staining and smooth muscle alpha actin immunolabeling, and decreased expression of fibrogenic genes in treated vs untreated animals. Moreover, JZL184 significantly decreased the influx of Ly6C+ infiltrating monocytes into the liver of CCl_4-exposed mice. Accordingly, JZL 184 reduced the hepatic expression of Ly6C mRNA and decreased the hepatic expression of IL1-β, CCL2, CCL4 and CCL5 mRNAs. In vitro studies demonstrated that JZL184 (i) reduced hepatic myofibroblast proliferation; (ii) down-regulated LPS-stimulation of inflammatory mediator expression (IL1-β, CCL2, CCL4 and CCL5 mRNAs) from peritoneal macrophages. Finally, MAGL mRNA expression was increased in PBMC from patients with alcoholic cirrhosis as compared to healthy subjects and further enhanced in LPS-exposed PBMC.
Conclusions: Pharmacological inhibition of MAGL accelerates liver fibrosis regression in a model of toxin-induced liver injury, most probably by a mechanism involving reduction of infiltrating pro-inflammatory monocytes into the liver and a decrease in inflammatory mediators produced by macrophages. These results unravel MAGL inhibition as a novel promising antifibrogenic approach.

P0427
PLATELET-DERIVED GROWTH FACTOR-D INTENSIFIES FIBROGENESIS THROUGH UPREGULATION OF TIMP-1 AND SIGNALING VIA BOTH PLATELET-DERIVED GROWTH FACTOR RECEPTOR TYPE ALPHA AND BETA
E. Borkham-Kamphorst[1], S.K. Meurer[1], E. Van de Leur[1], U. Haas[1], L. Tihaa[1], R. Weiskirchen[1]. *[1]Institute of Clinical Chemistry, RWTH-Aachen, Aachen, Germany*
E-mail: ekamphorst@ukaachen.de

Background and Aims: Platelet-derived growth factor-D (PDGF-D) is a more recent recognized growth factor involved in the regulation of several cellular processes, including cell proliferation, transformation, invasion, and angiogenesis by binding to and activating its cognate receptor PDGFR-β. In the experimental liver fibrotic models BDL and CCl_4, PDGF-D showed upregulation comparable to PDGF-B. Moreover, adenovirus PDGF-D gene transfer induced hepatic stellate cell proliferation and liver fibrosis. We now seek to further uncover the molecular mechanism of PDGF-D involvement in liver fibrogenesis.
Methods: PDGF-D stimulation in profibrogenic primary cells of portal myofibroblasts (pMF), hepatic stellate cells (HSC) were evaluated for fibrogenic markers and PDGF-D signaling pathways compared to the other PDGF isoforms.
Results: We found PDGF-D not to enhance collagen type I and a-SMA production, but instead to significantly upregulate TIMP-1 expression in both mRNA and protein levels, resulting in attenuation of MMP2 and MMP9 gelatinase activity as indicated by gelatinase zymography. Unexpectedly, PDGF-D incubation did decrease both PDGFR-α and -β in mRNA and protein levels, and PDGF-D did phosphorylate Tyr 754 and 1018, the specific Tyr for PDGFR-α. Tyr phosphorylations from PDGF-D stimulation showed identical to that of PDGF-B. For the first time we could also demonstrate that PDGF-D binds to the recombinant PDGFR-α-FC homodimers.
Conclusions: PDGF-D intensifies fibrogenesis by interfering with the fibrolytic activity of the TIMP1/MMP system and PDGF-D signaling through both PDGF-α and -β receptors.

LPS-STIMULATED MOUSE HEPATIC STELLATE CELLS SECRETE SPECIFIC FACTORS THAT DIRECTLY CONTRIBUTE TO THE ACUTE PHASE RESPONSE OF HEPATOCYTES
K. Breitkopf-Heinlein[1], R. Liebe[1], K. Waldow[2], S. Braun[2], M. Thomas[3], F. Schildberg[4], P. Knolle[4], U. Zanger[3], U. Klingmüller[2], M. Ebert[1], S. Dooley[1]. *[1]Medical Faculty at Mannheim; University of Heidelberg, Mannheim, [2]Systems Biology of Signal Transduction (B200) DKFZ, Heidelberg, [3]Margarete Fischer-Bosch Institute of Clinical Pharmacology, Stuttgart, [4]University of Bonn, Institute of Molecular Medicine and Experimental Immunology, Bonn, Germany*
E-mail: katja.breitkopf@medma.uni-heidelberg.de

Background and Aims: The acute phase response (APR) is a systemic inflammatory condition initiated by activated phagocytic cells, fibroblasts and endothelial cells to prevent tissue damage and initiate repair processes.
The aim of our study was to determine the contribution of hepatic stellate cells (HSC) towards the APR induction. To this end, we quantified the secretory output of HSC with respect to the main acute phase cytokines. Hepatocytes' response to the secretory HSC output was analysed by Fluidigm real time PCR analysis.
Methods: Primary mouse HSC were cultivated for 48 hours before adding LPS to the medium. The release of 23 cytokines and chemokines was analysed by Luminex cytokine array technology after 24 hours of LPS stimulation (50 ng/ml). The main acute phase cytokines IL6, IL1-beta and TNF-alpha were further quantified after 2, 6 and 24 hours of LPS stimulation (0/10/50/100 ng/ml).
Tissue culture supernatant of HSC following 24 hours stimulation with 100 ng/ml LPS was used to stimulate primary mouse hepatocytes for 24 hours. Expression of 48 acute phase proteins (APP) in hepatocytes was analysed by Fluidigm real time PCR analysis and compared to hepatocytes treated directly with LPS or IL6.
Results: In HSC, G-CSF, KC (Cxcl1), IL-12 (p70), MCP-1a (Ccl2), TNFα and MIP1a (Ccl3) were the most prominently and significantly upregulated secreted cytokines after 24 hours and transcription of Ccls -2, -3, -4, -5 and -7, as well as Cxcls -1, -2, -3 and -5 were upregulated by LPS together with IL1b, IL6 and TNFa in HSC. Stimulation of hepatocytes with conditioned medium from LPS-treated HSC led among others to increased mRNA levels of Saa1, Saa2 and Orm1. Other targets like Hepcidin, Saa3 and IL-33 were already upregulated by direct treatment with LPS alone.
Conclusions: Cytokine secretion data from HSC and expression data from hepatocytes exposed to HSC supernatant show a specific and intriguing role for HSC during the orchestration of the acute phase response following endotoxemia. Besides being amplifiers of macrophage-induced cytokine signalling, these cells produce an independent secretory profile with an impact on hepatocytes that is different from direct effects induced by IL6 or LPS only.

P0429
DELETION OF TIMP-1 (EXON 3) DOES NOT AFFECT HEPATIC FIBROGENESIS AND CARCINOGENESIS
N.D. Guenther[1], A. Lohse[1], J. Kluwe[1]. *[1]Gastroenterology and Hepatology, Hamburg University Medical Center, Hamburg, Germany*
E-mail: j.kluwe@uke.de

Background and Aims: TIMP-1 is induced during hepatic fibrogenesis and considered to promote fibrosis in the injured liver by inhibition of matrix metalloproteases (MMP) and degradation of extracellular matrix. Moreover, TIMP-1 displays anti-apoptotic properties and has been shown to be upregulated in patients with hepatocellular carcinoma (HCC). Therefore, TIMP-1 could be a functional link between fibrosis and carcinogenesis in the liver.
Aim: To characterize the role of Timp-1 in hepatic fibrogenesis and carcinogenesis.

Methods: Hepatic fibrosis was induced in male wild-type (wt) and TIMP-1-knockout (TIMP-1$^{-/-}$) mice by ligation of the common bile duct (BDL) or administration of CCl_4. HCC formation was induced by administration of either diethylnitrosamine (DEN) alone or in combination with CCl_4 treatment. Liver fibrosis was assessed by sirius red staining. Expression of fibrosis-related genes was quantified by real-time PCR. Liver injury was determined by ALT level measurement. Tumorload was quantified by counting the number of visible tumors and measuring the size of the largest tumor with a caliper.
Results: Both, wt and TIMP-1$^{-/-}$ mice developed hepatic fibrosis after BDL and CCl_4 as evaluated by sirius red staining. We could not detect the anticipated attenuation of liver fibrosis in TIMP-1$^{-/-}$ mice in either model (mean area of red BDL: wt 3.5% vs. TIMP-1$^{-/-}$ 3.0%, ns; CCl_4: wt 1.0% vs. TIMP-1$^{-/-}$ 0.9%, ns). Quantification of fibrosis-related genes showed similar expression of alpha-SMA, TGF-beta, Col1a1, MMP2, MMP9 mRNA. DEN administration led to formation of HCCs in both wt and Timp-1$^{-/-}$ mice at the age of nine months. Combined DEN/CCl_4 administration resulted in tumor formation after six months. In neither model significant differences in tumor number or size could be detected bewteen wt and Timp-1$^{-/-}$ mice (number of tumors: DEN alone: 13.9 vs. 16.6, ns, DEN + CCl_4: 17 vs. 22, ns; tumor diameter: DEN alone: 6.6 mm vs. 6.5, ns; DEN + CCl_4: 5.8 mm vs. 4.9 mm, ns).
Conclusions: TIMP-1 (exon 3) is dispensable for the development of hepatic fibrogenesis and carcinogenesis in mice.

DELTA LIKE LIGAND 4 DRIVES LIVER DAMAGE THROUGH REGULATING CHEMOKINES

Z. Shen[1], Y. Liu[2], J. Hu[3], O. Park[4], T. Feng[2], B. Dewidar[2], C. Xu[1], C. Yu[1], H. Li[5], H.G. Augustin[3], P. ten Dijke[6], B. Gao[4], M.P.A. Ebert[2], S. Dooley[2], Y. Li[1], H. Weng[2]. *[1]Department of Gastroenterology, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China; [2]Department of Medicine II, Medical Faculty Mannheim, Heidelberg University, Mannheim, [3]Division of Vascular Oncology and Metastasis, German Cancer Research Center (DKFZ), DKFZ–Center for Molecular Biology Alliance, Heidelberg, Germany; [4]Laboratory of Liver Diseases, National Institute on Alcohol Abuse and Alcoholism, National Institutes of Health, Maryland, United States; [5]Department of Gastroenterology, Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China; [6]Department of Molecular Cell Biology and Center for Biomedical Genetics, Leiden University Medical Centre, Leiden, Netherlands*
E-mail: honglei.weng@medma.uni-heidelberg.de

Background and Aims: Mutation of Jagged1 or Notch2 causes Alagille syndrome, a disease characterized by defective development of intralobular bile ducts and liver injury but no overt fibrosis. To date, the role of individual Notch ligand in liver fibrogenesis remains unknown.
Methods: Immunohistochemical and immunofluorescent staining were used to investigate the potential association between Notch ligands and liver fibrosis in 113 patients with chronic HBV infection. Notch ligands, which were found to express in patient myofibroblasts, were then functionally examined in carbon tetrachloride (CCl_4)- and bile duct ligation (BDL)-induced mouse liver damage models and cultured hepatic stellate cells (HSC), Kupffer cells (KC) and hepatocytes.
Results: Among detected Notch ligands, only Delta like ligand 4 (Dll4) expression was detected in myofibroblasts and correlated with inflammatory grades and fibrotic stages in HBV patients. Administration of recombinant Dll4 protein (rDll4) remarkably ameliorated hepatocyte apoptosis, inhibited inflammatory cell infiltration, decreased expression of cytokines and chemokines, and improved fibrosis in mice with 4 weeks CCl_4 challenge. *In vitro*, incubation with rDll4 did not directly influence apoptosis of hepatocytes, HSC activation, collagen I production in HSCs, and lipopolysaccharide (LPS)-induced cytokine expression in KCs. However, rDll4 administration remarkably decreased LPS-induced chemokine (e.g. CCL2) expression in both KCs and HSCs. In contrast to CCl_4 model, administration of rDll4 induced hepatic massive necrosis in BDL-operated mice and caused them to death within one week. Compared to sham BDL mice, inflammatory cell infiltration in liver tissues was remarkably inhibited in rDll4-treated BDL mice. In cirrhotic liver tissues, immunohistochemistry analyses demonstrated a significantly reverse association between CCL2 and Dll4 immune positivity.
Conclusions: Dll4 drives liver damage via regulating chemokines. Decrease of chemokines with rDll4 treatment exerts a compelling anti-inflammatory/anti-fibrotic role in CCl_4-induced chronic liver damage, whereas rDll4-mediated chemokine inhibition induces massive hepatic necrosis in BDL mice via disrupting set up of inflammation.

IL-4/IL-13 EXACERBATE LIVER FIBROSIS PROGRESSION THROUGH ALTERNATIVELY ACTIVATED MACROPHAGES

S.-Y. Weng[1], X.-Y. Wang[1], Y. Tang[2], Y.O. Kim[1], O. Molokanova[1], F. Brombacher[3], T. Bopp[4], H.-J. Schild[4], A. Waisman[2], D. Schuppan[1]. *[1]Institute of Translation Immunology and Research Center for Immunotherapy, University Medical Center, Johannes Gutenberg University Mainz, [2]Institute for Molecular Medicine, University Medical Center, Johannes Gutenberg University Mainz, Mainz, Germany; [3]University of Cape Town, Cape Town, South Africa; [4]Institute of Immunology and Research Center for Immunotherapy at UMC Mainz, Mainz, Germany*
E-mail: weng@uni-mainz.de

Background and Aims: Liver fibrosis progression and regression are modulated by cells of the immune system. T cells play roles in regulating macrophages by secreting cytokines such as IL-12, IL-4 and IL-13, inducing polarization into classically and alternatively activated macrophages (CAM and AAM), resp. The function of the AAM in liver is largely unexplored.
Methods: To investigate the function of IL-4Ra, IL-4 and IL-13 in liver fibrosis, systemic IL-4/IL-13 double KO mice and T-cell specific deletion of IL-4/IL-13 and IL-4Ra were generated. Liver fibrosis progression was modeled by administration of oral CCL4 in increasing dose for 6 weeks, and spontaneous (incomplete) regression by discontinuing CCL4 for another 2 weeks. Liver was harvested for Sirius Red staining, hydroxyproline quantification, immunohistochemistry and qPCR. Sera were collected for ALT measurement. Liver immune cells were analyzed by FACS.
Results: Collagen deposition was significantly reduced in systemic IL-4/IL-13 double KO mice. This was accompanied by 6-fold reduction of procollagen a1(I) and α-SMA transcripts, and a decreased ALT indicating suppressed liver injury. Since IL-4/IL-13 mediate immune-suppressive function, double KO mice also showed an increase in CD4 and CD8 T cells, monocytes and macrophages/Kupffer cells as assessed by FACS, in line with a (Th1/CAM) suppressive effect after CCL4 treatment. However, although IL-4/IL-13ΔCD4 mice showed a reduced procollagen a1(I) expression and IL-4RaΔCD4 mice showed a decrease of total Hyp compared to control mice, most of the other parameter of fibrosis showed no significant difference.
Conclusions: We demonstrate an important role of IL-4/IL-13 signaling in CCL4-induced fibrogenesis, since mice deficient in IL-4/IL-13 showed dramatic reduction of collagen deposition. It appears that Th2 T cells are less important promoters than AAM. Combined with our previous results in IL-4Ra deficient mice, this confirms AAM as central regulators of fibrogenesis during liver fibrosis progression.

P0432

NLRP3 INFLAMMASOME EXPRESSION IS REGULATED BY NUCLEAR FACTOR-KAPPAB (NF-κB) IN CULTURED HEPATOCYTES

S.G. Boaru[1], E. Borkham-Kamphorst[1], E. Van de Leur[1], C. Liedtke[2], R. Weiskirchen[1]. *[1]Institute of Molecular Pathobiochemistry, Experimental Gene Therapy and Clinical Chemistry, [2]Department of Internal Medicine III, RWTH University Hospital Aachen, Aachen, Germany*
E-mail: rweiskirchen@ukaachen.de

Background and Aims: The inflammasomes are cytoplasmic multiprotein complexes that are responsible for the activation of inflammatory reactions. They mediate the cleavage and activation of caspase-1 and IL-1β that in turn leads to a complex network of cellular reactions that at the end initiate local and systemic inflammation [1]. We have shown that the NACHT, LRR and PYD domains-containing protein 3 (NLRP3) is virtually absent in untreated cultured hepatocytes while stimulation with lipopolysaccharides (LPS) results in strong activation of NLRP3 expression in these cells [2]. In the present study we investigated the impact of NF-κB signalling on NLRP3 activation in primary hepatocytes.
Methods: Murine primary hepatocytes were isolated according to the collagenase method [3]. The NF-κB activation inhibitor QNZ and the adenoviral expression vector Ad5-CMV-IκB(S32A/S36A) expressing a hemagglutinin-tagged human superrepressor of NF-κB [4] were used to block NF-κB signalling. After LPS challenge, the expression of TNF-α, IL-1β and NLRP3 was analysed by qRT-PCR, Western blot and immunohistochemistry. The influence of NF-κB signalling on NLRP3 expression was further investigated in a novel murine hepatocytic cell system that can be Cre-dependently depleted for the NF-κB essential modulator (NEMO).
Results: We found that QNZ blocks LPS-induced expression of TNF-α, IL-1β and NLRP3 as demonstrated by qRT-PCR, Western blot and immunohistochemistry. Even more, the basal expression that was observed in uninfected control cells or in cells that were infected with a control virus (Ad5-CMV-Luc) was abrogated. Likewise, the superrepressor of NF-κB prevents expression of NLRP3. In cells that were depleted for NEMO (and Caspase 8), we could confirm that there is a close link of NF-κB activity and NLRP3 expression. As a consequence, the expression of Lipocalin 2 representing a biomarker of hepatic inflammation was blunted suggesting that NF-κB activity plays an important role in mediating inflammasome activity.
Conclusions: We conclude that NF-κB signalling is a necessary prerequisite for proper activation of the NLRP3 inflammasome in primary hepatocytes. Our data further suggests that targeting the NF-κB pathway will be potentially therapeutic useful to block hepatic inflammasome activity.

SELECTIVE LXR ALPHA INTESTINAL ACTIVATION REDUCES HEPATIC INFLAMMATION AND FIBROSIS DURING THE DEVELOPMENT OF CHRONIC LIVER INJURY

I. Pierantonelli[1], C. Pinto[1], E. Mingarelli[1], S. Saccomanno[1], L. Agostinelli[1], C. Rychlicki[1], L. Trozzi[1], A. Benedetti[1], M. Marzioni[1], A. Moschetta[2], G. Svegliati-Baroni[1]. *[1]Università Politecnica delle Marche, Department of Gastroenterology, Ancona, [2]Department of Interdisciplinary Medicine, University of Bari Aldo Moro, Bari, Italy*
E-mail: pierantonelli_irene@libero.it

Background and Aims: Hepatic fibrosis represents the wound-healing response of the liver to chronic injury and it is characterized by increased and altered deposition of newly generated extracellular matrix. The pathogenesis of liver fibrosis is not fully understood, leading to a lack in effective therapies. Liver X receptors (LXR α/β) are important regulators of lipid metabolism. While in the liver LXRs regulate cholesterol and fatty acid metabolism, intestinal LXRα activation has been implicated in reverse cholesterol transport pathway leading to high levels of the antinflammatory HDL. AIMS: to evaluate the effect of the selective intestinal LXRα activation on the development of hepatic fibrosis associated to chronic liver injury.
Methods: Male FVB/N mice (8–10 weeks old) with intestinal constitutive LXRα activation (iVP16LXRα) and their control (iVP16) were treated with twice weekly i.p. injection of Carbon Tetrachloride (1 μl/gr body weight) for 2 months.
Results: Immunohystochemistry for the macrophage marker F4–80 indicated lowered infiltration in iVP16LXRα liver ($p < 0.05$). Gene expression of the pro-inflammatory cytokines IL-6, TNFα, and MCP-1, and of the transcription factor NF-Kb were reduced in iVP16LXRα CCL4 mice ($p < 0.05$, $p < 0.05$, $p < 0.005$ and $p < 0.005$ respectively). Collagen synthesis and deposition was significantly reduced in iVP16LXRα mice compared to iVP16 as determined by type I collagen and TGFβ mRNA expression (both $p < 0.005$) and by Sirius Red morphometry ($p < 0.0005$). To study the mechanisms associated to the antinflammatory effect of intestinal LXRα activation, reverse cholesterol transport was proved by measuring intestinal gene expression of Abca1, that promotes the efflux of cholesterol; indeed Abca1 expression was increased in iVP16LXα CCL4 mice ($p < 0.005$) in line with the elevation of plasmatic HDL concentration in iVP16LXRα CCL4 mice ($p < 0.005$). Furthermore, intestinal LXRα activation is not associated to hepatic de novo lipogenesis as shown by gene expression of SREBP1c and FAS, and decreased triglyceride ($p < 0.005$) and cholesterol content ($p < 0.05$).
Conclusions: Specific intestinal LXRα activation reduces liver injury by increasing the level of the antinflammatory HDL cholesterol, thus leading to decreased hepatic fibrosis. Selective intestinal activation of LXRα might be considered as a new therapeutic approach to reduce liver fibrosis avoiding the occurrence of hepatic steatosis as a side effects associated to systemic LXR induction.

P0434

JNK1-DEPENDENT ER STRESS CONTRIBUTES TO HEPATIC STELLATE CELL ACTIVATION

L.F.R. Thoen[1], I. Mannaerts[1], F.J. Cubero[2], A. Paridaens[3], I. Colle[3], C. Trautwein[2], L.A. van Grunsven[1]. *[1]Liver Cell Biology lab, Vrije Universiteit Brussel, Brussels, Belgium; [2]Department of Internal Medicine III, University Hospital RWTH Aachen, Aachen, Germany; [3]Department of Hepato-Gastroenterology, Universiteit Gent, Gent, Belgium*
E-mail: lien.thoen@vub.ac.be

Background and Aims: The ability of a cell to sense, respond to and circumvent stress is essential for maintaining homeostasis. The endoplasmic reticulum (ER) is the site of synthesis, folding and modification of proteins where unfolded proteins can accumulate in stress conditions. This accumulation initiates an adaptive response which consists of three main signaling pathways, i.e. IRE1, PERK and ATF6. ER stress plays a role in the liver damage and chronicity during alcohol abuse, infection with the hepatitis B and C virus, non-alcoholic steatohepatitis and can even promote hepatocarcinogenesis. In addition, IRE1 activates JNK which is a crucial mediator of liver fibrogenesis. Our aim was to study the role of ER stress during early hepatic stellate cell (HSC) activation and investigate a possible link between JNK and ER stress in primary mouse HSCs.
Methods: In vitro and in vivo activated HSCs were analyzed for ER stress.

Results: The ER stress markers, XBP1spliced, BiP and Chop, showed an early peak in mRNA expression already 10 h after seeding primary mouse HSCs on plastic culture dishes, followed by a decreased expression at 24 h. Up to 10 days, the expression levels did not differ from the 24 h time point. This increased ER stress could also be seen in freshly isolated HSCs from mice 10 h after 1 CCl_4 injection suggesting that ER stress is an early event of HSC activation also in vivo. HSCs cultured as 3D spheroids showed prevention of early ER stress and expression of activation markers was inhibited compared to HSCs plated on plastic. However, when primary mouse HSCs were plated on a soft substrate (0.48 kPa), expression of activation markers was reduced but ER stress was not prevented. In addition, treatment of HSCs with JNK inhibitors prevents the ER stress and reduces culture-induced activation of primary mouse HSC. This role for JNK was confirmed using JNK1 KO mice where decreased ER stress and activation were observed when isolated HSCs were plated. No effect on ER stress and activation was seen in HSCs from JNK2 KO mice.
Conclusions: ER stress induction is an early event during HSC activation in vitro and in vivo. Inhibition of ER stress by culturing cells in 3D spheroids inhibits HSC activation while cells seeded on soft substrates are less activated but ER stress is not affected. Finally, we show that this ER stress is JNK1 dependent. Together this strongly suggests that JNK1-dependent ER stress contributes to HSC activation, but is not sufficient to drive the activation process.

