-fetoprotein levels (AFP) had AUC = 0.958 for HCC diagnosis. TP53 mutation was detected more frequently in HCC cases compared with controls (11 of 26 HCC compared with 6 of 48, $p = 0.006$) and mutated DNA concentration was higher in HCC cases compared with controls ($p = 0.004$). AUC for TP53 mutation concentration was lower than cfDNA concentration for diagnosis of HCC (AUC = 0.661). Furthermore, the addition of TP53 mutation concentration to cfDNA concentration did not appreciably improve AUC for HCC diagnosis (AUC = 0.772). cfDNA concentration was higher in patients with TP53 mutation ($p = 0.017$) and correlated with mutated DNA concentration ($p = 0.035$, $r = 0.52$). These factors were not independent diagnostic markers of HCC on logistic regression.

Conclusions: cfDNA levels are elevated in advanced HCC in West Africans and have moderate accuracy for HCC diagnosis. Though TP53 mutation is common in HCC, TP53 mutation detection appears dependent on cfDNA concentration and has lower utility for HCC diagnosis. Our data suggest cfDNA quantification alone or in combination with AFP may prove useful for HCC diagnosis in resource-poor settings.

P0357

AMINO ACID SIGNATURES IN RELATION TO THE RISK OF HEPATOCELLULAR CARCINOMA – A PROSPECTIVE CASE–CONTROL STUDY

M. Stepien[1], T. Duarte-Salles[1], V. Fedirko[2], D. Kumar[1], I. Romieu[1], A. Scalbert[1], M. Jenab[1], on behalf of the EPIC Group. *[1]International Agency for Research on Cancer, Lyon, France; [2]Emory University, Atlanta, United States*
E-mail: stepienm@fellows.iarc.fr

Background and Aims: Circulating levels of amino acid (AA) appear to be perturbed in hepatocellular carcinoma (HCC), but also in liver cirrhosis, obesity and diabetes, all of which are identified risk factors for HCC. However, from the current literature it is not clear whether observed associations are also apparent prior to HCC diagnosis. Therefore, we conducted a prospective study based on a large European cohort to characterise AA profiles in blood samples obtained on average 8.8 years prior to HCC diagnosis.

Methods: A nested-case control study was conducted within the prospective EPIC cohort of >520,000 participants from 10 European countries. During 8.8 years of follow up 147 HCC cases were identified and matched to 1 control each. AA levels in prospectively collected sera were measured with Biocrates AbsoluteIDQ-p180Kit. Log-transformed AA levels were z-standardized (Mean 0, SD 1). HBV/HCV status and liver enzyme levels were determined separately. Multivariable conditional logistic regression models were used to calculate odds ratios and 95% confidence intervals (OR; 95% CI) for individual AA, AA groupings and some of their specific ratios in relation to HCC risk.

Results: Six individual AA and two ratios were identified as the most predictive metabolites for HCC risk. The observed associations in multivariable models were inverse for leucine (OR = 0.46, 95% CI: 0.28–0.76), lysine (OR = 0.50, 95% CI: 0.32–0.78), glutamine (OR = 0.27, 95% CI: 0.13–0.56) and the ratio of branched chain to aromatic AA (OR = 0.27, 95% CI: 0.15–0.48; Fischer ratio). Phenylalanine (OR = 2.08, 95% CI: 1.32–3.26, $p = 0.01$), tyrosine (OR = 2.67, 95% CI: 1.65–4.30), glutamate (OR = 3.37, 95% CI: 1.82–6.24) and glutamate/glutamine ratio (OR = 4.32, 95% CI: 2.10–8.87) were positively associated with HCC risk. When the analyses were restricted to subjects diagnosed after 2 years from recruitment, all metabolites except phenylalanine maintained the associations. Controlling for hepatitis status or liver function markers had a confounding effect.

Conclusions: These findings based on sera collected up to many years prior to HCC diagnosis, show that circulating levels of aromatic (tyrosine, phenylalanine), branched chain (leucine), glutamate AA family (glutamine, glutamate) and lysine display strong HCC risk associations. The findings suggest that imbalances of specific AA and their impaired metabolism, possibly due to changes in liver function, may be involved in HCC development and may be further explored as potentially early predictors of HCC.

E-mail: chienj@ucla.edu

Background and Aims: Various factors have been identified in determining the risk of hepatocellular carcinoma (HCC) and cirrhosis in patients chronically infected with the hepatitis B virus (HBV). However, risk factors for HCC in cirrhotic patients are still unclear. We examined HCC risk in cirrhosis patients based on genetic factors, as well as seromarkers measured closest to cirrhosis diagnosis during follow-up.
Methods: The REVEAL-HBV cohort enrolled 4,155 HBsAg seropositive people from Taiwan who were followed up every 6–12 months until 30 June, 2004. At entry and follow-up visits, blood samples were tested for serological markers. Covariates included in the model were age, HBeAg serostatus, qHBsAg levels, alanine aminotransferase (ALT) concentration, alpha-fetoprotein (AFP) level, and the *ALDH2* rs671 SNP variant. Cox proportional hazards models were used to estimate the risk of HCC associated with different factors.
Results: A total of 301 people developed cirrhosis during follow-up. Of those 301 people, 76 were diagnosed with HCC during 2,462 person-years of follow-up. Compared to those who were diagnosed with cirrhosis between ages 30 and 39, patients aged 60 and older had an adjusted hazard ratio (HR [95% CI]) of 14.26 (3.17–64.08) [p = 0.0005] of developing HCC. Compared to ALT levels <15 U/L, those with ALT levels ≥45 U/L exhibited an adjusted HR (95% CI) of 3.68 (1.70–7.99) [p = 0.0010]. With an AFP level ≥20 ng/mL, the adjusted HR (95% CI) was 3.52 (1.78–6.93) [p = 0.0003] compared to AFP <10 ng/mL. HBeAg(+) participants showed an adjusted HR (95% CI) of 2.85 (1.49–5.46) [p = 0.0015] when compared to HBeAg(−) individuals with qHBsAg levels <1,000 IU/mL. Those with any genetic variation (AA or AG) of the *ALDH2* rs671 SNP had a protective effect with an adjusted HR (95% CI) of 0.35 (0.20–0.59) [p < 0.0001], when compared to the GG genotype.
Conclusions: Older age, the GG *ALDH2* variant, HBeAg seropositivity, high HBsAg levels, high ALT levels, and high AFP levels near cirrhosis diagnosis were associated with an increased risk of progression from cirrhosis to HCC in chronic HBV infected participants.

ESM-1 IS A MARKER OF MICROVASCULAR INVASION, SATELLITE NODULES, AND ADVERSE CLINICAL OUTCOME IN PATIENTS WITH HEPATOCELLULAR CARCINOMA TREATED BY SURGICAL RESECTION

J. Calderaro[1,2], J.-C. Nault[3], P. Bioulac-Sage[4], M. Tepper[5], E. Sauce[5], C. Laurent[6], C. Costentin[7], T. Decaens[8], J.-F. Blanc[9], D. Azoulay[10], A. Luciani[11], A. Laurent[10], N. Ganne-Carrié[12], M. Ziol[5]. *[1]Pathology, Henri Mondor University Hospital, [2]Inserm U955 Equipe 18, IMRB, Créteil, [3]Hepatology, Jean Verdier Hospital, Bondy, [4]Pathology, Pellegrin Hospital, Bordeaux, [5]Pathology, Jean Verdier Hospital, Bondy, [6]Surgery, Pellegrin Hospital, Bordeaux, [7]Hepatology, Henri Mondor University Hospital, Créteil, [8]Hepatology, CHU, Grenoble, [9]Hepatology, Pellegrin Hospital, Bordeaux, [10]Surgery, [11]Radiology, Henri Mondor University Hospital, [12]Hepatology, Jean Verdier Hospital, Créteil, France*
E-mail: julien.calderaro@hmn.aphp.fr

Background and Aims: The prognosis of patients with hepatocellular carcinoma (HCC) eligible for curative treatment who undergo surgical resection or radiofrequency ablation (RFA) is highly impacted by the detection of satellite nodules and/or microvascular invasion. However, these features are identified on surgical samples and can neither be detected by liver imaging, nor by examination of liver biopsy. We previously demonstrated that immunohistochemical expression of Endothelial Cell-Specific Molecule 1 (ESM-1) by endothelial stromal cells predicted early recurrence of HCC after radiofrequency ablation (RFA). The aim of the present study was to assess the frequency and the distribution of ESM-1 expression in surgical samples of HCC eligible for curative treatment, to correlate its expression to microvascular invasion, satellite nodules and to clinical outcome.
Methods: One hundred and fifty-one HCC cases treated by surgical resection and classified BCLC 0 (n = 7, 5%), A (n = 108, 71%), or B (n = 36, 24%) from 2 University Hospital were included. Clinical, biological, pathological and follow-up data were systematically recorded. Expression of ESM-1 was investigated by immunohistochemistry. Survival and time to recurrence were analyzed using Kaplan–Meier method, log-rank test and Cox univariate and multivariate analysis.
Results: ESM-1 expression was observed in 48% (72/151) of the cases. It was strictly restricted to stromal endothelial cells and regularly distributed throughout the tumor sample. The detection of ESM-1 positive stromal cells was highly related to microvascular invasion (p = 0.002) and satellite nodules (p < 0.001). In univariate analysis, ESM-1 expression was a predictive factor of early recurrence (p = 0.0147) and overall survival (p = 0.0539). In multivariate analysis, the only factor associated to disease-specific survival was the existence of satellite nodule (p = 0.002).
Conclusions: ESM-1 expression by endothelial stromal cells, detected in 48% of BCLC 0/A/B HCC surgical samples is highly related to the presence of satellite nodules and microvascular invasion. These findings strongly suggest its use as a simple and reliable prognosis marker in biopsy samples.

P0360

STAT6 rs3024974 MIGHT PREDICT WORSE PROGNOSIS IN HEPATOCELLULAR CARCINOMA PATIENTS

Y. Liao[1], B. Cai[1], Y. Li[1], L. Wang[1]. *[1]Department of Laboratory Medicine, West China Hospital, Sichuan University, Chengdu, China*
E-mail: wangll_wch@163.com

Background and Aims: The signal transducer and activator of transcription (STAT) 4 and 6 belong to STAT protein family. It has been demonstrated to be associated with autoimmune diseases. Recently, a genome-wide association study linked STAT4 rs7574865 with hepatocellular carcinoma (HCC) development. While another polymorphism of STAT4, rs3821236, which has comparable effect

with rs7574865, has seldom investigated. Besides, the role of STAT6 in HBV related diseases, including HCC, received scant attention.
Methods: In total, we recruited 948 Chinese Han subjects, including 220 HCC patients, 383 chronic HBV carriers and 345 natural clearance subjects. Four single nucleotide polymorphisms (SNPs) (STAT4 rs3821236, STAT6 rs324011, rs3024974, rs703817) were genotyped through high-resolution melting curve method.
Results: All the SNP distributions were in Hardy–Weinberg equilibrium (P > 0.05). In HCC patients, clinical characteristics including tumor size (5 centimetre as the cut-off), tumor number (single vs. multiple), portal vein tumor thrombus (Yes vs. No), distant metastasis (Yes vs. No) and portal vein invasion (Yes vs. No) were taken into consideration. STAT6 rs3024974 non-CC genotypes had a higher probability to develop tumor thrombus (OR = 2.75, 95% CI=1.30–5.84, P = 0.007) and portal vein invasion (OR = 2.34, 95% CI=1.08–5.07, P = 0.028). While no other polymorphisms (rs324011, rs703817 and rs3821236) associated with these HCC clinical characteristics. Additionally, we appraised whether these polymorphisms correlated with HBV susceptibility and HCC development. Results indicated that no polymorphisms of STAT4 and STAT6 were associated with HBV chronicity (P > 0.05) as well as HCC development. Then we combined HCC group with HBV group, and designated all the patients as the HBV carrier group. In comparison with natural clearance subjects, STAT4 rs3821236 GA genotype seemed to be a protective factor against HBV chronicity (OR = 0.61, 95% CI=0.45–0.83, P = 0.002), but allele model showed that allele A did not correlate with HBV chronicity (OR = 0.90, 95% CI=0.74–1.08, P = 0.267). No other SNPs or genotypes presented significant associations with HBV chronicity.
Conclusions: STAT6 rs3024974 associated with tumor thrombus and portal vein invasion and thus might predict, to some extent, worse outcome of HCC patients. However, all the selected polymorphisms were not explicitly associated with HBV susceptibility or HCC development and further high-quality studies were still necessitated.

P0361
HOST GENETIC POLYMORPHISMS WITH HEPATOCELLULAR CARCINOMA RISK IN CHINESE HAN POPULATION: A CASE–CONTROL STUDY

Y. Liao[1], B. Cai[1], Y. Li[1], J. Chen[1], L. Wang[1]. [1]*Department of Laboratory Medicine, West China Hospital, Sichuan University, Chengdu, China*
E-mail: wangll_wch@163.com

Background and Aims: Human Leukocyte Antigen (HLA) DP/DQ polymorphisms have been demonstrated to be associated with hepatitis B virus (HBV) clearance in different races in our previous study. And Signal Transducer and Activator of Transcription 4 might associate with HBV natural clearance in Tibetans. Till now, no studies concurrently investigated the association between the two genes with the pathological variables of the cancer.
Methods: In total, we enrolled 629 subjects into this study, including 379 chronic HBV patients and 250 HCC patients. Four single nucleotide polymorphisms (SNPs) (HLA-DP rs3077, rs9277535, HLA-DQ rs7453920 and STAT4 rs7574865) were genotyped through high-resolution melting curve method. Comparison was made between HBV and HCC patients to validate whether these SNPs associate with clinical traits of HCC.
Results: The distribution of all the polymorphisms was in Hardy–Weinberg equilibrium. We stratified all the HCC patients based on clinical characteristics including tumor size, portal vein tumor thrombosis and distant metastasis. Results indicated that rs7453920 allele A associated with increased risk of portal vein tumor thrombosis (OR = 6.92, 95% CI=3.68–13.04, p < 0.001), though this allele has been regarded as the protective allele toward HBV persistent infection. And STAT4 rs7574865 allele T correlated with reduced risk of portal vein tumor thrombosis (OR = 0.15, 95% CI=0.06–0.37, p < 0.001) and tended to increase the risk of a large tumor size (OR = 1.51, 95% CI=0.99–2.28, p = 0.053) (See Table 1). But none of all the SNPs connected with tumor size, distant metastasis as well as the venous invasion (P > 0.05).
Conclusions: Currently selected SNPs of HLA-DP/DQ, STAT4 seemed not to correlate with HCC development based on our present study. But STAT4 rs7574865 and HLA-DQ rs7453920 might correlate with portal vein tumor thrombosis and thus could predict the prognosis of HCC patients.

P0362
HEPATOCELLULAR CARCINOMA INCIDENCE IN CHRONIC HEPATITIS C PATIENTS ACCORDING TO ANTIVIRAL TREATMENT STATUS

T. Purevsambuu[1], S. Bota[2], F. Hucke[1], H. Hofer[1], P. Ferenci[1], W. Sieghart[1], M. Peck-Radosavljevic[1]. [1]*Department of Internal Medicine III, Division of Gastroenterology and Hepatology,* [2]*Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Medical University of Vienna, Vienna, Austria*
E-mail: tuulaigirl@yahoo.com

Background and Aims: Our aim was to assess the hepatocellular carcinoma (HCC) incidence during the time and HCC stage at the diagnosis in relation to antiviral treatment status.
Methods: We retrospectively collected data of HCV patients, who were diagnosed between 1989–2011 and treated at the AKH-University Hospital of Vienna. We analyzed the HCC incidence as well as the BCLC stage at the time of HCC diagnosis during the follow-up in HCV patients according to the HCV-treatment status.

Table 1 (abstract P0361). Correlation of HLA-DQ rs7453920 and STAT4 rs7574865 with clinicopathological characteristics in patients with HCC

Clinical characteristics	rs7453920				rs7574865			
	G (%)	A (%)	OR (95% CI)	p	G (%)	T (%)	OR (95% CI)	p
Tumor size								
≤5 cm	199 (94.8)	11 (5.2)	1.00		154 (73.3)	56 (26.7)	1.00	
>5cm	197 (91.2)	19 (8.8)	1.75 (0.81–3.76)	0.151	137 (64.6)	75 (35.4)	1.51 (0.99–2.28)	0.053
Tumor number								
single	286 (94.7)	16 (5.3)	1.00		205 (68.3)	95 (31.7)	1.00	
multiple	158 (91.9)	14 (8.1)	1.58 (0.75–3.33)	0.222	117 (68.8)	53 (31.2)	0.98 (0.65–1.47)	0.912
Portal vein tumor thrombosis								
No	289 (92.6)	23 (7.4)	1.00		211 (68.1)	99 (31.9)	1.00	
Yes	49 (64.5)	27 (35.5)	6.92 (3.68–13.04)	<0.001*	73 (93.6)	5 (6.4)	0.15 (0.06–0.37)	<0.001*
Distant metastasis								
No	401 (93.7)	27 (6.3)	1.00		295 (69.2)	131 (30.8)	1.00	
Yes	42 (95.5)	2 (4.5)	0.71 (0.16–3.08)	0.643	28 (66.7)	14 (33.3)	1.13 (0.57–2.21)	0.73
Venous invasion								
No	378 (93.1)	28 (6.9)	1.00		279 (69.4)	123 (30.6)	1.00	
Yes	68 (97.1)	2 (2.9)	0.40 (0.09–1.71)	0.199	46 (65.7)	24 (34.3)	1.18 (0.69–2.02)	0.539

*Values are regarded as statistically significant.

Results: We identified 2627 HCV patients in our Department. We had to exclude 126 patients due to insufficient follow-up data and 64 patients diagnosed with HCC simultaneously to the HCV-infection. Thus in the final analysis we included 2437 patients.
The overall HCC incidence after a median follow-up of 8 years (range: 0.5–24) was 10.3%, being significantly lower in patients who received antiviral treatment as compared with untreated patients: 5.9% vs. 19.1%, p < 0.0001. Also, the HCC incidence in the treated patients was significantly lower in patients who achieved a sustained virologic response (SVR) as compared with non-SVR patients: 1.8% vs. 12.6%, p < 0.0001.
In the group of SVR patients, overall the HCC incidence/year of follow-up was 0.2%; the annual HCC incidence according to the number of treatment until achieving SVR was: 1 treatment – 0.1%, 2 treatments – 0.5% and 3 treatments – 0.15% (p = 0.008).
The overall HCC incidence/year of follow-up in the non-SVR group was 1.25%; the annual HCC incidence according to the number of treatment received, was: 1 treatment – 1.3%, 2 treatments – 1.3%, 3 treatments – 0.9% and >3 treatments – 1.1% (p = 0.58).
The HCC incidence/year of follow-up in the untreated group was 11.6% (untreated vs. treated: p < 0.0001; comparison SVR vs. non-SVR: p = 0.01).
The median time between HCV and HCC diagnosis was 7 years (2–14) in SVR patients, 6 years (1–21) in non-SVR and 3 years (0.5–21) in non-treated patients.
The BCLC stage at the moment of HCC diagnosis in all patients, SVR, non-SVR and non-treated patients are presented in Table 1.

Table 1. BCLC stages at the time of diagnosis in different groups of patients in relation to the anti-HCV therapy status

BCLC stage	All patients (n = 2437)	SVR patients (n = 1011)	Non-SVR patients (n = 610)	Untreated patients (n = 816)
0	0.8%	0%	1.4%	0.6%
A	23.4%	31.5%	32.4%	17.8%
B	23.7%	26.3%	23.4%	23.6%
C	33.2%	36.9%	29.9%	34.4%
D	18.9%	5.3%	12.9%	23.6%

Conclusions: The patients, who received antiviral treatment, especially those with treated successful had a significantly lower HCC incidence and more cases of HCC were diagnosed in early stages, comparable with non-treated group.

P0363
SYSTEMATIC REVIEW AND META-ANALYSIS OF INCIDENCE AND RISK FACTORS OF HEPATOCELLULAR CARCINOMA IN UNTREATED HBV INFECTED PATIENTS

E. Raffetti[1], G. Fattovich[2,3], F. Donato[1]. *[1]Unit of Hygiene, Epidemiology and Public Health, University of Brescia, Brescia, [2]Department of Medicine, University of Verona, [3]Clinical Unit of Gastroenterology, Azienda Ospedaliera Universitaria Integrata Verona, Verona, Italy*
E-mail: e.raffetti@unibs.it

Background and Aims: The risk of hepatocellular carcinoma (HCC) in chronic hepatitis B virus (HBV) infection may vary in different clinical settings and not completely defined. We aimed to assess incidence rates, and factors related with occurrence, of HCC in untreated subjects with HBV chronic infection.
Methods: We performed a systematic review and meta-analysis searching for published articles in Medline, Embase, and the Cochrane Library up to October 2014 as well as in reference literature. We included longitudinal studies assessing HCC incidence in untreated HBV infected patients. The HCC estimates incidence rates (IRs) and their 95% confidence intervals (95% CIs) were extracted by each study and pooled together in random effects models. Assessment of heterogeneity and meta-regression analyses were done.

Results: 79 studies were included with a total of 363,838 participants and 3,472 HCC cases. In asymptomatic carries, the IRs of HCC were 0.04 (95% CI: 0.012–0.07), 0.19 (0.07–0.31) and 0.44 (0.23–0.66) per 100 person-years in Europe, North America and East Asia, respectively. In inactive carriers and subjects with chronic hepatitis, IRs were 0.02 (0.0–0.06) and 0.12 (0.03–0.27) in Europe, and 0.05 (0.03–0.06) and 0.49 (0.32–0.66) in East Asia, respectively. In compensated cirrhosis (Child–Pugh A), IRs were 2.03 (1.30–2.77), 2.89 (1.23–4.55) and 3.62 (2.65–4.58) in Europe, North America and East Asia, respectively. Meta-regression showed a statistically significant increase of IRs for age, male percentage, in North America and East Asia with respect to Europe, and in asymptomatic carriers, and patients with chronic hepatitis and compensated cirrhosis with respect to inactive carriers (Figure). Few studies, almost all performed in East Asia, investigated the role of alcohol, tobacco, diabetes and obesity and HBV genotype, so as no precise evaluation of their roles in progression of HBV infection to HCC could be done.

Variable	IR increase per 100 p-y	95% CI	p-value
Age (10 years)	1.09	1.05–1.14	<0.001
Gender (% males)	1.02	1.00–1.03	0.02
Area			
Europe	Reference		
North America [a]	3.10	1.00–9.98	0.05
East Asia	2.24	1.04–4.82	0.04
Disease status			
Inactive carrier	Reference		
Asymptomatic carrier	1.84	0.92–3.66	0.08
Chronic hepatitis	7.84	3.44–17.98	<0.001
Compensated cirrhosis	18.92	9.93–35.71	<0.001

[a] 70% Asiatic subjects.

Conclusions: The risk of developing HCC in untreated subjects with HBV chronic infection is strongly related with age, gender, area of residence, and HBV disease status.

P0364
CLINIC EVALUATION OF CIRCULATING MICRORNAS AS POTENTIAL BIOMARKERS OF HEPATOCELLULAR CARCINOMA IN PATIENTS WITH HBV CHRONIC INFECTION

G.P. Caviglia[1], M.L. Abate[1], E. Petrini[2], S. Gaia[2], P. Manzini[3], P. Carucci[2], M. Rizzetto[2], A. Smedile[2]. *[1]Dept. Medical Sciences, University of Turin, [2]Dept. Gastroenterology and Hepatology, [3]Blood Bank, Città della Salute e della Scienza Hospital, Turin, Italy*
E-mail: caviglia.giampi@libero.it

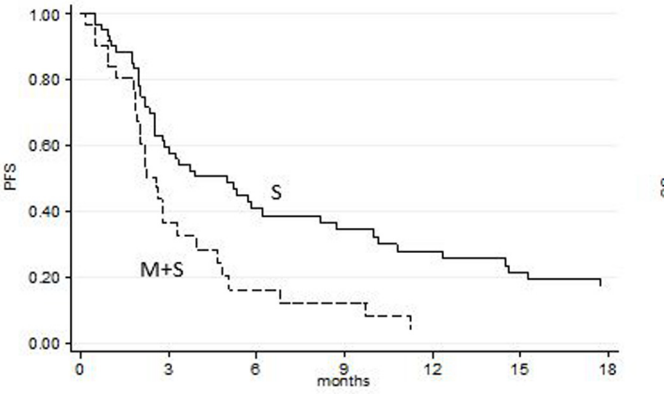
Background and Aims: Several studies showed that aberrant miRNA expression is associated with development and progression of hepatocellular carcinoma (HCC). Because of their stability in the circulation, miRNAs have been proposed as potential biomarkers of HCC.
The aim of this study was to examine whether some commonly deregulated miRNAs (miR-122, miR-21, miR-221 and miR-16) in HBV-related HCC may serve as diagnostic markers.
Methods: Serum expression of miRNA miR-122, miR-21, miR-221 and miR-16 was evaluated by real-time quantitative RT-PCR in 90 subjects: 33 patients with HBV-related HCC (age 61±10; F/M = 4/29), 30 patients with HBV-related cirrhosis (age 53±11; F/M = 11/19) and 27 blood donors as healthy controls (age 54±8; F/M = 9/18). Relative expression was correlated with clinical features among patients and controls.
Results: Median levels of miR-16, miR-122 and miR-221 were significantly different in patients with HCC or cirrhosis than in healthy controls (p < 0.001) whereas, only miR-122 levels differed in patients with HCC from cirrhotic patients (p = 0.024). Expression levels of mir-21 were similar in the 3 groups. miR-122 levels were significantly higher in patients with multifocal HCC than in patients with a single lesion (p = 0.024).

Area under the curve (AUC) analyses showed that serum levels of miR-122, miR-122 + miR-221, miR-122 + miR-16 and miR-122 + miR-221 + miR-16, are able to differentiate patients with HCC from patients with cirrhosis (AUC = 0.675; AUC = 0.704; AUC = 0.681; AUC = 0.703, respectively). Moreover, miR-16, miR-122 and miR-221, alone or in combination, were potential markers for discriminating HCC patients from healthy controls (AUC >0.9) and for discriminating patients with cirrhosis from healthy controls (AUC >0.9). In addition, a positive correlation between miR-122 levels and HCC nodules number (R = 0.390; p = 0.036), and a correlation between miR-16 and miR-122 levels, and ALT values (R = −0.464, p = 0.034; R = 0.449, p = 0.536, respectively) was found.
Conclusions: Among the four microRNAs analyzed, miR-122 significantly discriminates patients with HCC from cirrhotic patients and patients with HCC or cirrhosis from controls. miR-122 appears to reflect liver necro-inflammation, since we observed a positive correlation with ALT levels. Moreover, our study showed a correlation between miR-122 expression levels and HCC multifocality, suggesting the possible use of this miRNA for tumor stadiation. Nevertheless, miR-122 AUC values were not sufficiently high for HCC screening purposes in clinical practice.

P0365
EFFECTS OF METFORMIN ON CLINICAL OUTCOME IN ADVANCED HCC PATIENTS RECEIVING SORAFENIB

A. Caadei Gardini[1], M. Scartozzi[2], E. Scarpi[1], G. Marisi[1], L. Faloppi[3], S. Tamberi[4], E. Tamburini[5], G. Masi[6], F.G. Foschi[7], N. Silvestris[8], P. Ulivi[1], G. Luca Frassineti[1]. *[1]IRST-IRCCS, Forli, [2]Oncologia Cagliari, Cagliari, [3]Oncologia Ancona, Ancona, [4]Oncologia Faenza, Faenza, [5]Oncologia rimini, Rimini, [6]Azienda Ospedaliero-Universitaria Pisana, Pisa, [7]Medicina interna, Faenza, [8]Oncologico Bari, Bari, Italy*
E-mail: casadeigardini@gmail.com

Background and Aims: Several studies reported an association between type 2 diabetes mellitus (DM2) and hepatocellular carcinoma (HCC). Data from several retrospective studies and meta-analysis have demonstrated a risk reduction of about 50% of developing HCC in cirrhotic patients treated with metformin for DM2. Several in vitro studies have shown anti-tumor activity of metformin (M) in HCC. The aim of this study is to evaluate the different outcomes of patients that have received or not metformin during treatment with sorafenib (S).
Methods: From 257 patients diagnosed with HCC from 2004 to 2014, 93 patients consecutively treated with sorafenib were analyzed. Of these, 42 patients (45.2%) were diabetic and 31 (33.3%) of these have received M for DM2. Progression-Free Survival (PFS), Overall Survival (OS) and their 95% Confidence Interval (95% CI) were estimated by Kaplan–Meier method and compared with log-rank test.
Results: The concomitant use of S and M was associated with a median PFS of 2.6 months (95% CI 1.9–3.3) compared to 5.0 months (95% CI 2.5–8.2) for patients who have not received M ($p = 0.029$) (See Fog 1). The concomitant use of S and M was associated with a median OS of 10.4 months (95% CI 3.9–14.4) compared to 15.1 months (95% CI 11.7–17.8) for patients who have not received M (p = 0.014).
Conclusions: These findings could be explained by an increased tumor aggressiveness and resistance to S in patients treated with M. M usually enhanced the activity of S, but probably molecular alterations in transporter genes or transcription factors involved in M molecular action and pharmacokinetics could contribute to a different response to these drugs combination. Further studies are needed to confirm the data and to identify possible mechanisms of resistance that may occur during treatment with S.



P0366
HEPATITIS C TREATMENT AND FIBROSIS STAGE IN SUBJECTS WITH HEPATOCELLULAR CARCINOMA AND HEPATITIS C IN A SINGLE U.S. CENTER VETERAN POPULATION

A.U. Nookala[1], N.S. Shamsi[1], K.M. Newman[1], A. Knott-Johnson[2], P. Ricci[2]. *[1]Gastroenterology, University of Minnesota, [2]Gastroenterology, Veterans Administration Medical Center, Minneapolis, United States*
E-mail: nook0003@umn.edu

Background and Aims: It has been shown that subjects with increased fibrosis stage and those who failed to eradicate hepatitis C (HCV) have higher rates of hepatocellular carcinoma (HCC). Our aim was to study treatment and fibrosis stage in subjects with HCC and HCV infection.
Methods: We identified 4537 unique subjects in the Minneapolis VAMC Hepatitis C Clinical Registry with HCV infection from years 1997 to October 31, 2014. We conducted a retrospective chart review of 208 subjects from that Registry with HCV infection and HCC: we assessed their demographics, history of HCV treatment and response, and fibrosis stage. We compared the proportion of subjects who developed HCC according to successful response to treatment, treatment failure, or lack of treatment.
Results: 208 of the subjects had HCC in the setting of HCV infection from the Minneapolis VAMC Hepatitis C Clinical Registry (n = 4537). The median age was 60 years (range 46 to 79 years). All 208 subjects were male. 12/208 (5.8%) developed HCC following treatment and achievement of a sustained virologic response (SVR); all of these were cirrhotic. 196/208 (94.2%) who developed HCC were never treated or had failed treatment; of these, 79/196 (40%) did not have cirrhosis.
Conclusions: This is a descriptive study evaluating subjects with HCC and infected with HCV in relation to HCV treatment and fibrosis stage. Treatment of HCV did not remove the risk of development of HCC in a subgroup of patients with liver cirrhosis. Development of HCC in the absence of HCV eradication occurred in a sizeable proportion of subjects despite lower stages of fibrosis. Both findings suggest that additional risk factors for HCC development persisting after successful HCV eradication and/or prior to development of advanced fibrosis warrant investigation.

P0367

SARCOPENIA IS ASSOCIATED WITH A REDUCED SURVIVAL IN PATIENTS WITH HEPATOCARCINOMA UNDERGOING SORAFENIB TREATMENT

E. Gigante[1], G. Antonelli[1], P. Begini[1], F. Carbonetti[2], E. Iannicelli[2], P. Marchetti[3], A. Pellicelli[4], L. Miglioresi[4], G. Delle Fave[1], M. Marignani[1]. *[1]Digestive and Liver Diseases unit, [2]Radiology unit, [3]Oncology unit, St. Andrea Hospital, Faculty of Medicine and Psychology, University 'Sapienza', [4]Liver Unit, San Camillo Forlanini Hospital, Rome, Italy*
E-mail: elia.gigante@hotmail.it

Background and Aims: Sarcopenia, a condition characterized by muscle wasting, has been associated with poor outcomes in patients with cirrhosis and solid tumors, and with a higher toxicity rate during chemotherapy. Hepatocarcinoma (HCC), presently the third cause of cancer death worldwide, is diagnosed at advanced stage in up to 40% of all patients, and at this stage, the only approved treatment is sorafenib. We analyzed the influence of sarcopenia on the survival of HCC patients treated with sorafenib.

Methods: We conducted a retrospective study on 41 patients affected by advanced HCC treated with sorafenib. Patients who had performed an abdominal computed tomography (CT) 30 days within treatment start were enrolled, and data regarding survival, treatment toxicity, pre-treatment anthropometric features, and laboratory findings were collected. A transverse CT image with a multiplanar reconstruction (MPR) from L3 was collected from each scan and analyzed with SliceOmatic V 5.0, a software enabling specific tissue selection. The muscles' cross-sectional area at this level were selected and normalized for height, obtaining the skeletal muscle index (SMI). Presence of sarcopenia was defined by the presence of a SMI ≤41 cm^2/m^2 for women, and ≤53 cm^2/m^2 for men with a body mass index (BMI) ≥25 kg/m^2 and ≤43 cm^2/m^2 for those with a BMI <25 kg/m^2.

Results: Patients were mainly males (80.5%). Sarcopenia was present in more than one third of the patients (36.5%, 15/41), with no difference in sex distribution (M 30.3% vs F 62.5% p = 0.094). The two groups, with or without sarcopenia were compared. Baselines features were similar, no significant difference in albumin levels, international normalized ratio, BMI, baseline serum sodium, creatinine, bilirubin and MELD score were detected. Child–Pugh Score was significantly higher in the sarcopenic group [6 (5–8) vs 5 (5–8); p = 0.034]. Age was also slightly higher in the sarcopenic group: 74 (31–85) vs 64.5 (50–80) years, p = 0.043. Patients with sarcopenia had a reduced Overall Survival, 79 (95% CI 44–114) vs 181 (95% CI 140–223) weeks (p = 0,0013), as well as smaller survival after treatment of 24 vs 54 weeks (Figure 1). Time on treatment of sarcopenic patients was 12.3 vs 22.9 weeks (HR 1.83, Logrank test p = 0.0464), but there were no significant differences in the cause of interruption between the two groups.

Conclusions: Sarcopenia is present in a third of advanced HCC, and it is associated with a reduced OS as well as with reduction of the time on sorafenib treatment.

P0368

LONG TERM SURVIVAL AFTER REPEAT LIVER RESECTION FOR COLORECTAL LIVER METASTASIS IS POSSIBLE

G. Conte[1,2], M. Trochsler[1], G. Maddern[1]. *[1]Department of Surgery, The Queen Elizabeth Hospital and University of Adelaide, Adelaide, Australia; [2]University of Milan, Milan, Italy*
E-mail: grazia.conte1@gmail.com

Background and Aims: More than 50% of patients with colorectal cancer will develop liver metastases (CRLM). The surgical resection is the standardized treatment of choice and the only potentially curative, aided by chemotherapy.
Nevertheless 40% of the patients will have recurrence in the liver after the first operation, and 20–40% will be potential candidates to repeat hepatectomies.
The aim of our study was to evaluate the difference between first, second and third operation for CRLM in term of long term survival, tumour characteristics and intraoperative data.

Methods: A retrospective study of patients undergoing repeat hepatectomies at The Queen Elizabeth Hospital in Adelaide between 1997 and 2013 was performed.
In total 415 patients have been registered in our Liver Database between 1997 and 2013, 225 had CRLM.
We included a total of 37 patients who had a second liver resection for CRLM and 6 who had a third resection. The control group comprised the 182 patients who had only first resection.
Data collected concerned primary tumour and metastases' characteristics, liver resection, perioperative treatment, recurrence and survival. Data about recurrence included site, date of appearance, and treatment. The overall survival after repeat resection was determined and compared with that of patients underwent only first liver resection during the same period.

Results: The median time of follow-up was 35.4 months (range 1.43 and 210.46), 3 patients were lost to the follow-up. The median time between primary bowel resection and first liver resection was 274 days (range 29–1725), 344 days (range 35–1639) between first and second and 531 days (range 327–1161) between second and third resection.
The median disease free survival time was 32.61 months (range 1.43–210.46). The t student test on duration of the surgery and blood loss didn't show statistical differences in term of surgical difficulty between the three groups.
One patient who had a second hepatectomy died for MRSA sepsis.
All the other patients did not present perioperative mortality and major complications (Clavien grades III-IV).
The 1–3-5 and 10 year survival rates were respectively 89.2%, 47.7%, 30.4% and 20.2% after the second resection, and after the third resection were 83.3%, 50%, 33.3% and 33.3% respectively at 1–3-5 and 10 years. The comparison between those and the group of only one hepatectomy didn't show any difference.

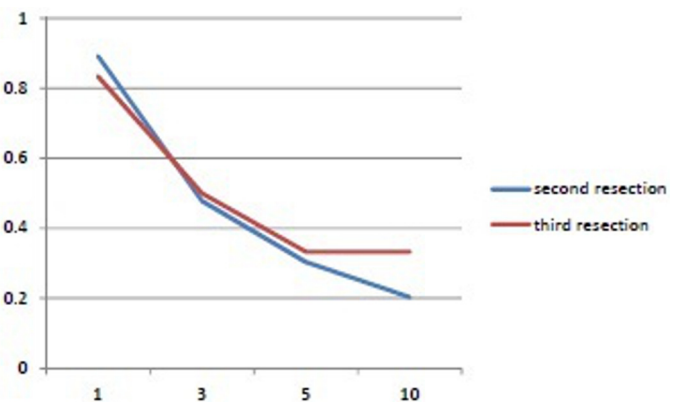

Figure 1. Comparison of survival between patients who had 2 resections and patients who had 3 resections (Kaplan–Meier test).

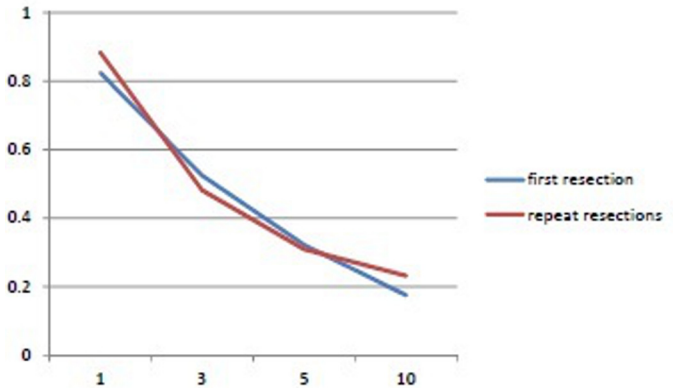

Figure 2. Comparison of survival between patients who had only 1 liver resection for colorectal metastases and patients who had repeat resections.

Conclusions: Definitively repeat resections are safe and improve long term survival.

P0369

CIRCULATING SCCA–IgM COMPLEX IS A USEFUL BIOMARKER TO PREDICT THE OUTCOME OF THERAPY IN HCC PATIENTS

F. Morisco[1], M. Guarino[1], G.G. Di Costanzo[2], A. Gallotta[3], G. Fassina[3], R. Tortora[1], C. Tuccillo[4], R. Granata[1], I. Loperto[1], F. Auriemma[1], N. Caporaso[1]. *[1]Department of Clinical Medicine and Surgery, Gastroenterology Unit, University of Naples "Federico II", [2]Liver Unit, AORN "A. Cardarelli", Naples, [3]Xeptagen SpA, Marghera, Venice, [4]Department of Clinical and Experimental Medicine "F. Magrassi and A. Lanzara", Gastroenterology Unit, Second University of Naples, Naples, Italy*
E-mail: maria.guarino86@gmail.com

Background and Aims: Every year HCC develops in about 3–4% of cirrhotic patients. The squamous cell carcinoma antigen (SCCA) was found elevated in liver cancer specimens by immunohistochemistry and detected by ELISA complexed with IgM (SCCA–IgM) in serum of patients with HCC. This study aimed to evaluate the ability of SCCA–IgM serum levels to predict the efficacy of HCC therapy.
Methods: From April 2012 to April 2014, 218 patients with a new diagnosis of HCC were enrolled in a prospective study. The diagnosis of HCC was made according to the AASLD 2010 guidelines. The patients were staged and treated according to BCLC Staging System; in particular, BCLC stage A and B were treated with loco-regional therapy (RF, LTA, PEI, TACE), and BCLC stage C were treated with Sorafenib. Response to therapy was evaluated with imaging techniques according to the mRECIST criteria. Serum SCCA–IgM levels were determined by the Hepa-IC kit (Xeptagen SpA, Venezia, Italy) at basal time. The quantization of the complex SCCA–IgM was expressed in Arbitrary Units (AU/mL).
Results: At the time of diagnosis, SCCA–IgM was reactive in 168/218 patients (77%), mean±SD: 274.4±263.2 AU/mL. In particular SCCA–IgM was detected in 95/121 (78%) patients with BCLC A and B, and 73/97 (75%) patients with BCLC C, with the mean±SD value of 258.7±280.5 AU/mL and 295.1±242.5 AU/mL, respectively. According to mRECIST criteria, 131/168 (78%) patients showed a positive response to therapy; in particular, 83/95 (87%) of BCLC A and B patients, and 48/73 (66%) of BCLC C patients. In non-responder patients (37/168) levels of SCCA–IgM (median: 165.1 AU/mL, range: 116.8–239.1 AU/mL) were significantly higher than levels measured in patients with partial, complete or stationary response to treatment (median: 126.7 AU/mL, range: 50.0–226.9 AU/mL) (Mann Whitney U Test $p < 0.05$).
Conclusions: These results suggest that the determination of SCCA–IgM complex may be helpful in predicting the response to therapy in patients with HCC.

P0370

ROLE OF GADOXETIC ACID-ENHANCED MAGNETIC RESONANCE IMAGING IN THE LONG-TERM FOLLOW-UP OF SMALL EQUIVOCAL HEPATIC LESIONS IN PATIENTS WITH COLORECTAL CANCER

J.Y. Cho[1], Y.J. Lee[2], H.-S. Han[1], Y.-S. Yoon[1], J. Kim[1], Y. Choi[1], W. Lee[1]. *[1]Surgery, [2]Radiology, Seoul National University Bundang Hospital, Seongnam, Korea, South*
E-mail: jychogs@gmail.com

Background and Aims: The initial abdominal computed tomography (CT) scans of patients with colorectal cancer sometimes reveal equivocal hepatic lesions. We evaluated the outcomes of equivocal hepatic lesions found by CT and the diagnostic accuracy of subsequent liver MRI.
Methods: Between January 1, 2009 and December 31, 2009, equivocal hepatic lesions of <1 cm in size on preoperative CT scans in patients who underwent colorectal cancer resection were included. Gadoxetic acid-enhanced liver MRI was subsequently performed in all patients.
Results: Overall, 121 equivocal hepatic lesions were detected on preoperative CT in 65 out of 494 patients (13.2%) who underwent colorectal surgery. Based on subsequent MRI, 11 lesions were classified as definitive metastatic lesions and 100 were benign lesions. Findings in the other 10 lesions were still inconclusive even after examining CT and MRI. Of the 11 lesions that were classified as metastatic lesion by MRI and were resected, 10 were pathologically confirmed as metastases and one lesion was a benign nodule. All 100 benign lesions were stable on follow-up imaging. Of the 10 equivocal lesions, 6 increased in size during the follow up, suggesting they were early metastases, while 4 were stable. The sensitivity and specificity for detecting liver metastases by gadoxetic acid-enhanced MRI of equivocal hepatic lesions found by CT were 100% (16/16) and 95.2% (100/105), respectively, if MRI was equivocal or indicated definite metastasis. The negative predictive value was 100% (100/100).
Conclusions: MRI is a useful diagnostic tool for assessing equivocal hepatic lesions that require further evaluation.

Ioka[17]. *[1]Surgery, Osaka Medical Center for Cancer and Cardiovascular diseases, Osaka, [2]Clinical Oncology and Pharmacogenomics, [3]Surgery, Kyoto University, Kyoto, [4]Experimental Therapeutics, Exploratory Oncology Research & Clinical Trial Center, National Cancer Center Hospital, Tokyo, [5]Surgery, Osaka University, Suita, [6]Surgery, National Hospital Organization Osaka National Hospital, Osaka, [7]Surgery, Shiga University of Medical Science, Ohtsu, [8]Hepato-Biliary-Pancreatic Surgery, Osaka City University, Osaka, [9]Surgery, Meiwa General Hospital, Nishinomiya, [10]Surgery, Kansai Medical University, Hirakata, [11]Gastroenterological Surgery and Oncology, Kitano Hospital, Osaka, [12]Surgery, Kyoto Prefectural University, Kyoto, [13]Frontier Science for Cancer and Chemotherapy, Osaka University, Suita, [14]Gastroenterology and Hepatology, [15]Biomedical Statistics and Bioinformatics, Kyoto University, Kyoto, [16]Surgery, Kobe University, Kobe, [17]Hepatobiliary and Pancreatic Oncology, Osaka Medical Center for Cancer and Cardiovascular diseases, Osaka, Japan*
E-mail: s-kobayashi@umin.ac.jp

Background and Aims: Gemcitabine/cisplatin combination therapy has been the standard palliative chemotherapy for patients with advanced biliary tract cancer (BTC). We aimed to evaluate the efficacy and safety of adding S-1 to gemcitabine/cisplatin combination therapy for patients with advanced BTC.
Methods: Patients with histologically or cytologically confirmed unresectable or recurrent BTC were eligible for inclusion. The primary endpoint was overall survival. Based on the results of our preceding phase I study, gemcitabine and cisplatin were administered intravenously at doses of 1,000 mg/m^2 or 25 mg/m^2, respectively, on day 1, and oral S-1 was administered daily at a dose of 80 mg/m^2 on days 1–7 every 2 weeks.
Results: Fifty patients enrolled between October 2011 and August 2012 were evaluated. After a median follow-up of 15.1 months (range, 2.4–24.4 months), the median overall survival time was 16.2 months [95% confidence interval (CI), 10.1–22.3 months], and the 1-year overall survival rate was 59.9% (95% CI, 46.2–73.5%). The grade 3–4 hematological toxicities were as follows: neutropenia (32%), anemia (32%), thrombocytopenia (10%), and febrile neutropenia (4%). The common grade 3–4 non-hematological toxicities were biliary tract infection (14%), anorexia/nausea (10%) and fatigue (8%).
Conclusions: Gemcitabine/cisplatin/S-1 combination chemotherapy offered a promising survival benefit with manageable toxicity in patients with advanced BTC. A randomized phase III trial to investigate the efficacy of this regimen compared to gemcitabine/cisplatin combination therapy in patients with advanced BTC is now underway (UMIN000014371/NCT02182778).

E-mail: jp.bronowicki@chu-nancy.fr

Background and Aims: GIDEON was a global observational study of patients with unresectable HCC treated with sorafenib, conducted in 39 countries and 5 global regions. GIDEON established a database of clinically relevant information, allowing retrospective analysis to identify prognostic factors for survival in sorafenib-treated patients.
Methods: Data were collected from >3000 unresectable HCC patients for whom the decision to treat with sorafenib had been made with a life expectancy >8 weeks. The safety population included patients with at least 1 dose of sorafenib and 1 follow-up assessment. Univariate and multivariate analyses were performed using Cox proportional hazards regression models to identify factors affecting their prognoses for survival. OS was paired with the following factors used individually as independent variables for the analyses: age; sex; region; largest tumour size; number of lesions; BCLC score; Child–Pugh status; extrahepatic spread; Child–Pugh status including ascites, bilirubin, albumin, *INR and* encephalopathy; ECOG PS; AFP; response to last previous TACE treatment; number of previous TACE treatments; hepatitis B and C; alcoholism; vascular invasion. Hazard ratios (HRs) with confidence intervals were calculated for each of the independent variables except for non-ordered categorical variables. Multivariable analyses were also performed. HRs were used to judge the strength of association between the dependent and independent variables.

Table: Results of univariate analysis

Variable	N	Hazard ratio	95% confidence interval
BCLC stage	2704	1.665	1.535, 1.807
Child–Pugh status	2717	2.114	1.924, 2.322
Total bilirubin <2, 2–3, >3	2897	1.596	1.469, 1.732
Albumin	2990	1.755	1.629, 1.892
INR <2, 2–3, >3	2408	1.040	0.872, 1.240
Ascites	3101	1.900	1.757, 2.056
Encephalopathy	3081	1.239	0.913, 1.681
ECOG PS	3018	1.680	1.573, 1.794
Extrahepatic spread	3213	1.313	1.189, 1.449
Largest tumour size	3213	1.538	1.395, 1.696
Number of lesions	2907	1.338	1.207, 1.483
Vascular invasion	3213	1.540	1.376, 1.725
Aetiology hepatitis B	3213	1.109	1.002, 1.227
Aetiology hepatitis C	3213	0.869	0.782, 0.966
Alcohol use	3213	1.138	1.032, 1.255
AFP <400, ≥400	2671	2.060	1.849, 2.296

Results: 3213 patients were included in the analyses. Prognostic values of baseline characteristics and staging systems for median

OS are shown in the table with HRs from the univariate analyses. Baseline characteristics and scoring/staging systems, including ECOG PS, Child–Pugh status and BCLC stage, appear to be prognostic factors for OS, as well as albumin, bilirubin and ascites. Encephalopathy and INR are not strong prognostic factors. Measures of extent of disease, including extrahepatic spread, larger tumour size, higher number of lesions and AFP, are prognostic factors of shorter survival time. Child–Pugh score is the most influential prognostic factor. Further analyses will be presented.
Conclusions: GIDEON data indicate that the scoring/staging systems including Child–Pugh status and BCLC stage appear to be useful prognostic factors for OS. The weight of each factor in Child–Pugh score may differ and it may be useful to find a new scoring system that can determine factors for survival in patients treated with sorafenib.