IDENTIFICATION OF MIR-192 AS A NOVEL KEY REGULATOR OF QUIESCENCE MAINTENANCE IN HUMAN HEPATIC STELLATE CELLS

M. Coll[1], A. El Taghdouini[2], L. Perea[1], I. Mannaerts[2], M. Vila-Cadasesus[3], J.J. Lozano[3], D. Blaya[1], D. Rodrigo-Torres[1], P. Ginés[1], L.A. van Grunsven[4], P. Sancho-Bru[1]. *[1]Liver Unit, Hospital Clínic, Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain; [2]Liver Cell Biology Lab, Faculty of Medicince and Pharmacy, Vrije Universiteit Brussel, Brussels, Belgium; [3]Bioinformatic Unit, Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain; [4]Liver Cell Biology Lab, Faculty of Medicince and Pharmacy, Vrije Universiteit Brussel, Brussels, Belgium*
E-mail: mdcoll@clinic.ub.es

Background and Aims: To identify regulatory pathways maintaining hepatic stellate cell (HSC) in a quiescent (q) phenotype is of outmost importance to develop new therapeutic strategies for the treatment of liver fibrosis. The aim of the present study is to identify miRNAs regulating the maintenance of the quiescent phenotype.
Methods: qHSCs and *in vitro* activated HSCs were assessed for gene and miRNA profiling by Affymetrix HG-U219 and miRNA-Taqman® Array. Expression profiles were integrated using the miRComb-R package. Functional studies were performed in human and mouse cultured HSCs.
Results: MiRNA analysis identified miR-192 as a highly expressed miRNA in isolated human quiescent HSC and down regulated in *in vitro* activated counterparts (Fold Change=8, $p = 0.01$). The miR-192 expression level was confirmed in whole liver of healthy and cirrhotic patients. However, no differences in plasma levels of miR-192 were found between cirrhotic and healthy patients. Computational integrative analysis of mRNA-miRNA expression profiles identified 18 predicted target genes for miR-192. In silico functional analysis with Ingenuity pathway software showed that miR-192 target mRNAs were significantly enriched in HSC activation canonical pathway. Integrative analysis was validated by over-expressing miR-192 in human HSC (Lx2) showing a reduction in expression in both predicted targets and activation markers. Assessment of miR-192 expression in different isolated liver cell types from mouse liver demonstrated that HSC are the main cell source of miR-192. The dynamics of miR-192 expression was assessed by isolating HSC at different time points from two fibrotic mouse models (CCL4 and BDL) showing that down-regulation of miR-192 takes place early in the progression of fibrosis. Moreover, functional validation was performed in mouse HSC. MiR-192 overexpression resulted in a significant reduction of both cell proliferation and migration.
Conclusions: miR-192 is a quiescent HSC enriched miRNA targeting genes involved in HSCs activation process and its expression is rapidly reduced upon in vitro and in vivo activation. These results suggest that miR-192 could be an important regulator of the maintenance of HSC quiescent phenotype and a potential target to interfere HSC activation.

PENTRAXIN-3 INDUCES HEPATIC STELLATE CELL ACTIVATION AND ATTENUATES THE INFLAMMATORY RESPONSE DURING HEPATIC INJURY

L. Perea[1], M. Coll[1], A. El Taghdouini[2], D. Rodrigo-Torres[1], D. Blaya[1], O. Morales-Ibanez[1], M. Llopis[1], L. Van Grunsven[2], J. Caballeria[1], P. Ginès[1], P. Sancho-Bru[1]. *[1]Liver Unit, Hospital Clínic, Institut d'Investigacions Biomèdiques August Pi i Sunyer, Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas, Barcelona, Spain, Barcelona, Spain; [2]Cell Biology, Faculty of Medicine and Pharmacy, Vrije Universiteit Brussel (VUB), Brussels, Belgium*
E-mail: luis.perea.s@gmail.com

Background and Aims: Pentraxin-3 (PTX3) is an acute phase protein locally released in response to pro-inflammatory stimuli regulating the innate immune system. However, the role of PTX3 in the liver and its potential participation in tissue remodeling is still unknown. The aim of this study was to investigate the role of PTX3 as a modulator of inflammation in liver injury.
Methods: PTX3 gene expression was assessed by quantitative PCR in primary human hepatic stellate cells (HSC), liver tissue from patients with compensated alcoholic cirrhosis ($n = 6$), alcoholic hepatitis (AH) ($n = 15$), control individuals ($n = 6$) and in experimental mouse models. PTX3 serum levels were determined by ELISA and tissue expression by inmunohistochemistry. Interference RNA and recombinant PTX3 were used in cultured cells and liver tissue slices from healthy and chronic CCl_4 treated mice.
Results: PTX3 hepatic gene expression was up-regulated in AH (FC=35; $p < 0.05$) and cirrhotic (FC= 6, $p < 0.05$) patients compared to healthy controls. PTX3 serum levels were increased in cirrhotic patients ($n = 60$) compared with healthy controls and serum levels were higher in patients with Child B and C compared to Child A ($p < 0.05$). Moreover, PTX3 expression was up-regulated in experimental models of chronic CCl_4 treatment and acute-on-chronic liver injury (chronic CCl_4 and LPS) ($p < 0.01$). Assessment of FACS-sorted mouse hepatic cell populations showed that neutrophils were the main PTX3 producing cell type in healthy liver, whereas macrophages and mainly HSC were the main cells expressing PTX3 in liver injury. Cultured activated HSCs and macrophages expressed PTX3 that was up-regulated upon stimulation with pro-inflammatory agents (TNFα, IL1β, LPS). While knock-down of PTX3 in HSCs (Lx2) induced a reduction of activation markers (α-SMA, COL1A1, LOX) ($p < 0.01$), stimulation with recombinant PTX3 induced activation of human primary HSC. Next, we evaluated the effect of PTX3 on healthy and fibrotic liver tissue slices showing that PTX3 attenuated the inflammatory response induced by LPS, reducing the expression of TNFα, MCP-1, CCL20, IL-6, RANTES.
Conclusions: PTX3 hepatic expression is increased in cirrhotic and HA patients and it is associated with disease severity. PTX3 is produced by HSCs and macrophages in liver injury, which may

induce HSC activation and modulate tissue inflammation. These results suggest that PTX3 is a novel marker of liver injury and might exert a role in promoting tissue remodeling and attenuating inflammation.

REACTIVE GAMMA-KETOALDEHYDES AS NOVEL ACTIVATORS OF HEPATIC STELLATE CELLS IN VITRO

L. Longato[1], F. Andreola[1], S. Davies[2], J.L. Roberts[2], G. Fusai[3], M. Pinzani[1], K. Moore[1], K. Rombouts[1]. [1]*Institute for Liver and Digestive Health, University College London, London, United Kingdom;* [2]*Pharmacology, Vanderbilt University, Nashville, United States;* [3]*Surgery, University College London, London, United Kingdom*
E-mail: l.longato@ucl.ac.uk

Background and Aims: Reactive lipid aldehydes formed during lipid oxidation such as 4-hydroxynonenal (4-HNE), are key activators of hepatic stellate cells (HSCs) to a pro-fibrogenic phenotype. γ-Ketoaldehydes (γ-KAs) are a family of acyclic highly reactive aldehydes, comprising the levuglandins, and their isomers (isolevuglandins), which are formed during oxidation of arachidonic acid, or as a by-product of the cyclooxygenase pathway. γ-KAs are highly reactive and form protein adducts and cross-links at a rate >100-fold compared to 4-HNE. Increased circulating concentrations of proteins cross-linked to γ-KAs are present in patients with alcoholic liver disease. Since the contribution of γ-KAs to liver injury has not been studied, we investigated whether the γ-KA levuglandin E_2 (LGE_2) can induce activation of HSCs.
Methods: Culture-activated, serum-starved primary human HSCs were exposed to LGE_2 (0.5pM– 5μM) for up to 48 hours. Endpoints measured included proliferation, cytotoxicity [lactate dehydrogenase (LDH) and MTS assays], RNA and protein expression, and collagen secretion in conditioned medium.
Results: Within hours, exposure to 5μM LGE_2 promoted severe cytotoxicity and apoptosis, indicated by LDH leakage, reduced MTS, increased PARP cleavage, JNK phosphorylation, and increased levels of the pro-apoptotic transcription factor CHOP. At lower, non-cytotoxic doses (50pM–500nM) LGE_2 promoted HSC activation as indicated by increased expression of a-SMA and vimentin, and sustained activation of selective signaling pathways (p42/44 ERK1/2 and JNK/SAPK), but had no effect on DNA synthesis or collagen production. Further, HSCs exposed to LGE_2 displayed a marked increase in mRNA expression for various cyto/chemokines including interleukin-8 (IL-8), CCL2/MCP-1, IL-6, and IL-1β. This was accompanied by increased secretion of bioactive IL-1β/IL-18, as measured by HEK-Blue reporter cells. The JNK inhibitor SP600125 prevented activation and expression of mRNA of these cyto/chemokines by LGE_2 but inhibitors of activation of NFkB (PDTC) or p38MAPK (SB203580) had no effect. Lastly, and of possible relevance for their mechanism of action, γ-KAs exposure also increased indices of endoplasmic reticulum stress, such as GRP78, ATF4, and IRE1 phosphorylation.
Conclusions: γ-KAs represent a newly identified class of activators of HSCs *in vitro*, which are biologically active at concentrations as low as 50pM, and are particularly effective at promoting a pro-inflammatory response.

P0439

HUMAN 3D HEPATIC CO-CULTURE MODEL FOR IN VITRO DRUG-INDUCED FIBROSIS TESTING

S.B. Leite[1], T. Roosens[1], I. Mannaerts[1], A.E. Taghdouini[1], M. Najimi[2], E. Sokal[2], C. Chesne[3], L.A. van Grunsven[1]. [1]*Liver Cell Biology, VUB,* [2]*Laboratory of Pediatric Hepatology and Cell Therapy, UCL, Brussels, Belgium;* [3]*Biopredic International, SAINT-GREGOIRE, France*
E-mail: sofia.batista.leite@vub.ac.be

Background and Aims: In Europe, liver cirrhosis accounts for around 170,000 deaths a year according to WHO. The lack of clinically efficient treatment for fibrosis, together with the fact that the pro-fibrotic profile of a drug is often detected only at later stages of the preclinical phase, highlights the need for better human models to study fibrosis. The aim of our work is to develop an *in vitro* model where drug-induced liver fibrosis can be mimicked. An efficient model as such, would not only lead to an early retraction during drug development of pro-fibrotic substances but also to develop treatments for liver fibrosis. Liver fibrosis is the result of scar tissue formation as a consequence of long term ECM deposition by activated hepatic stellate cells (HSCs). *In vitro*, HSCs can be activated directly but in the majority of the cases *in vivo* it is a response to hepatocyte injury.
Methods: We developed a 3D human co-culture model of primary HSCs and hepatocyte-like cells (HepaRG) with the aim of screening both pro- and anti-fibrotic compounds.
Results: Here we present the optimized 3D HepaRG/HSC co-culture conditions that allow the maintenance of non-activated HSCs for at least 21 days based on the gene expression of HSC markers Col1a1, Col3a1 and Loxl2. In parallel, no alteration of hepatocyte functionality including CYP induction, albumin secretion and hepatocyte-specific gene expression is observed as compared to 3D HepaRG monocultures. However, TGFb can still directly induce activation of the human HSCs while LPS induces a survival response (IL6, MMP1, CCL2, TNFa, ILb). When exposed to known hepatotoxicants, HSC activation is observed by the increased mRNA expression of HSC activation markers and collagen protein accumulation and secretion. This effect is enhanced when the co-cultures are exposed to an inflammatory cytokine cocktail reflecting inflammation-induced fibrogenesis.
Conclusions: The 3D hepatic co-cultures of primary HSCs and HepaRGs are an attractive tool to predict the (anti-) fibrotic profile of a compound *in vitro*. This model constitutes a big step forward from the regular 2D HSC and 2D/3D HepaRG mono-cultures.

P0440

ANTIFIBROTIC EFFICACY OF TGF-BETA RECEPTOR ANTAGONIST IN PRECISION-CUT HUMAN AND RAT LIVER SLICES

T. Luangmonkong[1], R. Mutsaers[1], D. Oosterhuis[1], P. Olinga[1]. [1]*Pharmaceutical Technology and Biopharmacy, University of Groningen, Groningen, Netherlands*
E-mail: theetheetmc@gmail.com

Background and Aims: Transforming growth factor beta (TGFβ) is recognized as a significant mediator in liver fibrogenesis, and inhibition of its signaling pathway is a potential target of antifibrotic agents. This study aimed to elucidate the antifibrotic efficacy of TGFβ receptor antagonist, LY2109761, and the involvement of the TGFβ signaling pathway in the early onset of fibrosis in precision-cut human and rat liver slices.
Methods: Precision-cut human and rat liver slices were incubated with LY2109761 for 48 and 72 hours. Viability of liver slices was assessed by the ATP content. The concentrations of LY2109761 used were non-toxic and in line with other in vitro models. Phosphorylated Smad2 and total Smad2, downstream signaling proteins of TGFβ pathway, were assessed by western blot. Gene expression of the fibrosis markers: Pro-collagen1A1 (PCOL1A1), α-Smooth Muscle Actin (αSMA), and Heat Shock Protein 47 (HSP47), were assessed by real-time qPCR.
Results: Activation of TGFβ signaling was observed during incubation with an increase in both phosphorylated Smad2 (36.9 and 2.4 fold) and total Smad2 (8.4 and 24 fold), in human and rat liver slices respectively. LY2109761 significantly inhibited phosphorylation of Smad2 up to 82±3% in human and up to 79±9% in rat liver slices. In contrast, total Smad2 expression was not affected. Gene expression of the fibrosis markers increased during incubation: PCOL1A1; 5.1 and 17.2 fold, αSMA; 1.1 and 2.3 fold, and HSP47; 1.6 and 5.3 fold, in human and rat liver slices respectively.

Following treatment with LY2109761, PCOL1A1 gene expression was significantly dose-dependently inhibited up to 96±2% in human and up to 95±2% in rat liver slices. αSMA gene expression was significantly inhibited up to 82±5% in rat liver slices. In contrast, HSP47 gene expression was significantly inhibited up to 66±6% in human liver slices.
Conclusions: TGFβ receptor antagonist shows antifibrotic efficacy in precision-cut liver slices. It significantly inhibits TGFβ signaling via the inhibition of Smad2 phosphorylation. Furthermore, inhibition of TGFβ signaling diminishes PCOL1A1 gene expression in both species, suggesting that PCOL1A1 is directly regulated by this signaling pathway. Species differences might exist in the regulation of αSMA and HSP47 by TGFβ. Furthermore, the results of this study reveal the involvement of TGFβ signaling pathway in the early onset of fibrosis in precision-cut human and rat liver slices.

P0441
TACKLING FIBROSIS USING TGF-β2 TARGETED AONS IN VIVO

A. Dropmann[1], H. Korhonen[2], F. Jaschinski[2], M. Janicot[2], N. Meindl-Beinker[1], S. Dooley[1]. [1]*Department of Medicine II, Section Molecular Hepatology, Heidelberg University, Medical Faculty Mannheim, University of Heidelberg, Mannheim,* [2]*Isarna Therapeutics GmbH, Isarna Therapeutics GmbH, München, Germany*
E-mail: anne.dropmann@medma.uni-heidelberg.de

Background and Aims: TGFβ2 has not been investigated thoroughly in CLD progression and HCC. After providing evidence that TGFβ2 plays a putative role in fibrogenesis, we now aim to selectively target TGFβ2 expression using antisense oligonucleotides (AONs) for attenuation or blockage of human liver disease progression.
Methods: Three CLD mouse models (CCl_4, BDL and $Mdr2^{-/-}$) were investigated representing different types of CLD background. TGFβ2 and TGFβ1 expression were compared by qRT-PCR. Human TGFβ2 mRNA, was specifically targeted using a 18mer AON in the hepatic cell line LX2. In vivo, we selectively inhibited TGFβ2 using AONs. For induction of chronic liver damage, mice were injected i.p. with CCl_4 twice/week for 4 weeks. After 2 weeks, subcutaneous AON application started in parallel twice per week. In the MDR2-KO model, the AON was administered for 4 weeks. The effect and efficacy of AON treatment was evaluated by tissue morphology and on protein and mRNA level. Typical fibrotic markers are currently investigated.
Results: In the CCl_4 liver injury and regeneration model, relative expression dynamics were similar for both TGFβ isoforms. HSC activation and collagen expression were accompanied with transient increases of TGFβ2 expression. Samples of MDR2-KO mice showed frequent TGFβ2 upregulation within 3 to 15 month as compared to wt. Accordingly, an elevation of TGFβ2 expression was determined 14 days after bile duct ligation (BDL). Interestingly, while TGFβ2 was strongly induced after 14 days, there was only slight induction of TGFβ1 expression at this time. In human HCC specimen with different etiologies, TGFβ2 was found to be prevalently expressed in the stroma. Immunohistological assessment of in vivo AON distribution after 24 h and 5 days revealed strongest signals in liver and kidneys. CCl_4 injured AON-treated animals showed reduced TGFβ2 mRNA expression levels. Hydroxyproline content, a surrogate marker of fibrosis, was significantly reduced in both injury models upon AON-treatment as compared to controls. Sirius Red staining also morphologically revealed a significant reduction (~34%) of collagen deposition in AON-treated mice.
Conclusions: Taken together, our results suggest a role of TGFβ2 in the process of CLD. We further conclude that in vivo application of TGFβ2 directed AON to CLD mouse models could contribute to fibrogenesis attenuation. Further studies are currently performed to determine mechanistic details of AON effects and define specifications of a potential AON based treatment of CLD.

P0442
UDCA-LPE MODULATES DIFFERENT SIGNALING PATHWAYS INVOLVED IN HEPATIC FIBROGENESIS

J. Su[1], W. Chamulitrat[1], W. Stremmel[1], A. Pathil[1]. [1]*Department of Internal Medicine IV, University of Heidelberg, Heidelberg, Germany*
E-mail: Jie.Su@med.uni-heidelberg.de

Background and Aims: Liver fibrosis with deposition and remodeling of extracellular matrix (ECM) is regulated by different signaling pathways. Ursodeoxycholyl Lysophosphatidylethanolamide (UDCA-LPE) is a synthetic bile acid-phospholipid conjugate with hepatoprotective and anti-fibrotic functions *in vitro* and *in vivo*. In this study we aim to elucidate signaling pathways, which mediate anti-fibrogenic action of UDCA-LPE.
Results: At membrane level ECM interacts with Integrin receptors, which promotes pro-fibrogenic signaling. After phosphorylation in response to Integrin engagement, FAK and SRC kinase mediate activation of myofibroblasts. After UDCA-LPE binding to Integrin β1, FAK is shortly activated by phosphorylation at Tyr 397 in CL48 cells. However, the binding of UDCALPE pulls Integrin β1 out from lipid raft, and consequently Integrin β1 loses the colocalization with SRC and FAK, which inhibits phosphorylation of FAK (Tyr 925 and Tyr 576/577) and SRC (Tyr416). The second messenger cAMP and cAMP dependent Protein Kinase A (PKA) can also suppress ECM production by inhibiting hepatic stellate cells differentiation. PKA is activated in 1 minute after UDCA-LPE treatment. Phosphorylation of ERK, B-RAF and C-RAF by UDCA-LPE was also investigated by western blot. UDCA-LPE induces pERK (Thr 202/Tyr 204). ERK is phosphorylated by MEK, which is mediated by B-RAF and C-RAF in CL48 cells. UDCA-LPE induces pB-RAF (Ser 445) and pC-RAF (Ser 338). We next investigated the crosstalk between Integrin, ERK and PKA signaling pathways. After Integrin-blocking Peptide RGD or FAK autophosphorylation inhibitor Y15 treatment, UDCA-LPE mediated phosphorylation of ERK is reduced and activation of C-RAF by UDCA-LPE is inhibited. These results suggest that activation of C-RAF and ERK by UDCA-LPE is dependent on Integrin-FAK signaling pathway. EGFR inhibitor AG1478 treatment also indicates, activation of C-RAF and ERK by UDCA-LPE is EGFR dependent. PKA inhibitor Rp-cAMP reduces pERK and inhibits B-RAF phosphorylation, suggesting activation of B-RAF and ERK is PKA dependent.
Conclusions: UDCA-LPE disturbs pro-fibrogenic integrin signaling by inhibiting FAK and SRC activity. Integrin and FAK are identified as an upstream signaling of activation of the EGFR/C-RAF/ERK pathway. UDCA-LPE further activates PKA, which subsequently induces B-RAF/ERK signaling. By inhibiting pro-fibrogenic pathways with concomitant activation of pro-proliferative ERK signaling, UDCA-LPE may improve hepatofibrogenesis and accelerate liver regeneration.

P0443
HYPERAMMONEMIA ACTIVATES HUMAN HEPATIC STELLATE CELLS AND IS A TARGET FOR TREATMENT OF PORTAL HYPERTENSION

F. De Chiara[1], R. Jalan[1], V. Balasubramaniyan[1], F. Andreola[1], M. Malago'[2], M. Pinzani[1], R.P. Mookerjee[1], K. Rombouts[1]. [1]*Institute of Liver and Digestive Health,* [2]*Division of Surgery, University College London, London, United Kingdom*
E-mail: francesco.chiara@ucl.ac.uk

Background and Aims: Ammonia induces astrocyte swelling and brain inflammation in cirrhotic animals. Ammonia lowering with Ornithine Phenylacetate (OP) in Bile Duct Ligated (BDL) rats reduces brain water, increases brain eNOS activity and reduces coma stage. Given the genotypic and phenotypic homology between astrocytes and hepatic stellate cells (HSC) [HSCs contain glutamine synthetase (GS) and astrocytes express HSC markers], this study tested the hypothesis that ammonia (i) modulates HSC activation and (ii) the

use of ammonia lowering agent, OP, lowers portal pressure in BDL rats, through reduced HSC activation.
Methods: *In vitro:* Primary humanHSC (hHSC) were cultured. Effects of NH_4Cl challenge (0.1–10mM over 24–72 hrs) on hHSC to proliferation (BrdU), metabolic activity (MTS assay), viability (Neutral-Red), ultrastructural changes (EM) and gene/protein expression were studied. To test recovery, ammonia treated cells were replenished with glutamine and in separate experiments, pre-treated with L-methionine-sulfoximine (MSO-GS inhibitor) to determine the importance of GS. *In vivo*: 28-day BDL rats were treated with saline or OP for 5 days and portal pressure measured at termination and tissues were harvested for studies.
Results: *In vitro:* Hyperammonemia in primary hHSC induced time-dependent decreases in proliferation and metabolic activity, whilst inducing cell swelling and a myofibroblast-like phenotype even at 50–100umol/L. Ultrastructurally, ammonia-treated hHSC caused a dose-dependent ER enlargement and this was reversible by replenishing the culture with glutamine. NH_3 inhibition of hHSC proliferation was dependent on GS activity as MSO with hyperammonemia induced cell detachment and prevention of recovery suggesting that glutamine is important for hHSC survival. *In vivo:* BDL rats, with hyperammonemia had increased hepatic expression of pro-fibrogenic hHSC-related genes (α-SMA, PDGFb-R, Myosin IIA/IIB and Coll1), low eNOS activity and DDAH-1 and high portal pressure (14.4 ± 0.8 mmHg), all of which were corrected by OP treatment (PP: 11.1 ± 0.3 mmHg, $P < 0.01$).
Conclusions: These novel data suggest that hyperammonemia modifies hHSC's and imparts a swollen myofibroblast phenotype, which is reversible upon ammonia reduction. *In vivo* ammonia lowering decreases pro-fibrogenic and activated HSC gene and protein expression and lowers portal pressure, highlighting ammonia as a target for portal hypertension therapy and the key role of HSC in this process.

THE HIPPO PATHWAY EFFECTOR YAP CONTROLS MOUSE HEPATIC STELLATE CELL ACTIVATION

I. Mannaerts[1], S.B. Leite[1], S. Verhulst[1], L.F. Thoen[1], S. Claerhout[2], G. Halder[2], L.A. van Grunsven[1], Liver Cell Biology Lab. *[1]Liver Cell Biology Lab, Vrije Universiteit Brussel, Brussels, [2]VIB Center for the Biology of Disease, and KU Leuven Center for Human Genetics, Katholieke Universiteit Leuven, Leuven, Belgium*
E-mail: inge.mannaerts@vub.ac.be

Background and Aims: Hepatic stellate cell activation is a wound-healing response to liver injury. However, continued activation of stellate cells during chronic liver damage causes excessive matrix deposition and the formation of pathological scar tissue leading to fibrosis and ultimately cirrhosis. The importance of sustained stellate cell activation for this pathological process is well recognized, and several signaling pathways that can promote stellate cell activation have been identified, such as the TGFβ-, PDGF-, and LPS-dependent pathways. However, the mechanisms that trigger and drive the early steps in activation are not well understood.
Methods: Primary HSCs are isolated from healthy and fibrotic BalbC mice. Microarray analysis on in vitro and in vivo activated HSCs (unseeded), identified significant changes in genes related to the Hippo pathway. 2D and 3D spheroid cultures are used to investigate the contribution of the hippo-effector protein YAP.
Results: We identified the Hippo pathway and its effector YAP as a key pathway that controls stellate cell activation. YAP is a transcriptional co-activator and we found that it drives the earliest changes in gene expression during stellate cell activation. Activation of stellate cells *in vivo* by CCl_4 administration or activation *in vitro*, caused rapid activation of YAP as revealed by its nuclear translocation and induction of target genes. Importantly, knock-down of YAP expression or pharmacological inhibition of YAP prevented hepatic stellate cell activation *in vitro*. Moreover, *in vivo* inhibition of YAP activity with a pharmacological inhibitor impeded fibrogenesis in mice.
Conclusions: YAP activation is thus a critical driver of hepatic stellate cell activation and inhibition of YAP presents a novel approach for the treatment of liver fibrosis.