P0373
TWELVE-YEAR OUTCOMES OF RADIOFREQUENCY ABLATION AS FIRST LINE TREATMENT FOR HEPATOCELLULAR CARCINOMA IN MILAN CRITERIA: ANALYSIS OF 804 PATIENTS IN A SINGLE CENTER

S.Y. Jang[1], S.Y. Park[1], W.Y. Tak[1], Y.O. Kweon[1], S. Lee[1], Y.R. Lee[1], M.H. Kim[1], S.J. Yeo[1]. [1]*Internal Medicine, Kyungpook National University Hospital, Daegu, Korea, South*
E-mail: magnolia1103@naver.com

Background and Aims: Radiofrequency ablation (RFA) has been widely performed for treatment of early hepatocellular carcinoma (HCC) as a curative treatment with advantage of minimal invasiveness and safety. Many studies have confirmed the safety and efficacy of RFA for HCC and reported excellent long-term prognosis. The aim of this study is to evaluate 12-year outcomes of RFA as an initial therapy for early HCC in a single center.
Methods: From Nov 2001 to Dec 2013, 804 patients who diagnosed as early HCC (total 804, mean size: 2.1 cm) were treated with percutaneous RFA as an initial option. The mean follow up time was 38.1 months (range: 0–151 months). RFA was performed with ultrasound-guidance to single nodular HCC, less than 5 cm in maximum diameter or multiple (up to 3) nodular HCCs, each diameter should be under 3 cm in maximum. Overall survival and disease free survival rates were estimated by the Kaplan–Meier method and the effect of risk factors on recurrence was assessed by the Cox proportional hazard model.
Results: The study population showed male dominance (male: n = 608, female: n = 196) and mean age was 60.3 years, ranging from 24 to 86 years old. Patients had better Child–Pugh class (A: n = 710, B: n = 93, C: n = 1) and AFP was elevated. (mean: 295.1, range: 0.7–42,690 ng/mL). Treatment failure occurred in 5 patients as mistargeting and insufficient coverage. Cumulative overall survival rates at 1-, 3-, 5-, 10-, 12-year were 92.9%, 83.4%, 59.4%, 42.8%, and 37.5% respectively. Cumulative disease free survival rates at 1-, 3-, 5-, 10-, 12-year were 75.7, 39.0%, 23.1%, 9.8%, and 4.9% respectively. Risk factors for tumor recurrence were age (HR = 1.334; 95% CI 1.102–1.613), tumor number (HR = 1.392; 95% CI 1.149–1.687) and size (HR = 1.260; 95% CI 1.103–1.440), AFP level (>200 ng/mL, HR = 1.324; 95% CI 1.026–1.708), and Child–Pugh score (HR = 2.132; 95% CI 1.656–2.745).
Conclusions: We analyzed the treatment outcome of RFA as first line treatment for early HCC, which showed good results of overall survival and disease free survival. Risk factors for recurrence were age, tumor number and size, AFP level, and Child–Pugh score.

P0374
PROGNOSIS OF EARLY-STAGE HEPATOCELLULAR CARCINOMA: THE CLINICAL IMPLICATION OF SUB-STAGES OF BARCELONA CLINIC LIVER CANCER SYSTEM

C.-W. Su[1,2], W.-Y. Kao[2,3], C.-C. Chang[3], T.-I. Huo[1,4], Y.-H. Huang[1,5], H.-C. Lin[1,2], J.-C. Wu[5,6]. [1]*Division of Gastroenterology, Department of Medicine, Taipei Veterans General Hospital,* [2]*Faculty of Medicine, School of Medicine, National Yang-Ming University,* [3]*Division of Gastroenterology, Department of Medicine, Taipei Medical University Hospital,* [4]*Institute of Pharmacology, School of Medicine,* [5]*Institute of Clinical Medicine, National Yang-Ming University,* [6]*Division of Translational Research, Department of Medical Research, Taipei Veterans General Hospital, Taipei, Taiwan*
E-mail: cwsu2@vghtpe.gov.tw

Background and Aims: Curative therapies are proposed for early-stage hepatocellular carcinoma (HCC) according to the Barcelona Clinic Liver Cancer (BCLC) staging system. We aimed to compare the prognoses between HCC patients in different sub-stages of BCLC stage 0 or A.
Methods: We enrolled 1266 treatment-naïve HCC patients with BCLC stage 0 or A at Taipei Veterans General Hospital from October 2007 to April 2014. Patients were stratified into five (0, A1–A4) sub-stages and factors in terms of overall survival and recurrence were analyzed. Hepatic resection surgery and radiofrequency ablation (RFA) were defined as curative treatment, while transarterial chemoembolization, best supportive treatment, systemic chemotherapy, sorafenib, radiotherapy, and chemo-radiotherapy were regarded as non-curative treatment.
Results: There were 184, 446, 272, 92 and 272 patients in sub-stage 0, A1, A2, A3 and A4, respectively. After a median follow up period of 69.4 months, the cumulative 5-year overall survival rates in these sub-stages were 72.1%, 65.8%, 48.8%, 33.2% and 46.0%, respectively ($p < 0.001$). Patients in the BCLC stage 0 and A1 had comparable prognoses (p = 0.136), and both of them had significantly higher overall survival rates than those in stage A2–A4 (all $p < 0.001$). However, there were no significant differences in overall survival between BCLC stage A2, A3 and A4. Multivariate analysis revealed that factors associated with overall mortality were serum albumin ≤3.5 g/dL ($p = 0.009$), alpha-fetoprotein (AFP) >20 ng/ml ($p < 0.001$), tumor size >3 cm ($p = 0.003$), BCLC stage A2–A4 (p = 0.013), and non-curative treatment (p < 0.001). Besides, there were 1012 patients who underwent curative treatments, including 480 patients with hepatic resection and 532 patients with RFA. Multivariate analysis disclosed that positive for anti-hepatitis C virus (p = 0.010), alanine aminotransferase >40 U/L (p = 0.001), AFP >20 ng/ml (p = 0.005), BCLC stage A2–A4 (p = 0.003), and RFA (p = 0.019) predicted higher incidence of developing recurrence.
Conclusions: The sub-stages of BCLC staging system provided good prognostic stratification for early-stage HCC. Patients with single tumor larger than 2 cm but without significant portal hypertension or jaundice had similar prognosis to those in BCLC stage 0. Moreover, treatment modality was crucial in determining the prognosis of early-stage HCC patients. Curative therapies, especially hepatic resection, should be performed in early-stage HCC.

P0375
THE VALIDATION OF HONG KONG LIVER CANCER STAGING SYSTEM AND COMPARISION WITH BARCELONA CLINIC LIVER CANCER FOR PREDICTION OF SURVIVAL AND TREATMENT IN HEPATOCELLULAR CARCINOMA PATIENTS

H.R. Kim[1], J.H. Kim[1], Y.J. Yoo[1], S.H. Kang[1], Y.S. Lee[1], S.J. Suh[1], Y.K. Jung[1], Y.S. Seo[1], H.J. Yim[1], J.E. Yeon[1], K.S. Byun[1]. [1]*Internal medicine, Korea University College of Medicine, Seoul, Korea, South*
E-mail: haerami@gmail.com

Background and Aims: In addition to world widely endorsed BCLC system, various algorithms and staging systems were developed in

many organizations, including the Hong Kong Liver Cancer (HKLC) staging. We validated the HKLC system and compared it with BCLC in HCC patients.
Methods: The medical records of 875 HCC patients from 2004 to 2009 were retrospectively reviewed. The data including performance status, Child–Pugh score, tumor characteristics, treatment modality and survival were collected.
Results: The etiology was predominantly chronic hepatitis B (CHB) (71.2%) and 90% of patients had child A and B liver function. Median follow up duration was 21.7 (0–178) months. Seventy-five percent of patients died during study period and median overall survival was 22.6 (0–181) months. The median overall survival was 45.44, 25.25, 21.25, 6.58, 3.19, 3.50, 3.00, 13.50 and 1.95 months in HKLC stage I, IIa, IIb, IIIa, IIIb, IVa, IVb, Va and Vb, respectively. Both HKLC and BCLC well differentiated the survival ($p < 0.001$). However, HKLC significantly well predicted 1 and 2 year of survival than BCLC (AUROC; 0.833 vs 0.801, $p = 0.0027$; 0.826 versus 0.799 in 2 year, $p = 0.0144$). In the patients in BCLC B and HKLC II, the curative therapy group recommended by HKLC showed better survival compared to TACE which recommended by BCLC (median overall survival; 55.57 vs. 28.22 months, $p = 0.013$). In BCLC B, the patients who treated according to HKLC showed better survival than who treated by BCLC (median overall survival; 45.34 vs. 31.00 months, $p = 0.004$). In BCLC subclass B1, the curative therapy was superior to TACE (median overall survival; 55.57 vs. 28.12 months, $p = 0.038$), while the differences were not significant in BCLC B2 and B3. In the patients in BCLC C and HKLC II, the curative therapy group recommended by HKLC showed better survival compared to systemic therapy which recommended by BCLC (median overall survival; 51.10 vs. 6.57 months, $p < 0.001$). Also, in BCLC C and HKLC III, the TACE group recommended by HKLC showed better survival compared to systemic therapy which recommended by BCLC (median overall survival; 15.78 vs. 5.87 months, $p = 0.007$).
Conclusions: The HKLC system showed better survival compared to BCLC system in our population. The more individualized therapy could be considered by HKLC for management of HCC patients to improve prognosis.

P0376
STRATIFICATION OF HEPATOCELLULAR CARCINOMA. THE PROGNOSTIC SCORE NIACE, AN ADDITIONAL AID TO THE BARCELONA CLINIC LIVER CANCER (BCLC) STAGING SYSTEM? MULTICENTER STUDY

X. Adhoute[1], G. Penaranda[2], J.-F. Blanc[3], J. Edeline[4], S. Naude[5], H. Perrier[1], O. Monnet[6], P. Castellani[1], V. Oules[1], O. Bayle[6], G. Conroy[5], S. Benali[1], G. Lefolgoc[1], B. Pol[7], J.-P. Bronowicki[5], J.-L. Raoul[8], M. Bourliere[1]. *[1]Hepatology, Hepatology Department Hôpital Saint-Joseph, [2]Biostatistics, Alphabio Laboratory, Marseille, [3]Hepatology, CHU Saint-André, Bordeaux, [4]Oncology, Centre Eugène Marquis, Rennes, [5]Hepatology, CHU Vandoeuvre les Nancy, Nancy, [6]Radiology, [7]Hepatobiliary Surgery Hôopital Saint-Joseph, [8]Oncology, Institut Paoli-Calmettes, Marseille, France*
E-mail: adhoute.xavier@neuf.fr

Background and Aims: NIACE score: 1×(Nodules 0 if <3, 1 if ≥3) + 1.5×(Infiltrating 0 if no, 1 if yes) + 1.5×(AFP: 0 if <200, 1 if ≥200 ng/ml) + 1.5×(Child–Pugh 0 if A, 1 if B) + 1.5×(ECOG PS 0 if 0, 1 if ≥1), distinguishes 2 groups with different survival [3 external validation cohorts of 543 BCLC C patients (pts)], regardless of treatment (poster session 1329 AASLD 2014).
To confirm the prognostic value of NIACE score in BCLC A, BCLC B HCC pts, regardless of treatment (excluded transplantation). To assess the NIACE score in HCC pts treated by transarterial chemoembolization (TACE) or Sorafenib.
Methods: Were selected over a period of 5 years (Marseille, Nancy, Rennes, Bordeaux): BCLC A pts n = 128, BCLC B pts n = 195; pts treated by TACE n = 230; BCLC C pts treated by Sorafenib n = 285. Evaluation of NIACE score on the entire cohort.
Results: In BCLC A pts NIACE distinguished with a threshold value ≤1, 2 groups with a different survival: NIACE ≤1 n = 85, 38 months [35–51] vs. >1 n = 43, 24 months [19–35] $p = 0.0042$.
In BCLC B pts, NIACE distinguished with a threshold value ≤2.5, 2 groups with a different survival: Marseille NIACE ≤2.5 n = 73, 22 months [18–27] vs. >2.5 n = 31, 13 months [9–16] $p = 0.0002$; Nancy NIACE ≤2.5 n = 85, 27 months [23–36] vs. >2.5 n = 6, 13 months [13–23] $p = 0.0015$.
NIACE score applied to HCC pts (BCLC A, B, C) treated by TACE, distinguished with a threshold value ≤2.5, 2 groups with a different survival: Marseille NIACE ≤2.5 n = 160, 28 months [26–35] vs. >2.5 n = 70, 9.6 months [7–12] $p < 0.0001$.
NIACE score applied to HCC pts (BCLC C) treated by Sorafenib, discerned with a threshold value <3, 2 groups with a different survival: Nancy NIACE <3 n = 28, 16 months [14–25] vs. ≥3 n = 55, 6 months [4–8] $p < 0.0001$; Rennes NIACE <3 n = 37, 10.6 months [4.1–17.1] vs. ≥3 n = 46, 5.1 months [2.9–7.4] $p < 0.0001$; Bordeaux NIACE <3 n = 44, 11.3 months [8.1–15.9] vs. ≥3 n = 75, 6 months [4.3–7.6] $p < 0.0001$.
Whatever the stage, the type of treatment, the probability of survival were significantly different between the different score's value and the score variation was correlated with the survival.
Conclusions: This study suggests the ability of NIACE score to discern among BCLC A, B, C HCC subgroups with different prognosis. This score may be also an aid to the decision making process, because it discerns among patients treated by TACE or Sorafenib, subgroups with different prognosis.
The NIACE score should be assessed in prospective studies to confirm its prognostic value and permit a sub classification of HCC useful for clinicians

P0377
TUMOR NUMBER IMPROVES THE PROGNOSTIC VALUE OF HEPATOMA ARTERIAL-EMBOLIZATION SCORE IN PATIENTS WITH HEPATOCELLULAR CARCINOMA TREATED WITH CHEMOEMBOLIZATION

Y. Park[1], S.U. Kim[1], B.K. Kim[1], J.Y. Park[1], D.Y. Kim[1], S.H. Ahn[1], Y.E. Park[2], J.H. Park[2], Y.I. Lee[2], H.R. Yun[2], K.-H. Han[1]. *[1]Internal Medicine, Institute of Gastroenterology, [2]Internal Medicine, Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, South*
E-mail: ksukorea@yuhs.ac

Background and Aims: The hepatoma arterial-embolization prognostic (HAP) score predicts survival outcome in patients with hepatocellular carcinoma (HCC) undergoing transarterial chemoembolization (TACE). We tried to validate HAP score in Korean subjects with HCC and investigated whether the prognostic performance of HAP score can be improved using additional clinical parameters.
Methods: A total of 280 patients with unresectable HCC treated with TACE between January 2003 and December 2009 were included. Validation and subsequent modification of HAP score was performed based on multivariate Cox regression models for overall survival (OS).
Results: The mean age of the study population (men 211 and women 69) was 59 years. Viral etiology of HCC accounted for 80.4% (n = 181 and 44 for hepatitis B and C virus). The median OS was 40.5 (95% confidence interval 34.0–47.0) months. On multivariate analysis, together with the original components of HAP score (serum albumin <3.6 g/dL, total bilirubin >0.9 mg/dL, alpha-fetoprotein >400 ng/mL, and tumor size >7 cm), tumor number ≥2 was selected as an independent unfavorable prognostic factor for OS (hazard ratio 2.3; $P < 0.001$). Accordingly, a modified HAP score by adding tumor number (HAPN) was established. Although both HAP and HAPN score discriminated the four different risk groups (log-rank test $P < 0.001$), HAPN score performed significantly better

than HAP score: areas under receiver operating curves for OS at 1 year (0.763 vs. 0.733), 3 years (0.717 vs. 0.658), and 5 years (0.728 vs. 0.645), respectively (all P < 0.05).
Conclusions: HAP score accurately predicted OS for Korean subjects with HCC undergoing TACE. However, addition of tumor number to the HAP score (HAPN score) improved the prognostic performance significantly. HAPN score might be useful in accurate prognostication and selection of optimal candidates for TACE.

P0378
TIME TO PROGRESSION OF AFP IS AN INDEPENDENT PROGNOSTIC FACTOR OF SURVIVAL IN HEPATOCELLULAR CARCINOMA TREATED WITH SORAFENIB. INTERNAL VALIDATION

M. Varela[1], L. Blanco-García[1], O. Castaño-Fernández[1], M.L. González-Diéguez[1], V. Cadahía-Rodrigo[1], C. Álvarez-Navascués[1], R. Pérez-Álvarez[1], A. Mesa[2], L. Hernández-Luyando[2], M. Rodríguez[1], Multidisciplinary team of hepatocellular carcinoma of Hospital Universitario Central of Asturias, Oviedo, Spain. *[1]Liver Unit, [2]Radiology, Hospital Universitario Central de Asturias, Oviedo, Spain*
E-mail: maria.varela.calvo@gmail.com

Background and Aims: Previously (JCT, 2014) we have showed that *time to progression of AFP* (TPA) is an independent indicator of overall survival (OS) in hepatocellular carcinoma (HCC) treated with sorafenib (SOR), just considering baseline characteristics. TPA was defined as the period of time since beginning of SOR until the moment in which AFP increases >20 ng/mL or it starts to rise from the nadir. The greater the TPA the greater is the survival. In this study we expand and refine the previous cohort and consider other factors that appear over time, in order to asses if TPA remains useful.
Methods: Unicentric prospective cohort recruited from JUL-07 to FEB-14, followed up until 23 October 2014. Patients without cirrhosis, ECOG-PS >2 and Child >7 (n = 29) were excluded. SOR was administered at the maximum tolerated dose until clinical progression, patient desire or serious adverse event. First radiologic control made at week 12, then every 16w. We analyzed baseline characteristics, side effects, TPA at day 90, time to radiologic progression and dose modifications.
Results: 121 consecutive patients were included: Child A–B7 (106–15), ECOG PS 0–1 (92–29); 36 BCLC-B, 85 BCLC-C. Basal AFP 45.8 ng/mL. Median duration of SOR was 8 months (P_{25}–P_{75}: 4–26). Median OS since the beginning of SOR to 2nd line therapy (n = 4), death (n = 92) or last visit was 12 months (P_{25}–P_{75}: 6–30).
Predictors of OS in univariate analysis: age (p = 0.003); symptoms [ECOG (0 vs 1): 18 vs 5 months; p < 0.001]; Child–Pugh [A vs B: 16 vs 8 months; p = 0.019]; BCLC [B vs C: 28 vs 10 months; p < 0.001]; hypertension and dermatological effects are associated with increased OS but p = 0.202, p = 0.357, respectively. The maximum tolerated dose (p = 0.037), duration of treatment (p < 0.001) and time to radiologic progression (p < 0.0001) are also associated with increased OS. Finally, patients with TPA >90 days have significantly higher OS than those with TPA ≤90 [23 months (95% CI: 14–32) vs 9 months (95% CI: 7–11), p = 0.0002].
Predictors of overall survival in the multivariate analysis: time to radiologic progression [p = 0.026], duration of SOR [p = 0.023], baseline ECOG PS [p = 0.001; HR 0.397 (95% CI: 0.234–0.673)] and TPA [p = 0.002; HR 2.144 (95% CI: 1.315–3.495)].
Conclusions: TPA maintains its prognostic value in patients with HCC treated with SOR, regardless of other baseline or time-dependent covariates. TPA can be a useful tool to help in the decision of passing to second-line treatment. External validation of this marker is warranted.

P0379
CANCER RELATED SYMPTOMS (PERFORMANCE STATUS 0 VS 1) DETERMINE PROGNOSIS OF HEPATOCELLULAR CARCINOMA PATIENTS TREATED WITH SORAFENIB. ANALYSIS OF A PROSPECTIVE DATA COLLECTION IN 207 PATIENTS

M. Varela[1], M. Reig[2], C. Álvarez Navascués[1], A. Forner[2], V. Cadahía[1], Á. Díaz[2], M.L. González-Diéguez[1], N. Llarch[2], M. Rodríguez[1], J. Bruix[2]. *[1]Liver Unit, Hospital Universitario Central de Asturias, Oviedo, [2]Liver Unit, Barcelona Clínic Liver Cancer (BCLC) Group, Hospital Clínic Barcelona, IDIBAPS, University of Barcelona. CIBERehd, Barcelona, Spain*
E-mail: mreig1@clinic.ub.es

Background and Aims: *Background:* All the studies that analyze sorafenib in hepatocellular carcinoma (HCC) include a wide spectrum of patients and the majority neglect the impact of the performance status (PS) for the prediction and analysis of overall survival (OS). *Aim:* To analyze the impact of baseline performance status (PS) and Child–Pugh score (CP) on the OS.
Methods: We analyzed 2 independent prospective cohorts of HCC patients treated with sorafenib between March 2008 and July 2011 [training cohort (TC) from the BCLC (n = 143) and validation cohort (VC) from Asturias (n = 64)]. Patients with PS >1 and Child–Pugh >7, encephalopathy and clinical ascites were excluded.
Results: Table 1 shows the baseline characteristics. The median treatment duration and OS were 6.7/11.7 months in the TC and 8.2/16.4 months in VC. PS was the only independent predictor of OS in both cohorts [TC: PS 0 vs. PS 1, HR 1.86 (1.12–3.1), p = 0.017; VC: HR 2.97 (1.73–5.11), p < 0.001]. Thereby, median OS according to PS was: PS 0 = 13.1 vs PS 1 = 5.4 months; p < 0.001 in the TC, and PS 0 = 21.1 months vs PS 1 = 5.9 months; p = 0.001 in the VC. Tumor burden, biochemistry parameters including AFP and CP stage were not significant. Median OS of CPA and CPB were not statically different [CP A 12.1 (n = 121)/B7 10.9 months (n = 22), p = 0.215 in TC; and CP A 16.9 (n = 60)/B7 3.9 months (n = 4), p = 0.411 in VC]. The impact of PS was maintained irrespective of BCLC-C stage. In the TC the median OS of "BCLC-C, CP A, PS 0" vs. "BCLC-C, Child–Pugh A, PS 1" was 9.9 vs. 5.4 months for "BCLC-C, CPB 7, PS 0" and 17.9 vs. 5.9 months for "BCLC-C, CP 7, PS 1". Presence of image detected ascites at baseline did not determine a different OS (p = 0.593).

Table 1.

Baseline characteristic	Training cohort (BCLC), n = 143	Validation cohort (HUCA), n = 64
Age, median [range]	64.13 [35–80]	64.81 [27–80]
Male/Female, n	122/21	50/14
HCV/Ethanol/HVB/others, n	83/39/14/7	25/26/5/8
Child–Pugh A/B, n	121/22	60/4
Performance status, 0/1, n	121/22	45/19
BCLC stage, B/C, n	73/70	18/46

Conclusions: The differentiation between PS0 and PS1 is key to predict the prognosis of patients with preserved liver function who initiate sorafenib treatment and to analyse their outcome. Differentiation between Child–Pugh score A and B7 does not have predictive capacity and thus, lacks adequate stratification capacity in this population.

P0380
NEW RECOGNIZATION OF THE NATURAL HISTORY AND GROWTH PATTERN OF HEPATIC HEMANGIOMA IN ADULTS

J. Li[1], Y. Yan[1], L. Huang[1], C. Liu[1], J. Yan[1], F. Xu[1]. *[1]Department of hepatic surgery I, Eastern Hepatobiliary Surgery Hospital, Second Military Medical University, Shanghai, China*
E-mail: ehbhyyq@163.com

Background and Aims: Treatment indications for hepatic hemangioma are still not clearly defined due to limited and inconsistent data that are available on the natural history of hepatic

hemangiomas and on their tendency to increase in size or to cause complications. This prospective cohort study was design to investigate the natural history and growth pattern of hepatic hemangioma in adults.
Methods: From April 2010 to March 2013, adult patients with hepatic hemangioma were screened and those who had no prior treatment to the hemangioma were enrolled. A routine follow-up was performed to observe the natural history and the tendency to cause complications of the lesions.
Results: A total of 236 patients were enrolled in the study. The median size of hemangiomas was 4.5 cm (range 0.6–19.2 cm). During a median follow-up period of 48 months (range 3–266 months), 61.0% patients had hemangiomas increased in size, 23.7% patients had stable lesions, and 8.5% patients had hemangiomas decreased in size. The peak growth period of hemangiomas was in patients <30 years age (0.46±0.41 cm per year) and the growth rate decreased significantly after 50 years of age (0.21±0.40 cm per year). Hemangiomas with size <2 cm had the lowest growth rate (0.16±0.42 cm per year). The peak growth rate of hemangiomas size was 8–10 cm (0.80±0.62 cm per year), then decreased rapidly to 0.47±0.91 cm per year while the hemangiomas >10 cm. Only 9 patients had severe symptoms caused by hepatic hemangioma, of which 3 were safely managed by observation. No patients presented with hemangioma-related complications.
Conclusions: Majority of hepatic hemangiomas have the tendency to increase in size but rarely cause complications. All the hemangiomas can be safely managed by observation, and no preventive treatment is required regardless of hemangioma size.
Chinese Clinical Trial Registry, number ChiCTR-OCS-11001298.

P0381
CLINICAL IMPACT OF ACHIEVING SUSTAINED VIROLOGICAL RESPONSE IN HEPATITIS C VIRUS-INFECTED PATIENTS WITH EARLY STAGE HEPATOCELLULAR CARCINOMA

K. Tsuchiya[1], Y. Asano[1], N. Tamaki[1], Y. Yasui[1], S. Suzuki[1], T. Hosokawa[1], H. Nakanishi[1], J. Itakura[1], M. Kurosaki[1], N. Izumi[1].
[1]*Department of Gastroenterology and Hepatology, Musashino Red Cross Hospital, Tokyo, Japan*
E-mail: tsuchiyakaoru5@gmail.com

Background and Aims: Because novel direct-acting antivirals against hepatitis C virus (HCV) improve sustained virological response (SVR) rates, the number of SVR patients with advanced fibrosis has been increasing. Therefore, the number of patients who develop hepatocellular carcinoma (HCC) after achieving SVR is expected to increase. We analyzed the clinical impact of SVR in patients with early stage HCC.
Methods: The cohort, comprising 679 early stage HCC patients with positive HCV antibodies, received an initial radiofrequency ablation (RFA) at our hospital. The cumulative recurrence rates of HCC, the dropout from the Milan criteria, and the survival rates were assessed and compared between SVR patients and non-SVR patients. Those patients who achieved SVR before initial RFA were defined as SVR patients.
Results: Between April 1997 and October 2014, 679 patients [mean age 70 years; males/females (M/F) 371/308; Child–Pugh class A/B/C 618/61/0] received RFA as an initial therapy. Overall, the cumulative survival rates at 1, 3, 5, 7, and 10 years were 97%, 89%, 70%, 55%, and 38%, respectively. The cumulative dropout rates from the Milan criteria at 1, 3, and 5 years were 13%, 41%, and 57%, respectively. The Child–Pugh scores of SVR patients (n = 32) were significantly lower than those of the non-SVR patients, and the cumulative survival rates were significantly higher than those of the non-SVR patients (5-year survival rate 76% vs 70%, p = 0.028). There was no significant difference in the cumulative recurrence rates of HCC between the SVR and non-SVR patients. Furthermore, to exclude the influence of liver function, we analyzed these rates in patients with a Child–Pugh score of 5 points. In patients with this score at the initial RFA, there was no significant difference in the cumulative survival rates, the recurrence rates, and the dropout from the Milan criteria between the SVR patients (n = 25) and non-SVR patients (n = 193).
Conclusions: The recurrence rates and the dropout from the Milan criteria in patients who developed HCC after achieving SVR were not low. In patients with a Child–Pugh score of 5 points, the overall survival was similar between the SVR and non-SVR patients. New agents that prevent the recurrence of HCC are necessary for patients who develop HCC after achieving SVR.

P0382
ANGIOTENSIN II TYPE 1 RECEPTOR ANTAGONISTS AS ADJUVANT THERAPY FOR HEPATOCELLULAR CARCINOMA PATIENTS TREATED WITH RADIOFREQUENCY ABLATION

A. Facciorusso[1], V. Del Prete[1], N. Crucinio[1], A. Di Leo[1], M. Barone[1].
[1]*Gastroenterology Unit, University of Foggia, Foggia, Italy*
E-mail: antonio.facciorusso@virgilio.it

Background and Aims: Preliminary data report beneficial effects of inhibitors of angiotensin II converting enzyme (ACE I) in decreasing hepatocellular carcinoma (HCC) recurrence after radical therapies. However, ACE I treatment was effective only in combination to other drugs and did not seem to improve significantly overall survival (OS). On the other hand, data on the adjuvant role of angiotensin II receptor 1 antagonists (sartans) are still lacking.
Aim of this study was to evaluate whether sartan therapy administered to hypertensive patients is associated to better outcomes in HCCs treated with radiofrequency ablation (RFA).
Methods: Data on 153 patients treated with RFA were reviewed. Study population was classified in three groups: patients who received neither ACE I nor sartans (Group 1), those under ACE I treatment (Group 2) and patients who received sartans (Group 3). Patients under antihypertensive therapy had been given sartans or ACE I for at least two years before RFA. Overall survival (OS) and time to recurrence (TTR) were analyzed by means of Kaplan–Meier analysis and compared with log-rank test. Antihypertensive therapy was entered in a Cox proportional model with all the main baseline clinical and tumoral parameters and tested for post-treatment outcomes in uni-multivariate setting.

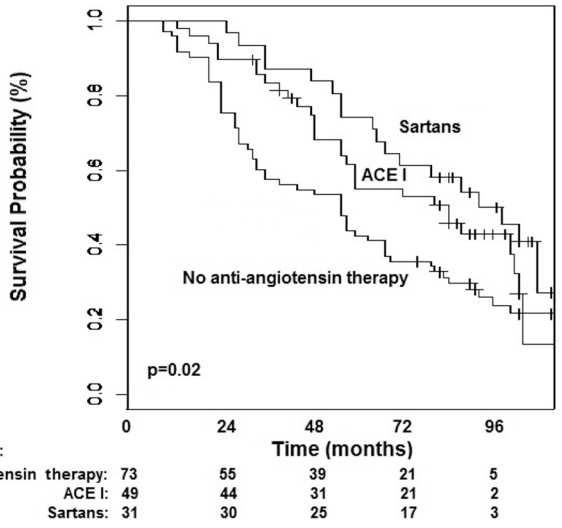

Figure 1.

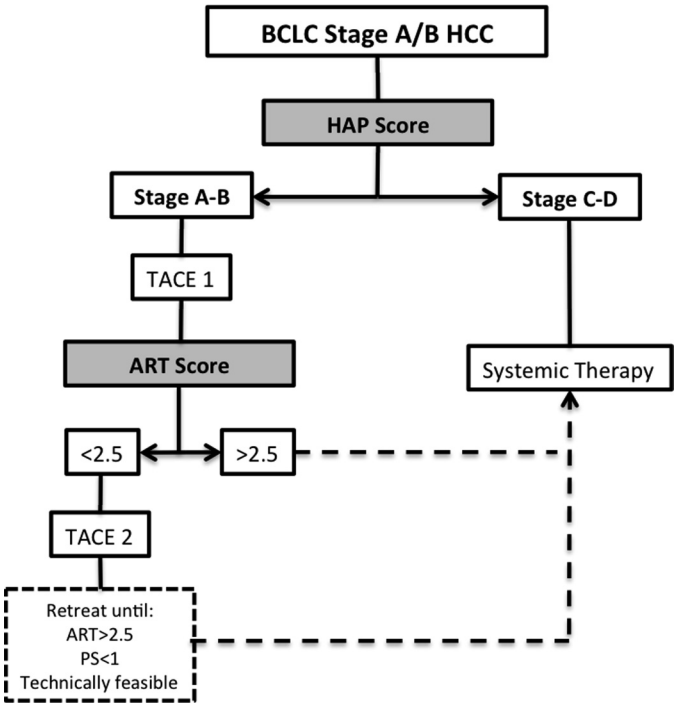
Results: Group 1 consisted of 73 (47.8%) patients, while 49 (32%) and 31 (20.2%) were in group 2 and 3, respectively. In the whole study population, median age was 68 years (range 39–86), 87.8% of patients were in Child–Pugh (CP) A score and 92% in Barcelona Clinic Liver Cancer (BCLC) A stage. Median maximum diameter

was 30 mm (10–40) and alpha-fetoprotein (AFP) was 25 (1.1–2100) UI/mL. No differences in baseline characteristics among the three group were reported.
Median OS was 48 months (95% confidence interval: 31–58) in group 1, 72 months (49–89) in group 2 and 84 (58–92) in group 3 (Figure 1; p = 0.02). Median TTR was 26 (15–42), 44 (33–72) and 69 (44–74) months in the three groups, respectively (p = 0.02). Sartan therapy resulted significant predictor of longer OS (HR: 0.39, 95% CI: 0.22–0.66; p = 0.04) and delayed TTR (HR: 0.47, 95% CI: 0.27–0.82; p = 0.02) at multivariate analysis.
Conclusions: Sartan therapy given to hypertensive patients resulted effective as adjuvant treatment in HCCs treated with RFA.

P0383
COMBINED SEQUENTIAL USE OF HAP AND ART SCORES TO PREDICT TRANSARTERIAL CHEMOEMBOLIZATION FAILURE IN HEPATOCELLULAR CARCINOMA: A MULTI-CENTER COMPARATIVE STUDY

D.J. Pinato[1], T. Arizumi[2], J.W. Jang[3], E. Allara[4], P. Suppiah[1], C. Smirne[5], G. Grossi[5], M. Pirisi[5], M. Kudo[2], R. Sharma[1].
[1]Experimental Medicine, Imperial College London, London, United Kingdom; [2]Gastroenterology and Hepatology, Kinki University School of Medicine, Osaka, Japan; [3]Internal Medicine, Catholic University of Korea, Incheon, Korea, South; [4]Public Health, Università degli Studi di Torino, Turin, [5]Internal Medicine, Università degli Studi del Piemonte Orientale, Novara, Italy
E-mail: david.pinato09@imperial.ac.uk

Background and Aims: The prognosis of patients with hepatocellular carcinoma (HCC) undergoing transarterial chemoembolization (TACE) is variable. We compared HAP and ART scores, established prognostic models in HCC, for accuracy of overall survival (OS) prediction.
Methods: Prognostic scores were studied in 83 consecutive unselected subjects with Barcelona Clinic Liver Cancer (BCLC) A/B stage from UK and Italy (training set) and 660 from Korea and Japan (validation set) all treated with conventional TACE using multivariate Cox regression and c-index analysis.



Results: In both training and validation sets, HAP (Hazard Ratio [HR] 3.1, 95% CI 1.8–5.3) and ART scores (HR 3.1, 95% CI 1.5–6.7) emerged as independent predictors of survival (p < 0.01) with HAP achieving better prognostic accuracy (c-index: 0.68) over ART (0.57). Subgroup analysis of BCLC-C patients receiving TACE (n = 63) revealed advanced HAP stage (p < 0.001) and radiological progression after initial TACE (p < 0.001) as adverse prognostic factors.
Conclusions: HAP and ART scores are validated indices in HCC patients undergoing initial TACE. In intermediate stage HCC, the HAP score is best suited for screening patients prior to initial TACE, whilst sequential ART assessment may improve early detection of chemoembolization failure. A separate, exploratory analysis of BCLC-C patients revealed that subjects with advanced HAP and early progression after initial TACE should not be considered for repeat TACE. We propose sequential integration of HAP and ART (Figure 1) to optimise TACE administration in patients within BCLC-B criteria.

ASSESSMENT OF TREATMENT RESPONSE BY SEQUENTIAL SERUM METABOLOMIC PROFILING AFTER PERCUTANEOUS RADIOFREQUENCY ABLATION OF HEPATOCELLULAR CARCINOMA

C. Goossens[1], P. Nahon[2], L. Le Moyec[3], M.N. Triba[1], N. Bouchemal[1], R. Amathieu[4], N. Ganne-Carrié[5], M. Ziol[6], J.-C. Trinchet[5], A. Diallo[7], O. Seror[8], P. Savarin[1]. *[1]Université Paris 13, Sorbonne Paris Cité, CSPBAT, UMR 7244, CNRS, Bobigny, [2]Service d'Hépatologie, Hôpital Jean Verdier, Bondy, [3]Université d'Evry Val d'Essonne, UBIAE, INSERM U902, Evry, [4]Service d'Anesthésie et des Réanimations Chirurgicales, Hôpital Henri Mondor, Créteil, [5]Service d'Hépatologie, Hôpital Jean Verdier, [6]Service d'Anatomopathologie, Hôpital Jean Verdier, [7]Département MSI, Hôpital Jean Verdier, [8]Service de Radiologie, Hôpital Jean Verdier, Bondy, France*
E-mail: corentine.goossens@gmail.com

Background and Aims: Radiofrequency Ablation (RFA) is commonly performed as a curative approach in patients with HCC. However, the risk of tumour recurrence is difficult to predict due to a lack of viable clinical and biological markers. Metabolomics appears to be a promising technique leading to the identification of new biomarkers. The aim of this work was to assess changes in serum metabolomic profiling of patients treated by RFA and to study their potential ability to predict tumour recurrence.
Methods: Sequential sera obtained before and after RFA procedure in 120 patients with HCC fulfilling Milan criteria developed in cirrhosis were investigated using Nuclear Magnetic Resonance (NMR) metabolomics. Sequential sera samples were drawn at 3 different points (before RFA, one day post procedure and at evaluation of efficacy within 3 months after RFA). With the combination of classical multivariate data analysis such as Principal Component Analysis (PCA) and Orthogonal Partial Latent Structure (OPLS), a multilevel OPLS analysis was also used in order to discriminate the metabolic intra-individual changes caused by the RFA intervention. Patients were prospectively followed-up and recurrence-free survival was studied.
Results: A specific serum metabolic fingerprint of the RFA procedure could be identified. Major changes of metabolites in the sera linked to the RFA intervention included an increase in the concentration of lactate, glutamine, 3-phenylpropionate and a decrease in the concentration of isoleucine, proline, N-acetyl functions of glycoproteins and phosphocholine-glycerophosphocholine (PC-GPC) post-RFA. Furthermore, two distinct serum metabolic profiles of HCC patients were identified according to viral or non-viral aetiology of liver disease, this distinction being further observed with specific and distinct metabolic responses after RFA procedure. During a median follow-up of 55 months, 61 (48%) patients experienced HCC recurrence. Among the viral-related HCC patients, those who were the better discriminated by the metabolomic profiles presented a

*Trend of correlation

Figure 1 (abstract P0384). Multilevel OPLS-DA score plot (A) and loading plot (B) of the within subject variation obtained from serum viral HCC patients before RFA, t0 (blue) and after 1–4 months post-RFA, t2 (red) (42 patients). Variations of metabolites are represented using a line plot between 0–4.5 ppm and are summarized in tabular form (C). Positive signals correspond to metabolites present at increased concentrations in the taken sera 1–4 months post-ablation period (t2). Conversely, negative signals correspond to metabolites present at increased concentrations in sera taken during pre-ablation period (t0).

lower rate of recurrence (58% *vs.* 81%, $P = 0.02$) than patients with a lower discrimination between their pre-RFA and delayed samples.
Conclusions: RFA in HCC patients leads to profound changes in the serum metabolome that further seem to be specific of the aetiology of liver disease. Sequential assessment of serum metabolomic profiles during follow-up of these patients provides new biomarkers of treatment efficacy and may help to predict HCC recurrence.

P0385
PROGNOSTIC IMPACT OF THE BAVENO IV STAGING SYSTEM OF PORTAL HYPERTENSION IN PATIENTS WITH CIRRHOSIS AND HEPATOCELLULAR CARCINOMA

F. Hucke[1], E. Pachta[1], T. Reiberger[1], M. Mandorfer[1], W. Sieghart[1], M. Peck-Radosavljevic[1]. [1]*Department of Gastroenterology/Hepatology, Medical University of Vienna, Vienna, Austria*
E-mail: florian.hucke@meduniwien.ac.at

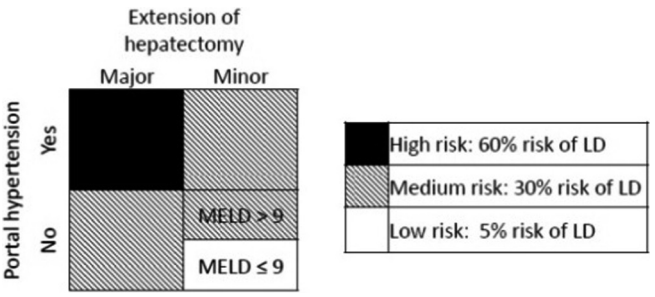
Background and Aims: D'Amico et al. proposed a portal hypertension (PTH)-staging system for patients with liver cirrhosis, which was acknowledged by the Baveno IV consensus workshop on methodology of diagnosis and therapy in PHT.
Here, we investigated the prognostic impact of this PTH-staging system in patients cirrhosis and the hepatocellular carcinoma (HCC).
Methods: Patients with liver cirrhosis diagnosed with HCC between 1994 and 2012 treated with non-surgical therapies at the Medical University of Vienna were included (n = 790). The PTH staging system (stage 1: no ascites/varices, stage 2: varices/no ascites; stage 3: ascites +/− varices; stage 4: bleeding +/− ascites) and several other clinically important parameters of liver function and tumor load were entered into univariate analysis. Variables with a p-value <0.05 were included into a multivariate Cox-regression model.
Additionally, the prognostic role of beta-blocker (BB) therapy was investigated in patients with PTH-stage >1.
Results: The PTH staging system was significantly associated with overall survival (OS) on univariate analysis and remained a significant prognostic factor upon multivariate analysis independent from BCLC stage, Child–Pugh stage, CRP-levels, MELD-score and tumor load. The median OS for PTH-stage 1/2/3/4 was 22/14/4/6 months ($p < 0.001$). Of 585 patients with PTH-stage >1, only 179 received betablocker-therapy which was associated with better median OS (BB vs. no BB: 10.2 vs. 5.8 months, $p = 0.026$).
Conclusions: The Baveno IV PTH staging system was an independent prognostic factor in patients with HCC. We noticed a severe under usage of BB in patients with portal hypertension and HCC. Patients who received BB had a significant better outcome than those without BB.

P0386

PREDICTING LIVER DECOMPENSATION AFTER RESECTION FOR HEPATOCELLULAR CARCINOMA: A RECURSIVE PARTITIONING ANALYSIS OF PROGNOSTIC FACTORS

D. Citterio[1], C. Sposito[1], A. Facciorusso[2], M. Flores Reyes[1], M. Mazzola[1], V. Mazzaferro[1]. [1]*Hepato-Pancreato-Biliary Surgery and Liver Transplantation Unit, National Cancer Institute (Istituto Nazionale Tumori), Milan,* [2]*Gastroenterology Unit, University of Foggia, Foggia, Italy*
E-mail: davide.citterio@istitutotumori.mi.it

Background and Aims: Liver resection (LR) is the treatment of choice for hepatocellular carcinoma (HCC) in well compensated liver cirrhosis. Various grades of liver decompensation (LD) after LR represent an important cause of morbidity and mortality difficult to predict preoperatively. Aim of this study was to define risk classes for LD based on preoperative variables.
Methods: In a single western institution, 543 HCC patients underwent resection over a 10 years period. Postoperative complications were recorded according to Dindo–Clavien's classification (DCC). LD was defined as postoperative occurrence of any of the following conditions associated with a DCC >1: clinically detectable ascites, prothrombin time <70% or bilirubin >3 mg/dL. Pre-operatively, clinically relevant portal hypertension (PH) was defined by the presence of esophageal varices or the coexistence of low platelet count ($<100\times10^3/mm^3$) and spleen diameter >120 mm. Major resection was defined as removal of 3 or more adjacent segments. Logistic regression was performed to identify risk factors to be included in a Recursive Partitioning Analysis (RPA) model in order to identify risk classes predicting LD on the basis of preoperative conditions.
Results: Median age of the patients was 68 years (IQR 62–73). 287 were HCV (52.8%). Most patients presented a well-preserved liver function, being 93.5% in Child–Pugh A with a median MELD score of 8 (IQR 7–10); PH was present in 163 (30%) cases. BCLC staging was: 0 in 76 (14%), A in 381 (70.2%), B in 64 (11.8%), C in 22 (4%). Major resections were 105 (19.3%) and minor 438 (80.7%). LD occurred in 108 patients (20%); logistic regression identified PH, major liver resection and MELD >9 as independent predictors of LD. RPA classifications identified three risk classes: low (5%), intermediate (30%) and high (60%) risk. Low-risk (226 patients) were patients without PH aimed at minor resections with a MELD score ≤9; intermediate risk (297 patients) were patients without PH aimed at major resections or those undergoing minor resections with PH or MELD >9; high-risk (20 patients) were patients with PH undergoing major resections. Median length of stay was significantly different among the three risk classes: 7, 8 and 11 days respectively ($p<0.001$), as well as liver-related mortality: 0.5%, 9% and 25% respectively.
Conclusions: Risk of LD can be accurately stratified preoperatively according to a simple algorithm built on presence of PH, planned extension of the hepatectomy and MELD score (Figure).



P0387

IDENTIFICATION OF OPTIMAL CUT-OFFS IN ALPHA-FETOPROTEIN AND THE "AFP SCORE" TO MAXIMISE THE ACCURACY OF SELECTION OF LIVER TRANSPLANT CANDIDATES WITH HEPATOCELLULAR CARCINOMA

I.A. Rowe[1,2], E. Tsochatzis[3], M. Shah[4], D. Haldar[1], D. Houlihan[1], S. Davies[5], E. Godfrey[6], S. Shetty[1], J. O'Beirne[3], H. Mergental[2], C. Duvoux[7], A. Burroughs[3], M. Hoare[4], T. Shah[2]. [1]*Centre for Liver Research, University of Birmingham,* [2]*Liver and Hepatobiliary Unit, Queen Elizabeth Hospital, Birmingham,* [3]*UCL Institute for Liver and Digestive Health, Royal Free Hospital, London,* [4]*Department of Medicine,* [5]*Department of Pathology,* [6]*Department of Radiology, University of Cambridge, Cambridge, United Kingdom;* [7]*Department of Hepatology, AP-HP, Groupe Henri Mondor, Creteil, France*
E-mail: i.a.c.rowe@bham.ac.uk

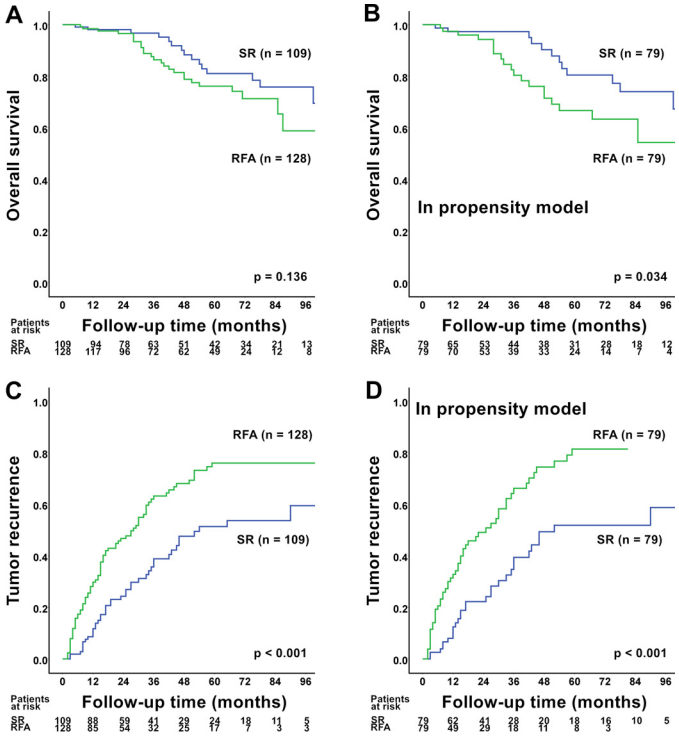
Background and Aims: Accurate prediction of HCC recurrence is critical in selection of candidates for liver transplantation (LT) to maintain acceptable outcomes. Current selection criteria include tumour size and number, serum alphafetoprotein (AFP) concentration, or combinations such as the AFP Score (Duvoux et al, Gastroenterology 2012). The optimal cut-off for AFP has not been defined and multiple, frequently arbitrary, cut-offs have been used. The cut-off for the AFP Score was defined at ≤2 in the original report but this has not been explored in other populations. The aim was to determine optimal cut-offs for AFP and the AFP Score in UK transplant recipients.
Methods: Patients from 3 UK centres, transplanted between 1996 and 2011 were included. Tumour size and number on pre-LT imaging, and AFP from the time of listing were analysed. Optimal cut-offs for the prediction of HCC recurrence by AFP and the AFP Score were determined using receiver operator characteristic (ROC) curve analyses in a derivation cohort of 209 patients from one centre. Cut-offs were then validated in a cohort of 294 patients from two independent centres.
Results: The characteristics of the derivation cohort were: median age 58.5 years, 82% male, 44% HCV infection, and 85% within the Milan criteria on imaging pre-LT. The area under the ROC curve was not different for AFP alone (0.74; 95% CI 0.62–0.85) and the AFP Score (0.74; 95% CI 0.64–0.84). Using traditional methods to select cut-offs the identified specificity values were between 0.71 and 0.76. The use of cut-offs based on these methods excluded 10–25% of patients with potentially favourable outcomes post-LT. Cut-offs were therefore identified by setting specificity at 0.9 to maximise opportunities for LT. Using this method the cut-off for AFP was found to be 497 (subsequently rounded to 500), and for AFP Score to be ≤3. Implementing these cut-offs in the validation cohort allowed identification of patients with low vs. high risk of recurrence after LT: AFP, 5-year recurrence risk 13.0 vs. 34.8% ($p<0.05$); AFP Score 5-year risk 12.8 vs. 44.1% ($p<0.001$).
Conclusions: Using traditional methods to identify cut-offs in selection of transplant candidates with HCC identifies cut-offs that are insufficiently specific. This disadvantages many patients who would otherwise benefit from transplantation. In individuals largely within the Milan criteria a cut-off of AFP 500 or an AFP Score of ≤3 increases the accuracy of candidate selection whilst still permitting transplantation in the majority.