P0445
OBETICHOLIC ACID, AN FXR AGONIST, REDUCES HEPATIC FIBROSIS IN A RAT MODEL OF TOXIC CIRRHOSIS

L.D. Verbeke[1], I. Mannaerts[2], R. Schierwagen[3], S. Klein[3], I. Vander Elst[1], P. Windmolders[1], R. Farre[4,5], M. Wenes[6,7], M. Mazzone[6,7], F. Nevens[1], L.A. van Grunsven[2], J. Trebicka[3], W. Laleman[1]. *[1]Division of Liver and Biliopancreatic disorders, University Hospitals Leuven, KU Leuven – University of Leuven, Leuven, [2]Liver Cell Biology Laboratory, Vrije Universiteit Brussel, Brussels, Belgium; [3]Department of Internal Medicine I, University of Bonn, Bonn, Germany; [4]Translational Research Center for Gastrointestinal Disorders, KU Leuven – University of Leuven, Leuven, Belgium; [5]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos II, Barcelona, Spain; [6]Laboratory of Molecular Oncology and Angiogenesis, Vesalius Research Center, Department of Oncology, KU Leuven – University of Leuven, [7]Laboratory of Molecular Oncology and Angiogenesis, Department of Oncology, VIB, Leuven, Belgium*
E-mail: Len.verbeke@med.kuleuven.be

Background and Aims: Hepatic stellate cells (HSC) drive hepatic fibrosis following chronic liver injury. Although controversial, the bile acid-responsive farnesoid-X receptor (FXR) might antagonize hepatic fibrogenesis via inhibition of HSC activation. We aimed to investigate both the preventive and therapeutic effects of the FXR agonist obeticholic acid (INT-747) on fibrosis in a rat model of toxic cirrhosis.
Methods: Cirrhosis was induced by thioacetamide (TAA) intoxication for 18 weeks. INT-747 was given during the last 4 weeks of (prophylactic) or for 4 weeks after ending (therapeutic) intoxication. Vehicle-treated rats served as controls. At sacrifice, degree of fibrosis (image analysis, hydroxyproline), hemodynamic (liver perfusion) and biochemical parameters were assessed. HSC activation, proliferation, apoptosis, hepatic nuclear-factor kappa B (NF-κB) activation, pro-inflammatory and pro-fibrotic cytokines were determined (RT-PCR, western blot). The effect of INT-747 was further evaluated on these latter parameters on isolated HSC, Kupffer cells, hepatocytes and liver sinusoidal endothelial cells.
Results: INT-747 significantly decreased fibrogenesis during TAA-administration and reversed fibrosis in established cirrhosis. As a consequence, portal pressure decreased through reduced total intrahepatic vascular resistance. These beneficial effect related to HSC de-activation by decreased expression of pro-fibrotic (transforming growth-factor β, connective tissue growth factor, platelet-derived growth factor β-receptor, tissue inhibitor of metallopeptidase-1) and pro-inflammatory cytokines (e.g. monocyte chemo-attractant protein-1) via down-regulated NF-κB. INT-747 also affected hepatic markers of cell turn-over. In vitro, a direct effect of INT-747 on HSC was excluded.
Conclusions: FXR agonist INT-747 reverses fibrosis in toxic cirrhotic rats by decreased HSC activation, indirectly via decreased hepatic inflammation.

P0446

INHIBITORY EFFECT OF DIETARY CAPSAICIN ON LIVER FIBROSIS IN MICE

S. Bitencourt[1], L. Stradiot[1], S. Verhulst[1], L. Thoen[1], I. Mannaerts[1], L.A. van Grunsven[1]. [1]*Liver Cell Biology Laboratory, Vrije Universiteit Brussel, Brussel, Belgium*
E-mail: leslie.stradiot@vub.ac.be

Background and Aims: The activation of hepatic stellate cells (HSCs) is the main event during liver fibrosis development. Capsaicin, the active pungent compound of chili peppers, is widely consumed as food additive. In the liver, it can modulate the activation, proliferation and migration of HSCs in vitro. The aim of this study is to evaluate the inhibitory effects of dietary capsaicin on HSCs related to cholestatic and hepatotoxic-induced liver fibrosis in mice and its underlying mechanism of action.
Methods: In vivo: male Balb/c mice (n = 5 per group) received dietary capsaicin (0.01% mixed in the chow) after 3 days of bile duct ligation (BDL) or before and during chronic carbon tetrachloride (CCl_4) treatment. Liver tissue sections were investigated by histology, immunohistochemistry and real-time PCR. HSCs were FACS-isolated and activation markers were analyzed by real-time PCR. In vitro: freshly isolated HSCs were electroporated with DsRed-GFP-LC3B plasmid, cultured and treated with 100 μM capsaicin for 7 days and the autophagic flux quantified using ImageJ.
Results: Dietary capsaicin partially improved liver damage in BDL mice and inhibited further progression of the injury. The beneficial effects were accompanied by fewer necrotic areas, a decrease in collagen deposition and downregulation of profibrogenic markers in isolated HSCs. In the CCl_4 model, dietary capsaicin prevented livers from injury development and inhibited the upregulation of activation markers. However, capsaicin could not attenuate the CCl_4-induced fibrosis when it was already established. Furthermore, capsaicin-treatment reduced autophagic flux.
Conclusions: Dietary capsaicin decreases the severity of liver injury in murine BDL and hinders fibrogenesis in the BDL and CCl_4-induced liver fibrosis models. This anti-fibrotic potential of capsaicin could partly be due to its inhibitory effect on autophagic flux. Collectively, these results support that daily dietary consumption of capsaicin has beneficial effects on liver injury, especially on HSC activation.

P0447

CHANGES IN LIVER EXTRACELLULAR MATRIX DURING LIVER INJURY REGULATE HEPATIC PROGENITOR CELL PROLIFERATION AND DIFFERENTIATION

M. Klaas[1], V. Jaks[1]. [1]*Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia*
E-mail: mariliis.klaas@ut.ee

Background and Aims: The extracellular matrix (ECM) is composed of proteins and other macromolecules that forms a network between cells. ECM is a dynamic structure and its remodelling is tightly controlled in normal liver homeostasis. Life-threatening pathological conditions such as liver cirrhosis and liver cancer arise when ECM remodelling becomes excessive or uncontrolled. Liver fibrosis is characterised by major changes in the liver ECM composition with the steepest increase in type I collagen deposition. In addition to collagens, laminins and fibronectin, the ECM is composed of other various smaller molecules that are tissue specifically disposed at the sites of injury. Our aim was to characterise the changes in the liver ECM components in an injured liver and to investigate how they influence liver regeneration.
Methods: We utilised perfusion-based chemical decellularisation of the mouse liver combined with quantitative analysis of the proteome to identify which ECM proteins are significantly upregulated or downregulated during acute liver injury. The expression profile of the differentially expressed proteins was characterised by immunohistochemistry and microscopy. The effect of the selected ECM proteins on hepatic progenitor cell proliferation and differentiation was evaluated in in vitro culture.
Results: We identified 4 structural and 4 regulatory ECM components that were upregulated during liver injury. 12 structural and 3 regulatory ECM components were found to be significantly downregulated. A strong increase in collagens type I, type V and fibronectin indicate that liver damage in acute mouse liver injury model is mainly characterised by fibrosis which is accompanied with the reduction of the basal membrane components and elastic fibers. Analysis of the *in vitro* culture of hepatic progenitor cells on selected substrates revealed that proteins upregulated during liver injury mainly supported cell proliferation but proteins that are reduced in damaged ECM support cell differentiation.
Conclusions: Changes in the liver ECM during liver damage regulate the regenerative response which is important for repairing the damage. Our findings indicate that acute liver injury causes a significant change in the balance of main structural liver ECM components and upregulation of several regulatory ECM proteins which together support the proliferation of hepatic progenitor cells and liver regeneration.

BENEFITS OF ISOLATING HSC USING FLUORESCENCE-BASED CELL SORTING

M. Bartneck[1], K.T. Warzecha[1], C.G. Tag[1,2], S. Sauer-Lehnen[1,2], F. Heymann[1], C. Trautwein[1], R. Weiskirchen[2], F. Tacke[1]. [1]*Department of Medicine III,* [2]*Institute of Molecular Pathobiochemistry, Experimental Gene Therapy and Clinical Chemistry, RWTH-University Hospital, Aachen, Germany*
E-mail: mbartneck@ukaachen.de

Background and Aims: Hepatic stellate cells (HSC) are the main effector cells for liver fibrosis. Thus, isolation of highly pure primary HSC from healthy or diseased mouse liver is an evitable tool for functional studies on HSC biology and evaluating antifibrotic approaches *in vitro*. At present, most protocols for isolating primary murine HSC employ density gradient centrifugation only, however, this may result in contaminations with other cell types such as Kupffer cells (KC). We aimed at optimizing HSC isolation by adding an additional subsequent step of fluorescence-activated cell sorting (FACS) via a UV laser.
Methods: HSC were isolated from livers of healthy mice and mice subjected to experimental fibrosis. HSC isolation by iohexol-based density centrifugation was compared to a method with subsequent FACS-based sorting. We assessed cellular purity, viability, morphology, and functional properties like proliferation, migration, activation marker and collagen expression.
Results: FACS-augmented isolation resulted in a significantly increased purity of stellate cells (>99%) compared to iohexol-based density centrifugation alone (60–95%), primarily by excluding HSC-KC cell doublets. Importantly, this method is also applicable to young animals and mice with liver fibrosis. Viability and characteristics of HSC transdifferentiation (αSMA, collagen, desmin) *in vitro* were preserved upon FACS-based isolation. During the maturation of primary HSC in culture, we did not observe HSC proliferation by time lapse microscopy for several days. Strikingly, FACS-isolated, differentiated HSC showed very limited responses to lipopolysaccharide (LPS) stimulation.
Conclusions: Isolating HSC from mouse liver by adding an additional step of cell sorting significantly increased cell purity by removing contaminations from other cell populations especially KC, without affecting viability or differentiation.

P0449

NON STEROIDAL ANTI INFLAMMATORY DRUGS IN LIVER FIBROSIS

E. Akhan[1], O. Oğuz[2], E. Çetin[2], R. Çetin Atalay[3]. [1]*Molecular Biology and Genetics,* [2]*Electrical and Electronics, Bilkent University,* [3]*Bioinformatics Department, informatics institute, ankara, Turkey*
E-mail: eceakhan88@gmail.com

Background and Aims: Liver fibrosis is an abnormal wound healing process resulting in extracellular matrix accumulation. If not treated, liver fibrosis leads to cirrhosis, which is a non-reversible stage of the disease. It is known liver fibrosis triggers the infiltration of inflammatory cells into the liver tissue and necrosis. Therefore, alteration of the inflammatory process in damaged liver may result in the regression of fibrosis. On the other hand, non-steroidal anti-inflammatory drugs (NSAIDs) are widely used to prevent the inflammatory processes in various diseases. Clinically used NSAIDs, Aspirin, Ibuprofen, Naproxen and Flurbiprofen have been reported to be non-hepatotoxic. In this study we investigated the effects of these drugs and some novel NSAI compounds on the liver fibrosis.
Methods: Liver fibrosis model was generated by i.p. treatment of C57BL/6 male mice with CCl_4 twice a week for 4 weeks. The daily doses of drugs solved in simple syrup and administered by gavage for five days than mice were sacrificed. Non-fibrotic male mice used as negative controls whereas fibrotic mice used as positive control. α-SMA, Collagen levels in liver tissues and serum ALT/AST levels were evaluated. Collagen staining levels were quantified by the region based pixel intensity normalization algorithm using MATLAB. We further investigated the ongoing inflammation in liver by analyzing the expression of macrophage and T-cell markers.
Results: We demonstrated a obvious decrease in liver α-SMA and collagen levels in NSAID treated group compared to non-treated group. In addition, the apparent decrease in collagen staining upon NSAID treatment was further evaluated by the quantitative image analysis. The serum AST levels showed a decrease in all treated groups. The comparative analysis of the drugs indicated that Naproxen had the most significant effects whereas least decrease in α-SMA, Collagen levels were observed with Ibuprofen. Although Flurbiprofen had similar bioactivities on tissue in α-SMA, Collagen levels; less decrease in serum AST level was found. Overall, we confirmed that there is a supression in this inflammatory process.
Conclusions: The oral administrations of common NSAIDs to treat the liver fibrosis in mice, promote the regression of this disease as demonstrated by both quantitative microcopy and serum AST levels. These drugs mainly eliminated by renal excretion, therefore based on our results, we propose the repurposing of non-hepatotoxic NSAIDs for the treatment of liver fibrosis in clinics.

P0450

KCa3.1 CHANNELS ARE UPREGULATED IN HEPATOCYTES OF CIRRHOTIC PATIENTS

L.S. Møller[1,2], A.D. Fialla[1], R. Schierwagen[3], M. Biagini[4], W. Reul[3], S. Klein[3], M. Rabjerg[4], L.K. Hansen[2], O. Schaffalitzky de Muckadell[1], R. Koehler[2], J. Trebicka[5]. [1]*Department of Medical Gastroenterology, Odense University Hospital,* [2]*Institute of Molecular Medicine, University of Southern Denmark, Odense C, Denmark;* [3]*Department of Internal Medicine, University of Bonn, Bonn, Germany;* [4]*Department of pathology, Odense University Hospital, Odense C,* [5]*Department of Internal Medicine, University of Bonn, Bonn, Denmark*
E-mail: linda@sevelsted.com

Background and Aims: KCa3.1 is a calcium activated potassium channel, which regulates proliferation, migration and cell volume. The channel has been identified in circulating blood cells (erythrocytes, lymphocytes and macrophages), endothelial and epithelial cells in colon and airway. Its inhibition is suggested as target for therapy of lung and kidney fibrosis. Little is know about its role in liver fibrosis. Recently, we found that KCa3.1 deficient mice show augmented hepatic fibrosis upon liver injury. The present study investigated KCa3.1 channel expression in hepatic stellate cells (HSC), hepatocytes and Kupffer cells in vitro, as well as expression and cellular localization in human liver biopsies.
Methods: *Cellular studies:* In primary isolated hepatocytes, Kupffer cells and HSC we measured KCa3.1 gene expression by quantitative polymerase chain reaction. We incubated quiescent and culture-activated hepatic stellate cells with the specific KCa3.1 channel inhibitor TRAM-34 and the activator SKA-31 and evaluated effect on mRNA expression of collagen 1, smooth muscle actin and tumor growth factor β.
Human biopsies: liver biopsies from 54 patients representing normal, alcoholic cirrhosis, autoimmune disease or severe inflammation or fibrosis due to other aetiologies were included. Immunohistochemical stain was performed for KCa3.1 channel expression. Double fluorescent immune stain was performed to investigate KCa3.1/macrophage co-localization.
Results: KCa3.1 channel inhibition with TRAM-34 suppressed collagen production in HSC, but did not change the myofibroblastic phenotype. No changes were seen by channel activation by SKA-31 KCa3.1 mRNA was 300 and 100 times higher in macrophages and hepatocytes compared to HSC.
In normal human biopsies KCa3.1 channel expression was low or absent, but an abundant expression was seen in hepatocytes of cirrhotic livers. The channel was found only in a minor percentage of the macrophages.
Conclusions: Our study questions the potential anti-fibrotic effect of channel blockers, but demonstrates an upregulation of KCa3.1 channels in hepatocytes during cirrhosis, which might play a pathogenic role.

P0451

LASER CAPTURE MICRODISSECTION REVEALS CELL-SPECIFIC DNA METHYLATION SIGNATURES IN KEY FIBROSIS MODIFIER GENES IN CHRONIC LIVER DISEASE

T. Hardy[1], V. Sharkey[1], M. Zeybel[2], J.C. Mathers[1], J. French[3], S. White[1], D.A. Mann[1], Q.M. Anstee[1], J. Mann[1]. [1]*Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom;* [2]*Dept. of Hepatology, Koc University, Istanbul, Turkey;* [3]*Dept. of Surgery, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom*
E-mail: Timothy.Hardy@ncl.ac.uk

Background and Aims: Recent studies examining differential DNA methylation of key genes known to regulate fibrosis in human chronic liver disease have been at the whole tissue level; however, it is likely that DNA methylation patterns are cell-specific. Thus, our aim was to examine whether DNA methylation signatures of key fibrosis modifier genes vary according to cell type and acinar location in human chronic liver disease.
Methods: Sections from explanted liver from 6 patients transplanted for ALD were stained with H+E and subjected to laser capture microdissection (LCM); areas containing (i) principally hepatocytes or (ii) fibrotic bands containing myofibroblasts were selected. DNA methylation profiles of PDGFA and PPARA were determined using pyrosequencing.
Results: PDGFA was significantly hypermethylated in hepatocytes relative to fibrotic bands containing myofibroblasts (CpG 1: 38±4.3% vs 25±2.15%, $p < 0.03$; CpG 2: 16.9±1.87% vs 11.3±1.29%, $p < 0.02$). In contrast, PPARA methylation was increased in fibrotic areas compared to hepatocytes, although this did not reach significance (CpG:1 1.42±0.22% vs 0.84±0.14%).
Conclusions: Cell-specific DNA methylation signatures exist in key fibrosis modifier genes in chronic liver disease. These results show that investigation of DNA methylation patterns in human diseases on an epigenome-wide scale should be interpreted with caution if cell specificity is not accounted for.

P0452

CHANGES IN DNA METHYLATION AND HYDROXYMETHYLATION DURING HSC ACTIVATION

A. Page[1], J. Mann[1], D. Mann[1]. [1]*Newcastle University, Newcastle upon Tyne, United Kingdom*
E-mail: agata.page@ncl.ac.uk

Background and Aims: DNA methylation (5mC) is an epigenetic mark that is an established regulator of gene transcription with an important role in liver fibrosis. Currently, there is only very basic knowledge available as to how DNA methylation controls the phenotype of hepatic stellate cells (HSC), the key cell type responsible for onset and progression of liver fibrosis. Evidence has shown that presence of higher levels of DNA methylation around gene promoters correlate with low or no transcriptional activity. However, recently discovered 5-hydroxymethylcytosine (5hmC), generated by oxidation of 5mC through action of TET enzymes, is actually involved in gene activation and its patterns are often altered in human diseases. In this study we investigated the role of 5mC and 5hmC in liver fibrosis.
Methods: Levels of 5mC and 5hmC were assessed by slot blot in a range of animal liver fibrosis models and diseased human livers. Expression levels of TET enzymes and DNA methyltransferases (DNMTs) were measured by qRT-PCR and WB. Reduced representation bisulfide sequencing (RRBS) method was used to examine 5mC and 5hmC patterns in quiescent and in vivo activated rat HSC.
Results: Expression of TET enzymes and therefore global levels of 5hmC, are both downregulated in activated rat HSC and in diseased human livers. Moreover, DNMTs expression is changed in human and rat samples suggesting changed levels of 5mC. Using RRBS, we examined the exact genomic positions of changed methylation patterns in quiescent and in vivo activated rat HSC.
Conclusions: We found significant differences in TET and DNMT protein expression between quiescent and activated rat HSC as well as in human samples, which in turn cause alteration in the HSC DNA methylome and hydroxymethylome. Changes in DNA methylation during HSC activation may bring new insights into the molecular events underpinning fibrogenesis and may provide biomarkers for disease progression as well as potential new drug targets.

Liver immunology including viral hepatitis

HSF1 REGULATES INFLAMMASOME NLRP3-MEDIATED INNATE IMMUNITY VIA ACTIVATING BETA-CATENIN SIGNALING IN LIVER ISCHEMIA AND REPERFUSION INJURY

J. Zhu[1], M. Zhang[1], S. Yue[2], M. Zhou[2], M. Ke[2], R.W. Busuttil[2], J.W. Kupiec-Weglinski[2], Q. Xia[1], B. Ke[2]. [1]*Department of Liver Surgery, Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China;* [2]*The Dumont-UCLA Transplant Center, Department of Surgery, David Geffen School of Medicine at UCLA, Los Angeles, United States*
E-mail: bke@mednet.ucla.edu

Background and Aims: Heat shock transcription factor 1 (HSF1), a major regulator of heat shock gene transcription, might play important roles in the regulation of cell stress and disease state. In response to injurious agents, the inflammasome NLRP3 mediates caspase-1 activity to drive innate immune response. Although heat shock response has been implicated to differentially regulate immune response, little is known the functional role of macrophage HSF1 in the regulation of inflammasome NLRP3 activation during liver ischemia and reperfusion injury (IRI). This study was designed to explore the intracellular signaling networks regulated by HSF1 in NLRP3-mediated innate immune response triggered by IR stress in a mouse liver.
Methods: Myeloid specific HSF1 knockout ($HSF1^{M\text{-}KO}$) and HSF1 transgenic ($HSF1^{flox/flox}$) mice (n = 6/group) were subjected to 90 min partial liver warm ischemia followed by 6 h of reperfusion. In parallel *in vitro* study, bone marrow-derived macrophages (BMMs) from $HSF1^{M\text{-}KO}$ or $HSF1^{flox/flox}$ were transfected with HSF1-expressing vector (pBabe-HSF1) or beta-catenin siRNA/nonspecific siRNA (100 nM), and then incubated with LPS (100 ng/ml).
Results: Myeloid-specific HSF1 knockout (HSF1M-KO) increased the expression of NLRP3 and cleaved caspase-1 leading to exacerbating hepatocellular injury, as evidenced by increased sALT levels and hepatocellular necrosis/apoptosis. Unlike in HSF1flox/flox controls, HSF1M-KO increased macrophage/neutrophil trafficking and pro-inflammatory IL-1β/IL-18 levels in ischemic livers. Consistent with the in vivo results, LPS-stimulated BMMs from HSF1M-KO markedly increased NLRP3/caspase-1 activity and IL-1β production. In contrast, transfection of LPS-stimulated BMMs with pBabe-HSF1 depressed NLRP3/caspase-1 yet increased β-catenin phosphorylation. Furthermore, knockdown of β-catenin with siRNA treatment in HSF1-expressing cells readily activated NLRP3/caspase-1 and TLR4, which in turn enhanced NF-κB activation and increased expression of proinflammatory mediators.
Conclusions: This study demonstrates that myeloid specific HSF1 deletion triggers inflammasome NLRP3/caspase-1 activation in IR-induced inflammation. Induction of HSF1 promotes β-catenin signaling, which in turn negatively regulates NLRP3/caspase-1 activation. By documenting the crucial role of macrophage HSF1 in the regulation of NLRP3-mediated innate immune-driven local inflammatory responses, our findings provide the rationale for a novel therapeutic strategy against IRI in organ transplant recipients.