P0388

SURGICAL RESECTION VERSUS RADIOFREQUENCY ABLATION FOR SINGLE HEPATOCELLULAR CARCINOMA ≤2 cm IN A PROPENSITY SCORE MODEL

P.-H. Liu[1,2], C.-Y. Hsia[2,3], C.-Y. Hsu[1,2], Y.-H. Lee[1,2], Y.-H. Huang[1,4], Y.-Y. Chiou[2,5], H.-C. Lin[1,2], T.-I. Huo[1,2,6]. *[1]Department of Medicine, Taipei Veterans General Hospital, [2]Faculty of Medicine, National Yang-Ming University School of Medicine, [3]Department of Surgery, Taipei Veterans General Hospital, [4]Institute of Clinical Medicine, National Yang-Ming University School of Medicine, [5]Department of Radiology, Taipei Veterans General Hospital, [6]Institute of Pharmacology, National Yang-Ming University School of Medicine, Taipei City, Taiwan*
E-mail: stuartliu@gmail.com

Background and Aims: The long-term therapeutic efficacy between surgical resection (SR) and radiofrequency ablation (RFA) for single hepatocellular carcinoma (HCC) ≤2 cm remains undetermined.
Methods: Between 2002 and 2013, 237 (SR in 109 and RFA in 128) patients with Barcelona Clínic Liver Cancer (BCLC) very early stage HCC were enrolled. Their overall survival (OS) and recurrence-free survival (RFS) were compared. Propensity score matching analysis identified 79 matched-pairs of patients to compare the outcomes.
Results: At baseline, SR patients were younger and had larger tumor (both $p < 0.05$). The 5-year OS rates were 81% for SR and 76% for RFA group ($p = 0.136$, Figure A), and 5-year RFS rates were 49% *versus* 24% for SR and RFA, respectively ($p < 0.001$, Figure C). In the propensity model, the baseline variables were well-balanced between two treatment groups. SR was significantly associated with better OS and RFS compared with RFA; the 5-year OS rates were 80% *versus* 66% ($p = 0.034$, Figure B), and 5-year RFS rates were 48% *versus* 18% ($p < 0.001$, Figure D) for SR and RFA group, respectively. The Cox proportional hazards model identified RFA as an independent predictor for mortality and tumor recurrence in the propensity model (hazard ratio: 2.120 and 2.421, respectively; both $p < 0.05$). Patients with recurrent HCC had inferior prognosis compared with patients without recurrence ($p = 0.001$). However, the survival after recurrence was similar between patients initially treated with SR or RFA ($p = 0.415$).



Conclusions: SR provides better long-term OS and RFS compared to RFA in patients with BCLC very early stage HCC. SR should be considered as the first-line treatment for these patients.

P0389

CAN WE PREDICT MICROVASCULAR INVASION IN HCC ON FDG PET-CT?

V. Agarwal[1]. *[1]Department of Nuclear Medicine, Medanta The Medicity Hospital, Gurgaon, India*
E-mail: stanley2005vishal@yahoo.com

Background and Aims: The purpose of this study is to correlate clinicopathologic and PET-CT parameters with the presence of microvascular invasion (MVI) at histopathologic examination (HPE) in patients with hepatocellular carcinoma (HCC) who underwent liver transplantation.
Methods: We assessed 224 patients with HCC undergoing liver transplantion and a pre-transplant PET-CT. Three physicians (two nuclear physicians and one radiologist) analyzed the following tumor parameters in consensus: size, multi-focality, pattern of uptake, quantitative FDG uptake (SUV), pattern of enhancement and distance to closest vessel. The size and number of lesions, tumor differentiation and the presence or absence of microvascular invasion were determined at HPE and these findings were analysed vis-a-vis to the imaging parameters on PET-CT.
Results: None of the clinical parameters was predictive of MVI; however on uni-variate analysis, MVI was significantly associated with multi-focality, uptake pattern and distance to the closest vessel on FDG PET-CT. By applying multiple logistic regression analysis, uptake pattern (heterogeneous and peripheral FDG uptake) was found to be the only independent risk factor for MVI.
Conclusions: Heterogeneous and peripheral FDG uptake on PET-CT was the only parameter that correlated significantly with MVI.

P0390

BASELINE BILIRUBIN AND NOT CHILD–PUGH A OR B7 PREDICTS SURVIVAL OF BCLC B PATIENTS TREATED WITH SORAFENIB. THE CLINICAL APPROACH TO THE STRATIFICATION DEBATE

A. Gazzola[1], R. Di Donato[1], M. Reig[1], N. Llarch[1], A. Forner[1], A. Darnell[2], J. Rimola[3], C. Ayuso[3], J. Bruix[1]. *[1]BCLC. Liver Unit. IDIBAPS. CIBERehd. University of Barcelona, [2]BCLC. Radiology Department. IDIBAPS. University of Barcelona, [3]BCLC. Radiology Department. IDIBAPS. CIBERehd. University of Barcelona, Hospital Clínic i Provincial de Barcelona, Barcelona, Spain*
E-mail: alessiagazzola@yahoo.it

Background and Aims: BCLC-B stage includes multifocal hepatocellular carcinoma (HCC) without extrahepatic disease, Child–Pugh score (CP) A–B and performance status (PS) 0. In some cases the recommended treatment for this stage (TACE) is discarded for unfeasibility or failure. Thus, a relevant percentage of patients is considered for sorafenib [treatment stage migration (TSM) or untreatable progression (UP) concepts]. Some authors have proposed to stratify the BCLC-B stage according to CP points but this dismisses the fact that CP >7 patients require transplant consideration if the HCC burden does not exceed selection criteria. If this is the case, the hepatic impairment prevents treatment benefit. The aim of this study is to identify predictors of survival (OS) in properly selected BCLC-B patients treated with sorafenib.
Methods: We prospectively included BCLC-B patients (PS 0, no vascular invasion/extrahepatic spread), CPA/B7 without encephalopathy/clinical ascites at sorafenib start (800 mg/day). Follow-up was performed with 4 week-clinical/laboratory monitoring and radiological control at 4 wks and then every 8 wks. Treatment continued until symptomatic progression, intolerance or entry in 2nd line trials.
Results: Between October 2007 and March 2014, 99 BCLC-B patients began sorafenib (86% males, 58% HCV, 81% CPA). After a median follow-up and treatment duration of 12.7 and 8.3 months (P33 5.4;

P66 11.6), the median OS was 14.8 months (14 if censored at 2nd line). OS did not differ according to CP (CP A: 13.9 months; CP B: 12.7). The uni–multivariate analysis of CP parameters identified baseline bilirubin (TB) as the only independent OS predictor. OS was significantly longer in patients with normal TB (TB <1.2 mg/dl) vs. those with elevated TB (16.3 months vs. 12.3 months). The predictive role of TB is kept at the same HR and 95% CI irrespective of the baseline variables included in the model: CP parameters and previous decompensation; CP parameters and ascites controlled by diet +/− diuretics; CP parameters and BCLC-B naive/BCLC-B due to TSM or UP baseline characteristics + CP parameters + previous decompensation + ascites controlled by diet +/− diuretics [TB HR = 1.64, 95% CI (1.147–2.357) in all analysis].
Conclusions: Stratification of patients into Child–Pugh A vs. B7 does not predict OS in this population and its use does not provide useful information. Contrarily, baseline TB should be used for prediction and prognostic stratification of BCLC-B patients treated with sorafenib.

P0391
PRIOR HISTORY OF ARTERIAL HYPERTENSION IS NOT A CONTRAINDICATION TO SORAFENIB AND IS ASSOCIATED TO A BETTER SURVIVAL IN PATIENTS WITH ADVANCED HCC

R. Di Donato[1], A. Gazzola[1], M. Reig[1], A. Garcia Alvarez[2], E. Santiago[3], F. Torres[4], A. Forner[1], A. Darnell[5], C. Ayuso[6], J. Bruix[1].

E-mail: RDONATO@clinic.ub.es

Background and Aims: Sorafenib is a multikinase inhibitor with antiangiogenic/antiproliferative effect. It presents a specific pattern of adverse reactions: dermatological reactions, hypertension (HT), hypophosphatemia and diarrhea. It is controversial if this drug is tolerable in patients (pts) with history of HT or if such comorbidity may influence overall survival (OS). This prospective study analyzes if prior existence of HT is associated with worse tolerance and lower efficacy of sorafenib and to evaluate if this comorbidty may affect OS.
Methods: We included patients with HCC, Child–Pugh (CP) A or B7 points, without encephalopathy or clinical ascites, with controlled arterial pressure (AP) and without active cardiovascular disease in an intensive program of cardiovascular evaluation. Clinical and laboratory examination was done every 4 weeks and CT-scan before starting the treatment, after 4 weeks and then every 8 weeks. All but 11 pts started at full dose (800 mg/day). Dose adjustments were applied according to clinical tolerance and therapy was maintained until symptomatic progression, intolerance or inclusion in 2nd line trials.
Results: Between October 2007 and March 2014, 208 pts started sorafenib and 105 were included: 93% male, 53.5% HCV, 54% BCLC-C, 89% CP-A, 93% PS0; 49% of the pts had prior history of HT and most were under treatment (47/52 pts). Median systolic AP was 128 mmHg (90–169) and diastolic AP was 78 (50–96), 26% of the pts were diabetics. Median follow up, treatment duration and OS were 11.2 months (mo), 6.1 mo and 12.7 mo, respectively. Pts with HT did not require more dose modifications or treatment interruptions, than pts without HT. In multivariate analysis, none of the analyzed factors (HT, treatment of HT, basal values of AP, diabetes) was predictor of OS. However, if stratifying pts according to history of HT and values of AP as CTCAE 4.03, those with normal values showed longer OS [17.6 vs 9.42 months (p = 0.025); HR: 2.955 (95% CI 1.103–7.917) p = 0.031]. Similarly, pts with optimal or normal values of AP (≤129/84 mmHg; n = 47) according to the European Society of Cardiology and with prior history of HT, showed better survival [17.6 vs 10.4 months (p = 0.037), HR: 2.296 (95% CI 1.033–5.106) p = 0.041].
Conclusions: History of HT is not a contraindication to sorafenib in pts with advanced HCC if AP is adequately controlled. Treatment duration and tolerability are not affected by HT and OS may be even longer in pts with HT.

P0392
TRANSARTERIAL CHEMOEMBOLISATION IN PATIENTS WITH METASTATIC HEPATOCELLULAR CARCINOMA

D. Bettinger[1], R. Spode[1], R. Thimme[1], M. Schultheiß[1]. *[1]Department of Medicine II, University Hospital Freiburg, Freiburg, Germany*
E-mail: dominik.bettinger@uniklinik-freiburg.de

Background and Aims: Hepatocellular carcinoma (HCC) is often diagnosed in an advanced stage and therefore treatment is limited due to impaired liver function and the lack of highly effective systemic treatment possibilities. Sorafenib is the treatment of choice in advanced metastatic HCC. Several studies have shown that treatment with transarterial chemoembolisation (TACE) in metastatic HCC can improve overall survival (OS) in these patients. It was therefore the aim of our study to investigate efficacy of TACE and and its impact on OS in patients with metastatic HCC.
Methods: 215 Patients with metastatic HCC who were treated at our Liver Center between 2003 and 2014 were included in the analysis. Medical records, laboratory parameters and imaging studies were analyzed. Treatment of metastatic HCC, efficacy and OS were assessed.
Results: The study population compromised 215 patients with metastatic HCC (185 [86%] male, median age 69 years). The main cause of liver disease was alcohol (35.8% of patients). 85% of our patients were classified as BCLC C whereas the remaining 15% were in BCLC D. Most common sites of metastases were the lung (48.8%) and extrahepatic lymph nodes (46.5%). Sorafenib treatment was performed in 71 of 215 patients (33%), TACE in 65 of 215 patients (47.1%) and a combination of both in 23 patients. Patients treated with TACE were all in BCLC C. In patients without multiple metastases treatment with TACE led to a significantly better OS compared to no TACE treatment (12 vs. 4 months, p < 0.001). Multivariate Cox regression analyses revealed TACE (HR 0.62; 95% CI:0.39–0.97, p = 0.037), multifocal intrahepatic HCC (HR 2.21; 95% CI:1.27–3.84, p = 0.005) and MELD score (HR 1.10; 95% CI:1.03–1.18, p = 0.005) as significant independent prognostic factors in these patients.
Conclusions: In advanced, metastatic HCC treatment of intrahepatic tumor using TACE may be associated with improved survival highlighting the prognostic importance of treating intrahepatic HCC even in patients with metastatic disease.

SELF-ASSEMBLED LIVER ORGANOIDS RECAPITULATE HEPATO-BILIARY ORGANOGENESIS IN VITRO

P.M. Baptista[1], D. Vyas[2], E. Moran[2], A. Atala[2], L. Reid[3], S. Soker[2].
[1]Centro de Investigacion Biomedica de Aragon, Instituto de Investigacion Sanitaria de Aragon, Zaragoza, Spain; [2]Wake Forest Institute for Regenerative Medicine, Wake Forest University Health Sciences, Winston-Salem, [3]Molecular and Cell Physiology, University of North Carolina at Chapel Hill, Chapel Hill, United States
E-mail: pbaptista.iacs@aragon.es

Background and Aims: Bioengineering of a fully functional tissue requires precise recapitulation of normal tissue development.

Specifically for the liver, one may use bipotent human liver progenitor cells (hFLCs) capable of differentiation into hepatocytes and cholangiocytes. The goal of the current study was to develop a system that would efficiently recapitulate embryonic development of hepatic parenchymal tissue and bile ducts, using decellularized liver extracellular matrix (ECM) as scaffolds.

Methods: hFLCs were seeded on decellularized liver ECM discs (300 μm thickness, 8 mm diameter) and were cultured for up to 3 weeks in presence of hepatic differentiation medium. Immunofluorescence microscopy was used to determine the extent of progenitor cell differentiation into hepatocytes and cholangiocytes. Urea, albumin and drug metabolism were quantified as paramaters of liver function.

Results: hFLCs seeded on acellular liver ECM discs differentiated into hepatocytes and cholangiocytes. The cells showed predominant albumin expression along with loss of α-feto protein (AFP) expression at 3 weeks (Fig. 1D,E). The cells also expressed other mature hepatocyte markers like HNF-4α, α-1-antitrypsin and cytochrome P450 1A2, 2A and 3A (Fig. 1B–E). The cells in the ductular structures expressed bile duct specific markers like CK19, SOX9, EpCAM, ASBT, β-catenin and the presence of apical primary cilia (stained with α-acetylated tubulin), thus demonstrating differentiation towards cholangiocyte lineage along with maintaining apico-basal polarity (Fig. 1B–E). Urea and albumin secretion was higher in the liver disc organoids compared to control hFLCs cultured in petri dishes. Several metabolites of the drugs diazepam and 7-ethoxycoumarin were also detected by LC-MS/MS, showing broad cytochrome P450 activity in these organoids.

Conclusions: Our results demonstrate the efficient generation of bioengineered human liver tissue with hFLC that recapitulates stepwise development of hepatocyte and bile duct formation (Fig. 1A). Altogether, this study demonstrates the potential of this technology to study and mimic human liver development. These models provide novel approaches for liver bioengineering, drug discovery and toxicology, and ultimately for the treatment of liver disease.

ACUTE BLEEDING AND STORED RBC TRANSFUSION ATTENUATES LIVER REGENERATION FOLLOWING PARTIAL HEPATECTOMY

R. Abramovitch[1], N. Nachmansson[1], I. Matot[2]. [1]*The Goldyne Savad Institute of Gene Therapy, Hadassah Hebrew University Medical Center, Jerusalem,* [2]*Anesthesiology & Intensive Care, Tel-Aviv Sourasky Medical Center, Tel-Aviv, Israel*
E-mail: rinat@hadassah.org.il

Background and Aims: Liver regeneration, a process that rapidly compensates for the acute loss of liver parenchyma, plays a critical role in patients requiring large liver resections or living-donor liver transplantation. These operations are frequently associated with massive blood loss with subsequent red blood cell (RBC) transfusion. Avoiding further liver injury in the remaining liver parenchyma and inhibition of liver regeneration is of profound clinical importance. While the liver is one of the targets for injury in low flow states associated with hemorrhage, concerns have recently been raised about the safety and efficacy of RBC transfusion. In a rat model of partial hepatectomy (PHx), our aims were to study the impact of blood loss on liver regeneration, and to evaluate whether RBC transfusion modifies the liver regeneration processes.

Methods: Liver regeneration was assessed in a rat model of 50% PHx. Rats were randomized into 4 experimental groups: (I) Control hepatectomy (PHx; n = 24); (II) bleeding (3 ml) and PHx (n = 24); (III) bleeding (3 ml) and PHx followed with fresh RBC resuscitation (n = 24); (IV) bleeding (3 ml) and PHx followed with "aged" RBC resuscitation (n = 24; RBC stored for 7 days). Rats were sacrificed at 1, 2, 4 and 7 days after PHx, bleeding and resuscitation (6/time point) for histological evaluation, for serum liver enzymes (ALT and AST) and for cytokines levels (IL-6 and TNFa). Histological samples were immunostained with BrdU for assessment of hepatocyte proliferation.

Results: Acute bleeding interfered with the regenerative process of the liver following PHx. In rats subjected to 50% PHx and bleeding, liver regeneration was delayed and hepatocyte proliferation significantly reduced when compared to rats that had only PHx (figure). Resuscitation with fresh RBC but not with "aged" RBC, restored liver regeneration kinetics (figure). The delay in liver regeneration due to acute bleeding was associated with increased liver injury, as assessed by elevated ALT and AST levels. IL-6 is critical for initiation of liver regeneration process. Plasma IL-6 levels were increased at 24 hours post PHx and with RBC transfusion, however, were significantly reduced with PHx and bleeding.

Conclusions: Avoiding blood loss and transfusion of stored RBC in patients undergoing PHx is of great importance to ensure the regenerative period. Resuscitation with fresh RBC restores liver regeneration capacity.

MIR-22-TARGETED CYCLIN A EXPRESSION IN GI CANCER CELLS IS REGULATED BY BILE ACID RECEPTOR

Y.-J.Y.Y. Wan[1], F. Yang[1]. [1]*Pathology, University of California Davis Health System, Sacramento, United States*
E-mail: yvonnewan98@gmail.com

Background and Aims: Due to the significant tumor suppressive role of microRNA-22 (miR-22), it is important to understand the mechanism by which miR-22 is expressed and regulated. Identification of miR-22 downstream targets would help us to understand its tumor suppressive effect as well. Farnesoid X receptor (FXR) is abundantly expressed in the liver and intestines and plays a pivotal role in maintaining the health of the gastrointestinal tract. As a transcriptional factor, FXR can exert its biological effects by regulating microRNAs.
Methods: Using standard molecular biology approaches, the current study was designed to understand the regulation of miR-22 by FXR and identify additional downstream miR-22 targets in liver and colon cell lines.
Results: The results showed miR-22 was transcriptionally regulated by FXR through direct binding to an invert repeat-1 (IR-1) motif located at 1012 to 1025 bp upstream from miR-22. Among the studied primary and secondary bile acids, chenodeoxycholic acid (CDCA), which has the highest binding affinity to FXR, induced miR-22 level in both Huh7 liver and HCT116 colon cells in a dose-dependent manner. In addition, cyclin A2 (CCNA2) was identified as a miR-22 novel target in liver and colon cancer cells. The sequence of miR-22, which is conserved in mice, rats, humans, and other mammalians, aligns with the sequence of 3′ UTR of CCNA2. CDCA treatment and miR-22 mimic reduced the expression of CCNA2 in Huh7 and HCT116 cells. In mice, reduction of miR-22 is accompanied by the induction of hepatic and ileal CCNA2 protein levels in 3 month old FXR knockout (KO) mice. In human specimens, the expression levels of miR-22 and CCNA2 are inversely correlated in liver and colon cancers.
Conclusions: Taken together, our data showed that FXR-induced miR-22 in suppression of CCNA2 is a novel pathway for FXR to exert its protective effect in the gastrointestinal tract.

P0396

EMRICASAN, A POTENT PAN CASPASE INHIBITOR, RAPIDLY REDUCES CASPASE ACTIVITY AND BIOMARKERS OF APOPTOSIS IN PATIENTS WITH HEPATIC IMPAIRMENT BUT NOT IN HEALTHY VOLUNTEERS: IMPLICATIONS FOR SAFETY, SELECTIVITY AND MECHANISM OF ACTION

A.P. Spada[1], P.C. Contreras[1], M.C. Huyghe[1], M. Morris[1], G.C. Burgess[1]. [1]*Conatus Pharmaceuticals, San Diego, United States*
E-mail: aspada@conatuspharma.com

Background and Aims: Emricasan, (formerly IDN-6556) is a potent, orally active caspase inhibitor currently in five on-going Phase 2 clinical trials, in patients with various etiologies and severity of liver disease. Caspases are enzymes that are critically involved in apoptosis and the maturation of the pro-inflammatory cytokines, IL-1and IL-18. Apoptosis and caspase activity are elevated in many liver diseases and are closely associated with disease severity and progression. We have studied the effect of emricasan on caspase activity and markers of apoptosis in subjects with hepatic impairment, severe renal impairment and matched healthy volunteers.
Methods: Emricasan was administered as a single 50 mg oral dose to subjects with mild (n = 12), moderate (n = 8) or severe (n = 8), hepatic impairment and 8 matched healthy controls. In a second study, emricasan was administered as a single 50 mg dose to 8 subjects with severe renal impairment and 8 matched healthy controls. In both studies, serial blood samples were collected over a 48 hour period and analyzed for markers of apoptosis, cell death and caspase enzymatic activity using, M30 Apoptosense, M65 and caspase Glo 3/7 assays, respectively.
Results: All 28 subjects with hepatic impairment experienced rapid and significant reductions, ($p < 0.05$), relative to Baseline for all of these markers of mechanistic activity and pharmacodynamic response following a single 50 mg oral dose of emricasan. In subjects with severe renal impairment, caspase activity and M65 were elevated relative to controls and emricasan had no effect on these markers. Emricasan also had no effect on caspase activity or markers of apoptosis the cohorts of healthy volunteers.
Conclusions: Emricasan did not reduce levels of caspase activity in healthy volunteers or in subjects with severe renal impairment following a single 50 mg oral dose. However, emricasan efficiently reduced caspase activity and markers of apoptosis and general cell death in all subjects with hepatic impairment. Combined, these observations suggest that reduction in systemic caspase activity result from reduced efflux of active caspase from diseased organs rather than inhibition of caspase activity in the systemic circulation. These observations provide new and potentially fundamental insight into the cellular mechanisms of how emricasan affects apoptosis. They also suggest that emricasan is uniquely suited to treat liver diseases where excessive caspase production is implicated.