P0454

AN ADDITIONAL HEME OXYGENASE-1 KNOCKOUT INCREASES MATURATION OF DENDRITIC CELLS AND LIVER INFLAMMATION IN Mdr2 KNOCKOUT MICE

R. Barikbin[1], M. Sandmann[2], A. Quaas[2], K. Karimi[1], G. Sass[1], G. Tiegs[1]. [1]*Institue of Experimental Immunology and Hepatology,* [2]*Institute of Pathology, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany*
E-mail: r.barikbin@uke.de

Background and Aims: Deletion of the multi drug resistance protein 2 (Mdr2) in mice causes hepatic inflammation and fibrosis with progression to hepatocellular carcinoma (HCC) at about 12 month of age (Mdr2 knockout; Mdr2ko; FVB.129P2-$Abcb4^{tm1Bor}$). We have recently shown that induction of heme oxygenase-1 (HO-1) in Mdr2ko mice interferes with liver inflammation, fibrosis formation and proliferation. We established a double knockout mouse for Mdr2 and HO-1 (Mdr2/HO-1ko) to further investigate effects of HO-1 on chronic liver inflammation and its consequences.
Methods: Liver damage was monitored by alanine aminotranferase (ALT) levels. Liver hydroxyproline content was measured as a fibrosis marker. Spleen weight was measured as a marker of inflammation. Leukocyte infiltration and neoductuli formation was visualized by H&E staining of liver slices. Flow cytometry was used to analyze liver immune cell populations. Bone marrow derived dendritic cells (BM-DCs) were analyzed for cytokine production and expression of maturation markers. Female and male (F/M) FVB/N background control (wt), Mdr2ko, and Mdr2/HO-1ko mice were analyzed at the age of 12 weeks.
Results: ALT levels were significantly up-regulated in Mdr2ko (F/M), and male Mdr2/HO-1ko mice compared to wt, while female Mdr2/HO-1ko display even higher ALT levels. Liver hydroxyproline levels were significantly higher in Mdr2/HO-1ko mice (F/M) compared to Mdr2ko mice (F/M). Spleen weight was doubled in Mdr2ko (F/M) mice compared to wt, while Mdr2/HO-1ko (F/M) mice showed a 5 fold elevated spleen weight. In histological liver

stainings, Mdr2ko and Mdr2/HO-1ko mice (F/M) showed similar levels of leukocyte infiltration and neoductuli formation and were significantly up-regulated compared to wt mice. Flow cytometry data showed increased frequencies of T-cells and NKT-cells as well as $CD11c^+$ dendritic cells (DCs) in Mdr2/HO-1ko mice compared to Mdr2ko mice. In addition DCs showed increased surface expression of CD86. BM-DCs from Mdr2/HO-1ko showed a 5 fold increase in MHCII-, and CD86-expression as well as a 5 fold increase in IL-12 production even without LPS restimulation compared to Mdr2ko.
Conclusions: Mdr2/HO-1ko mice have a stronger fibrotic and inflammatory phenotype compared to the single Mdr2ko. The stronger inflammation can be explained by higher frequencies of $CD3^+$ T-cells, NKT-cells and mature DCs. High production of IL-12 in BM-DCs indicate a stronger Th1 response in Mdr2/HO-1ko mice compared to Mdr2ko.

P0455
IL-4Ra REGULATES LIVER FIBROSIS DIFFERENTLY DURING PROGRESSION AND REVERSAL PHASES BY MODULATING THE RATIO OF M1 VS M2 MACROPHAGES

S.-Y. Weng[1], S. Vijayan[1], X.-Y. Wang[1], Y. Tang[2], K. Padberg[1], Y.O. Kim[1], F. Brombacher[3], J. Crosby[4], M. McCaleb[4], A. Waisman[2], D. Schuppan[1]. *[1]Institute of Translation Immunology and Research Center for Immunotherapy, University Medical Center, Johannes Gutenberg University Mainz, [2]Institute for Molecular Medicine, University Medical Center, Johannes Gutenberg University Mainz, Mainz, Germany; [3]University of Cape Town, Cape Town, South Africa; [4]Isis Pharmaceuticals, Carlsbad, United States*
E-mail: weng@uni-mainz.de

Background and Aims: In response to various stimuli, macrophages can be functionally divided into M1 (inflammatory) and M2 (anti-inflammatory) groups. Alteration of the M1-M2 ratio likely impacts liver fibrosis progression and reversal. IL-4Ra, which is activated by IL-4 and IL-13 has been linked to M2 polarization. However, the functional role of IL-4Ra in liver fibrosis progression and reversal remained unclear.
Methods: Balb/c or C57BL6 mice with systemic or conditional deletion of the IL-4Ra were treated with CCL4 via oral gavage for 6 weeks, to induce advanced liver fibrosis (parenchymal progression model). The reversal phase is determined 2 weeks after the last treatment. Mdr2 KO mice model were used as a bililary fibrosis model. The extent of liver fibrosis was determined by hydroxyproline measurement and Sirius Red morphometry. Fibrosis and inflammation related transcripts were determined by qPCR. Macrophage subsets were quantified by FACS analysis and IHC. For therapeutic intervention, control or IL-4Ra specific antisense oligonucleotides injected i.p. into fibrotic mice.
Results: IL-4Ra was prominently upregulated in Mdr2 KO mice with spontaneous biliary fibrosis, and less markedly in CCL4-treated mice. CCL4-treated IL-4Ra KO mice had 25% less fibrosis than their wildtype littermates. T and B cells, granulocytes, M2 macrophages were significantly decreased, however, the M1 macrophages population were increased. To specifically characterize the function of IL-4Ra in macrophages, IL-4RaΔLysM mice were generated and treated with 6 weeks of CCL4. These mice showed no difference in T and B cell numbers, but a significant reduction of CD11bloF4/80hiCD206+ M2 resident macrophages. This was accompanied by significantly attenuated fibrosis in the $IL\text{-}4Ra^{\Delta LysM}$ mice. Surprisingly, in wildtype mice M2 macrophages were remarkably increased during the resolution phase of CCl_4-induced fibrosis (up to week 2 after discontinuation of CCL4). Here, fibrosis resolution was significantly retarded in $IL\text{-}4Ra^{\Delta LysM}$ mice. In the therapeutic setting, a potent antisense oligonucleotide against IL-4Ra inhibited the progression but retarded the regression of fibrosis.
Conclusions: Our studies demonstrate that IL-4Ra in general and in macrophages in particular modulates fibrosis progression and reversal in discordant ways. Unexpectedly, M2 macrophages contribute to fibrogenesis but speed up fibrolysis. Modulation of IL-4Ra by antisense oligonucleotides should be an effective therapy to retard immune mediated fibrosis progression.

RE-EVALUATION OF HBV CLINICAL PHASES BY SYSTEM BIOLOGY IDENTIFIES UNAPPRECIATED ROLES FOR THE INNATE IMMUNE RESPONSE AND B CELLS

T. Vanwolleghem[1,2], J. Hou[1], G.W. van Oord[1], A.C. Andeweg[3], A.D. Osterhaus[3], S.D. Diepstraten-Pas[3], H.L. Janssen[1,4], A. Boonstra[1]. *[1]Hepatology and Gastroenterology, Erasmus MC, Rotterdam, Netherlands; [2]Hepatology and Gastroenterology, Antwerp University Hospital, Antwerp, Belgium; [3]Viroscience, Erasmus MC, Rotterdam, Netherlands; [4]Liver Clinic, University Health Network, Toronto, Canada*
E-mail: t.vanwolleghem@erasmusmc.nl

Background and Aims: Host factors that identify distinct clinical phases of a chronic HBV infection – immune tolerant (IT), immune active (IA), inactive carrier (IC) and HBeAg negative (ENEG) hepatitis phases – are poorly defined. We performed a systems biology study to identify host markers that can differentiate between these disease phases.
Methods: Serum samples from untreated chronic HBV patients ($n = 71$) were used for multiplex cytokine measurements, quantitative HBsAg, HBeAg levels, HBV genotype and mutant analysis. Leukocytes were phenotyped using multicolour flowcytometry and whole blood transcriptome profiles were generated.
Results: HBV viral load, HBeAg and HBsAg levels ($P < 0.001$), but not leukocyte composition differed significantly between distinct phases. Serum MCP-1, IL-12p40, IP-10, MIP-1β levels were different between two or more clinical phases ($P < 0.05$). The lowest number of HBV precore mutations was found in IT patients ($P < 0.01$). Comparison of blood transcriptomes identified 64 differentially expressed genes between clinical phases. The gene signature distinguishing IA from IT and IC patients was predominantly composed of highly upregulated immunoglobulin encoding genes. Furthermore, gene-set enrichment analysis corroborated abundant expression of B cell function-related genes in IA patients, and pointed towards increased ISG transcript levels in IT patients compared to subsequent phases. Finally, NK cell activities were clustered in clinical phases with biochemical liver damage (IA and ENEG phases).
Conclusions: HBV clinical phases are characterised by distinct blood gene signatures. Innate interferon and B cell responses are highly active during the IT and IA phases, respectively. This suggests that the presumed immune tolerance in chronic HBV infections needs to be redefined.

E-mail: drvolarevic@yahoo.com

Background and Aims: Reactive oxygen species (ROS) production regulates the function and activity of liver infiltrated immune

cells, particularly T cells and macrophages. Graphene quantum dots (GQD) are grapheme sheets with lateral dimensions less than 100 nm. Laser ablation-generated GQD produce ROS upon irradiation with blue light, while in the absence of photoexcitation they display a potent ROS-quenching ability. Since effects of GQD on either normal or pathologic immune responses have not been explored so far, by using Concanavalin A (Con A) induced hepatitis, we aimed to investigate immunomodulatory and cytoprotective effects of GQD in liver pathology.

Methods: We investigated the effects of GQD (50 mg/kg i.v.) in Con A-induced hepatitis (Con A; 12 mg/kg i.v.) by using wild type BALB/c and ST2 deficient mice. We estimated liver injury and inflammation by liver enzyme tests, histology, cytokine production, intracellular staining of immune cells, by determining apoptosis and autophagy in the liver.

Results: GQD accumulated in liver and reduced Con A-mediated liver damage, as demonstrated by histopathological analysis and a decrease in liver lipid peroxidation and serum levels of liver transaminases. The cleavage of apoptotic markers caspase-3/PARP and mRNA levels of proapoptotic mediators Puma, Noxa, Bax, Bak1, Bim, Apaf1, and p21, as well as LC3-I conversion to autophagosome-associated LC3-II and expression of autophagy-related (Atg) genes Atg4b, Atg7, Atg12, and beclin-1, were attenuated by GQD, indicating a decrease in both apoptosis and autophagy in the liver. This was associated with the reduced liver infiltration of immune cells, particularly the T cells producing pro-inflammatory cytokine IFN-γ, and a decrease in IFN-γ serum levels. In the spleen of GQD-exposed mice, mRNA expression of IFN-γ and its transcription factor T-bet was reduced, while that of the IL-33 ligand ST2 was increased. The hepatoprotective effect of GQD was less pronounced in ST2-deficient mice, indicating that it might depend on ST2 upregulation. In vitro, GQD inhibited splenocyte IFN-γ production, reduced the activation of extracellular signal-regulated kinase in macrophage and T cell lines, inhibited macrophage production of the free radical nitric oxide, and reduced its cytotoxicity towards hepatocyte cell line HepG2.

Conclusions: GQD alleviate immune-mediated fulminant hepatitis by interfering with T cell and macrophage activation and possibly by exerting a direct hepatoprotective effect.

P0458
AGGRAVATION OF LIVER DAMAGE IN Ceacam1 (CARCINOEMBRYONIC ANTIGEN-RELATED CELL ADHESION MOLECULE 1)-DEFICIENT MICE IN IMMUNE MEDIATED LIVER INJURY

A.K. Horst[1], C. Wegscheid[1], A. Quaas[2], G. Tiegs[1]. [1]*Experimental Immunology and Hepatology,* [2]*Department of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*
E-mail: c.wegscheid@uke.de

Background and Aims: The T cell mitogenic plant lectin concanavalin A (ConA) induces acute immune-mediated liver injury, evident by elevation of plasma transaminases (ALT) and release of IFNgamma and TNFalpha. The cellular adhesion molecule CEACAM1 is expressed on epithelia, endothelia, and leukocytes. CEACAM1 has been originally identified as an intercellular, homophilic adhesion molecule on hepatocytes. The CEACAM1 isoform with a long cytoplasmic domain contains an ITIM that is pivotal in for the negative regulation of leukocyte activation, more specifically, CEACAM1-long suppresses the activity of NK-cells, T cells and myeloid cells. This negative regulation is important in modulation of innate immunity in both infection and sterile inflammation. Thus, elucidation of CEACAM1-dependent regulatory mechanisms in immune mediated liver injury might open novel therapeutic perspectives for human liver disorders.

Methods: *Ceacam1*$^{-/-}$ and wildtype (wt) were injected with a sublethal dose of ConA (5 mg/kg) or saline, respectively. After 24 hrs, ALT activity and expression of cytokines were determined by ELISA. Splenic and hepatic T cell populations were analysed by FACS. Tregs were adoptively transferred from wt or *Ceacam1*$^{-/-}$ donors into wt recipients.

Results: ConA-induced liver damage was exacerbated in *Ceacam1*$^{-/-}$ mice, evident by significant elevation of ALT and an exaggerated Th1-cytokine response. Further, CEACAM1-expression on CD4+ T cells, CD4^{+}Foxp3^{+} regulatory T cells (Treg), and CD8^{+} T cells was increased after ConA treatment. *Ceacam1*$^{-/-}$ mice displayed lower Treg frequency in both liver and spleen. A protective effect of *Ceacam1*$^{-/-}$ Tregs in ConA hepatitis opposed to CEACAM1-expressing Tregs was not observed.

Conclusions: Aggravation of liver damage in *Ceacam1*$^{-/-}$ mice suggests a CEACAM1-dependent regulation of immune-mediated liver disease. Our data indicate an immune modulatory function of CEACAM1 in the ConA-model by regulating CD4^{+} and CD8^{+} T cell abundance and polarization. Future studies will describe the functional role of CEACAM1 in regulation of Treg activity and a Th1-polarized immune response yielding liver protection.

P0459
NATURAL KILLER CELL PHENOTYPIC PROFILE IN HEPATOCELLULAR CARCINOMA (HCC) IS PREDICTIVE OF CLINICAL OUTCOME AFTER CURATIVE TREATMENT

E. Cariani[1], M. Pilli[2], V. Barili[2], E. Porro[2], E. Biasini[2], A. Olivani[2], R. Dalla Valle[3], C. Ferrari[2], G. Missale[2]. [1]*Clinical Pathology Toxicology Ospedale Civile S. Agostino-Estense, Modena,* [2]*Infectious Diseases and Hepatology, Azienda Ospedaliero-Universitaria di Parma,* [3]*Department of Surgery, University of Parma, Parma, Italy*
E-mail: ecariani@hotmail.com

Background and Aims: Natural killer (NK) cells are known to be involved in the immunological control of liver cancer. Limited studies have addressed phenotypic and functional characteristics of NK cell response in HCC. We investigated NK cell phenotype association with clinical outcome after liver resection or percutaneous ablation.

Methods: 76 consecutive Caucasian HCC patients with HCV-related liver disease and 12 patients with HCV-related liver cirrhosis as controls were evaluated. Phenotypic analysis was carried out by staining for NKCD56, NKG2A, NKG2D, NKp30, NKp46, CD3ζ, perforin and granzyme B. Data analysis was performed by unsupervised hierarchical clustering of NK cell subsets frequency. Overall survival of the generated patient clusters was analyzed by log rank test.

Results: Our data indicate a significantly higher level of NKG2A ($p < 0.0001$), CD3ζ ($p = 0.0002$) and perforin ($p = 0.017$) expression in cirrhotics (controls) compared to HCC patient.
Hierarchical clustering of HCC patients identified three clusters, one of which was characterized by significantly lower overall survival ($p = 0.0002$). Comparison of different parameters among clusters revealed significantly lower level of CD3ζ ($p < 0.0001$), granzyme B ($p = 0.0003$) and perforin (<0.0001) expression in patients with worse survival that maintained higher level of NKG2A ($p = 0.018$), NKp30 ($p = 0.034$) and NKp46 ($p = 0.0002$) compared to patients with better outcome.

Conclusions: The analysis of NK cell phenotype suggests a cytotoxic defect in HCC patients compared to patients with liver cirrhosis. This defect could play a role in the clinical outcome after curative treatments for HCC. Altogether these results further support the relevant role played by NK cells in the immunopathogenesis of HCC, indicating a rational for immunotherapeutic strategies aimed at restoring NK-mediated anti-tumor activity.

P0460

CD3hiCD4- Vγ9/Vδ2 TCR+ GAMMA DELTA T CELLS WITH TH1 AND NK-LIKE PHENOTYPE ARE INDUCED IN PATIENTS WITH CHRONIC HEPATITIS B

Roberts[9], C. Smith[10], R.L. Carithers[11], D.L. Levine[1], J. Keith[1], M.E. Valiga[1], M. Betts[12], H. Janssen[3], A.S.F. Lok[13], K.-M. Chang[1]. *[1]Gastroenterology, University of Pennsylvania, Philadelphia, [2]Department of Biostatistics, University of Pittsburgh, Pittsburgh, United States; [3]University of Toronto, Toronto, Canada; [4]University of Texas Southwestern, Dallas, [5]University of California San Francisco, San Francisco, [6]Virginia Commonwealth University, Richmond, [7]Virginia Mason Medical Center, Seattle, [8]Harvard University, Boston, [9]Mayo Clinic, Rochester, [10]Mayo Clinic, Plymouth, [11]University of Washington Medical Center, Seattle, [12]University of Pennsylvania, Philadelphia, [13]University of Michigan, Ann Arbor, United States*
E-mail: jangjune.park@gmail.com

Background and Aims: Gamma delta (γδ) T cells are non-conventional innate-like cells that recognize ligands induced by stress or pathogens and have potential roles in host defense, tumor surveillance, and immune regulation. Based on preliminary detection of CD3hiCD4- T cells expressing γδ T cell receptor (TCR) in blood of patients with chronic hepatitis B (cHBV), we asked if γδ T cells are: (1) induced during chronic and acute infection; (2) distinct in phenotype and function; (3) associated with clinical and virological status of HBV infection.

Methods: 200 subjects with cHBV, 20 uninfected controls and 12 subjects with acute hepatitis B (aHBV) were recruited for immune analysis between February 2011 and December 2013 from 10 medical centers in North America. The frequency, phenotype, and function of CD3hiCD4- γδ T cells in peripheral blood lymphocytes were examined by multi-parameter cytometry in all subjects, with further evaluation of γ/δ TCR subtype, cytokine profile and Tbet expression in 24 cHBV (12 with flares, 12 without flares), 8 aHBV and 15 uninfected controls. Statistical analysis included the use of non-parametric tests, Chi-square or Fisher's Exact test as appropriate.

Results: We report that: (1) circulating CD3hiCD4- γδ T cells (mostly Vγ9+Vδ2+) are increased in frequency in cHBV compared to aHBV or control subjects (median 3.1% vs. 0.7% vs 1%, $p < 0.0001$); (2) CD3hiCD4- γδ T cells from cHBV subjects showed reduced CD28 and PD-1 expression with increased NK receptor expression (e.g. CD56, CD94, CD158a, NKG2A) compared to conventional CD3intCD4- T cells. Further analysis of Vγ9+Vδ2+ γδ T cells showed that they display a Th1 (but not Th17) phenotype with markedly increased IFNγ production (median 49% vs 14%, $p < 0.0001$) and Tbet expression (MFI 7592 vs 635, $p < 0.0001$) compared to conventional CD3int CD4- T cells; (3) While γδ T cell frequency did not associate with sALT or HBV DNA titers, γδ T cells from cHBV patients with sALT flares showed surprisingly lower IFNγ production than γδ T cells from stable cHBV patients (median 41% vs. 61%, $p = 0.0116$).

CHB (n = 200)	*CD3hiCD4-γδ T cells	Conventional CD3int CD4- T cells	p-value (Wilcoxon)
%CD28	49.4	75.7	<0.0001
%PD-1	12.6	19.5	<0.0001
%CTLA-4	6.3	6.1	0.8666
%CD56	21.6	7.4	<0.0001
%CD94	60.3	7.9	<0.0001
%CD158a	6.6	4.5	0.0003
%NKG2A	40.5	4.9	<0.0001
%NKG2D	90.2	86.1	0.0038

Conclusions: Chronic but not acute hepatitis B is associated with increased frequency of circulating γδ T cells with a highly Th1 phenotype. Analysis is ongoing to define the role of γδ T cells in HBV pathogenesis and outcome, given their reduced Th1 phenotype in cHBV patients with sALT flare.

P0461

INCREASED LIVER GAMMA DELTA T CELLS ACCOMPANIED BY ENHANCED INNATE IMMUNE RESPONSES IN MOUSE MODEL OF ACUTE HEPATITIS B VIRUS (HBV) INFECTION BY HYDRODYNAMICS-BASED IN VIVO TRANSFECTION OF HBV-DNA

M. Chen[1], H. Peng[1], L. Chang[1], H. Ren[1]. *[1]Institute for viral hepatitis, Second Affiliated Hospital of Chongqing Medical University, Chongqing, China*
E-mail: chenggming@aliyun.com

Background and Aims: It is well known that the immune responses to HBV antigens and HBV replication during the acute phase of HBV infection might play a key role in viral clearance. γδT cell is one type of innate immune cell which exerts functions in the early phase of immune responses. Our previous studies showed abnormal features of γδT cell from CHB patients. Here, a further study was conducted to investigate the characteristics of liver γδT cells as well as other innate immune responses during acute HBV infection, and to explore their roles in acute HBV infection and viral clearance.

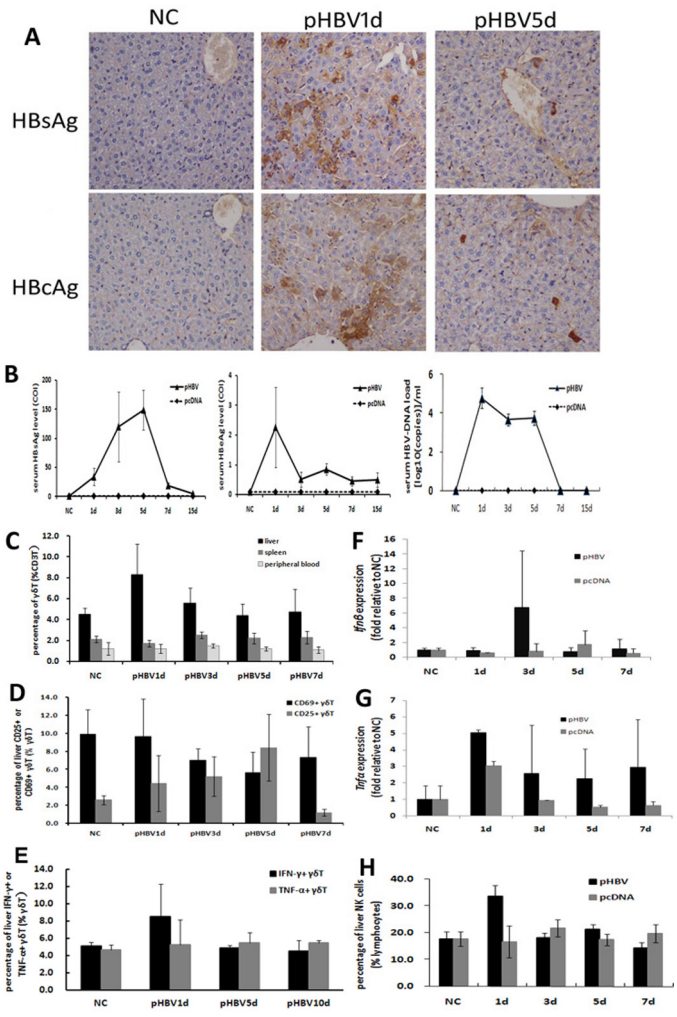

Figure: Changes in liver γδT cells and the innate immune responses in a murine acute HBV infection model. (A) HBsAg and HBcAg expression in liver tissue at 1d and 5d post injection with pHBV plasmid; (B) level of serum HBV antigen and HBV-DNA after pHBV plasmid injection; (C,D,E,H) percentage of liver γδT cells (C), CD25+ or CD69+ γδT cells (D), IFN-γ- or TNF-α-producing γδT cells (E), or NK cells after pHBV plasmid injection; (F,G) RNA expression of IFN-β and TNF-α in liver specimen after pHBV plasmid injection.