Nrf2 MUTATIONS ARE AN EARLY AND FREQUENT EVENT IN THE DEVELOPMENT OF RAT HEPATOCELLULAR CARCINOMA

A. Columbano[1], S. Giordano[2], A. Perra[1], M.A. Kowalik[1], G.M. Ledda-Columbano[1], A. Petrelli[2], S. Menegon[2], L. Quagliata[3], L. Terraciano[3], P. Zavattari[1]. [1]*Biomedical Sciences, University, Cagliari,* [2]*Oncology, University, Torino, Italy;* [3]*Pathology, University, Basel, Switzerland*
E-mail: columbano@unica.it

Background and Aims: Hepatocellular carcinoma (HCC) is a multistage process, but the nature of the molecular changes associated to the different steps, particularly the very early ones, is unknown. The Nrf2–Keap1 pathway is now recognized as a major cellular defense mechanism against oxidative and electrophilic stresses; however, its exact role in cancer development is unclear.
Methods: To unveil the role of Nrf2 in HCC, we used the Resistant-Hepatocyte (R-H) rat model, which identifies distinct lesions (preneoplastic foci, dysplastic nodules, early and advanced HCCs) at well-defined timings. Identification of *Nrf2/Keap1* mutations and the expression of target genes of this pathway were performed by Sanger analysis and qRT-PCR. Immunohistochemistry was used to detect the activation of the pathway in the pre- and neoplastic lesions.
Results: Mutations of *Nrf2* are very frequent in early preneoplastic lesions (70%). All the mutations were missense, involved the Nrf2-Keap1- binding regions and were associated with a strong increase of expression of the *Nrf2*-target genes (*Nqo1, Gclc, Gst4)*, in both pre- and neoplastic lesions. HCCs arising 10 and 14 months later also showed a high percentage of *Nrf2/Keap1* mutations (70 and 56%, respectively), suggesting that mutation of these genes is critical for HCC development. *Nrf2* silencing inhibited the ability of rat tumorigenic cells to grow in soft agar and to develop HCC when injected into syngeneic rats.
Conclusions: This study demonstrates that *Nrf2* mutation is a very early and frequent event, suggesting that dysregulation of the Nrf2-Keap1 pathway is likely essential for the clonal expansion of preneoplastic hepatocytes to HCC.

P0398

CHANGE OF FIBROSIS PATTERN AFTER AUTOLOGOUS BONE MARROW CELL INFUSION IN PATIENTS WITH ADVANCED LIVER CIRRHOSIS

J.K. Kim[1], Y.N. Park[2], J.I. Lee[1], D.Y. Kim[1], S.H. Ahn[1], K.-H. Han[1], K.S. Lee[1]. *[1]Dept. of Internal Medicine, [2]Dept. of Pathology, Yonsei University College of Medicine, Seoul, Korea, South*
E-mail: drcecilia@hanmail.net

Background and Aims: Although we previously published positive clinical results of human clinical trial of autologous bone marrow cell infusion (ABMI) therapy for advanced liver cirrhosis (LC) (Kim JK et al. Cell Transpl 2010), change of fibrosis stage could not be shown. Because the patients had thick advanced fibrotic band, small change could not be evaluated by current staging system. Recently, enhanced detection and quantification of collagen fibers are possible using the nonlinear optical microscopy. The aim of this study is to show the change of fibrosis after ABMI in patients with advanced LC.
Methods: Patients with Child–Pugh B or C LC and no viable hepatocellular carcinoma (HCC) underwent ABMI. Autologous BMCs were harvested and infused into peripheral vein after RBC depletion and mononuclear cell concentration. Patients were followed up every month during first 6 months of study period after the ABMI. Liver biopsy was performed before ABMI, and 1, 3, and 6 months after ABMI, if the patient agreed. Repeated biopsy samples were imaged by Genesis™ system (Histoindex, Singapore), a second harmonic generation and two-photon excitation fluorescence technology-based commercial devise. Collagen features were divided into portal, septal or fibrillar collagen as previous report (Xu et al. J Hepatol 2014).
Results: Twenty patients were screened and 19 patients (M:F=9:10) were enrolled. Mean age was 52 year-old. Repeated biopsy samples were available in 8 patients for this study. Seven patients had B-viral LC and one had alcoholic LC. Only at 3 months after ABMI, aggregated collagen, string area, number of crosslinks, portal collagen percentage, portal aggregated collagen percentage, portal string area, portal and aggregated string area, portal and aggregated number of thin strings, portal number of crosslinks, septal number of thin strings, septal string area, septal and aggregated string area, fibrillar number of strings, fibrillar string area, fibrillar and aggregated string area were significantly decreased compared to baseline ($p < 0.05$, respectively).
Conclusions: ABMI improved not only hepatic function but also collagen deposition. However, significant collagen decrease was noted only at 3 months after ABMI.

P0399

Notch1 IS A MASTER REGULATOR OF THE SENESCENCE SECRETOME THROUGH REPRESSION OF CEBPβ

M. Hoare[1], Y. Ito[1], T.-W. Kang[2], S. Menon[1], R. Salama[1], L. Zender[2], M. Narita[1]. *[1]Cambridge Institute, Cancer Research UK, Cambridge, United Kingdom; [2]Department of Internal Medicine I, University Hospital, Tuebingen, Tuebingen, Germany*
E-mail: matthew.hoare@cruk.cam.ac.uk

Background and Aims: Oncogene-induced senescence (OIS) is an intrinsic tumour suppressor mechanism, but its impact on tumorigenesis is largely dependent on the nature of SASP, the senescence-associated secretory phenotype. Major components of the SASP include TGFβ1 and pro-inflammatory cytokines, such as IL1, IL6, and IL8, that have pleiotropic context-dependent effects.
Methods: We utilised the well validated ER:Ras^{G12V} IMR90 HDF in vitro model which undergo Ras-induced senescence (RIS) with 4OHT. Genetic manipulation was achieved through retroviral gene transfer; transcriptional profiling by mRNA-seq; validation through qPCR and immunoblotting.
Results: Previously, we have shown that Notch1, a highly conserved receptor is up-regulated in RIS. In contrast to the up-regulation of Notch1, downstream signaling is dynamically regulated: the cleaved, active intracellular domain of Notch1 (N1ICD) and Notch-target genes were transiently up-regulated at an early phase of RIS, but down-regulated at full senescence. The dynamic expression pattern of N1ICD and TGF-β1 expression were nearly identical, and inversely correlated with the cytokines, IL1 and IL8. Inhibition of Notch1 signaling, through expression of a dominant-negative form of the Notch1 binding partner MAML1, led to a reduction in TGF-β1, but increased IL1 and IL8 expression during RIS. In addition, ectopic restoration of N1ICD in established RIS cells drove reciprocal secretome changes with reduced IL1 and IL8 and increased TGF-β1, suggesting Notch1 signaling plays a critical role in secretome switching.
It has been shown that the SASP in RIS is regulated by two major transcription factors, NFkB and CEBPβ. Strikingly, over-expression of N1ICD strongly down-regulated CEBPβ, but not NFkB, in fully established RIS cells. Further, expression of ectopic CEBPβ in N1ICD-expressing cells partially restored levels of IL6/8. These data indicate that Notch1 represses pro-inflammatory cytokines by down-regulating CEBPβ. Finally, Notch1 up-regulation in RIS was confirmed in several mouse models: the murine Kras-driven pancreatic intraepithelial neoplasia and Nras-driven hepatocyte senescence models.
Conclusions: We propose that the transition to OIS is correlated with a switch from Notch1-driven TGFβ1-rich secretome to a CEBPβ-driven IL1/8 rich secretome, and that dynamic Notch1 signaling modulates senescence and its long-term fate strictly through a non-cell-autonomous fashion.

MICRORNA SIGNATURE OF EARLY-STAGE HEPATOCELLULAR CARCINOMA ARISING IN HCV-RELATED CIRRHOSIS

G. Ghittoni[1], L. Veronese[1], F. Torello Viera[1], V. Curti[2], M. Ghitti[3], L.L. Rosa[1], V. Ravetta[1], L. Siciliani[1], S. Rossi[1]. *[1]VI Department of Internal Medicine, IRCCS Policlinico San Matteo Foundation, [2]Department of Earth and Environmental Sciences, Laboratory of Immunology and Genetic Analysis, University of Pavia, [3]Department of Earth and Environmental Science, Laboratory of Statistics and Bioinformatics, University of Pavia, Pavia, Italy*
E-mail: giorgiaghittoni@gmail.com

Background and Aims: Systems currently used to stage hepatocellular carcinomas (HCCs) perform poorly in prognostic settings. The availability of tumor biomarkers that reliably correlate with disease outcome would facilitate treatment and follow-up strategy planning. To identify such markers, we analyzed the microRNA profiles of HCCs and the cirrhotic tissue in which they develop.
Methods: Ten patients with HCV-related cirrhosis underwent resective surgery for solitary, early-stage HCCs. In each case, we

collected one sample of tumor and two samples of tumor-free cirrhotic tissue (near and at a distance from the tumor) and used them to construct 30 small RNA libraries for next-generation sequencing. The reads that emerged were clustered and aligned against the MiRBase with CLC Genomic Workbench software.
Results: A total of 2,329 mature microRNAs were found. Annotated microRNAs with a mean read number per sample of >20 underwent parametric and randomized statistical analyses. Those associated with *P values* of ≤0.01 in both analyses were considered differentially expressed between tissue types. Of the 617 microRNAs subjected to statistical analysis, 35 exhibited expression levels in HCC that were significantly different from those found in one or both tumor-free cirrhotic tissues; two of the 35 were also differentially expressed in the two types of cirrhotic tissue. Eighteen of the 35 had never been reported as dysregulated in HCC.
Conclusions: We identified an HCC-signature set of 35 microRNAs, which distinguishes HCCs from background cirrhotic tissues. It should provide a good starting point for subsequent research aimed at identifying biomarkers correlating with HCC outcome.

P0401
THE SERINE PROTEASE FSAP (FACTOR VII ACTIVATING PROTEASE) MAINTAINS THE DIFFERENTIATED STATE OF MOUSE HEPATOCYTES
A. Martinez-Palacian[1], S. Kanse[1]. [1]*Department of Biochemistry, Institute of Basic Medical Sciences, University of Oslo, 0372 Oslo, Norway*
E-mail: adoracim@medisin.uio.no

Background and Aims: FSAP, encoded by the *Habp2* gene, is a serine protease secreted by hepatocytes as an inactive zymogen that circulates in the blood. We have recently demonstrated a novel anti-fibrotic role for FSAP in the liver. The aim of this study was to analyze the effect of FSAP on hepatocyte differentiation and proliferation.
Methods: Primary hepatocytes isolated from BALB/c wild type (WT) or FSAP-deficient mice and the mouse hepatocyte cell line AML-12 were used as *in vitro* models. The use of knockout hepatocytes was further supported by the use of siRNA-mediated knock-down of the gene for FSAP and the addition of exogenous FSAP protein. Transcript levels were analyzed by qRT-PCR, protein levels by Western blotting and DNA synthesis by BrdU incorporation.
Results: Primary hepatocytes and AML-12 cells lacking expression of endogenous FSAP show a reduction in HNF4α (Hepatocyte Nuclear Factor 4α) and an increase in AFP (alphafetoprotein) transcript levels compared to WT cells. Besides, Transforming Growth Factor beta-1 (TGFβ) almost completely abolishes HNF4α mRNA levels in FSAP-depleted cells, while the reduction in WT cells is around 50%. Basal reduction on HNF4α mRNA is not due to an Epithelial-Mesenchymal Transition (EMT): silencing of the gene for FSAP does not down-regulate E-cadherin protein levels nor up-regulates mRNA levels of the EMT-inducing transcription factors (TFs) SNAI1, ZEB1 and ZEB2. Moreover, FSAP depletion does not impair the TGFβ-induced up-regulation of these TFs.
Preliminary results show that exogenous FSAP induce a 30% increase in basal BrdU incorporation in hepatocytes. Exogenous FSAP can overcome the anti-proliferative effect of TGFβ in FSAP-deficient hepatocytes, but not in WT cells, suggesting that lack of endogenous FSAP decreases the sensitivity to TGFβ inhibitory effects.
Conclusions: We have for the first time described a novel role for FSAP in hepatocyte differentiation. It contributes to mantain HNF4α expression and AFP repression but does not affect EMT. This, together with its potential role on proliferation, provides a mechanistic insight into the effect of FSAP on hepatocytes that is relevant for hepatocellular carcinoma.

P0402
COMBINATION THERAPY FOR HEPATOCELLULAR CARCINOMA: A SYSTEMS BIOLOGY PERSPECTIVE ON THE SYNERGISTIC ANTITUMOR ACTIVITY OF SORAFENIB WITH PI3K/AKT PATHWAY INHIBITORS
T. Ersahin[1], N. Tuncbag[2], A. Acar[2], R. Cetin-Atalay[2]. [1]*Department of Molecular Biology and Genetics, Bilkent University,* [2]*Graduate School of Informatics, ODTU, Ankara, Turkey*
E-mail: ersahin@bilkent.edu.tr

Background and Aims: Sorafenib, a multi-kinase inhibitor with anti-angiogenic functions, is the only FDA-approved molecular-targeted agent for the treatment of patients with advanced Hepatocellular carcinoma (HCC). Yet, Sorafenib shows limited overall survival benefit associated with resistance and tumor recurrence. Current mono-target- or single pathway-centric drug designs are not sufficient for effective therapy of advanced HCC. Since Sorafenib targets angiogenic VEGFR and PDGFR kinases and RAF/MEK/ERK signaling, the primary mechanism of resistance to Sorafenib and tumor recurrence in HCC patients emerges to be the compensatory PI3K/AKT signaling. In this study, we analyzed the synergistic effects of Sorafenib and PI3K/AKT inhibitors on HCC cell growth, determined possible mechanisms underlying synergistic mechanism of action by transcriptome analysis, and further showed that combination therapy leads to tumor regression in HCC xenografts *in vivo*.
Methods: Cytotoxic activities of the PI3K/AKT pathway small molecule inhibitors were shown by SRB and RT-CES assays in HCC cell lines having normal or hyperactive AKT kinase. Apoptotic cell death and suppression of cell cycle progression were shown by flow cytometry, immunofluorescence and western blots experiments. Transcriptome profiling of inhibitor treated cells were performed with RNA-sequencing. Therapeutic efficacy of combination therapy was shown *in vivo* in athymic mice bearing HCC xenografts.
Results: We showed the cytotoxic activities of isoform specific PI3K inhibitors and AKT inhibitors (Akti-1,2 and Akti-2) alone and in combination with Sorafenib *in vitro*. We revealed the molecular mechanisms of action of single agent and combination therapies using transcriptome profiling. We determined the predominant role of PI3K isoform p110α in PTEN-deficient HCC cells. We showed that combining Sorafenib with PI3K/AKT inhibitors enhances anti-tumor efficacy of Sorafenib and results in tumor regression *in vivo*.
Conclusions: Our results provide *in vitro* and *in vivo* experimental evidence of the therapeutic potential of combination therapies with Sorafenib and PI3K/Akt inhibitors for the treatment of advanced HCC.

P0403
STEATOTIC LIVER AS A SOURCE OF HEPATIC PROGENITOR CELLS WITH THERAPEUTIC POTENTIAL
W.-Y. Lu[1], A. Tsuchiya[2], L. Boulter[3], R. Guest[1], D. Wojtacha[1], T. Bird[1], T.Y. Man[1], D. Hay[1], J. Iredale[4], S. Forbes[1]. [1]*MRC Centre for Regenerative Medicine, University of Edinburgh, Edinburgh, United Kingdom;* [2]*Division of Gastroenterology and Hepatology, Niigata University, Niigata, Japan;* [3]*Institute of Genetics and Molecular Medicine,* [4]*Centre for Inflammation Research, University of Edinburgh, Edinburgh, United Kingdom*
E-mail: w.y.lu@ed.ac.uk

Background and Aims: Ductular reactions (DRs) are observed in chronic liver injuries. In mice, ductular reactions have been studied extensively in models such as Choline-Deficient Ethionine (CDE) supplemented diet and 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) diet. On contrary, DRs in models of fatty liver disease is less studied. We aim to investigate the DR in fatty liver disease and the plausibility to isolate Hepatic Progenitor Cells (HPCs) from fatty liver to use as an alternative to whole organ transplant.
Methods: C57BL6 mice were supplemented with High Fat Diet, Choline Deficient (CD) diet, Methionine-Choline Deficient (MCD)

diet to activate DRs. HPCs were isolated by Fluorescence Activated Cell Sorting (FACS) based on previously described HPC markers (CD45-/CD31-/Ter119-/EpCAM+/CD24+). HPCs were cultured at clonal density either in a conventional two dimensional system or a three dimensional manner to form liver organoids. *In vitro* expanded HPCs were transplanted into recipient mice with liver injury via intrasplenic injection. Recipient livers were analysed for engraftment and liver repopulating capacity of HPCs.

Results: Mice fed with MCD diet have the most robust DR among the models of steatosis we tested. The degree of DR is even comparable to the widely used CDE diet (10 fold higher than healthy control). Isolated HPCs can be expanded *in vitro* in both 2-dimensional and 3-dimensional manner. Expanded HPCs maintain the expression of HPC markers, CK19, Sox9, and Osteopontin after long term culture. Furthermore, expanded cells are phenotypically stable with normal chromosome number. Expanded HPCs from MCD liver express the same markers as HPCs isolated from CDE treated liver, with similar expression of HPC marker EpCAM, CD24, CD133, LGR5. Expanded HPCs can differentiate along the hepatocyte lineage and are capable of synthesising albumin and store glycogen *in vitro*. Transplanted HPCs engraft and repopulate the liver parenchyma in a large scale after liver injury.

Conclusions: We found that mice supplemented with Methionine-Choline Deficient (MCD) diet, a model of steatohepatitis have robust DRs. HPCs isolated from MCD treated liver can be expanded in vitro and repopulate the liver after transplantation. This proves the potential of using HPCs isolated from fatty liver that are rejected for transplant for cell therapy in the future.

P0404

CYCLIN E1 EXPRESSION LEVEL DETERMINE THE ANTI-PROLIFERATIVE RESPONSE OF THE PHARMACOLOGICAL Cdk2 INHIBITOR ROSCOVITINE IN HEPATOMA CELLS AND LIVER

Y.A. Nevzorova[1], W. Hu[1], N. Hoeltke[1], U. Haas[1], C. Trautwein[2], C. Liedtke[1]. *[1]Department of Internal Medicine III, RWTH Aachen University, Aachen, Germany; [2]Department of Internal Medicine III, RWTH Aachen University, Aachen, Germany, Aachen, Germany*
E-mail: ynevzorova@ukaachen.de

Background and Aims: The cyclin-dependent kinase inhibitor Roscovitine (Rosc) has been regarded as a promising anti-cancer agent. In the present study we investigated the anti-proliferative effects of Rosc in hepatoma cells and liver in order to test if Rosc could be a therapeutic option for the treatment of HCC.

Methods: The properties of Rosc were analyzed in murine hepatoma cells *in vitro* and in mice following partial hepatectomy (PH) *in vivo*. Potential off-target effects of Rosc were investigated in mice with ubiquitous deletion of Cyclin E1 ($CcnE1^{-/-}$), Cyclin E2 ($CcnE2^{-/-}$) or hepatocyte-specific inactivation of Cdk2 ($Cdk2^{\Delta hepa}$), respectively.

Results: *In vitro,* cell cycle activity was dramatically reduced by Rosc in Hepa1–6 hepatoma cells in a dosage-dependent manner. *In vivo*, Rosc treatment significantly diminished DNA-synthesis and completely blocked both Cdk2 and Cdk1 kinase activities in livers of wildtype (WT) mice 48 h after PH. However, 72 h post-surgery, delayed DNA-synthesis, full restoration of Cdk1 kinase activity and slight activation of Cdk2 occurred in Rosc-treated mice. We previously demonstrated that genetic deletion of Cdk2 had no effect on liver regeneration. Intriguingly, Rosc application after PH inhibited DNA-synthesis in WT and $Cdk2^{\Delta hepa}$ livers to the same extend. Thus, the inhibitory effect of Rosc in liver is not mediated *via* Cdk2 but most likely through inhibition of both Cdk2 and Cdk1. Cdk2 activity is controlled by E-Cyclins. To evaluate the role of E-Cyclins for the inhibitory effect of Rosc, $CcnE2^{-/-}$ and $CcnE1^{-/-}$ mice were treated with Rosc and subjected to PH. In $CcnE1^{-/-}$ mice, Rosc treatment resulted in strong cell cycle inhibition after PH. In contrast, Rosc induced only slightly reduced DNA-synthesis in $CcnE2^{-/-}$ mice, which was associated with over-expression of CcnE1. In hepatoma cells with different CyclinE1 expression levels due to conditional gene ablation or adenoviral over-expression we found a strong synergistic cell cycle inhibition by CyclinE1 ablation and Rosc treatment, while adenovirus-mediated CyclinE1 over-expression partially rescued the cell cycle arrest by Rosc.

Conclusions: Rosc may inhibit proliferation of healthy regenerating hepatocytes and immortalized hepatoma cells most likely through blocking of Cdk1 and Cdk2, as initially suggested. The inhibitory effect of Rosc inversely correlates with endogenous levels of CyclinE1 expression. This suggests that only HCC patients with moderate hepatic CyclinE1 expression may benefit from a potential Rosc therapy.

P0405

MOLECULAR MECHANISMS UNDERLYING THE UNPRECEDENTED LIVER REGENERATION INDUCED BY ALPPS SURGERY

M. Langiewicz[1], A. Schlegel[1], H. Bostjan[1], R. Graf[1], P.-A. Clavien[1]. *[1]Visceral and Transplantation Surgery, Universitatsspital Zurich, Zurich, Switzerland*
E-mail: magda.langiewicz@usz.ch

Background and Aims: In many patients with advanced liver cancer a curative resection is not possible with a one-step procedure. A novel surgical approach, ALPPS (Associating Liver Partition with Portal vein for Staged hepatectomy) may be used for unresectable disease due to its ability to induce massive acceleration of liver regeneration. We hypothesize that transection is sufficient to activate plasma proteins necessary for accelerated liver regeneration, and that PVL is necessary to stimulate liver growth.

Using a novel ALPPS mouse model, we aim at studying the molecular mechanisms underlying accelerated liver growth.

Methods: Liver tissue was collected at early time points after Step 1 of ALPPS procedure (30min, 1 h, 4 h, 8 h, 12 h) and analysed by RNA deep sequencing. Plasma samples were collected 30min after ALPPS Step 1 for proteomics analysis by protein enrichment, albumin depletion, and mass spectrometry. Each protein fraction is confirmed for activity by inducing accelerated regeneration upon injection into mice treated with PVL only.

Results: Injection of plasma derived from mice having undergone ALPPS show a significant increase in liver growth compared to plasma from sham-operated mice. Plasma proteins appear to be the major contributors to the accelerated liver growth underlying ALPPS surgery. Transcript analysis shows that differential gene expression occurs 8 hours after the first step of ALPPS. Liver growth is mainly characterized by a hyperplastic reaction reflected as an increased number of hepatocytes entering the cell cycle.

Conclusions: ALPPS is conducive to accelerated liver regeneration through proteins circulating in the plasma as early as 30 minutes after ALPPS Step 1 procedure. Liver growth associated gene expression is observed already within 8 hrs. Identification of plasma proteins stimulating liver growth may have a high therapeutic value in liver disease and associated surgery.

P0406

DELETION OF Cdk1 IN THE LIVER INDUCES CHANGES IN PYRUVATE METABOLISM

M. Caldez[1,2], X.Q. Teo[3], N. Van Hul[1], P. Lee[3,4], P. Kaldis[1,2]. *[1]Institute of Molecular and Cell Biology (IMCB), A*STAR, [2]Department of Biochemistry, National University of Singapore (NUS), [3]Singapore Bioimaging Consortium, A*STAR, [4]Clinical Imaging Research Centre, National University of Singapore (NUS), Singapore, Singapore*
E-mail: mjcaldez@imcb.a-star.edu.sg

Background and Aims: Conditional loss of Cdk1, a master regulator of cell division, leads to restoration of liver mass

after partial hepatectomy (PHx) without cell division. Lack of hepatic Cdk1 induces changes in the expression of genes involved in mitochondrial metabolism and lipid synthesis, and aerobic glycolysis. Understanding changes in metabolic pathways in the context of cell division in the liver could help to detect novel interactions between cell cycle and metabolism, opening a window to discover enzymatic reactions most amenable to therapeutic intervention.

Methods: In order to investigate the relationship between energy metabolism and cell division, we used a functional MRI approach to trace hyperpolarized [^{13}C]-pyruvate *in vivo* in a mouse model of liver regeneration at different time points after PHx (2 h, 24 h, 36 h, 48 h, and 96 h) selected in accordance to the transition of hepatocytes through the cell cycle. Gene expression was assessed using qPCR and WB.

Results: Cdk1$^{Liv-/-}$ mice displayed increased levels of alanine at 36 h and 48 h after PHx compared to their control littermates. This was consistent with an increased mRNA expression of *Gpt2* and *Got2*, two central enzymes in amino acid metabolism, gluconeogenesis and tricarboxylic acid (TCA) cycle. We also found a significant down regulation of *Idh1*, *Idh2* and *Idh3* from the TCA cycle, that regulates the generation of 2-oxoglutarate, a cofactor required for *Gpt2* to transform pyruvate to alanine, as well as the generation of the redox potential in the mitochondria. In order to understand the relationship between the increased alanine metabolism, the downregulation of genes related to the mitochondrial redox potential and cell division, we selected a set of genes involved in oxidation-reduction based on RNAseq data previously obtained at 96 h after PHx in Cdk1$^{Liv-/-}$ mice. Gene expression analysis confirmed that many genes from energy metabolism (i.e. *G6pdx*), carbon metabolism (i.e. *Mthfd1* and *Mthfd2)* fatty acid (*i.e. Abcd2*) and xenobiotic metabolism (i.e. *Ptgs*), displayed an opposite expression levels when compared cells that divide uncontrollably (samples from primary liver tumors) to cells that do not divide (samples from Cdk1$^{Liv-/-}$) suggesting that during cell division there are profound changes in the gene expression of metabolism.

Conclusions: The results from this preliminary study suggest that the block of cell division in the Cdk1$^{Liv-/-}$liver can induce a profound reprogramming in energy metabolism.

P0407
HUMAN INDUCED PLURIPOTENT STEM CELL-DERIVED EXTRACELLULAR VESICLES REVERSE HEPATIC STELLATE CELL ACTIVATION

D. Povero[1], N.P. Goyal[1], L. De Araujo Horcel[2], A. Eguchi[1], P.M. Ordonez[1], A.E. Feldstein[1]. *[1]Department of Pediatrics, University of California San Diego, La Jolla, United States; [2]Centro Universitario Lusiada, São Paulo, Brazil*
E-mail: dpovero@ucsd.edu

Background and Aims: Stem cells, and in particular induced pluripotent stem cells (iPSCs) represent a promising therapeutic approach for fibrotic diseases. Their use, however, is currently limited by issues such as scaling up production and eliminating cells with tumor-forming potential. Extracellular vesicles (EVs) are membrane surrounded structures released by cells, including iPSCs, and contain a footprint of the cell of origin. Here we tested the hypothesis that iPSC-derived EVs (iPSC-EVs) have an anti-fibrogenic effect on hepatic stellate cells (HSC), the key cell involved in liver fibrosis.

Methods: Human iPSC were generated as previously described (Israel MA et al., Nature, 2012). IPSC-derived EVs were isolated by differential centrifugation, quantified by FACS and characterized by dynamic light scattering and electron microscopy. Human HSC (LX2) were maintained in a quiescent-like phenotype by low-serum media and then treated with TGF-β (10 ng/mL) in presence or absence of iPSC-EVs or EV-free media for up to 16 h. Analysis of HSC phenotype, proliferation and chemotaxis were evaluated. Internalization of iPSC-EVs into HSC was assessed by fluorescent tracing techniques.

Results: Characterization of EVs identified microparticles (MP) as the main extracellular vesicle population released by iPSC. The fluorescent tracing assay detected iPSC-EVs internalized in HSC particularly after 6 h of incubation with EVs. The exposure of HSC to iPSC-derived EVs induced a 2-fold down-regulation of the pro-fibrogenic genes α-SMA, Collagen1α1 and TIMP-2 compared to cells treated with TGF-β and EV-free media ($p < 0.005$). A further analysis of the HSC responses occurring during fibrogenesis showed that iPSC-derived EVs reduced HSC proliferation and chemotaxis by 1.5-fold compared to TGF-β and MP-free media+TGF-β-treated HSC ($p < 0.05$). Previous studies have demonstrated that activated HSC may revert to an inactive phenotype (iHSC), which is similar but distinct from quiescence (qHSC). We observed that HSC exposed to iPSC-derived EVs share some quiescence-associated genes such as PPAR-γ, Nr1d2 and Foxj1 but showed a greater up-regulation of inactivation-associated genes, such as IL7R, Csf2rb and Ly86 compared to TGF-β-activated HSCs.

Conclusions: Our study uncovers iPSC-derived EVs as a potential anti-fibrotic therapeutic approach and demonstrates that they activate regenerative programs in HSCs by inducing a phenotypical switch from activated to their inactivated state.

P0408
THE REGULATION OF LIVER VOLUME GAIN AND REGENERATION-ASSOCIATED STEATOSIS THROUGH Pten

E. Kachaylo[1], C. Tschuor[1], M. Linecker[1], P. Limani[1], M. Foti[2], R. Graf[1], B. Humar[1], P.-A. Clavien[1]. *[1]Laboratory of the Swiss Hepato-Pancreatico-Biliary (HPB) Center, University Hospital Zurich, Zurich, [2]Département de Physiologie Cellulaire & Métabolisme, Centre Médical Universitaire, Geneve, Switzerland*
E-mail: ekaterina.kachaylo@usz.ch

Background and Aims: Successful liver regeneration is associated with the transient accumulation of lipids in hepatocytes, likely for the provision of energy to fuel the regenerative process. How this transient steatosis is regulated is ill-understood. The loss of Pten from liver induces rapid redistribution of peripheral fats into liver. Given that Pten also controls the growth-promoting Akt-mTORC1 pathway, Pten may act after resection to facilitate lipid import and to drive liver volume gain. To explore this possibility, we are analysing inducible, hepatocyte-specific *Pten* knockout mice following hepatectomy.

Methods: Pten levels were assessed in hepatectomized wild-type mice. *AlbCre$^{tg/+}$PTEN$^{fl/fl}$* and *AlbCre$^{+/+}$PTEN$^{fl/fl}$* (control) mice were studied shortly after tamoxifen induction. Regeneration was monitored via weight gain, proliferative activity and cyclin levels. Lipid content was quantified through a sulpho-phospho-*vanillin* protocol.

Results: In wild type mice, Pten levels dropped along with pronounced T389-Akt phosphorylation at 16 h post resection, coinciding with the peak of transient steatosis. In parallel, fatty acid import (Cd36) and β-oxidation (Cpt1a, Hadha/b) increased, whilst lipogenesis (Acc, Scd, Fasn) decreased. Inducing Pten loss In *AlbCre*tg/+PTENfl/fl mice resulted in spontaneous lipid accumulation. Two and three days after resection however, lipid content was similar to controls, yet liver weight gain was accelerated. Notably, the increased liver weight gain was not accompanied by elevations in proliferative markers, suggesting an involvement of hypertrophy.

Conclusions: Our results demonstrate a growth-promoting function for Pten downregulation during liver regeneration. The reduction in Pten may aid liver growth through (i) the release of inhibition of the hypertrophic Akt-mTORC1 pathway, and through (ii) the provision of energy via facilitated lipid import.

LKB1: A KEY REGULATOR OF HEPATOCYTES PROLIFERATION AND GENOME INTEGRITY

V. Maillet[1,2,3], M. Diribarne[1,2,3], V. Fauveau[1,2,3], G. Merlen[1,2,3], S. Morizur[1,2,3], C. Perret[1,2,3], C. Desdouets[1,2,3]. [1]*INSERM U1016, Institut Cochin,* [2]*Université Paris Descartes, Sorbonne Paris Cité,* [3]*CNRS UMR 8104, Institut Cochin, Paris, France*
E-mail: vanessa.maillet@inserm.fr

Background and Aims: Liver Kinase B1 or LKB1 (also called Serine Threonine Kinase 11) is an evolutionarily conserved protein kinase which is involved in a diverse array of cellular processes, including energy homeostasis, cell polarity, apoptosis and cell growth. All these processes play a role in cancer initiation and progression. Their relative contribution to LKB1-mediated tumor suppression remains unclear. Interestingly, previous results have demonstrated that haploinsufficiency of LKB1 in the liver leads to the development of Hepatocellular Carcinomas. In the current study, we evaluate the potential effect of LKB1 deletion on hepatocyte proliferation.
Methods: We use hepatocyte specific LKB1 knockout mice to dissect the role of LKB1 in hepatocyte proliferation. We study the kinetics of liver regeneration after partial hepatectomy (PH). Livers (Control and KO) are dissected at different time points after PH in order to analyze DNA replication, division completion and various signaling pathways involved in hepatocyte proliferation.
Results: We first observe that following partial hepatectomy, LKB1 (−/−) hepatocytes exhibit early entry into S phase and prolonged proliferation leading to hepatomegaly. The priming events, lipid droplets accumulation and protein anabolic responses appear to be intact in LKB1 KO livers. Interestingly in KO hepatocytes, AMPK (AMP-activated protein kinase) is phosphorylated as cells proceed through S phase. Deletion of LKB1 impacts on G1/S transition by regulating the expression of key players involved in the initiation of S phase such as Cyclin A2, Cdc6 and E2F1. On the other hand, loss of LKB1 in hepatocytes also alters genomic integrity. LKB1 (−/−) hepatocytes present a block in metaphase/anaphase transition, associated with the increase of mitotic errors. A recent transcriptomic analysis highlighted the activation of different markers of the Spindle Assembly Checkpoint, such as Mad2 and BubR1. In line with these results, we observe that LKB1 deficient hepatocytes present an alteration of ploidy profile at the end of the regenerative process.
Conclusions: Collectively, these findings emphasize the key role of LKB1 in the regulation of hepatocyte proliferation and particularly on the maintenance of DNA and ploidy integrity.

P0410

CHARACTERIZATION OF THE SLOWLY CYCLING CELL POPULATION IN MOUSE LIVER

J. Viil[1], V. Jaks[1]. [1]*Department of Cell Biology, University of Tartu, Tartu, Estonia*
E-mail: janeli.viil@ut.ee

Background and Aims: In many tissues, undifferentiated adult stem/progenitor cells are crucial for the tissue maintenance in normal conditions and for the recovery after injury. In the liver, however, the normal tissue turnover is achieved by the replication of its fully differentiated parenchymal cells. The existence of liver stem cells and their contribution in liver maintenance and regeneration is still under debate. Since tissue specific adult stem cells are considered to be slowly cycling or quiescent we used label retaining cell (LRC) assay to determine the localization and properties of potential liver stem cells.
Methods: Rosa26-rtTa mice that express ubiquitously expressed reverse tetracycline-dependent transactivator were crossed with H2B-GFP mice that express Histone 2B-enhanced green fluorescent protein (EGFP) fusion protein under the control of tetracycline response element to create double transgenic rtTa-GFP mice. For the induction of H2B-GFP expression (cell labeling) mice receive doxycycline (tetracycline analogue) in drinking water and after removing doxycycline from drinking water the dividing cells gradually lose their label whereas quiescent cells retain their GFP label (LRCs).
Results: We determined the optimal time for the admission of doxycycline, traced the label up to 20 weeks and identified the localization and the repertoire of markers of label-retaining GFP-positive cells under normal conditions. We discovered that slowly cycling liver cells concentrated mainly in the portal areas, particularly in bile ducts, and expressed biliary epithelial cell markers. We also found few LRCs among hepatocytes. These parenchymal LRCs, however, were individually scattered throughout the liver and had lower GFP expression. In addition, we studied the behaviour of LRCs in chronic liver injury and looked at the changes in LRC compartment after partial hepatectomy (PH) and CCl_4 intoxication. We found that proliferation of liver LRCs, indicated by the loss of GFP signal in biliary ducts, occurred after induced chronic injury (DDC diet and bile duct ligation). PH and CCl_4, on the other hand, did not affect the quiescent state of biliary LRCs, although we could detect less parenchymal LRCs after liver regeneration.
Conclusions: These results suggest that LRCs in bile ducts enter the cell cycle and take part in liver regeneration in response to chronic liver injury and only part of parenchymal LRCs contribute to the recovery from liver resection or CCl_4 intoxication.

P0411

PREGNANCY INDUCES SELECTIVE CHANGES IN HEPATIC GENES INVOLVED IN CELL PROLIFERATION AND APOPTOSIS IN MICE

L. Grenfell[1], M. Hanson[1], K. Lillycrop[1], G. Burdge[1]. [1]*University of Southampton, Southampton, United Kingdom*
E-mail: l.r.grenfell@soton.ac.uk

Background and Aims: During pregnancy the liver undergoes substantial structural and metabolic adaptations to meet the nutritional demands of the mother and fetus; however, the underlying mechanism is poorly understood. To address this, we analysed the expression of the liver transcriptome in non-pregnant and early, mid and late pregnancy mice.
Methods: C57/Blk6 Virgin mice (90 day old, $n \geq 6$) were mated and culled on d7, d14 or d18 gestation, or culled without mating. Livers were collected, weighed and snap frozen. Cell diameter was measured using haematoxylin and eosin (H&E). Proliferating cells were identified by immunohistochemistry using an anti-Ki67 antibody. Statistics were performed using either a one-way ANOVA with a Bonferroni *post hoc* test or Kruskal–Wallis with a Dunns *post hoc* test (threshold for significance $P < 0.05$). RNA was extracted and expression of the transcriptome was analysed using the Illumina MouseRef-8 v2.0 Expression BeadChip and analysed using IPA software (>2-fold changes in average signal were considered significant).
Results: There was no significant change in liver weight at d7, while liver weight at d14 was 20% ($P = 0.004$) and at d18, 60% ($P \leq 0.001$) greater compared to non-pregnant mice. This was accompanied by a 20% increase in cell diameter at d14 and 17% at d18 (both $P = 0.025$). The proportion of proliferating cells was unchanged at d7, but was increased at d14 and at d18 compared to non-pregnant liver. The expression of 115 genes was significantly altered (41 down and 74 up) at d14 and 123 (46 down and 77 up) at d18. Of these, 79 genes were changed at both time points. The top changed pathways at both d14 and d18 included small molecule biochemistry, molecular transport, organismal and tissue development. This reflected changes in genes consistent with increased cell proliferation at d14 and d18, and inhibition of apoptosis at d18 gestation.
Conclusions: These findings suggest that pregnancy-associated liver growth in mice is initiated between d7 and d14 of gestation.

This involves both hypertrophy and hyperplasia, accompanied by inhibition of apoptosis at d18. One possible interpretation is that the nutritional demands of the rapidly growing fetus in late gestation exceeds that which can be met by maternal liver growth mediated by cell proliferation alone and so may require decreased cell turnover in order to facilitate a sufficient increase in functional capacity.

P0412

NETRIN-1 PROTECTS AGAINST HEPATOCYTIC CELL DEATH UPON UPR THROUGH SUSTAINED TRANSLATION IN AN UNC5A/C-DEPENDENT FASHION

T. Lahlali[1], M.-L. Plissonnier[1], M. Michelet[1], C. Romero-Lopez[2], B. Ducarouge[3], F. Zoulim[1], P. Mehlen[3], R. Parent[1]. *[1]Inserm U1052-UMR CNRS 5286, Team 15, Centre de Recherche en Cancérologie de Lyon, Lyon, France; [2]Instituto de Parasitología y Biomedicina López-Neyra IPBLN-CSIC, CSIC, Parque Tecnológico de Ciencias de la Salud, Avda. del Conocimiento s/n, Armilla, Granada, Spain; [3]Inserm U1052-UMR CNRS 5286, Team 1, Centre Léon BERARD, Centre de Recherche en Cancérologie de Lyon, Lyon, France*
E-mail: thomas.lahlali@laposte.net

Background and Aims: The unfolded protein response (UPR) is a hallmark of viral and non-viral hepatic diseases and is involved in hepatic oncogenesis. Netrin-1 is an anti-apoptotic secreted factor up-regulated in many cancer types in which chronic Endoplasmic Reticulum (ER) stress is observed. To restore ER homeostasis, cells activate UPR, which may also trigger or impede apoptosis through different processes including DAPK activation. In hepatocellular carcinoma, cells are resistant to UPR-induced apoptosis, prompting us to study the anti-apoptotic role of Netrin-1 upon UPR in the hepatic context.
Methods: UPR was experimentally induced by DTT and tunicamycin in vitro (Huh7.5 cells, HepaRG cells, primary human hepatocytes) and in WT or Netrin-1-overexpressing mice, respectively. Netrin-1 translation was studied through polysome isolation in vitro, in mice, and in liver resections. Netrin-1 5′UTR was studied by SHAPE and DMS and its ability to recruit the ribosomal 40S subunit. Apoptosis induction was monitored after RNAi depletion or forced expression of Netrin-1 and various effectors of the Netrin-1/UNC5 pathway through DNA fragmentation, caspase-3 and PP2A activities in vitro and in mice.
Results: Functional UPR activation, as determined by GRP94, CHOP, and XBP1s mRNA expression, was verified in all systems. SHAPE and DMS experiments showed that Netrin-1 5′UTR bears highly structured motifs and autonomously recruits ribosomal 40S subunits. Netrin-1 mRNA remained strongly associated with translational units upon global shut-down of protein translation caused by UPR compared to the cap-dependent translated Gus and β-actin mRNAs in HepaRG hepatocyte-like cells, Huh7.5 hepatoma cells, mice livers, and in UPR(+) patient resections. In the absence of Netrin-1, Netrin-1 receptors UNC5A and C trigger apoptosis through activation of the DAPK1/PP2A/PR65b complex. Netrin-1 overexpression in mice protected against UPR-induced cell death as evaluated by caspase-3 and TUNEL assays.
Conclusions: These results indicate that Netrin-1 (i) is resistant to global translational repression upon UPR in hepatocytes, probably through IRES-dependent mechanisms, (ii) could protect cells against UPR-related cell death after binding to UNC5A and C, leading to the inhibition of DAPK1-mediated apoptosis and (iii) may condition the overall survival rate of hepatocytic cells upon UPR, a frequently activated cellular function in the context of hepatocarcinoma-associated chronic liver diseases.

P0413

D-DOPACHROME TAUTOMERASE: NOVEL REGULATOR OF HEPATIC AUTOPHAGY

A.L. Eheim[1], C. Bahr[1], M. Berriel Diaz[1], S. Herzig[1]. *[1]Molecular Metabolic Control, German Cancer Research Center, Heidelberg, Germany*
E-mail: ashley.l.eheim@gmail.com

Background and Aims: Characterized as an adipokine, d-dopachrome tautomerase (DDT) also functions as a ligand for CD74 signaling, and is expressed in various other tissues including liver. Examination of array/qPCR data showed DDT to be significantly increased in livers of high-fat diet fed mice compared to controls. The Comparative Proteomic Analysis Software Suite database indicated DDT interacts with several proteins involved in cell metabolismand autophagy, both of which are known to be disturbed in high-fat diet-induced NAFLD. The aim of this study was to explore a possible link between dysregulated DDT expression and liver cell function.
Methods: Mouse hepatocytes, AML12 and Hepa1–6 cells were used in siRNA-mediated knockdown experiments. Vesicle formation was monitored via bright-field and fluorescent microscopy. Gene expression was analyzed by qPCR and/or immunoblot. For analysis of autophagosomes, cells were transduced with a GFP-LC3B tandem autophagy sensor via baculovirus.
Results: qPCR revealed higher expression of DDT in AML12 cells and primary hepatocytes compared to Hepa1–6 cells. Various assays were performed to assess cellular function following DDT knockdown. While slight impairment of proliferation was observed, the most striking effect was formation/accumulation of cytoplasmic vesicles. Vesicle accumulation was consistent between primary hepatocytes and AML12 cells, but absent in Hepa1–6 cells. Interestingly, treatment with forskolin led to a decrease in the number and size of vesicles, which was absent in controls. As the structures induced by DDT knockdown had lipid droplet-like morphology, staining for neutral lipids was performed. Two independent staining approaches did not stain these structures, indicating the vesicles do not contain neutral lipids. However, treatment of AML12 cells with an autophagy inhibitor, chloroquine phosphate, led to an induction of vesicles in the cytoplasm resembling those in DDT knockdown cells. Evaluation of various autophagy markers showed dysregulated p62, ATG5 and ATG7 in DDT knockdown cells. Finally, with use of the LC3B tandem sensor, vesicles were marked as inhibited autophagosomes.
Conclusions: Overall, knockdown of DDT appears to inhibit autophagy in vitro, with inhibition characterized by accumulation of ATG5 and p62 leading to the formation of autophagosomes, which do not fuse with lysosomes. These data are the first to indicate DDT may have a functional role in hepatic autophagy, a novel link that warrants further investigation.

P0414

CONSTITUTIVE ANDROSTANE RECEPTOR-MEDIATED DOWN-REGULATION OF MIR-122 IN LIVER

Y.A. Pustylnyak[1,2], Y.A. Kazantseva[3], A.A. Yarushkin[3], A.A. Tulupov[1,4], V.O. Pustylnyak[1,3,4]. *[1]Novosibirsk State University, [2]Central Clinical Hospital SB RAS, [3]Institute of Molecular Biology and Biophysics SB RAMS, [4]The Institute International Tomography Center of the Russian Academy of Sciences, Novosibirsk, Russia*
E-mail: pustylnyak@ngs.ru

Background and Aims: MiR122 is a major hepatic miRNA, accounting for more than 70% of total liver miRNA population. MiR122 is involved in hepatocyte proliferation, differentiation, apoptosis and associated with liver diseases, including HCC. Mir122 is an intergenic miRNA with its own promoter. Pri-miR122 expression is regulated by liver enriched transcription factors, mainly by HNF-4a, which mediates expression via interaction with

DR1 site. Phenobarbital-mediated constitutive androstane receptor (CAR) activation is associated with the decrease of miR-122 level in liver. CAR can modulate pathways involved in liver regeneration after PH, induce direct hyperplasia and has profound effects on hepatic carcinogenesis. CAR can inhibit HNF4a transcriptional activity by competing with HNF4a for binding to the DR1 motif in gene promoters. In present study we investigated HNF4a-CAR crosstalk in the regulation of the hepatic miR122 level.
Methods: Mice were treated ip with TCPOBOP and/or 5α-androstan-3α-ol (Andr). Gene expression levels were measured by real-time PCR. Western blot analysis was performed to determine any changes in proteins. ChIP assay was performed on the chromatin extracted from livers to demonstrate the recruitment of transcription factors to their respective binding sites on the gene promoters.
Results: The level of miR122 was significantly repressed by treatment with TCPOBOP, which is an agonist of mouse CAR. In order to assess the involvement of the CAR on the down-regulation of miR122, the TCPOBOP treatment was repeated in the presence of CAR inverse agonist Andr. When Andr was given prior to TCPOBOP, it caused an increase of the hepatic levels of miR122 compare to TCPOBOP treated only. ChIP assays demonstrated that TCPOBOP-activated CAR inhibited HNF4a transactivation by competing with HNF4a for binding to DR1 site in pri-miR122 promoter. Transcription factors replacement was strongly correlated with miR122 down-regulation. CAR interaction with DR1 site was abolished after Andr co-treatment. CAR-mediated down-regulation of miR122 was correlated with up-regulation of its targets, including Cyclind1, E2f1 and E2f1-target gene, cMyc, which promote G1/S cell cycle progression. Long-term TCPOBOP treatment caused a significant increase in both the liver mass and liver-to-body weight ratio.
Conclusions: Thus, our results provide evidence to support the conclusion that CAR activation decreases miR122 level through suppression of HNF4a transcriptional activity.

P0415
CELL CYCLE REGULATION IS DELAYED IN A MODEL OF LIVER REGENERATION AFTER SERIAL PARTIAL HEPATECTOMY

M. Caldez[1,2], N. Van Hul[1], P. Kaldis[1,2]. *[1]Institute of Molecular and Cell Biology (IMCB), A*STAR (Agency for Science, Technology and Research), [2]Department of Biochemistry, National University of Singapore (NUS), Singapore, Singapore*
E-mail: mjcaldez@imcb.a-star.edu.sg

Background and Aims: Hepatocytes enter the cell cycle to recover the original liver mass, when confronted with liver damage. Since little is known about the condition of the liver after it has regenerated, here we describe a new model to study the regulation of the cell cycle in a mouse model of serial partial hepatectomy (PHx).
Methods: Serial PHx consists of the subsequent removal of different liver lobes: first the median and left lobes (PH1), 2 weeks later the superior right lobe (PH2) and 2 more weeks later, the inferior right lobe (PH3). Livers were collected at 24, 48, 72, and 96 h after each PHx. These time points correspond to the transition from G1 to S phase, from G2 to mitosis, and the transition through mitosis, respectively. Analysis was done by IHC, WB, and RT-PCR.
Results: BrdU incorporation, a marker of DNA replication in S phase, was decreased from 25% $BrdU^+$ cells at 48 h after PH1 to 20% after PH2 and to 15% after PH3. While the peak of BrdU incorporation was observed at 48 h for PH1 and PH2, it was delayed to 72 h after PH3. Interestingly, a peak of 60% of $Ki67^+$ hepatocytes was observed at 72 h after PH1 and a peak of 35% after PH2, with a gradually decrease over time. However, 65% of $Ki67^+$ hepatocytes was already observed at 48 h after PH3 and remained at that level until 96 h. These results suggest that the progression through the cell cycle could be affected by serial PHx, with a decrease in the number of cells transiting through the cell cycle after PH2 and a delay in the timing of the transition through the cell cycle after PH3. Our study of gene expression revealed an important decrease after PH2 and PH3 in the level of cyclin A1 and A2 as well as cyclin B1, B2, B3 and Cdk1, controlling the transition through G2 and cell division, respectively. A significant downregulation was detected in the levels of cyclin D1 after PH2 and PH3, suggesting that there may be a defect in the regulation of signalling pathways in early phases of liver regeneration. Finally, while Cdk4 and Cdk6 did not display significant changes, the expression of Cdk2 was slightly delayed after PH3 only, indicating that other earlier phases of cell cycle progression may not be affected.
Conclusions: Our study indicates that up to 90% of the liver can be resected using the serial PHx protocol with a high viability of the mice. Nevertheless, cell cycle regualtion in the different hepatectomies seem to differ in their molecular mechanism, which will need to be studied in more details in the future.