Methods: pcDNA-HBV1.3 (pHBV) plasmid containing HBV genome was injected into mice with hydrodynamics method. HBV antigenemia and serum HBV-DNA were measured with electrochemiluminescence and polymerase chain reaction (PCR) respectively. HBsAg and HBcAg expression in liver tissue were detected by immunohistochemical staining. Intrahepatic leukocytes were isolated, and flow cytometry was used to detect the percentage of γδT, CD25+ or CD69+ γδT, IFN-γ- or TNF-α-producing γδT cells, NK and T cells. Furthermore, total mRNA of liver tissue was prepared and real-time quantitive PCR was applied to detect gene expression involved in the innate immune responses, including TLR3, TLR7, TLR9, IRF3, IRF7, IFN-β, IFN-α, TNF-α and IL12a.
Results: At day 1 post injection (p.i), serum HBsAg, HBeAg and HBV-DNA were positive, and high percentage of HBsAg- or HBcAg-positive hepatocytes showed in liver specimen. Then liver HBsAg or HBcAg expression decreased sharply and showed negative after 7 days p.i. A murine acute HBV infection model was established. On day 1 p.i, the percentage of liver γδ T cells in pHBV group significantly increased (8.3±4.3%) compared to the normal mice (4.5±0.6%) and the pcDNA control group (3.8±1.6%). And liver γδ T also showed enhanced CD25 expression and IFN-γ production. At the same time, gene expression of IRF7, IFN-β or TNF-α in liver biopsies from pHBV group was significantly higher than pcDNA group. Furthermore, the percentage of liver NK cells sharply increased at 1 d p.i.
Conclusions: The percentage and functions of liver γδ T cells enhanced in the early phase of acute HBV infection. And these changes were correlated with hepatocyte HBV antigen expression and the boosted innate immune responses. Our results demonstrated that enhanced γδ T cells along with boosted innate immune responses might play important role in acute HBV infection and viral clearance.

P0462
CXCR6 MEDIATES RECRUITMENT OF ACTIVATED NATURAL KILLER CELLS IN CHRONIC LIVER DISEASE

R. Parker[1], C. Weston[1], G. Webb[1], G. Hirschfield[1], T. Schall[2], D. Adams[1]. *[1]Centre for Liver Research, University of Birmingham, Birmingham, United Kingdom; [2]ChemoCentryx Inc., Mountain View, United States*
E-mail: richardparker@nhs.net

Background and Aims: The CXC-chemokine receptor CXCR6 is widely expressed on lymphocytes where expression is linked with a tissue-infiltrating effector phenotype. Previous work from our group has shown CXCL16, the ligand for CXCR6, promotes lymphocyte adhesion to cholangiocytes in inflamed human liver. In the present study we examined expression of CXCR6 and investigated the role of CXCR6 in mediating trafficking of leukocytes across hepatic endothelium.
Methods: Explanted liver tissue was obtained from the transplant program at University Hospitals Birmingham NHS Foundation Trust. Expression of CXCR6 and CXCL16 were analysed by rt-PCR, immunohistochemistry and flow cytometry. The role of CXCR6 in lymphocyte trafficking was analysed in a dynamic flow assay system with CO335224–4B, a small molecule inhibitor of CXCR6 (ChemoCentryx Inc, USA).
Results: Gene expression of CXCL16 was increased on bile ductules and endothelium in inflammatory liver disease, with the highest expression seen in in PBC. Serum CXCL16 concentration did not differ significantly between healthy controls and patients with chronic liver disease, except for patients with PBC who had significantly lower concentrations of circulating CXCL16 ($p < 0.001$). CXCR6 expression was enriched on liver-infiltrating lymphocytes (2-way ANOVA compared to blood $p < 0.001$). In cirrhosis, T lymphocytes and NKT cells showed significantly reduced CXCR6 expression compared to normal liver, whereas NK cell CXCR6 expression tended to increase. NK CXCR6 expression was associated with $CD56^{hi,}$ $Nkp30^{+}$ and $CD16^{-}$ expression, indicating an effector phenotype. NK CXCR6 expression was highest in PBC (one-way ANOVA $p = 0.03$). Inhibition of CXCR6 with a small molecule inhibitor reduced transendothelial migration of NK cells across hepatic endothelium under flow (Two-way ANOVA $p < 0.001$).
Conclusions: CXCR6 is enriched on effector NK cells in the inflamed human liver. This is particularly marked in PBC, where highest CXCL16 expression was also observed. Interestingly patients with PBC had lower peripheral CXCL16 concentration, which may be due to sequestration in the liver. A small molecule inhibitor of CXCR6 inhibited NK cell migration demonstrating the ability of CXCR6 to mediate NK cell recruitment though human hepatic endothelium. CXCR6 may be a therapeutic target in chronic inflammatory liver disease.

INFLUENCE OF KILLER CELL IMMUNOGLOBULIN-LIKE RECEPTORS (KIRS) AND THEIR HLA LIGANDS ON VERTICAL TRANSMISSION AND CHRONICITY OF HEPATITIS C VIRUS IN CHILDREN

E.-J. Pavon-Castillero[1], A. Ruiz-Extremera[2,3,4], M. Florido[1], P. Muñoz de Rueda[1,3], J.-A. Muñoz-Gamez[1], J. Casado[1], A. Carazo[1], R. Quiles[1,3], A. Gila[1,3], S. Jimenez-Ruiz[5], A.B. Martin[1], J. León[1,3], J. Salmeron[1,3,5]. *[1]Clinical Management Unit of Digestive Diseases, Support unit for research, University Hospital San Cecilio, [2]Pediatric unit, University Hospital San Cecilio, University Hospital Virgen de las Nieves, [3]Ciberehd, Instituto de Salud Carlos III, [4]Pediatric deparment, [5]Medicine Department, Granada University, Granada, Spain*
E-mail: estherjpavon@yahoo.es

Background and Aims: There is adequate evidence on the vertical transmission (VT) of the maternal viral load of hepatitis C virus (HCV) during delivery and on HIV coinfection, but they do not explain all cases. The objective was to study the role of the immunogenetic profile (HLA, KIR, and KIR-ligand binding) of mothers and children in HCV-VT and chronicity
Methods: The study included 98 HCV-RNA(+) mothers and their 120 children. Among the 24 children infected, the disease became chronic in 8 and the virus was cleared in 16. We determined HLAclassI (A, B, Cw), HLAclassII (DRB1, DQA1, DQB1, DPA1, DPB1), Bonferroni-corrected P-value (Pc), and 16 KIRs (KIR2DL1, 2DL2, 2DL3, 2DL4, 2DL5, 3DL1, 3DL2, 3DL3, 2DS1, 2DS2, 2DS3, 2DS4, 2DS5, and 3DS1), by Luminex.
Results: *VT study:* Children with KIR2DL3 have a lower risk of infection (OR: 0.07, P = 0.019). The presence in the mother of Cw*06 (OR: 5.8, P = 0.007, Pc = 0.07) and Cw*0602 (OR: 5.7, P = 0.007, Pc = 0.08) increases the risk of infection of the child. Regarding C1 and C2 ligands, the presence of HLA-C1 in mothers and/or their children reduced the risk of infection (mothers: OR: 0.2, P = 0.009, children: OR: 0.3, P = 0.042), whereas the presence of HLA-C2 ligand increased the risk (mothers: OR: 6.2, P = 0.019, children: OR: 3.3, P = 0.042). Among the statistically significant associations found, we highlight that KIR binding to C1 ligand protected against VT and KIR binding to C2 ligand favored VT.
Chronicity: The presence in the mother of DQA1*01 (OR: 2.1, P = 0.009, Pc = 0.036), KIR2DS1 (OR: 7.2, P = 0.042) or KIR3DS1 (OR = 13, P = 0.013) favors chronicity in the child. The presence of allele DQB1*03 (OR: 0.05, P = 0.012, Pc = 0.048) and KIR2DS3 (OR: 0.5, P = 0.013) in the child and homozygosity for KIR3DL1/3DL1 (OR: 0.08, P = 0.0013) and for HLA-Bw4/Bw4 ligand (OR: 0.06, P = 0.022) were associated with viral clearance, whereas the binding of KIR3DS1 with Bw4 (OR = 7.2, P = 0.042), the binding of KIR2DS1 with C2 (OR = 7.2, P = 0.042), and heterozygosity for KIR3DL1/3DS1 (OR = 13, P = 0.013) favored viral chronicity.
Mother/child allele concordance: In the joint analysis of all HLAs, higher concordance was found between mothers and children with chronic infection vs those who had cleared the virus (67%±4.06 vs 57%±1.34, P = 0.045).

Conclusions: Studies of genetic factors in mothers and newborns are necessary to understand the processes underlying VT and the risk of chronic infection in the newborn. It can be affirmed that type C1 and C2 HLA ligands and their binding to KIRs are related to VT, while HLA-Bw4 ligands are associated with viral chronicity

P0464

KNOCKDOWN OF Gpbar1 (TGR5) RENDERS MICE HIGHLY SUSCEPTIBLE TOWARDS *Listeria monocytogenes* INFECTION

M. Reich[1], P. Lang[1], D. Häussinger[1], V. Keitel[1]. [1]*Gastroenterology, Hepatology and Infectious Diseases, Heinrich-Heine University, Duesseldorf, Germany*
E-mail: verena.keitel@med.uni-duesseldorf.de

Background and Aims: TGR5 (Gpbar1) is a membrane-bound bile acid receptor expressed in macrophages of several organs such as lung, liver and intestine as well as in peripheral blood mononuclear cells [1–3]. Stimulation of TGR5 inhibits the nuclear translocation of p65 and NF-κB transcriptional activation [3,4], thus reducing LPS-mediated production of pro-inflammatory cytokines [1,2]. Aim of the present study was to determine the role of TGR5 in an animal model for pathogen defense.
Methods: Male, 8–12 week old TGR5 knockout (KO) and WT mice were injected intravenously with 8×10^4 CFU/ml *L. monocytogenes* and observed for 7 days. On the 3rd day after infection with 2.5×10^4 CFU/ml bacterial titers were determined in spleen and liver. Serum levels of AST, ALT and LDH were measured using Spotchem-analyzer. Cytokine levels were determined in serum using Luminex cytometric bead assay. HE staining was carried out for all liver samples.
Results: Following L. monocytogenes infection TGR5 KO displayed a 50% mortality rate within a week of inoculation, while 90% of the TGR5 WT animals survived. In addition higher *L. monocytogenes* titers were detected in liver and spleen of TGR5 KO than in WT animals and HE staining revealed significantly more inflammatory infiltrates in livers from TGR5 KO mice. Accordingly, the levels of AST/ALT and LDH were elevated in serum from TGR5 KO animals as compared to the WT littermates. Furthermore, TGR5 KO mice had increased serum cytokine levels after *L. monocytogenes* infection as compared to WT mice.
Conclusions: Compared to WT littermates, TGR5 knockout mice showed higher *Listeria monocytogenes* titers in liver and spleen despite elevated serum inflammatory cytokines, such as TNFalpha. Accordingly, TGR5 KO mice were unable to control bacterial infection and systemic inflammation and thus displayed a significantly increased mortality rate.

PERSISTENT INTRAHEPATIC Vγ9Vδ2 T-CELLS IMPAIRMENT IN HCV-INFECTED PERSONS

E. Cimini[1], V. Bordoni[1], U. Visco-Comandini[2], M. Montalbano[2], R. Lionetti[2], A. Sacchi[1], R. Casetti[1], N. Tumino[1], M.R. Capobianchi[3], F. Martini[1], C. Agrati[1]. [1]*Cellular Immunology Laboratory,* [2]*Clinical Department,* [3]*Virology Laboratory, National Institute for Infectious Diseases "Lazzaro Spallanzani", Rome, Italy*
E-mail: eleonora.cimini@inmi.it

Background and Aims: δγHepatitis C virus (HCV) persistence in the host results from inefficiency of both innate and adaptive immune responses to eradicate the infection. Among innate immune cells, a functional impairment of peripheral Vγ9Vδ2 T-cells was described during chronic HCV infection; this functional defect can be partially restored by using IFN-α, opening the possibility to boost antiviral innate immune response. Unfortunately, no data are available on intrahepatic Vγ9Vδ2 T-cells that instead, may represent the key actors in the anti-HCV response. Aim of our work was to compare intrahepatic and peripheral Vγ9Vδ2 T-cells in chronic HCV-infected patients (HCV) and in healthy donors (HD) subjected to gut resection surgery.
Methods: Phenotypic and functional features of intrahepatic and peripheral Vγ9Vδ2 T-cells were analyzed in 17 chronic HCV patients and in 14 HD by flow cytometry and ELISA assay.
Results: Irrespective of HCV infection, intrahepatic compartment was characterized by a lower frequency of Vγ9Vδ2 T-cells than in the peripheral blood. Although expressing an effector/activated phenotype, intrahepatic Vγ9Vδ2 T-cells showed a drastic reduction of their ability to produce IFN-γ after specific stimulation both in HCV and in HD subjects. Nevertheless, while intrahepatic Vγ9Vδ2 T-cells from HD can be functionally restored by using IFN-α co-stimulation, intrahepatic Vγ9Vδ2 T-cells from HCV-patients are refractory also to IFN-a co-stimulation, suggesting an exhaustion profile. Accordingly, Vγ9Vδ2 T-cells from HCV-patients presented a higher PD-1 expression than HD both in peripheral and intrahepatic compartments, probably due to persistent antigenic stimulation.
Conclusions: Overall, intrahepatic Vγ9Vδ2 T-cells from HCV patients presented an exhaustion phenotype and are functional impaired also after IFN-α co-stimulation. New studies are mandatory in order to identify molecular mechanisms inducing this functional anergy and to discover pathway able to restore Vγ9Vδ2 T-cell functionality.

IL-33 KNOCK OUT MICE ARE SENSITIZED TO SEVERE ConA LIVER INJURY BUT NOT CCl_4-MEDIATED LIVER INJURY

M. Imran Arshad[1], G. Noel[2], A. Filliol[2], V. Genet[2], C. Lucas-Leclerc[3], J.-P. Girard[4], C. Piquet-Pellorce[2], M. Samson[2]. [1]*Université de Rennes 1, U.1085 Inserm,* [2]*Université de Rennes 1, IRSET – U.1085 Inserm,* [3]*Université de Rennes 1, CHU Rennes, Rennes,* [4]*IPBS-CNRS, Université de Toulouse, Toulouse, France*
E-mail: michel.samson@univ-rennes1.fr

Background and Aims: IL-33/ST2 axis play a protective role during acute hepatitis but little is known about the functional role of endogenous IL-33 in liver patho-physiology. We aimed to decipher the functional role of IL-33 by using IL-33 deficient mice during immune cell mediated and hepatotoxic driven liver injury.
Methods: We used a genetic model of acute hepatitis by using IL-33 deficient mice in ConA (a T cell-mediated hepatitis) and CCl_4 (a hepatotoxic agent-induced hepatitis) induced acute liver injury. The liver functions (AST/ALT), signature of cytokines and characterization of infiltrate cell in WT and IL-$33^{-/-}$ mice were carried out by biochemistry, qPCR and flow cytometry analyses.
Results: Our results demonstrated that IL-$33^{-/-}$ mice exhibited more severe ConA liver injury than WT mice evidencing a protective effect of IL-33 in this hepatic model while no difference was

observed in CCl_4-hepatitis between WT and IL-33$^{-/-}$ mice. The ConA-induced hepatic injury was associated with increased TNF-α, IL-1-β, IFN-γ and IL-6 cytokines in WT and IL-33$^{-/-}$ mice. The level of TNF-α and IL-1-β but not of IFN-γ and IL-6 was significantly higher in IL-33$^{-/-}$ mice than WT control. The intra-hepatic percentage of NK, NKT cells, T cells and B cells was not altered significantly between WT and IL-33$^{-/-}$ mice following ConA-hepatitis.
Conclusions: We evidenced that the genetic ablation of IL-33 sensitized the mice to severe ConA liver injury but not CCl_4-mediated liver injury.

PHENOTYPIC DISTORTION AND FUNCTIONAL ANOMALY OF LIVER DENDRITIC CELLS IN PRESENCE OF SUPPRESSOR MYELOID CELLS IN A MURINE MODEL OF NON-ALCOHOLIC FATTY LIVER DISEASE

S. Mohammad Fazle Akbar[1], S. Chen[2], M. Al-Mahtab[3], Y. Hiasa[4].
[1]Department of Medical Sciences, Toshiba General Hospital, Tokyo, Japan; [2]Department of Endocrinology and Reumatology, The Second Affiliated Hospital of Santou University Medical College, Guangdong, China; [3]Department of Hepatology, Bangabandhu Sheikh Mujib Medical University, Dhaka, Bangladesh; [4]Department of Gastroenterology and metabology, Ehime University Graduate School of Medicine, Toon, Japan
E-mail: sheikh.akbar@po.toshiba.co.jp

Background and Aims: Although non-alcoholic fatty liver disease (NAFLD) is characterized by increased inflammatory mucosal milieu, it is also associated with impaired antigen-specific immunity as evidenced by low response to hepatitis B surface antigen (HBsAg)-based vaccines. We checked the mechanisms underlying this in a murine model of NAFLD and exploring the functional capacities of most potent antigen-presenting cells, dendritic cells (DC).
Methods: A murine model of NAFLD was produced by feeding C57BL/6 mice with high-calorie and high-fat diet (520 calories/100 g, 50% fat). Control C57BL/6 mice received normal laboratory chow (360 calories/100 g, 13% fat). Hepatic DC, liver non-parenchymal cells (NPC), immunogenic myeloid cells and suppressor myeloid cells were isolated from murine liver by using density gradient and flow cytometry. Hepatic DC were cultured with liver NPC, immunogenic myeloid cells expressing $CD11b^+$ GR1− and $CD11b^+$ $GR1^+$ suppressor myeloid cells for 48 hours. Subsequently, DC were retrieved from the culture by magnetic-activated cell sorting. Subsequently, the expressions of costimulatory antigens on DC, production of cytokines by DC, and activation of HBsAg-specific lymphocytes by DC were evaluated.
Results: DC cultured with liver NPC and immunogenic myeloid cells had almost similar potential to activate HBsAg-specific T cells in antigen-specific manner and induced comparable levels of proinflammatory cytokines (IL-12, TNF-alpha, and IFN-gamma). However, DC cultured with suppressor myeloid cells of NAFLD mice had significantly lower capacity to present HBsAg to T cells and to induce proliferation of HBsAg-specific T cells ($p < 0.05$). Significantly lower levels of IL-12, TNF-alpha, and IFN-gamma were produced and significantly lower levels of CD86 and CD80 were expressed by DC cultured with liver-derived suppressor myeloid cells compared to DC co-cultured with liver NPC and liver-derived immunogenic myeloid cells ($p < 0.05$). In vivo, NAFLD mice produced significantly lower levels of antibody to HBsAg (anti-HBs) and induced lower magnitudes of HBsAg-specific T cells being immunized by HBsAg compared to those produced by control mice ($p < 0.05$).
Conclusions: Among different immunocytes, myeloid suppressor cells expressing $CD11b^+$ $GR1^+$ appears to down regulate DC function and compromise antigen-specific immunity and response to HBsAg-based vaccination in NAFLD.

E-mail: helene.fontaine@cch.aphp.fr

Background and Aims: The ANRS CO22 HEPATHER ["Therapeutic options in a French cohort of HBV and/or HCV hepatitis"] is a multicentre cohort (32 centres) aiming to include 15,000 HCV- and 10,000 HBV-infected patients with a centralized biological collection and a specific information system. Given the limited number of non-Asian data on HBV/HCV coinfection, we compared the baseline characteristics of HBV/HCV coinfected patients in this cohort with those of HBV or HCV mono-infected patients.
Methods: 14,698 patients were included on November 19th 2014. Of 1099 patients with both HBV and HCV markers, 92 of the 93 patients with markers of active HBV and HCV infection (B/C patients) were analyzed and matched, each with 4 patients HBV- and 4 HCV-mono-infected patients on age, gender and duration of infection.
Results: Results are summarized in the Table. In B/C patients,
1. metropolitan origin (48%) was less prevalent than in C patients (63%) and more prevalent than in B patients (29%);

2. the prevalence of naive patients (49%) was higher than in C patients (33%);
3. overweight, obesity were less frequent and arterial hypertension more frequent than in B patients;
4. extensive fibrosis and cirrhosis (F3/F4 stages) (42%) were comparable to C patients (40%) and more frequent than in B patients (15%, p < 0.001);
5. a low rate of HBV DNA (<50 IU/mL) more frequent than in B patients (87% vs 62%, p < 0.001).

Table: Comparison of the characteristics of HBV/HCV coinfected and HBV or HCV matched mono-infected patients in the HEPATHER cohort at baseline

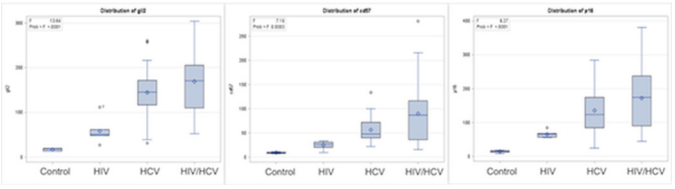
	BC (N = 92)	C (N = 368)	P
HCV treatment-naive	49%	33%	0.01
Metropolitan origin	48%	63%	0.01
Genotype 1 / 3	63% / 15%	63% / 14%	NS
F4 / F3 fibrosis stage	31% / 11%	33% / 7%	NS
Suspected cirrhosis	34%	42%	NS
Obesity/overweight	14%	21%	NS
Diabetes	15%	14%	NS
Arterial hypertension	34%	27%	NS
Undetectable viral load at enrolment Median 6.095 log	43%	49%	NS
Treated	29%	38%	NS
Metropolitan origin	48%	29%	<0.001
Delta-Coinfection	3%	3%	NS
F4 / F3 fibrosis stage	31% / 11%	9% / 6%	<0.001
Suspected cirrhosis	34%	13%	<0.001
Obesity/overweight	14%	26%	0.028
Diabetes	15%	10%	NS
Arterial hypertension	35%	24%	0.05
HBV DNA <50	87%	62%	<0.001

Conclusions: HBV co-infection was not associated with the severity of HCV-associated chronic hepatitis. In contrast, HCV co-infection harmfully impacted on fibrosis and reduced HBV replication in B/C co-infected patients. Thus, HCV treatment initiation must be prioritized in patients with an HBV/HCV coinfection, regardless of the severity of the liver disease.

P0469
MARKERS OF TISSUE REPAIR AND CELLULAR AGING ARE INCREASED IN LIVER TISSUE OF PATIENTS WITH DUAL CHRONIC HIV/HCV INFECTIONS

M. Swiderska-Syn[1], S. Choi[1], A. Lan[2], G. Ferrari[1], A.M. Diehl[1], S. Naggie[1,3]. *[1]Duke University School of Medicine, Durham, [2]University of North Carolina School of Medicine, Chapel Hill, [3]Duke Clinical Research Institute, Durham, United States*
E-mail: susanna.naggie@duke.edu

Background and Aims: When compared to HIV-uninfected persons, treated HIV-infected patients have an excess risk of chronic conditions, including liver disease, and experience excess liver related morbidity and mortality. Because fibrosis is an age-associated disease process and one regulated by activation of the fetal morphogen, Hedgehog (Hh) signaling, we compared histologic activity of markers for tissue repair, fibrogenesis and cellular aging in patients with HIV, HIV/HCV, and HCV infections.
Methods: Formalin-fixed liver tissue sections were identified for HIV/HCV, HIV, and HCV patients and non-infected controls. Patients were matched by age, gender, race/ethnicity, CD4 absolute (HIV infection), HIV viral suppression (HIV infection), and METAVIR stage of liver fibrosis (HCV infection). Specimens were stained with antibodies against (1) components of the Hh pathway [Sonic Hh (Shh) ligand, Glioblastoma 2 (Gli2), Patched (Ptc)] and ASMA to assess liver repair; (2) resident T lymphocytes (CD3, CD8, CD56, CD28), CXCL16 (NKT cytokine); (3) markers of cellular aging (CD57 and p16INK4a). Student's t test and ANOVA were used to compare histologic changes across the study groups.
Results: Overall 59 liver specimens were identified: 5 non-infected, 7 HIV, 25 HCV, 27 HIV/HCV patients. The cohort was 45% female, 54% black, and mean age at liver biopsy was 46 years (±8.7). Thirty-two percent of patients had severe liver fibrosis (METAVIR stage 3/4). HIV patients had a median CD4 of 651 cells/mm3 (±386) and 79% were on ARVs. All infected patients had greater expression of markers of tissue repair and fibrogenesis (Gli2 p < 0.0001, Shh p < 0.0001, Ptc p = 0.0214, ASMA p < 0.0001), T cell populations (CD3 p < 0.0001, CD8 p = 0.0362, CD28 p < 0.0001, CD56 p < 0.0001) and cytokines (CXCL16 p < 0.0001), and markers of cellular aging (CD57 p = 0.0003 and p16INK4a p < 0.0001) than non-infected controls (Figure). Incremental increases in histologic activity from HIV to HCV to HIV/HCV co-infection were identified for many markers (Figure).
Conclusions: Patients with HIV infection have increased markers of liver tissue repair and fibrogenesis, T cell populations including NK cells, and increased markers of cellular aging. This is true regardless of HCV co-infection. The additive effect of HIV and HCV co-infection was evident for a majority of the markers suggesting that patients with HIV/HCV have a greater fibrogenic response to tissue injury and more severe immune dysregulation which may result in more rapid cellular aging and age related disease.