P0416
RELEVANCE OF BMP9-MEDIATED SIGNALING IN OVAL CELL FUNCTION DURING LIVER INJURY. CROSSTALK WITH THE HGF/Met PATHWAY

A. Addante[1], M. García-Álvaro[1], C. Roncero[1], L. Almalé[1], N. Deleyto[1], M. Fernández[1], I. Fabregat[2], B. Herrera[1], A. Sánchez[1]. *[1]Department of Biochemistry and Molecular Biology, Faculty of Pharmacy, Complutense University of Madrid (UCM), Instituto de Investigación Sanitaria del Hospital Clínico San Carlos (IdISSC), Madrid, Spain; [2]Bellvitge Biomedical Research Institute – IDIBELL, L'Hospitalet de Llobregat, Barcelona, Spain*
E-mail: aaddante@ucm.es

Background and Aims: Oval cells constitute a bi-potential progenitor cell population from adult liver. Under chronic liver disease, they become activated and start to proliferate and differentiate into cholangiocytes and/or hepatocytes to compensate for the cellular loss and contribute to maintain liver homeostasis. However, some evidences support a pro-fibrogenic and pro-tumorigenic role for these cells. BMP9, a member of the BMP family, has recently emerged as a critical regulator of liver pathology. Specifically, results from our group and others have evidenced a pro-tumorigenic action of BMP9 in HCC cells. This prompted us to explore the potential role for BMP9 in regulation of liver progenitor cells function.
Methods: For that, we have used oval cell lines harboring a genetically inactivated met tyrosine kinase ($Met^{-/-}$ cells) and their control (Metflx/flx cells) that allow us to explore a potential signaling interaction between HGF and BMP9. We show that BMP9 induces Smad1/5/8 signaling in both Metflx/flx and $Met^{-/-}$ cells, but interestingly, Met significantly potentiates BMP9-induced signaling. To understand how this affects cell response to BMP9, we run functional assays.
Results: Our results indicate that BMP9 elicits a decrease in cell number, which is associated with induction of a moderate but significant apoptotic response. This effect is consistently more pronounced in $Met^{-/-}$ cells. Importantly, HGF is able to prevent BMP9 effects. In addition to acute BMP9 treatment, we have submitted oval cells to chronic treatment with BMP9. Phenotypic and functional characterization of these cells (named as B9T-OC) has evidenced an up-regulation of epithelial and hepatic lineage markers (E-cadherin, HNF4a and albumin) and concomitant loss of mesenchymal and hematopoietic stem cell markers.
Conclusions: Altogether, our findings reveal a novel role for BMP9 as an important regulator of oval cell phenotype and survival. While acute BMP9 treatment elicits a suppressor activity, chronic treatment promotes acquisition of a more epithelial and differentiated phenotype. Additionally, we evidence a novel

functional crosstalk between HGF/Met and BMP9 pathways in regulation of oval cell survival, whose biological significance has not yet been clarified. In vivo studies, using a model of chronic liver damage associated with expansion of oval cells, are being conducted in wild type and BMP9 knockout mice. They will help us to further clarify the role played by BMP9 in liver injury and how it may determine oval cell fate.

Nlrp3 INFLAMMASOME INCREASES HEPATIC FIBROSIS BY INDUCING INFLAMMATORY SIGNALS IN HEPATIC STELLATE CELLS

C. Rychlicki[1], L. Agostinelli[1], E. Mingarelli[1], S. Saccomanno[1], C. Pinto[1], I. Pierantonelli[1], L. Trozzi[1], M. Marzioni[1], S. De Minicis[1], G. Svegliati-Baroni[1]. [1]*Gastroenterology, Polytechnic University of Marche, Ancona, Italy*
E-mail: gsvegliati@gmail.com

Background and Aims: Hepatic fibrosis represents the wound-healing response process to chronic liver injury, independently from aetiology. Hepatic stellate cells (HSCs) are the main liver extracellular matrix producing cells and also exert proinflammatory activity. The NLRP3 inflammasome mediates the release of proinflammatory cytokines in response to cellular danger signals in various organs, but its role in the progression of hepatic injury has to be determined. Thus, aim of the study was to evaluate the role of NLRP3 inflammasome in fibrosis development and in HSCs behaviour.
Methods: Wild-type (WT) C57BL/6 and *Nlrp3*^{A350VneoR} (*Nlrp3*$^{-/-}$) mice underwent bile duct ligation (BDL) and were sacrificed at 3 weeks. Quiescent HSCs (quHSCs) from WT mice were obtained after 12 hours of culture, while *in vitro* activated HSCs (AcHSCs) were obtained after 6 days of culture.
Results: Compared to WT, *Nlrp3*$^{-/-}$ BDL mice showed a significant reduction in inflammasome activation in the liver (Caspase-1, IL1β and IL18 gene expression) that was associated to significantly decreased hepatic TLR4, TLR9 and IL6 mRNA levels. Type I collagen, TGFβ, CTGF and TIMP1 gene expression were significantly reduced in *Nlrp3*$^{-/-}$ BDL mice. This led to reduced collagen deposition measured by Sirius Red staining in *Nlrp3*$^{-/-}$ BDL mice. *In vitro* HSCs activation was associated to significantly decreased gene expression of inflammasome components (NLRP3/ASC/Caspase-1/IL1β/IL18) compared to (qu)HSCs. However, (Ac)HSCs stimulation with the pathogen-associated molecular pattern LPS induced expression of the NLRP3/Caspase-1/IL1β/IL18 pathway, without affecting neither type I collagen mRNA nor cell proliferation. After priming with LPS, incubation with the damage-associated molecular pattern ATP was needed for the release of IL1β. (Ac)HSCs incubation with recombinant IL1β further stimulated the NLRP3/Caspase-1/IL1β pathway and lead to increased TGFβ and CTGF gene expression and HSCs migration.
Conclusions: NLRP3 inflammasome contributes to hepatic fibrosis by increasing the inflammatory response (increased IL1β and IL18 gene expression) and inducing a paracrine loop that maintains TLRs activation and IL6 production. IL1β released by (Ac)HSCs stimulates fibrogenesis and cell migration in an autocrine manner. Several new therapeutic targets can be identified in the NLRP3 inflammasome pathway to treat hepatic fibrosis.

E-mail: Lemol1970@gmx.de

Background and Aims: Activated myofibroblasts play a central role in liver fibrosis via expression of most of the scar tissue that characterizes fibrosis and cirrhosis. While collagen type I is mainly expressed in bone, collagen type III is largely restricted to soft tissue (myo-) fibroblasts Moreover, for studying gene functions in *vivo*, models for specific target inducible gene disruptions using cell type-specific gene promoters are needed. Therefore, we aimed to generate a mouse line with an inducible (myo-) fibroblast specific Col3a1 promoter controlling Cre recombinase expression.
Methods: A 204 kb BAC from a genomic library (Children's Hospital Oakland Research Institute) that contains the full-length mouse Col3a1 gene (RP23–324D9) was selected for recombineering in a EL250 bacteria targeting cassette encoding CreERT2 and a kanamycin resistance gene flanked by two FRT sites. This construct was integrated into the ATG-start codon of the Col3a1 gene by homologous recombination. The FRT-flanked kanamycin resistance cassette was subsequently deleted by arabinose-induced expression of Flp recombinase. The purified, linearized Col3a1-CreERT2 BAC DNA fragment was microinjected into the pronucleus of C57BL/6N oozytes. Transgenic founder mice were identified by PCR genotyping of tail tips.
Results: To test the CreERT2 mouse line, a double-fluorescent Cre reporter mouse that expresses membrane-targeted Tomato prior to Cre-mediated excision and membrane-targeted green fluorescent protein after excision was used. Bi-transgenic Col3a1-CreERT2/Tomato mice were treated with CCl_4 for three weeks, to induce liver fibrosis and with tamoxifen for the last five days, to induce Cre recombination. Thereafter, mice were analyzed *in vivo* using confocal laser scanning microscopy showing a massive GFP signal compared to control animals without tamoxifen treatment. Dual-label fluorescent immunohistochemistry using liver sections demonstrated perfect co-localization of GFP positive cells with procollagen a1(III) stained areas and of GFP with a-SMA, indicating that all GFP positive cells were activated myofibroblasts.
Conclusions: We generated a conditional Col3a1a-CreERT2 mouse that promises to be highly useful for the study of myofibroblast activation, gene expression and antifibrotic target discovery in liver fibrosis.

E-mail: lkaps@students.uni-mainz.de

Background and Aims: Efficient *in vivo* transport of active siRNA to specific liver cells remains challenging. Compared to lipoplex or polyplex formulations, cationic nanohydrogel particles (NHP)

can serve as superior oligonucleotide carriers [Siegwart DJ et al, PNAS 2011]. We have designed NHP [Nuhn L et al, ACS Nano 2012] that serve as stable carriers for siRNA, avoid carrier aggregation under physiological conditions and promote size-dependent gene silencing *in vitro* [Nuhn L et al, Biomacromolecules 2014].

Results: NHP composed of block copolymers [pentafluorophenyl methacrylate and tri(ethylene glycol) methyl ether methacrylate] loaded with negative control siRNA up to 600 nM siRNA concentrations which are far above concentrations for *in vivo* knockdowns and of a size of 30 to 40 nm did not show cytotoxicity for murine 3T3 fibroblasts, Raw or MHS macrophages, or for HepG2 human hepatoma cells and AML-12 murine benign hepatocytes. In media with 10% fetal calf serum FITC-labelled NHP were taken up efficiently and dose-dependently by all cells tested, reaching up to 90% after 1 h incubation as determined by FACS analysis. NHP loaded with procollagen a1(I) or CD68 siRNA yielded a robust knockdown in 3T3 and Raw cells, respectively, after 48 h of incubation as determined by qPCR.

In vivo studies using near infrared labelled NHP loaded with Cy5 labelled procollagen a1(I) siRNA were performed in mice with CCl_4-induced liver fibrosis [Popov Y et al., Hepatology 2009]. After intravenous injection NHP distributed preferentially to the liver (80%), as determined by *in vivo* and *ex vivo* near infrared imaging. Double labelling immunohistochemistry and *ex vivo* FACS analysis revealed a preferential colocalization with myofibroblasts (α-SMA positive) and macrophages (CD45+, F4/80+, CD11b+). NHP loaded with procollagen a1(I) siRNA generate an up to 80% *in vivo* knockdown in CCl_4-induced liver fibrosis. Efficient knockdown was further confirmed by decreased liver collagen (Sirius red staining and hydroxyproline content).

Conclusions: siRNA loaded NHP accumulate in liver and especially in (myo-) fibroblasts and macrophages/Kupffer cells. Due to their intrinsic specificity for nonparenchymal cells, an apparent lack of toxicity and a high loading capacity, they are attractive carriers for siRNA-based antifibrotic or immune modulatory therapies.

SELECTIVE INHIBITOR OF WNT/β-CATENIN/CBP SIGNALING AMELIORATES HEPATITIS C VIRUS-INDUCED LIVER FIBROSIS IN MICE

K. Kimura[1,2], Y. Tokunaga[2], T. Ohtsuki[2], Y. Hayashi[3], K. Munekata[2], T. Hishima[3], M. Kohara[2]. *[1]Division of Hepatology, Tokyo Metropolitan Komagome Hospital, [2]Department of Microbiology and Cell Biology, Tokyo Metropolitan Institute of Medical Science, [3]Department of pathology, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan*
E-mail: kkimura@cick.jp

Background and Aims: Chronic hepatitis C virus (HCV) infection is one of the major causes of developing serious liver diseases, including liver cirrhosis and hepatocellular carcinoma (HCC). An estimated with one million people die from cirrhosis worldwide each year. Unfortunately, at present there are not-sufficient effective anti-fibrotic drugs for liver cirrhosis. In this study, we investigated the anti-fibrotic activities of PRI-724, a selective small molecule inhibitor of β-catenin/CBP (cyclic AMP response element binding protein) interaction, using hepatitis C transgenic mouse model mimicking chronic HCV infection, which induced fibrosis.

Methods: The anti-fibrotic activity of PRI-724 was assessed by using HCV GT1b transgenic mice at 18 months after HCV genome expressing, which mimic chronic HCV infection and develop liver fibrosis and HCC. PRI-724 was continuously injected with mice for 6 weeks using osmotic pump. We observed histological features, serum ALT activity, HCV core protein level, the number and characteristics of the intrahepatic leukocytes. Liver fibrosis was monitored by histology with Silver stain, Masson trichrome, Sirius red staining and quantification of hepatic hydroxyproline amounts. Furthermore, mRNA expression levels in the liver following PRI-724 treatment were analyzed by quantitative real-time PCR.

Results: Continuous subcutaneous infusion of PRI-724 (1 mg/kg/day) for 6 weeks reduced collagen fibrils and collagen levels in the liver as indicated by Silver stain, Masson trichrome, Sirius red staining and quantification of hydroxyproline levels, respectively. There was no change in ALT levels after treatment, suggesting that anti-fibrotic effect of PRI-724 was not caused by cytotoxic or cytolytic activities. We found that although the MMP-8 (collagenase-2) and MMP-9 mRNA expression in the liver of HCV Tg mice was suppressed, PRI-724 administration induced both MMPs mRNA expression in the liver. Consistent with this result, we showed that intrahepatic neutrophils and macrophages increased in the liver after PRI-724 injection.

Conclusions: PRI-724 ameliorated HCV-induced liver fibrosis in mice model. MMP-8 and MMP-9 induction might contribute to the resolution of fibrosis by PRI-724. Thus, we suggested that PRI-724 would be one of the candidates of anti-fibrotic drugs for HCV-induced liver fibrosis.

REINTRODUCTION OF miR19b INHIBITS HEPATIC STELLATE CELL-MEDIATED FIBROGENESIS

E.B. Warner[1], C.R. Culberson[1], N. Feilen[1], L.W. Schrum[1]. *[1]Liver Pathobiology, Carolinas Healthcare Systems/Cannon Research Center, Charlotte, United States*
E-mail: elizabeth.warner@carolinashealthcare.org

Background and Aims: Hepatic stellate cell (HSC) activation mediated by transforming growth factor beta (TGFb) is a key event in hepatic fibrosis. MicroRNA 17–92 (miR17–92) cluster consisting of miR17a-18a-19a-20a-19b and 92 modulate components of the TGFβ pathway. MiRs in this cluster are differentially expressed during liver injury, with miR19b significantly downregulated. Further, miR19b is a regulator of TGFb signaling in HSCs. Several mRNAs critical to HSC activation and TGFb signaling, such as TGFb receptor II (TGFbRII), are miR19b targets. We *hypothesize* that HSC-targeted reintroduction of miR19b by adeno-associated virus, serotype 2 (AAV2), will inhibit fibrosis during hepatic injury.

Methods: Culture activated (day 10) primary Sprague-Dawley rat HSCs, isolated by standard pronase/collagenase perfusion, were used. HSCs were treated with tyrphostin-1 (500μM, 4 hours), media changed, and cells transduced with AAV2 (5000 MOI) containing GFP with mature-miR19b (AAVmiR) or truncated miR19b control (AAVcon) under transcriptional regulation of the collagen α1(I) promoter for 24 or 48 hours. Additionally, Sprague-Dawley rats underwent sham or bile duct-ligation (BDL). AAVmiR or AAVcon (5×10^{11}, 1×10^{12}, or 2×10^{12} VG/rat) was injected via portal vein at the time of BDL/sham surgery. Tissues were harvested at necropsy 1 or 2 weeks post BDL/AAV2 surgery. In both models, pro-fibrotic gene expression and markers of HSC activation were measured by qRT-PCR and Western blot. AST/ALT levels in rat plasma and collagen deposition in FFPE liver sections were also examined.

Results: *In vitro*, pro-fibrotic mRNA and protein expression [αSMA, colα2(I), and TGFbRII] were significantly downregulated in AAVmiR transduced HSCs compared to AAVcon. Transduction was confirmed by viewing GFP positive cells by fluorescent microscopy. *In vivo*, hepatic collagen deposition was decreased by 80% in BDL/AAVmiR *vs* BDL/AAVcon treated animals, despite the obvious injury induced by BDL. AST/ALT levels were also reduced. Further, pro-fibrotic mRNA and protein expressions were significantly decreased in AAVmiR animals. Expression of miR19b increased in a dose dependent manner in AAVmiR treated animals.

Conclusions: AAV2 reintroduction of miR19b ameliorated fibrosis by inhibiting fibrotic gene expression and HSC activation, which correlated with increased miR19b expression. These data support HSC-targeted reintroduction of miR19b as an effective anti-fibrotic therapy.

ROLE OF APOPTIC DNA AND EXTRACELLULAR CORE HISTONES IN INFLAMMASOME ACTIVATION IN PRIMARY HUMAN HEPATIC STELLATE CELLS

F. Andreola[1], K. Rombouts[1], M. Rodriguez[1], C. Imber[2], R. Jalan[1].
[1]UCL Institute for Liver & Digestive Health, [2]Division of Surgery, Royal Free London Foundation Trust, University College London, London, United Kingdom
E-mail: f.andreola@ucl.ac.uk

Background and Aims: Hepatocyte cell death is accompanied by extensive release of cleaved genomic DNA (mono- and polynucleosomes) in the extracellular compartment. As sustained hepatocyte cell death is implicated in the development of hepatic fibrosis, portal hypertension and liver cancer, this study aimed to investigate the effect of nucleosomes (from apoptotic hepatocytes) and extracellular histones on human Hepatic Stellate Cells (hHSC) and their role in inflammasome activation.
Methods: Cleaved nucleosomes were obtained (a) from apoptotic hepatocytes and (b) by nuclease digestion of intact nuclei. Nucleosome-associated DNA was purified. Core histones (H3 and H4) were purchased. Primary hHSCs were cultured in serum-enriched growth medium followed by serum deprivation for 24-hours before treatments. Dose-dependent responses of hHSC cells to uncleaved, cleaved nucleosomes and purified DNA (0.5–2 μg/ml range) and to purified extracellular histones (5–50 μg/ml) were tested. Cell viability (MTS assay) and IL1β/IL18 secretion (hIL1β/18 reporter cells) were tested. TLR4 transactivation by histones was evaluated using hTLR4 reporter cells.
Results: Treatment with mono- and polynucleosomes derived from hepatocytes induced early and progressive dose-dependent cell injury and death of the primary hHSC. Neither the uncleaved nucleosomes nor the purified nucleosome-associated DNA had any effect. To test whether the core histones could be the mediators of the observed response to cleaved nucleosomes, HSCs were treated with both a mixture of histones and H3 and H4 isoforms; a dose-dependent change in cell morphology but not in viability was observed, mostly in response to H3. As HSCs express TLR4, we tested if histones induced transactivation of TLR4, leading to inflammasome activation and IL1β/IL18 secretion. Exposing hTLR4 reporter cells to histones led to a dose-dependent response (20-fold, with highest dose of H3). Treatment of hIL1β/18 reporter cells with supernatants from histone-treated hHSCs, resulted in a significantly higher transactivation.
Conclusions: These data show for the first time that the core histones (most potently H3), but not the DNA, in the cleaved nucleosomes from apoptotic hepatocytes affect primary hHSC cell biology in vitro and induce a proinflammatory response probably through TLR4-signaling. Therefore targeting extracellular histones and/or TLR4 signalling could result in attenuation of hHSC activation and inflammation associated with liver injury.

DELIVERY OF RELAXIN ATTENUATES ESTABLISHED LIVER FIBROSIS BY SUPPRESSING COLLAGEN CROSS-LINK AND ENHANCING COLLAGEN DEGRADATION

J.K. Kim[1], J.I. Lee[1], H.Y. Chang[2], C.O. Yun[3], K.S. Lee[1]. *[1]Gangnam Severance Hospital, Yonsei University College of Medicine, [2]Medical Research Center, Gangnam Severance Hospital, Yonsei University College of Medicine, [3]Dept. of Bioengineering, College of Engineering, Hanyang University, Seoul, Korea, South*
E-mail: drcecilia@hanmail.net

Background and Aims: Liver fibrosis is characterized by excess accumulation and repressed degradation of extracellular matrix. While means of alleviating already established liver fibrosis has scarcely been reported, relaxin is showing some promising results. In this study, we investigated whether a single adenoviral delivery of relaxin gene would attenuate established liver fibrosis in rats.
Methods: Liver fibrosis induced by 8 weeks of thioacetamide (TAA) treatment is known to persist without recovery at least 2 months. Rats were infected once with either relaxin-expressing adenovirus (TAA+Relaxin) or control virus (TAA+Vector) via tail vein after 8 weeks of TAA treatment. They were sacrificed either 3 days or 3 weeks after the adenovirus infection.
Results: Morphometric analysis of sirus red stained area demonstrated that TAA+Relaxin group had significantly decreased fibrosis at 3 weeks after the virus delivery although this change was not prominent at 3 days after the treatment. The assessment of *collagen α1(I)* [*Col1α(I)*] expression agreed with the histological evaluation. Expression of relaxin receptor (*Rxfp1*, *Relaxin-like family peptide receptor-1*) increased in both TAA+Vector and TAA+Relaxin rats at 3 days after the delivery, although TAA+Relaxin group had more prominently increased *Rxfp1*. After 3 weeks, TAA+Vector rats had reversed *Rxfp1* expression when TAA+Relaxin rats still had increased *Rxfp1* level. Liver *α-smooth muscle actin* (*α-SMA*) mRNA in both TAA+Vector and TAA+Relaxin rats was increased after 3 days but reversed to the normal level after 3 weeks. Analysis of *TGFβ* and *MMP9* mRNA demonstrated the similar pattern. Expression of *lysyl oxidase homolog 2* (*LOXL2*), which is crucial in the formation collagen cross-links, was increased in TAA+Vector and TAA+Relaxin rats at 3 days after virus treatment. Although both groups had attenuated *LOXL2* expression after 3 weeks, TAA+Relaxin group had further decreased *LOXL2* expression compared to that of the normal liver. Expression of tissue inhibitor of metalloprotiase-2 (TIMP-2), that prevent collagen degradation, was elevated in both groups at 3 days after the virus treatment. While TAA+Vector group still had sustained elevation of TIMP-2 expression, TAA+Relaxin rats had suppressed TIMP-2 expression after 3 weeks.
Conclusions: A single delivery of relaxin gene in the liver attenuated established hepatic fibrosis by suppressing collagen cross-links and enhancing collagen degradation.

INHIBITION OF MONOACYLGLYCEROL LIPASE ACCELERATES LIVER FIBROSIS REGRESSION

A. Habib[1], J. Wan[1], P. Hedge[1], E. Weiss[1], A. Brouillet[2], J. Lodder[1], R. Moreau[1], S. Lotersztajn[1]. *[1]INSERM U 1149, Center for Research on Inflammation, Paris Diderot University, Paris, [2]INSERM U 955, Equipe 18, Creteil, France*
E-mail: aida.habib@inserm.fr

Background and Aims: Monoacylglycerol lipase (MAGL) is the rate-limiting enzyme in the degradation of monoacylglycerols, which are short-lived intermediates of lipid catabolism. MAGL is also a pivotal component of the endocannabinoid system, since this enzyme metabolizes 2-arachidonoyl-glycerol, an endocannabinoid receptor ligand, into arachidonic acid. Recent studies have identified inhibition of MAGL as an interesting anti-inflammatory strategy in several experimental models of chronic inflammatory diseases. In the present study, we investigated the impact of MAGL inhibition on liver inflammation and fibrosis regression.
Methods: Liver fibrosis regression was studied in C57BL/6 mice exposed to chronic administration of carbon tertrachloride (CCl_4) for 6 weeks. Injections were discontinued and mice were daily administered with the MAGL inhibitor JZL184 (15 mg/kg, i.p.) or vehicle for up to 4 days. In vitro studies were performed on isolated murine peritoneal macrophages and hepatic myofibroblasts, and on PBMC from alcoholic cirrhotic and healthy subjects. Sirius red staining was quantified by morphometry. Fibrogenic and inflammatory gene expression was analyzed by RT-PCR. The identity of intrahepatic leucocytes were analyzed by FACS.
Results: JZL184 accelerated fibrosis regression 4 days after cessation of CCl_4 administration, as shown by a reduction of sirius red