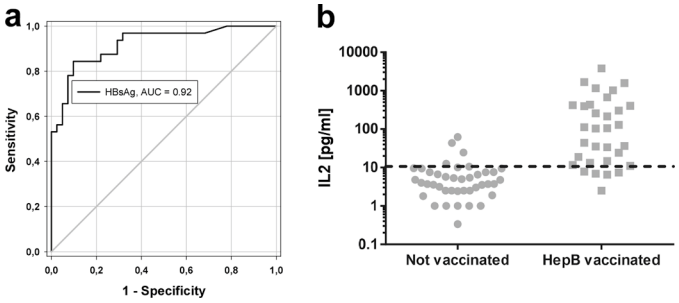


P0470
DEVELOPMENT OF A NOVEL IGRA ASSAY TO TEST T CELL RESPONSIVENESS TO HBV ANTIGENS IN WHOLE BLOOD OF CHRONIC HEPATITIS B PATIENTS

W. Dammermann[1], F. Bentzien[2], E.-M. Stiel[1], C. Kühne[1], S. Ullrich[3], J. Schulze zur Wiesch[1], S. Lüth[1]. *[1]1. Department of Medicine, [2]Department of Transfusion Medicine, [3]Department of Anatomy and Experimental Morphology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*
E-mail: w.dammermann@uke.de

Background and Aims: Interferon gamma release assays (IGRA) have been developed to support the easy and fast diagnosis of diseases like tuberculosis, and CMV in transplant patients. IGRAs focus on cellular immunity especially memory T cells and thus also allow rapid screening prior to complex flow cytometric testing. We developed a novel, sensitive whole blood based cytokine release assay capable of assessing T cell responsiveness to HBV antigens in Hepatitis B patients and assessing hepatitis B vaccination status in healthy individuals.
Methods: 72 chronic Hepatitis B patients (CHB), 8 acute hepatitis B patients (AHB), 3 hepatitis B resolvers (RHB) and 80 healthy controls (HC) were tested by ELISA for IFNγ- and IL2-secretion in whole blood after challenge with synthetic peptide libraries of Hepatitis B core antigen (HBcAg) or Hepatitis B surface antigen (HBsAg). D-Glucose was supplemented to enhance cytokine secretion.
Results: The developed IGRA test reliably differentiated between Hepatitis B patients, vaccinees and unvaccinated healthy controls. CHB patients showed a weaker IFNγ response to HBcAg (52±16 pg/ml) compared to the AHB and RHB groups (97±39 pg/ml and 116±29 pg/ml, respectively), whereas HC remained unresponsive (13±2 pg/ml). IL2 levels after HBcAg challenge were also higher in the AHB and RHB groups compared to CHB and HC (50±21 and 312±143 pg/ml vs. 15±5 and 14±9 pg/ml, respectively). HBsAg stimulation led to increased IFNγ and IL2 levels in the AHB group (48±13 and 24±12 pg/ml) and even higher

levels in HC due to a high hepatitis B vaccination rate (49±10 and 170±59 pg/ml). CHB patients developed weaker IFNγ or IL2 responses to HBsAg (34±13 and 17±8 pg/ml, respectively). For HC, IL2 release after HBsAg stimulation depicted hepatitis B vaccination status with a diagnostic sensitivity and specificity of 85% and 90%.
Conclusions: Our novel IGRA whole blood based cytokine release assay constitutes an easy and robust tool for screening HBV specific cellular immunity in comparison to flow cytometry or ELISPOT.

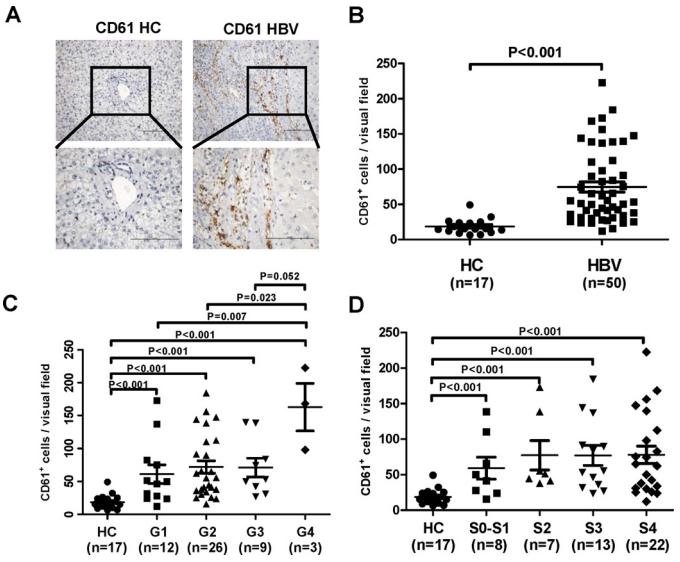


P0471
NKp46 AND TRAIL ARE THE MAJOR NK CELL RECEPTORS INVOLVED IN ANTI-HCV ACTIVITY OF NK CELLS IN VITRO
B. Krämer[1], C. Zwank[1], A. Glässner[1], P. Kokordelis[1], F. Wolter[1], D. Kaczmarek[1], P. Lutz[1], F. Göser[1], H.D. Nischalke[1], C.P. Strassburg[1], U. Spengler[1], J. Nattermann[1]. [1]*Department of Internal Medicine I, University of Bonn, Bonn, Germany*
E-mail: m.benjamin.kraemer@gmail.com

Background and Aims: Accumulating evidence indicates a pivotal role of natural killer (NK) cells for the early control and natural course of HCV infection. Various NK cell receptors have been implicated in anti-HCV activity but their individual contribution remained unclear.
Here, we show that NKp46 and TRAIL are the major NK cell receptors involved in anti-HCV activity of NK cells *in vitro*.
Methods: 14 healthy and 9 HCV-infected individuals were enrolled into this study. NK cells were isolated by negative selection using the MACS human NK cell enrichment kit (Miltenyi). Anti-HCV activity of IL-2 or IFN-a stimulated NK cells was studied in the presence or absence of blocking antibodies specific for CD54, 2B4, NKp30/44/46/80, NKG2D, TRAIL, and DNAM, respectively, using the HCV HUH7 replicon model.
Results: In IFN-a stimulated NK cells from healthy donors blocking of TRAIL (40%) had the strongest impact on anti-HCV activity, followed by NKp46 (35%), and NKG2D (11%). Of note, simultaneous blockade of TRAIL and NKp46 synergistically decreased anti-viral NK cell activity and displayed the strongest effect of all tested antibody combinations. In contrast, blockade of receptors on NK cells from HCV infected patients is less effective and hierarchy is altered: NKp46 (30%) > TRAIL (22%) > NKG2D (9%).
Analyzing IL-2 stimulated NK cells TRAIL (21%) > NKp46 (20%) > DNAM (8%) to have a significant effect on anti-HCV activity. Concurrent blocking of NKp46 and TRAIL had the strongest impact on NK cell function. Surprisingly, blocking these receptors on IL-2 stimulated NK cells of HCV infected donors is more effective: NKp46 (42%) > TRAIL (28%) > DNAM (17%).
Conclusions: Our data indicate that a variety of different NK cell receptors may play a role in anti-HCV activity and indicate an especially important role for NKp46 and TRAIL. In HCV infection activity of NKp46 is more effective than TRAIL, irrespective of IL2 or IFN-a stimulation.

P0472
ACCUMULATION OF PLATELETS IN THE LIVER MAY BE AN IMPORTANT CONTRIBUTORY FACTOR TO LIVER INJURY IN CHRONIC HEPATITIS B VIRUS INFECTION
R. Su[1], H. Wu[2], R. Huang[3], G. Wang[4], Y. Liu[5], X. Yan[4], Y. Xiong[4], J. Xia[4], C. Wu[4]. [1]*Department of Infectious Diseases, Nanjing Drum Tower Hospital, Nanjing Medical University,* [2]*Department of Pathology, Nanjing Drum Tower Hospital, Nanjing University Medical School,* [3]*Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Traditional Chinese and Western Medicine, Nanjing University of Chinese Medicine,* [4]*Department of Infectious Diseases,* [5]*Department of Laboratory Medicine, Nanjing Drum Tower Hospital, Nanjing University Medical School, Nanjing, China*
E-mail: dr.wu@nju.edu.cn

Background and Aims: Besides haemostatic properties, platelets have the features of inflammatory cells. Platelets have been shown to be contributed to the pathogenesis of acute liver damage of self-limited viral hepatitis and hepatitis B virus (HBV)-associated liver cancer in mouse models. However, the association between the platelets and chronic HBV infection remains largely unknown. We tried to clarify whether an accumulation of platelets in the liver contributes to liver injury and fibrosis in chronic HBV infection.
Methods: Fifty patients with chronic HBV infection who underwent liver biopsy were included. Seventeen healthy liver tissue samples were obtained from donors whose livers were used for transplantation. The platelets (marked by CD61) in the liver tissues were identified by immunohistochemistry. Nonspecific inflammatory cells such as CD68+ macrophages and monocytes in the liver of patients were also measured by immunohistochemical staining. According to the modified histology activity index described by Scheuer, the degree of hepatic inflammation and fibrosis of liver fibrosis in patients with chronic HBV infection was graded.



Results: Patients with chronic HBV infection had a significantly more extensive CD61+ platelets in the liver tissues compared to healthy controls (74.68±7.38 vs. 18.69±2.59 /HPF, $P < 0.001$). Patients with chronic HBV infection with higher inflammatory grading (G) scores had more CD61+ platelets in their livers compared to those with lower scores ($P < 0.05$). However, no association between liver platelets and fibrotic staging (S) scores was found in the patients ($P > 0.05$). The platelets in the liver tissues were strongly positively correlated with the nonspecific inflammatory cells such as CD68+ macrophages ($r = 0.625$, $P < 0.0001$) and MAC387+ monocytes ($r = 0.780$, $P < 0.0001$). The platelets in the liver tissues of patients with chronic HBV infection

were also positively correlated with alanine transaminase (r = 0.325, P = 0.023) and total bilirubin levels (r = 0.292, P = 0.042).
Conclusions: The accumulation of platelets in the liver may be involved in hepatic injury of patients with chronic HBV infection. Platelets may accumulate in the liver and take part in the pathogenesis of the liver injury in chronic HBV infection through the mechanism involving the nonspecific inflammatory cells such as macrophages and monocytes.

P0473
THE HEPATITIS C VIRUS MODIFIES CXC CHEMOKINE EXPRESSION INDUCED BY INFLAMMATORY CYTOKINES AND FACILITATES THEIR PRODUCTION IN RESPONSE TO EPIDERMAL GROWTH FACTOR

C. Gröpper[1], N. Triller[1], R. Bartenschlager[2], D. Häussinger[1], J.G. Bode[1]. *[1]Department of Gastroenterology, Hepatology and Infectious Diseases, Universityhospital, Heinrich-Heine University, Düsseldorf, Heinrich-Heine University, Düsseldorf, [2]Department of Infectious Diseases, Molecular Virology, University of Heidelberg, Heidelberg, Germany, University of Heidelberg, Heidelberg, Germany*
E-mail: christina.groepper@uni-duesseldorf.de

Background and Aims: HCV has evolved powerful mechanisms to manipulate antiviral and innate immunity and to interfere with the inflammatory host response. Thereby the local composition of inflammatory and immune cells is largely determined by the pattern of chemokines released from the different cell types of the liver. The study investigates the influence of HCV on basal and inducible expression of the CXC chemokines CXCL1 to 3 and 8 in response to inflammatory cytokines and epidermal growth factor.
Methods: Huh-7 cells either infected with the HCV cc strain JC1 or harbouring the HCV subgenomic replicon were used to analyse the impact of HCV on cellular signalling and basal as well as inducible chemokine expression.
Results: HCV enhances TNFα- and IL-1β-inducible expression of CXCL1, 2 and 8. Surprisingly, HCV further facilitates EGF to induce the production of CXCL1 to 3 and 8 while EGF was almost incapable to do so in the absence of HCV. Thereby inhibitor studies and gene knockdown by siRNA suggest that the expression of CXCL-8 requires the activation of MEK1 and NF-κB but also depends on the sensitization of the EGF receptor (EGFR) tyrosine kinase activity, which is due to the HCV-dependent reduction of TC-PTP, an endogenous negative regulator of EGFR. Most interestingly, the data further suggest that HCV enhances basal expression of these chemokines via induction of an EGF-dependent autocrine circuit.
Conclusions: The data presented indicate, that HCV enhances TNFα- and IL-1β-inducible production of CXCL1, 2, 3 and 8 and extends the spectrum of EGF target genes towards these chemokines. The latter mechanism is employed by HCV to enhance basal chemokine expression via an EGF-dependent autocrine circuit.

P0474
CHARACTERISATION OF THE IMMUNE PROFILES OF CHRONIC HEPATITIS B PATIENTS FOLLOWING NUC DISCONTINUATION BY CyTOF MASS CYTOMETRY

L. Rivino[1], M. Van Den Berg[1], N. Le Bert[2], S. Koh[2], U.S. Gill[3], N.K. Hansi[3], G.R. Foster[3], A. Bertoletti[1,2], P.T. Kennedy[3]. *[1]Emerging Infectious Diseases, Duke-NUS Graduate Medical School, [2]Infection & Immunity Program, Singapore Institute for Clinical Sciences, Agency for Science, Technology & Research (A*STAR), Singapore, Singapore; [3]Hepatology Unit, Centre for Digestive Diseases, Blizard Institute, Barts and The London SMD, QMUL, London, United Kingdom*
E-mail: u.gill@qmul.ac.uk

Background and Aims: It is currently not possible to predict whether the discontinuation of nucleos(t)ide analogues (NUCs) in Chronic Hepatitis B virus (HBV) patients will be followed by viral relapse and hepatic flares (HF). Through the utilisation of cytometry time of flight (CyTOF), a novel mass cytometry technology, in conjunction with traditional flow cytometry tools, we aim to establish an immune profile associated with the onset of HF upon therapy discontinuation.
Methods: Cytokine and chemokine serum levels (IL-1β, IL-6, TNF-α, IL-10, CXCL-8, CXCL-10) were measured longitudinally using Luminex in chronic HBV patients who developed HF (n = 6) and those who did not (n = 2) upon discontinuation of NUCs. HBV-specific T cell responses were assessed after *in vitro* expansion of patient peripheral blood mononuclear cells with overlapping HBV peptides pools. An in-depth longitudinal analysis of the expression of 35 markers involved in the activation, differentiation, exhaustion and anti-viral effector function of T and NK cells is performed by CyTOF mass cytometry.
Results: The rise in serum ALT following viral relapse after therapy discontinuation are associated with a significant increase in the serum levels of CXCL-10 and IL-10. Despite comprehensive analysis of HBV-specific T cells using HBV peptides, functional antigen-specific T cells in the periphery were not detected. Preliminary analysis by CyTOF reveals significant differences in the frequency and functionality of T and NK cell populations longitudinally (during and after discontinuation of therapy), between patients characterised by viral relapse and those with immune control.
Conclusions: Consistent with previous studies, HF are associated with increased serum levels of CXCL-10 and IL-10 while HBV-specific T cells remain undetectable in the periphery. The absence of circulating virus-specific CD8+T cells during HF suggests that hepatic inflammation following NUC withdrawal in chronic HBV patients is induced independent of virus-specific CD8+ T cells. CyTOF technology allows us to investigate an unprecedented number of parameters (currently up to 42) for a more detailed assessment of biomarkers associated with sustained immune control of HBV.

P0475
POST-LIVER TRANSPLANT FIBROSIS ALLOGRAFT PROGRESSION IS ASSOCIATED WITH INCREASED LEVELS OF SOLUBLE NKG2D LIGANDS

S. Iacob[1,2], G. Wu[1], I. Kabar[1], A. Huesing[1], H.H. Schmidt[1], S. Beckebaum[1], V. Cicinnati[1]. *[1]Department of Transplant Medicine, University Hospital Münster, Münster, Germany; [2]Gastroenterology and Hepatology Center, Fundeni Clinical Institute, Bucharest, Romania*
E-mail: msiacob@gmail.com

Background and Aims: Histological abnormalities are commonly present in late post-transplant biopsies, including variable stages of fibrosis. Fibrosis proved to be strongly related to transplant-related factors in several studies. The aim of our study was to investigate clinical and immunological risk factors for different stages of fibrosis occurrence following LT.
Methods: A total of 174 LT recipients were enrolled in the study. Cytokines were assessed by flow cytometry with the "BD Cytometric Bead Array (CBA) Human Th1/Th2/Th17 Cytokine Kit". Assessment of soluble major-histocompatibility complex class I-related chain A (sMICA), soluble major-histocompatibility complex class I-related chain B (sMICB) and soluble UL16 binding protein 2 (sULBP2) was realized by enzyme linked immunosorbent assay. Screening for anti-HLA class I, class II, or MICA antibodies was performed using Luminex technology. Chi-square test was used for comparing categorical data and Kruskal–Wallis test was used for comparing continuous variables. Multiple regression analysis was performed to identify independent risk factors for progression of fibrosis after LT.
Results: The following variables were statistically significant different according to different stages of fibrosis (F0 to F4 METAVIR): higher donor age (p = 0.03), high serum levels of TNF alpha (p = 0.04), IL6 (p < 0.0001), presence of anti-HLA class I Ab

($p = 0.03$), higher serum levels of sMICA ($p = 0.04$), sMICB ($p = 0.007$) and ULPB2 ($p = 0.004$), presence of HCV ($p < 0.0001$), presence of recurrent cholangitis ($p = 0.02$). Presence of anastomosis stenosis ($p = 0.052$) and IL10 serum levels ($p = 0.058$) reached only marginal statistical significance. Time from LT to fibrosis stage evaluation did not differ between different stages of fibrosis. Mean time from LT to fibrosis evaluation was 66.9 months. Independent variables associated with progression of fibrosis following LT were: HCV infection, recurrent episodes of cholangitis, and higher serum levels of IL6, sMICA and presence of non-DSA HLA class I antibodies.
Conclusions: sMICA, IL6 serum levels, non-DSA HLA class I antibodies and recurrent episodes of cholangitis should prompt screening for fibrosis progression and may be useful for performing protocol liver biopsies also in non-HCV recipients.

P0476
EXPERIMENTAL INTERVENTION AGAINST CCL5/RANTES ATTENUATES LIVER FIBROGENESIS AND THE PROGRESSION OF HEPATOCELLULAR CARCINOMA

A. Mohs[1], F.J. Cubero[1], N. Kuttkat[1], A.E. Proudfoot Fichard[2], A. de Bruin[3], C. Trautwein[1]. *[1]Department of Medicine III, University Hospital RWTH Aachen, Aachen, Germany; [2]Merck Serono Geneva Research Centre, Geneva, Switzerland; [3]Institute for Pathology, School of Veterinary Medicine, University of Utrecht, Utrecht, Netherlands*
E-mail: amohs@ukaachen.de

Background and Aims: Hepatocellular carcinoma (HCC), the malignant transformation of hepatocytes, often arises on the basis of chronic liver inflammation, resulting in liver fibrosis. In this process, immune cells play a crucial role. In the current study, we investigated whether therapeutic intervention with Evasin-4 – a CCL5/RANTES inhibitor – affects the development of hepatic fibrogenesis. Additionally, we evaluated the role of CCL5/RANTES in liver fibrosis as well as HCC initiation and progression, in an experimental model of chronic liver injury.
Methods: Evasin-4 was injected i.p. daily in 6-week-old $NEMO^{\Delta hepa}$ mice for 2 months. Additionally, the role of CCL5/RANTES in the development of fibrosis and tumour initiation and progression was analysed in an experimental model of chronic liver injury by generating $NEMO^{\Delta hepa}/CCL5^{-/-}$ mice using hepatocyte-specific NEMO knockout ($NEMO^{\Delta hepa}$) and constitutive CCL5/RANTES ($CCL5^{-/-}$) mice. The progression of liver fibrosis and HCC development was evaluated with molecular biological methods (Western Blot, qRT-PCR and immunodetection).
Results: Pharmacologic intervention of the CCL5/RANTES pathway using Evasin-4 in $NEMO^{\Delta hepa}$ mice led to a significant improvement of liver fibrosis, as evaluated by Collagen IA1 and Sirius red staining. Furthermore fibrosis reduction was confirmed by markers of hepatic fibrosis and collagen deposition (αSMA, Collagen IA1, TGF-β, MMP-2 and MMP-3). One year-old $NEMO^{\Delta hepa}/CCL5^{-/-}$ mice exhibited improvement of hepatic fibrogenesis as assessed by protein analysis and immunodetection methods. No differences were found between $NEMO^{\Delta hepa}$ and $NEMO^{\Delta hepa}/CCL5^{-/-}$ mice regarding tumour initiation in the liver. However, $NEMO^{\Delta hepa}/CCL5^{-/-}$ mice displayed smaller and less malignant tumours compared with $NEMO^{\Delta hepa}$ mice. In addition, $NEMO^{\Delta hepa}/CCL5^{-/-}$ tumours displayed significantly reduced proliferation and less pronounced angiogenesis compared with $NEMO^{\Delta hepa}$ livers.
Conclusions: Therapeutic modulation of the CCL5/RANTES pathway with Evasin-4 significantly attenuated progression of of hepatic fibrosis. Deletion of CCL5/RANTES in $NEMO^{\Delta hepa}$ mice leads to the amelioration of hepatic fibrogenesis and HCC progression. These results indicate that CCL5/RANTES is an attractive target for the treatment of chronic liver disease.

FLUORESCENCE MICROSCOPY IDENTIFIES COMPLEX HETEROGENEITY OF ANTIGEN PRESENTING CELLS IN NORMAL HUMAN LIVER

O.L. Strauss[1,2], R. Dunbar[2,3], C. Mansell[3], V. Feisst[2,3], A. Bartlett[1,2], A. Phillips[1,2,3]. *[1]Surgery, University of Auckland, [2]Maurice Wilkins Centre, [3]School of Biological Sciences, University of Auckland, Auckland, New Zealand*
E-mail: o.strauss@auckland.ac.nz

Background and Aims: Antigen presenting cells (APC) of the mononuclear phagocyte system (MPS) are an important population of cells involved in the tissue homeostasis and the immune response in autoimmunity, infection and cancer. APC have been thoroughly characterized in tissues such as the human skin and lymph node but despite growing evidence in animal tissue there is a dearth of evidence characterising APC in human liver [1]. Having an improved understanding of the composition of liver APC and their location within the liver lobule is vital to appreciating changes that occur in disease and identifying potential therapies to target them.
Methods: Normal liver tissue was obtained following resection of benign vascular malformations or from living donor liver transplant biopsies. Multicolour immunofluorescence microscopy (MIM) was performed on fresh frozen and formalin fixed paraffin embedded samples. Parenchymal, endothelial, epithelial and stellate cells were identified using a mixture of markers and APC were initially characterized using subset specific markers, then further characterized using a variety of chemokine receptors, Fc receptors, and scavenger receptors. All findings were observed on a minimum of three donors.
Results: MIM allowed for the accurate distinction between APC and non-APC cells. KCs were scattered throughout the liver lobule and uniformally expressed CD68, CD16, CD163, CD169, HAM-56, and CD206. KC were composed of (i) distinctly large spindle cell shaped cells located predominantly in zones 1, 2 and were $CCR2^{+}PU.1^{+}CD14^{+}CD64^{hi}CD45^{hi}$ and (ii) smaller circular $CCR2^{-}PU.1^{-}$ cells with a lower expression of CD45. Myeloid DC were located in the portal tracts and the liver hosted CD1c, CD141 and pDC subsets. Monocytes were found throughout the sinus were composed of a mixture of $CD14^{+}$ and $CD16^{+}$ cells, they also expressed CD36 and Lyve-1.
Conclusions: We have used MIM as a powerful tool to characterize the complexity of the liver lobule and identify hitherto unappreciate heterogeneity in human KCs that follows an acinar distribution. We have also identified the major DC and monocyte subets and as a result allowed for a means to further characterize these populations to identify changes that occur in disease and facilitate the identification of therapeutic targets specific to APC in the liver.

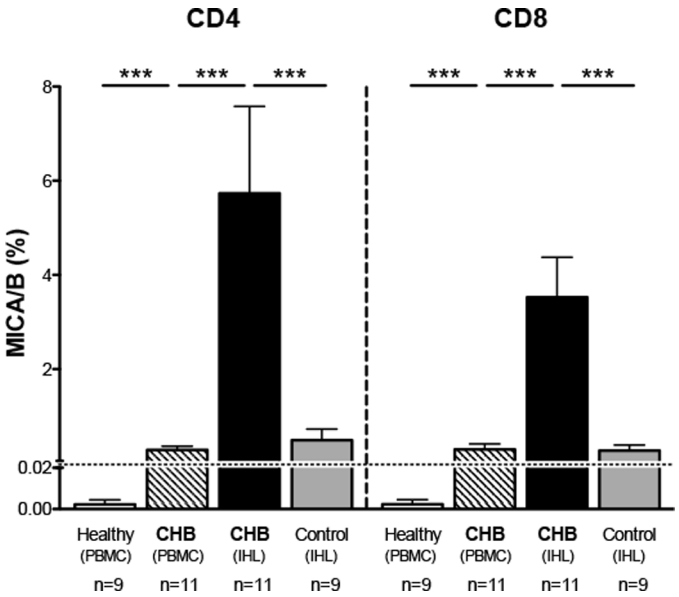
E-mail: mail.huangweichen@gmail.com

Background and Aims: NK cells are emerging as potent regulators of adaptive immunity; we have recently shown that they can kill hepatitis B virus (HBV)-specific T cells in a contact-dependent manner (Peppa JEM 2013). The TRAIL pathway was involved in NK cell deletion of T cells but blocking studies implicated additional pathways. In this study we explored the role of NKG2D-dependent interactions between NK cells and T cells.

Methods: We evaluated peripheral blood from healthy individuals and patients with chronic hepatitis B (CHB). Intrahepatic lymphocytes were isolated from liver tissue of biopsies (CHB) or resections (controls). A MICA-transfected B lymphoblast cell line, C1R MICA, was used to assess NK cell activation and cytotoxicity. Global, activated and HBV-specific T cells from the circulation and liver were stained with NKG2D-L mAb. NK cell depletion and NKG2D-blocking mAb were used for functional experiments.



Results: The activatory receptor NKG2D was maintained at high levels on NK cells from patients with HBV and further increased on intrahepatic NK cells. NKG2D-ligands (NKG2D-L) are not usually expressed on T cells but were upregulated on T cells (CD4>CD8) in CHB patients, particularly those with liver inflammation. NKG2D-L were preferentially expressed on activated and HBV-specific T cells, and strikingly enriched on T cells in the CHB liver compared to their circulating counterparts or to T cells in control livers without inflammation. Following NKG2D pathway blockade in vitro, there was a small but consistent rescue of circulating and intrahepatic HBV-specific CD4 T cells from CHB patients with ongoing liver inflammation. (NKG2D-L)-expressing cells were able to trigger activation and cytotoxicity of NK cells from patients with CHB in an NKG2D-dependant manner. We therefore concluded that the NKG2D pathway allows bidirectional cross-talk between T and NK cells. In support of this, the NKG2D+ fraction of NK cells were more activated (HLA-DR+) in patients with CHB than controls, particularly in the infected liver.

Conclusions: These results imply that NKG2D-L expressing T cells drive activation and cytotoxicity of NK cells in the HBV-infected liver, promoting deletion of HBV-specific T cells. Thus NKG2D-dependent CD4 T cell/NK cell interactions may support innate immunity at the expense of the adaptive arm in CHB.

P0479

NAIVE-LIKE CD8+ T CELLS SPECIFIC FOR SUBDOMINANT HEPATITIS B VIRUS EPITOPES ARE PRESENT IN CHRONICALLY INFECTED PATIENTS

A. Schuch[1,2], M. Kiraithe[1,2], J. Lang[1,3], C. Neumann-Haefelin[1], R. Thimme[1]. *[1]Department of Internal Medicine II, University Hospital Freiburg, [2]Faculty of Biology, [3]Faculty of Medicine, University of Freiburg, Freiburg, Germany*

E-mail: anita.schuch@uniklinik-freiburg.de

Background and Aims: Virus-specific CD8+ T cells are rarely detectable ex vivo by conventional tetramer stainings in chronically HBV-infected patients. This lack of HBV-specific CD8+ T-cell responses may be explained by insufficient priming or terminal deletion due to T-cell exhaustion.

Methods: To characterize HBV-specific CD8+ T cells not detectable by conventional methods we used a combination of tetramer-associated magnetic bead enrichment and multiparametric flow cytometry and performed phenotypic, functional and viral sequence analyses.

Results: By using this enrichment strategy we were able to detect 74 CD8+ T-cell populations specific for 4 HLA-A0201 restricted HBV epitopes (Core18–27, Env183–191, Env335–343 and Pol455–463) in 31 chronically HBV-infected patients suggesting that these cells are not completely deleted. Interestingly, a proportion of the analyzed CD8+ T cells specific for Env183–191, Env335–343 and Pol455–463 epitopes had a naïve-like phenotype (25%, 48% and 19% respectively) defined by high expression of CD45RA, CCR7 and CD27 and low expression of CD11a. By contrast, enriched CD8+ T cells specific for the immunodominant Core18–27 epitope predominantly showed an effector-memory phenotype (CD45RA-, CCR7-, CD27+, CD11a+). However, the presence of wild type sequences in patients with naïve-like HBV-specific CD8+ T cells indicated that the presence of naïve-like cells is not due to infection with a variant HBV containing mismatched epitopes. Moreover, the presence of HBV-specific CD8+ T cells with naïve-like phenotype did not correlate with any clinical parameter such as HBeAg status, viral load or transaminases and was independent of antiviral treatment. Further investigations will address the underlying mechanisms for possible priming defects and clarify whether intrinsic CD8+ T-cell defects, dysfunction of antigen-presenting cells, lack of CD4+ T-cell help or immunoinhibitory cytokines such as IL-10 may play a role in this setting.

Conclusions: Our results indicate that HBV-specific CD8+ T cells are not completely deleted in chronically infected patients, but are rather maintained at a very low frequency. Furthermore, a substantial fraction of CD8+ T cells specific for subdominant HBV epitopes display a naïve-like phenotype despite ongoing viral replication. This suggests that insufficient priming of HBV-specific CD8+ T cells may also contribute to CD8+ T-cell failure in chronic HBV infection and that therapeutic vaccination may be a feasible approach in this patient cohort.

ROLE OF THE IMMUNE MICROENVIRONMENT DURING HEPATOCELLULAR CARCINOMA

A. L'Hermitte[1], S. Pham[1], M. Anson[1], A.-M. Denoyelle[1], G. Couchy[2], C. Perret[1], J. Zucman-Rossi[2], C. Desdouets[1], J.-P. Couty[1], Institut Cochin, INSERM U1016, CNRS UMR8104, Team: "Cell cycle and liver physiopathology", Université Paris Descartes, Université Paris Diderot, Paris, France. *[1]Institut Cochin, INSERM u1016, [2]Institut Universitaire d'Hématologie, INSERM u674, Paris, France*
E-mail: antoine.lhermitte@inserm.fr

Background and Aims: Hepatocellular carcinoma (HCC) is the 3rd cause of cancer-related death worldwide. Collective data evidenced the tumor microenvironment (TME) as a key actor during carcinogenesis. Using relevant liver tumor mouse models mimicking human beta-catenin-dependent tumorigenesis, we identified 2 critical interconnected effectors of the TME controlling this oncogenic process: the invariant Natural Killer T cells (iNKT) and LECT2. Their specific deletion leads to the emergence of highly invasive HCC associated with lung metastasis (Anson M et al., 2012).
Our aim is to address functionally the regulatory role of LECT2 on the inflammatory response driven by tumor development.
Methods: Preneoplastic ($Apc^{-/-}$) and tumoral (Lpk-myc) models (WT and LECT2 deficient) that recapitulate human beta-catenin-dependent HCC are used. Immune liver content is analysed by flow cytometry, cell sorting and immunohistochemistry. The expression of LECT2 is analysed from a large cohort of human HCC samples by TaqMan qPCR.
Results: We found a significant accumulation of myeloid cells ($CD11c^{-}$ $CD11b^{+}$ $F4/80^{+}$ $Ly6C^{hi}$ $Ly6G^{-}$) in HCC livers and impressively more in the absence of LECT2. These cells were found to express LECT2 receptor CD209a. We investigate the mechanism by which LECT2 exerts its effects using Bone-Marrow-Derived-Macrophages (BMDM) from WT and LECT2-deficient mice, pretreated with r-LECT2 and/or LPS. We found that (1) LECT2 regulates drastically LPS-induced TNFa secretion, (2) BMDM from LECT2-deficient mice are hypersensitive to LPS exposure compared to WT. Translated *in vivo* (HCC), myeloid cells exhibit immature phenotype evidenced by low level of MHC class II and CD1d that associated with a substantial increase in their ability to produce IL-10. These results suggest that LECT2 regulates the inflammatory response during HCC through a major targeting of myeloid cell functions that might impact subsequently on iNKT cells.
We evidenced that undifferentiated structures arising within LECT2-deficient tumor nodules harbor a molecular signature associated with EMT/metastasis. Finally, we found that LECT2 expression inversely correlates with tumor grades and the presence of significant inflammatory human HCC emphasizing its role in both differentiation and inflammation under oncogenic process.
Conclusions: Our data suggest that LECT2 controls functionally liver myeloid cells to regulate an inflammatory response compatible with the maintenance of hepatocyte differentiation.

GENOME WIDE MIRNA: MRNA INTEGROME ANALYSIS REVEALS KEY PATHWAYS, BIOLOGICAL PROCESSES AND GENE FAMILIES IN CD4+ T CELLS THAT DIFFERENTIATE VARIOUS STAGES OF HBV INFECTION

A. Kumar Singh[1], R. Geffers[2], S.B. Rooge[1], A. Varshney[1], N. Trehanpati[1], M. Vasudevan[3], M.K. Sharma[4], A. Bhardwaj[1], S.K. Sarin[1]. *[1]Research, Institute of Liver and Biliary Sciences, New Delhi, India; [2]Array Facility, Helmholtz Centre for Infection Research, Braunschweig, Germany; [3]Bionivid Technology Pvt Ltd, Bangalore, [4]Hepatology, Institute of Liver and Biliary Sciences, New Delhi, India*
E-mail: shivsarin@gmail.com

Background and Aims: CD4 + T cell immune responses play an important role in pathogenesis during various stages of hepatitis B virus infection. However, the molecular mechanisms by which CD+ T cells exert their modulatory activity are largely unknown. We investigated the role of miRNA mediated regulatory control of mRNA expression and key pathways and molecular mechanism of CD4+ T cells at different stages of HBV infected patients.
Methods: Three groups of patients [Acute Viral Hepatitis, AVH-B (n = 4, mean age 45yr, M/F = 2); Chronic HBV with raised ALT (n = 9, HBeAg+ = 5, mean age 38yr, M = 6) and Chronic HBV with persistently normal ALT (n = 12, HBeAg+ = 3, mean age 34 yr, M = 7)] and matched controls (n = 11, mean age 33 yr, M = 6) were studied. Microarray based whole genome gene expression analysis and whole miRNA expression analysis of CD4+ T cells was performed using Agilent Platform. Differentially expressed transcripts (Genes and miRNAs) between patient groups and key pathways and biological processes regulated were identified by various statistical methods. Differentially expressed gene sets and their targeting differentially expressed miRNA along with pathways and biological categories regulated by them were subjected to Integrome analysis to identify disease baseline and stage specific signatures of HBV infection.
Results: We identified a total of 116 genes and 53 differentially expressed miRNAs in one or more of the infection stages. Integrome analysis revealed 28 key pathways, biological categories and gene families that were enriched in baseline infection and unique to specific infection stages harbouring the identified genes and miRNAs (Figure 1). Network modelling analysis revealed HBV infection stage specific and baseline clustering of pathways, gene families and key biological categories. Some of the biological events and gene families enriched include Apoptosis, Calcium Signalling, Key Cellular processes (Adhesion, Cell cycle, Differentiation, Migration, Proliferation), Cell surface, Chemokines, and Cytokines, Immune response, MAPK signaling, NFKB signalling and TGFbeta signalling pathway.
Conclusions: Integrome analysis revealed induction of unique cluster of miRNAs and repression of their target genes that differentiates acute and chronic infection stage, chronic infection with and without hepatic injury in CD4+ T cells.

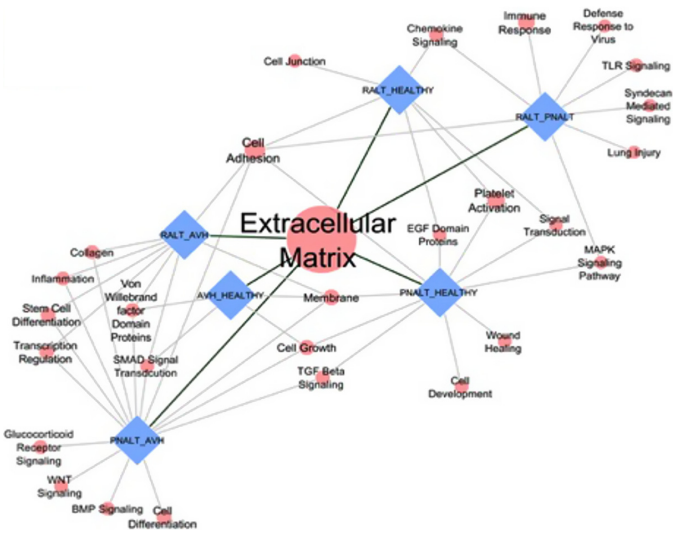

Figure 1. Key pathways and biological processes regulated by miRNA:mRNA in CD4+ T cells during different stages of HBV infection.

IMPROVING NATURAL KILLER CELLS CYTOTOXICTY AND HARNESSING HEPATOCYTE CANCER PROGRESSION BY MIR-486-5P

A.A. Bassiouni[1], M.A. Rahmoon[1], R.A. Youness[1], A.I. Gomaa[2], I. Waked[2], G. Esmat[3], H.M. El Tayebi[1], A.I. Abdelaziz[1]. *[1]The Molecular Pathology Research Group, Department of Pharmacology and Toxicology, Faculty of Pharmacy and Biotechnology, German University in Cairo, Cairo, [2]Hepatology, National Liver Instiute, Menoufiya University, Menoufiya, [3]Endemic Medicine and Hepatology Department, Faculty of Medicine, Cairo University, Cairo, Egypt*
E-mail: aya.bassiouni@gmail.com

Background and Aims: Insulin-like Growth Factor-1 Receptor (IGF1R) activation mainly through IGF-2 is a hallmark in Hepatocellular carcinoma (HCC), stimulating several mitogenic signaling pathways most importantly PI3K/Akt/mTOR pathway. Among the immune cells, IGF-1R showed high expression on Natural Killer (NK) cells, and it was also reported to have a prominent role in NK cell differentiation and proliferation mainly through IGF-1. NK cells are known to be the first native defender against HCC activated by NKG2D receptor, mediating its cytotoxicity mainly through perforins release. In our previous work, let-7a and miR-615-5p were proved to be tumor suppressors through targeting IGF-2. IGF-1R expression was found to be regulated by several miRNAs; however, miR-486-5p has never been investigated in HCC. So the aim of this study was to control the HCC tumor progression through the direct impact of miRNAs on NK cells as well as their target hepatocytes in an immunotherapeutic approach.
Methods: In-silico analysis was preformed to predict potential miRNAs targeting IGF1R. Huh7 cells were cultured and NK cells were isolated from 27 HCC patients. Both cell types were transfected by the miRNAs of interest using lipofection. Total RNA was extracted and quantified using qRT-PCR. Viability and proliferation analysis were performed using MTT and BrdU assays. Significance of results was determined by unpaired student t-test ($p < 0.05$) and graphed using Graph Pad Prism 5.0 software.
Results: Bioinformatic analysis predicted miR-486-5p, miR-615-5p and let-7a to target IGF-1R with high scores. Gain and loss of function of miR-486-5p, miR-615-5p and let-7a showed significant down regulation of both IGF1R and its downstream oncoprotein mTOR in Huh7 cells. Cellular viability and proliferation of Huh7 cells were repressed by miR-486-5p comparable to the validated tumor suppressors miR-615-5p and let-7a. Upon ectopic expression of miR-486-5p in NK cells of HCC patients both NKG2D and perforins expression were significantly elevated. However, a significant down regulation of IGF-1R was observed. Interestingly, IGF-1 which is a validated target of miR-486-5p was found to be significantly upregulated in NK cells of HCC patients.
Conclusions: MiR-486-5p is a novel tumor suppressor microRNA. In the current study, it was shown to have a dual role in enhancing NK cell cytotoxicity through inducing IGF-1 expression and harnessing the tumor progression of its target hepatocyte via IGF-axis repression.

CHANGES IN LIVER IMMUNITY UPON HBV INFECTION: A COMPARISON OF HUMANISED MICE AND HUMANS

L.-E. Wai[1], C.T. Keng[2], D. Zheng[2], A. Tan-Garcia[3], E. Ceccarello[1], C. Tham[3], A.T. Tanoto[3], A. Bertoletti[1,3], Q. Chen[2]. *[1]Viral Hepatitis Unit, Singapore Institute for Clinical Sciences, [2]Humanized Mouse Unit, Institute of Molecular and Cell Biology, [3]Program of Emerging Infectious Diseases, Duke-NUS Graduate Medical School, Singapore, Singapore*
E-mail: wai_luen@sics.a-star.edu.sg

Background and Aims: The lack of robust animal models to study chronic HBV infection and immunopathogenesis has been a roadblock to the development of effective therapies. Humanised mouse models containing both human hepatocytes and immune system have been proposed as potential models for studying HBV pathogenesis. However, there has been little direct comparison of humanised mouse liver immunity with that of humans. Our aim is to compare how similar intrahepatic immune cells in HBV-infected humanised mice are to those from pathologic human livers.
Methods: Humanised mice containing both human hepatocytes and a matching immune system (HIL mice) were generated by reconstituting NOD-*scid IL2rg*$^{-/-}$ mice with CD34^{+} cells from human fetal livers. HIL mice were infected with either mock control or HBV, and their liver immune cells isolated at 4, 10 and 20 weeks post-infection. Intrahepatic immune cells were also isolated from perfused healthy and HBV-infected pathologic human livers. Intrahepatic immune cells from humanised mice and humans were analysed for immune cell frequency and functional responses.
Results: Despite high levels of intrahepatic immune reconstitution in humanised mice, immune subset frequencies of uninfected and HBV-infected HIL livers differed from healthy and HBV-infected human livers. In particular, HIL mouse livers had higher CD4/CD8 T cell ratios and lower frequencies of NK, γδ T and MAIT cells as compared to human livers. Furthermore, HBV-infected HIL mice did not show any expansion of HBV-specific T cells, that were not detected despite the use of a comprehensive pool of HBV peptides covering the whole HBV proteome in ELISPOT assays. However, the majority of HBV-infected but not mock-infected mice developed liver damage and robust human serum cytokines responses starting 8 weeks post-infection. The liver inflammatory events were linked with a specific enrichment of CD14+CD16+ inflammatory monocytes and dendritic cells that closely mimics what is seen in pathological human livers.
Conclusions: Although intrahepatic lymphocyte populations and virus-specific immunity could not be fully recapitulated in HBV-infected HIL mice, the intrahepatic inflammatory events triggered by HBV infection are similar to those detected in HBV chronically infected humans. We posit that this model can be exploited to disentangle the immunological mechanisms of chronic liver inflammation secondary to chronic HBV infection.

CD3(+)CD56(+) NK-LIKE T CELLS SHOW REDUCED ANTI-VIRAL ACTIVITY IN ACUTELY HCV/HIV INFECTED PATIENTS

P. Kokordelis[1,2], B. Krämer[1,2], C. Boesecke[1,2], E. Voigt[3], P. Ingiliz[4], A. Glässner[1,2], F. Wolter[1,2], C.P. Strassburg[1,2], U. Spengler[1,2], J.K. Rockstroh[1,2], J. Nattermann[1,2]. *[1]Internal Medicine I, University of Bonn, [2]German Center for Infection Research (DZIF), Bonn, [3]Praxis am Ebertplatz, Köln, [4]Medical Center for Infectious Diseases (MID), Berlin, Germany*
E-mail: pavlos.kokordelis@ukb.uni-bonn.de

Background and Aims: In Western Europe and the US approximately 30% of HIV(+) patients are co-infected with the hepatitis C virus (HCV), which has become a major cause of morbidity and mortality. In HIV(−) patients CD3(+)CD56(+) NK-like T cells, a subset of innate lymphocytes, have been suggested to modulate outcome of acute hepatitis C. However, it remained unclear whether these cells display direct anti-HCV activity and how HIV co-infection may modulate functions of CD3(+)CD56(+) NK-like T cells.
Methods: 36 HIV(+) patients with acute hepatitis C (spontaneous clearance: n = 13; chronic course: n = 23) were studied. 8 HCV(+)/HIV(−) patients, 12 HIV(+) patients with chronic hepatitis C, 8 HIV(+)/HCV(−) patients and 12 healthy individuals were enrolled as controls. Frequency, phenotype and IFN-γ secretion was studied by flowcytometry. CD3(+)CD56(+) NK-like T cell-mediated inhibition of HCV replication was analyzed using the HuH7A2HCVreplicon model.

Results: Frequencies of CD3(+)CD56(+) NK-like T cells did not differ significantly between the study groups. Phenotypic analysis revealed that acutely HCV infected patients displayed a significantly lower frequency of CD161(+)CD3(+)CD56(+) NK-like T cells compared to controls. Of note, frequency of CD161-expressing cells was positively correlated with IFN-γ production. We found, IL-12/IL-15 stimulated CD3(+)CD56(+) NK-like T cells from healthy donors effectively block HCV replication in vitro. Supernatants of IL-12/IL-15 stimulated CD3(+)CD56(+) NK-like T cells also significantly inhibited HCV replication in vitro, suggesting that non-cytolytic mechanisms may play a major role. In addition, we only observed minimal killing of HuH7A2HCVreplicon cells by CD3(+)CD56(+) NK-like T cells and could confirm that blocking of IFN-γ with a specific antibody significantly reduced the anti-viral activity of these cells. However, when CD3(+)CD56(+) NK-like T cells from HIV(+) patients were studied we found HIV infection to be associated with a significantly impaired IFN-γ production, irrespective of HCV co-infection. In line with this observation, CD3(+)CD56(+) NK-like T cells from HIV(+) patients were significantly less effective in blocking HCV replication in vitro than cells from healthy individuals.
Conclusions: Taken together, our data indicate that CD3(+)CD56(+) NK-like T cells have the potential to block HCV replication but are functionally impaired in HIV(+) patients. This might represent a novel mechanism of dysregulated immune response in HIV/HCV co-infected patients.

P0485
FUNCTIONAL IMMUNE RESTORATION CORRELATES WITH HBsAg DECLINE AND MAY PREDICT TREATMENT RESPONSE ON SEQUENTIAL NUC THERAPY IN CHRONIC HEPATITIS B

U.S. Gill[1], D. Peppa[2], L. Micco[2], H.D. Singh[2], G.R. Foster[1], M.K. Maini[2], P.T. Kennedy[1]. [1]*Hepatology Unit, Centre for Digestive Diseases, Blizard Institute, Barts and The London SMD, QMUL,* [2]*Division of Infection & Immunity, UCL, London, United Kingdom*
E-mail: u.gill@qmul.ac.uk

Background and Aims: Sequential/combined therapeutic approaches comprising Pegylated-Interferon (Peg-IFNα) and nucleot(s)ide analogues (NUC) are being given greater consideration as treatment strategies for chronic hepatitis B (CHB) to achieve HBsAg loss. We demonstrated boosting of NK cells in eAg^- patients treated with Peg-IFNα *(Micco et al, J. Hepatol, 2013),* and postulated this effect could be maintained with sequential NUC therapy. Differential NK cell responses in patients receiving sequential NUCs were analysed and correlated with HBsAg response, to elucidate a possible treatment advantage with Peg-IFNα exposure.
Methods: PBMC from 18 eAg^+ patients during Peg-IFNα therapy were utlised. 9/18 patients considered Peg-IFNα non-responders after 48-weeks therapy progressed to sequential NUCs and were followed until virally suppressed. Phenotypic and functional analysis of NK cell subsets was performed by multicolour flow-cytometry and findings correlated with on-therapy HBsAg changes.
Results: Peg-IFNα expanded $CD56^{bright}$ NK cells by 3-fold ($p = 0.0001$) which was maintained on sequential therapy. NK cell receptor expression was analysed. All receptors, except NKG2C, were maintained on sequential NUCs, with marked augmentation in the expression of NKp30 and NKp46 on $CD56^{bright}$ NK cells ($p \leq 0.05$). These NK cells maintained their ability to degranulate and produce IFNγ during sequential therapy, functional restorations not seen on NUCs alone ($p = 0.0001$ and 0.002 respectively). TRAIL expression was analysed; this decreased on sequential NUCs, but remained higher than baseline. 6/9 patients had significant declines in HBsAg (>0.5 $\log_{10}$ IU/ml) on sequential NUCs. We noted that only these patients showed the ability to increase the proportion of functional NK cells ($IFN\gamma^+$ and $CD107^+$) on sequential NUCs. Additionally only these responders demonstrated a reduction in TRAIL expression on sequential NUCs, compared to those without HBsAg decline, who showed the reverse.
Conclusions: Restoration of NK cell cytotoxic/effector functions is seen on sequential therapy, but only in those patients with HBsAg decline. Lower expression of TRAIL also correlates with treatment response, in line with our finding that $TRAIL^+$ NK cells can delete antiviral T-cells (*Peppa et al, JEM 2013*). IFNγ, CD107 and TRAIL expression on NK cells may predict those patients who are likely to demonstrate HBsAg decline on sequential therapy. Given these findings, the TRAIL pathway may be a potential future target in order to improve treatment outcomes in CHB.

P0486
HEPATIC APOPTOSIS INFLUENCED BY DEFICIENCY OF GROUP VIA CALCIUM-INDEPENDENT PHOSPHOLIPASE A2 LEADS TO PRO-INFLAMMATORY RESPONSE BY KUPFFER CELLS

J. Inhoffen[1], W. Wei[1], S. Tuma-Kellner[1], W. Stremmel[1], W. Chamulitrat[1]. [1]*University Heidelberg HospitalInternal Medicine IV, Heidelberg, Germany*
E-mail: walee.chamulitrat@med.uni-heidelberg.de

Background and Aims: Emerging data indicate that group VIA calcium-independent phospholipase A2 (iPLA2β) regulates macrophage chemotaxis towards apoptotic cells. We have previously shown that iPLA2β deficiency causes an accumulation of hepatocyte apoptosis which leads to increased inflammation. The aim of the present study was to determine whether hepatic apoptosis with iPLA2β deficiency would alter M1/M2 response of resident Kupffer cells (KC) and Th1/Th2/Th17 response in lymphocytes, and whether this response could be modified by CD95/FasL-induced liver injury in vivo.
Methods: KC and splenocytes were isolated from control (WT) and $iPLA2\beta^{-/-}$ male mice and were respectively stimulated by 1 μg/mL LPS or 10 μg/mL ConA in vitro. In another set of experiments, mice were injected with 0.125 μg/g body weight CD95/FasL antibody for 6 h. Cytokine expression and release were measured by qRT-PCR and ELISA. Histology and immunohistochemistry was performed on secondary lymphoid organs.
Results: KC isolated from $iPLA2\beta^{-/-}$ mice secreted lower levels of IL-6, TNF-α, IL-10, and in vitro LPS-stimulated KC from mutant livers released cytokines at strongly suppressed levels compared with WT KC (for example IL-6 release in mutant vs. WT: 4-fold vs. 12-fold increase). On the contrary, upon CD95/FasL-induced apoptosis in vivo, KC from the mutant livers released increased IL-6 while those from WT livers displayed suppressed secretion. LPS stimulation in vitro in mutant KC led to an increased release of IL-6 and TNF-α (mutant vs. WT: 5 and 16 vs. 3 and 5 fold increase for IL-6 and TNF-α, respectively). The release of IL-4 and TGFβ1 by KC was not markedly altered among WT and mutant livers. In secondary lymphoid organs, apoptosis in spleen and mesenteric lymph node (MLN) of the mutants was increased, and this was consistent with decreased tingible body macrophages (i.e., activated macrophages) in MLN. Splenocytes isolated from the mutants secreted increased levels of IL-6, IFNγ, and IL-17.
Conclusions: Whole-body iPLA2β deficiency led to suppressed innate immunity with a defect in cytokine release by KC. The mutant splenocytes displayed increased levels of pro-inflammatory cytokines which may induce autoimmunity. Upon increased apoptosis in vivo, the mutant KC released exaggerated levels of IL-6 which may promote inflammatory response and liver injury. Thus, iPLA2β's ability to regulate hepatic apoptosis leads to altered functions of immune cells, and this may be related to autoimmune diseases such as autoimmune hepatitis.

DOMINANCE OF HLA-B RESTRICTED VIRUS-SPECIFIC CD8+ T CELL EPITOPES IN CHRONIC HBV INFECTION

J. Lang[1], M. Kiraithe[1], R. Thimme[1], C. Neumann-Haefelin[1].
[1]*Department of Medicine II, University Hospital Freiburg, Freiburg, Germany*
E-mail: julia.lang@uniklinik-freiburg.de

Background and Aims: HBV-specific CD8+ T cells are essential for HBV clearance and are an attractive target for immunotherapeutic intervention. However, the HBV-specific CD8+ T cell repertoire is poorly characterized. Indeed, <10 HLA-B restricted HBV-specific CD8+ T cell epitopes are described to date, although recent findings in the field of HIV and HCV infection clearly demonstrate a dominant role of these epitopes. We therefore aimed to identify novel CD8+ T-cell epitopes in HBV-infection and also address the relative contribution of HLA-A versus HLA-B restricted epitopes.
Methods: 30 patients with chronic HBV (genotype D) and low viremia were screened for HBV-specific CD8+ T-cell responses using overlapping peptides spanning all HBV proteins in a matrix setup in an elispot assay. Positive responses were confirmed by intracellular interferon gamma staining, optimal epitopes were fine-mapped and HLA restriction was determined. In addition, the autologous viral sequences corresponding to the identified epitopes were analyzed in the patients.
Results: 10 out of 30 patients targeted at least one CD8+ T cell epitope (range: 1–10). In total, we identified 27 CD8+ T cell responses. Interestingly, responses targeted core, polymerase and X proteins, but completely spared the surface antigen. None of these responses targeted previously described HBV-specific CD8+ T cell epitopes. To date, we were able to fine-map 10 novel CD8+ T cell epitopes. Importantly, most of these epitopes were restricted by HLA-B alleles (4 x HLA-B*35; 2 x HLA-B*7; 1 x HLA-B*14; 1 x HLA-B*15). In one epitope restricted by HLA-B*35:02 we found evidence for the selection of viral escape mutations.
Conclusions: In our cohort, HBV-specific CD8+ T cell responses are dominantly restricted by HLA-B alleles. These findings indicate that previous studies on HBV-specific immunity mainly focussing e.g. on HLA-A*02 restricted CD8+ T cell epitopes may not necessarily be conferrable to the complete CD8+ T cell repertoire. They also suggest that HLA-B restricted CD8+ T cell epitopes may be important targets for immunotherapy. The absence of T-cell responses located in the surface-Protein implies a dominant role of the HBs antigen in immune regulation and persistence of HBV.

E-mail: x.zhou@erasmusmc.nl

Background and Aims: Interferon (IFN) signaling represents the first line of host innate defense against invading viral pathogens. Recently, Pegylated IFN-α has been successfully used as an off-label drug for treating hepatitis E virus (HEV) infection. The molecular mechanisms, however, at how IFN signaling interact with HEV infection remain undefined, hampering more wide scale implementation of IFN-α therapy for HEV-infected patients. We comprehensively investigate the interplay between IFN signaling and HEV infection.
Methods: Subgenomic replication and full-length HEV and HCV infectious cell culture models were used. Viral kinetics of five HEV patients treated with Pegylated IFN-α were analyzed.
Results: Screening of 36 cytokines revealed that HEV replication is in general insensitive to regulation by such humoral factors, except for IFN-α that exerts moderate anti-HEV effects in vitro (41% inhibition, $P \leq 0.01$, 1000 IU/ml for 72 hrs). Remarkably, IFN-α completely abrogates of HCV replication. This difference of anti-viral activity is reflected in clinical success of IFN-α therapy towards HCV and HEV infection respectively. Whereas chronic HCV patients respond to IFN-α therapy often with a sharp drop in viral load within the first few days upon treatment, only 1 out of 5 chronic HEV patients exhibited a rapid decline in viral load whereas the others displayed only minor changes during the first month of treatment. In vitro, HEV apparently corrupts antiviral IFN responses via attenuating STAT1 phosphorylation and accordingly suppresses IFN-α-induced transcription of interferon stimulated genes (ISGs; 18 genes tested). In apparent agreement for a role of canonical IFN-α signaling in specifically limiting HEV infection, blocking constitutive IFN signaling (absent of exogenous IFN stimulation) by inhibiting JAK1 results in a release of HEV production (an approx. 5-fold increase over JAK1 proficient cells, $P \leq 0.01$) but not HCV infection. Mechanistically, this effect related to constitutive mTOR-dependent 4E-BP1 activation and subsequent transcription of ISGs as supported from experiments involving RNAi gene silencing, lentiviral overexpression approaches as well as experiments in mouse embryonic fibroblasts generated from mice genetically deficient for 4E-BP1.
Conclusions: IFN-α treatment exerts moderate but delayed antiviral activity against HEV infection in experimental models and in patients. 4E-BP1 restricts HEV infection and mediate the anti-HEV effects of IFN-α throuht modulationg ISG induction.

INTRACELLULAR CRAWLING OF LYMPHOCYTES THROUGH HEPATIC SINUSOIDAL ENDOTHELIAL CELLS – A NOVEL STEP IN THE ADHESION CASCADE?

D.A. Patten[1], C.J. Weston[1], H. Dawes[1], G.K. Wilson[2], D.H. Adams[1], S. Shetty[1]. [1]*Centre for Liver Research, School of Immunity and Infection,* [2]*HCV research group, School of Immunity and Infection, University of Birmingham, Birmingham, United Kingdom*
E-mail: d.a.patten@bham.ac.uk

Background and Aims: Excessive lymphocyte recruitment into liver tissue is a hallmark of all chronic inflammatory liver diseases. The recruitment of lymphocytes occurs within the low shear environment of hepatic sinusoids, which are lined by highly specialised endothelial cells (HSEC). We have previously described transcellular migration through HSEC mediated by atypical adhesion molecules (CLEVER-1 and VAP-1). Our aims were to study the underlying mechanisms of this process to identify new targets to treat inflammatory liver disease.
Methods: Using confocal microscopy and flow-based adhesion assays, we compared lymphocyte migration across primary human HSEC and human umbilical vein endothelial cell (HUVEC) monolayers under physiologically relevant shear stress. We also analysed and quantified the junctional molecule expression of these cells in vitro by immunofluorescence and cell-based ELISA. Chemokine expression and monolayer transcellular permeability were also assessed by qPCR and the FITC-dextran assay, respectively. Immunofluorescent staining of human liver tissue was performed to study lymphocyte-endothelium interactions within the hepatic sinusoids.
Results: Live cell imaging of lymphocyte recruitment under conditions of shear stress identified inflammatory cells that

migrated into HSEC and subsequently exhibited novel cell-to-cell crawling. This process was dependent on IFN-γ and occurred predominantly in HSEC when compared to a more conventional vascular endothelium [human umbilical vein endothelial cells (HUVEC)]. Expression of chemokine transcripts and transcellular permeability were similar in both endothelia, whereas distinct differences were identified in junctional molecule expression, with HSEC lacking occludin and expressing lower levels of JAM-A than vascular endothelium. In support of these findings immunofluorescent analysis of human liver tissue demonstrated CD3+/CD4+ cells within sinusoidal endothelial cells.
Conclusions: We demonstrate a novel behaviour of lymphocyte migration which occurs during interactions with primary human HSEC. This process appears to be mediated by the unique junctional expression pattern of HSEC and microenvironmental stimuli such as IFN-γ. We believe this is a novel step in the adhesion cascade that could have implications for treating chronic inflammatory liver disease and modulating intrahepatic immunity.

P0490
NK CELL DYNAMICS IN CHRONIC HEPATITIS B PATIENTS ARE ASSOCIATED WITH HBsAg CLEARANCE AFTER COMBINATION TREATMENT WITH PEGINTERFERON ALFA-2A AND ADEFOVIR
F. Stelma[1,2], A. de Niet[1,2], L. Jansen[1,2], R.B. Takkenberg[1], H.L. Janssen[3,4], M.J. Sinnige[2], N.A. Kootstra[2], E.M. van Leeuwen[2], H.W. Reesink[1]. *[1]Gastroenterology and Hepatology, [2]Experimental Immunology, Academic Medical Center, Amstedam, Amsterdam, [3]Gastroenterology and Hepatology, Erasmus Medical Center, Rotterdam, Netherlands; [4]Toronto Centre for Liver Disease, Toronto Western & General Hospital, Toronto, Canada*
E-mail: f.stelma@amc.nl

Background and Aims: The role of natural killer (NK) cells in the clearance of HBsAg is not well understood. Furthermore, it is unknown whether the NK cell phenotype could predict treatment outcome in patients with chronic hepatitis B.
Methods: In a prospective study, 92 (44 HBeAg pos, 48 HBeAg neg) chronic hepatitis B (CHB) patients (HBV DNA >17,182 IU/ml) were treated with peginterferon alfa-2a and adefovir for 48 weeks. PBMC's were collected at baseline, during therapy and follow-up. Response was defined as HBsAg loss at week 72 (functional cure). From this cohort NK cell characteristics of 7 responders (3 HBeAg pos, 4 HBeAg neg) and 7 matched non-responders were analysed, together with 7 healthy controls (HC). Markers of NK cell activation, proliferation, migration and functionality were measured by flowcytometry. Subsequently, 35/44 baseline (BL) samples of HBeAg-positive CHB patients were analysed.
Results: At BL, the NK cell subset distribution ($CD56^{bright}$ and $CD56^{dim}$) of CHB patients was comparable to HC. At end of treatment (EoT), the percentage – as well as absolute numbers – of $CD56^{bright}$ NK cells had increased significantly (11.3% at BL to 44.4% at EoT, $p < 0.0001$), whereas $CD56^{dim}$ NK cells had decreased. At BL, patients with HBsAg loss had significantly lower expression of chemokine receptor CX_3CR1 on $CD56^{bright}$ and inhibitory receptor NKG2A on $CD56^{dim}$ NK cells compared to non-responders (gMFI CX_3CR1 149.7 vs. 222.1, $p < 0.05$ and $NKG2A^+$ 37.3% vs. 50.9% $p < 0.05$). At end of treatment $CD56^{bright}$ TRAIL expression and total NK cell IFNy production was higher in responders compared to non-responders. These differences at BL were not found in BL samples from HBeAg-positive patients with HBeAg seroconversion, but without HBsAg loss (CX_3CR1 $CD56^{bright}$ $p = 0.89$ and $NKG2ACD56^{dim}$ $p = 0.85$).
Conclusions: Baseline expression of inhibitory receptor NKG2A on $CD56^{dim}$ and chemokine receptor CX_3CR1 on $CD56^{bright}$ NK cells are significantly different in CHB patients with HBsAg loss upon peginterferon/ADF combination therapy compared to non-responders. This suggests that NK cells may play a role in the clearance of HBsAg upon peginterferon based therapy.

P0491
IDENTIFICATION OF CD8+ T-CELL EPITOPES SPECIFIC FOR HEPATITIS C VIRUS GENOTYPE 4
H. Luxenburger[1], K. Nitschke[1], F. Grass[1], J. Bärmann[1], R. Thimme[1], C. Neumann-Haefelin[1]. *[1]Medicine II, University of Freiburg Medical Center, Freiburg, Germany*
E-mail: hendrik.luxenburger@uniklinik-freiburg.de

Background and Aims: Virus-specific CD8+ T-cell responses play an important role in the outcome of hepatitis C virus (HCV) infection. Thus, the identification of CD8+ T-cell epitopes is essential for the development of successful vaccination strategies against HCV. To date, most HCV-specific CD8+ T-cell epitopes have been defined in HCV genotype 1 infection. However, in some countries with the highest prevalence of HCV infection, such as Egypt, most patients are infected with HCV genotype 4. Currently, no HCV genotype 4 specific CD8+ T-cell epitopes have been identified.
Methods: In this study, we compared recognition of 93 well described HCV genotype 1-specific CD8+ T-cell epitopes in 20 patients chronically infected with HCV genotype 1 and 14 patients chronically infected with genotype 4. Next, we predicted 40 HCV genotype 4-specific CD8+ T-cell epitopes restricted by 8 different HLA class I alleles most commonly expressed in our genotype 4-infected patient cohort. These epitope candidates were tested for recognition in genotype 4-infected patients.
Results: Only 30% of genotype 1 CD8+ T-cell epitopes are conserved in genotype 4. Indeed, 70% of the 93 genotype 1-specific T-cell epitopes had at least one sequence variation in genotype 4. We were able to detect CD8+ T-cell responses in the majority of genotype 1-infected patients using this set of epitope peptides. However, no CD8+ T-cell responses to these genotype 1-derived epitopes were observed in patients infected with genotype 4. Importantly, we were able to confirm six novel CD8+ T-cell epitopes in genotype 4 infection, restricted by 4 different HLA alleles that are frequently expressed in HCV genotype 4-infected patients.
Conclusions: Epitopes previously identified in HCV genotype 1 infection are not commonly targeted in patients infected with HCV genotype 4. Importantly, we were able to identify the six first HCV genotype 4-specific CD8+ T-cell epitopes. These epitopes may be important targets for vaccination strategies in countries with high prevalence of HCV and dominance of HCV genotype 4 infection. These results further indicate that despite the similarity of HCV genotypes 1 and 4 in respect to antiviral therapy, T-cell based vaccines need to be adapted to the respective genotype.

ASSOCIATION OF CYCLIN D3 GENE PROMOTER HYPERMETHYLATION WITH HEPATITIS B e ANTIGEN POSITIVE STATUS AND INCREASED VIRAL REPLICATION IN HEPATITIS B VIRUS INFECTED PATIENTS
M.M. Kgatle[1], P. Vivekanandan[2], H. Hairwadzi[1]. *[1]Medicine, University of Cape Town, Cape Town, South Africa; [2]Biological Science, Indian Institute of Technology, New Delhi, New Delhi, India*
E-mail: mankgopo.kgatle@gmail.com

Background and Aims: Approximately 400 million people are chronically infected with Hepatitis B virus (HBV) worldwide. HBV integrates into human genome and triggers an innate methylation response that inactivates the viral inserts but also methylates adjacent host DNA. If the tumour suppressor and other cell-regulating genes are affected, these epigenetic changes could cause hepatic inflammation, fibrosis and HBV-induced hepatocellular carcinoma (HCC). We have previously shown that many gene promoters, including Cyclin D3 (CCND3) are hypermethylated in HBV patients. CCND3 gene regulates the cell cycle through

interaction with tumour suppressor genes. High CCND3 protein expression is present in cirrhotic livers with HBV-induced HCC, suggesting an important role in HCC development. We investigated whether CCND3 gene promoter hypermethylation was associated with hepatitis B e antigen (HBeAg) status and viral replication.
Methods: Bisulfite DNA sequencing technique was used to analyse CCND3 gene promoter CpG islands for the presence of hypermethylation in HBV-infected patients and normal controls. DNA samples were extracted from 30 individuals; 10 HBeAg positive, 10 HBeAg negative and 10 normal controls. Bisulfite converted DNA was cloned, sequenced and then analysed with BioEdit Sequence Alignment Editor to create ClustalW multiple alignment of the CCND3 gene promoter sequence extracted from Ensembl human genome 19 assembly with the bisulfite converted sequence of positive clones. The demographic and clinical data of the study patients was analysed using STATA 13.
Results: CCND3 gene promoter hypermethylation was significantly higher in HBeAg positive (80%) compared to HBeAg negative (40%) individuals ($p = 0.001$). No methylation was detected in normal controls. HBeAg positive patients had significantly higher DNA levels ($p = 0.02$) compared to HBeAg negative patients.
Conclusions: CCND3 gene promoter hypermethylation was associated with HBeAg positive status and high viral load. The high viral load most likely leads to a higher rate of HBV genome integration and therefore methylation. Patients with sustained viral replication have more epigenetic changes. This may explain the documented association of cirrhosis and HCC with high viral load and HBeAg status. However, the role of genotype, type and position of HBV inserts in triggering methylation needs further investigation with larger cohort.

SELECTIN-TARGETING NANOPARTICLES FOR IMMUNOMODULATORY THERAPY OF LIVER DISEASES
M. Bartneck[1], C.T. Schlößer[1], K.T. Warzecha[1], T. Lammers[2], C. Trautwein[1], K. Moog[3], H. Kunz[3], R. Zentel[3], M. Barz[3], F. Tacke[1].
[1]Department of Medicine III, RWTH-University Hospital, [2]Department of Experimental Molecular Imaging (ExMI), Helmholtz Institute for Biomedical Engineering, Medical Faculty, RWTH Aachen, Aachen, [3]Institute of Organic Chemistry, Johannes Gutenberg-Universität Mainz, Mainz, Germany
E-mail: mbartneck@ukaachen.de

Background and Aims: Selectins are cell adhesion mediating molecules, which specifically facilitate leukocyte recruitment to various tissues. Specific inhibition of L, E, or P selectin receptors using artificial ligands may represent a novel strategy to manipulate immune cell behavior for ameliorating inflammatory liver disease.
Methods: We synthesized four different fluorescently labelled polymer-carbohydrate conjugates P1-P4 (Dh=10 nm) with a poly N-(2-hydroxypropyl)methacrylamide (pHPMA) backbone. The conjugates can be divided into 2 classes, SLe^x-pHPMA conjugates [non-sulfonated (P1) and sulfonated (P2)] and mimetics thereof [non-sulfonated (P3) and sulfonated (P4)], which present the single carbohydrates of the natural Ligand SLe^x involved in selectin binding randomly among the polymer back bone. Mimetics are promising since they reduce the 51-step synthesis of SLe^x-pHPMA conjugates dramatically. Binding to different selectin receptors was assessed via surface plasmon resonance. We isolated different human primary cells, and studied their interactions with the constructs *in vitro* using cell culture (mRNA expression of inflammatory mediators and migration assays) and flow cytometry (particle interaction studies). Ultimately, the biodistribution and usability of the polymer-carbohydrate conjugates as nanotherapeutics were assessed *in vivo* in healthy C57BL/6J mice as well as in a model of acute liver injury based on carbon tetrachloride (CCl_4).
Results: The constructs bound with different intensities to distinct human primary cells *in vitro* as assessed using flow cytometry. P2 and P4, if added to macrophage cultures prior to treatment with lipopolysaccharides (LPS) led to a significantly increased expression of TNF *in vitro*, and P2 also significantly stimulated CCL2 production by human macrophages, compared to LPS alone. P3 significantly inhibited macrophage migration *in vitro*. In homeostasis, all constructs accumulated in hepatic macrophages, and P3 most clearly accumulated in liver. In CCl_4-based acute liver injury, P1 significantly increased whereas P3 significantly attenuated liver injury reflected by histology and transaminase levels. P4 exhibited no significant effects on liver injury.
Conclusions: Selectin-directed conjugates appear to exhibit a strong potential as immunomodulatory agents for the treatment of liver diseases based on their effects on macrophage migration and activation as evidenced *in vitro* and *in vivo*.

NATURAL KILLER AND NATURAL KILLER T CELLS FROM IMMUNE ACTIVE HEPATITIS B e ANTIGEN NEGATIVE PATIENTS EFFECTIVELY INDUCE APOPTOSIS AND SUPPRESS COLLAGEN PRODUCTION IN HEPATIC STELLATE CELLS
S.T.T. Le[1,2], D. Lourensz[1], F. Rusli[3], P. O'Neill[3], K. Visvanathan[2], W. Sievert[3]. *[1]Centre for Inflammatory Diseases, Monash University, [2]Innate Immune Laboratory, St Vincent's Hospital, [3]Gastroenterology and Hepatology, Monash Health, Melbourne, Australia*
E-mail: stle1@student.monash.edu

Background and Aims: Natural killer (NK) cells have been shown to attenuate hepatic fibrosis in transgenic HBV murine models. There is a paucity of data regarding the role of human NK and NKT cells in hepatitis B virus associated fibrogenesis. The aim of this study was to investigate the potential anti-fibrotic effects of human NK and or NKT cells from immune active HBV patients on HSC.
Methods: Immune active (IA) HBV was defined as ALT ≥5 ULN and Immune control (IC) was defined as normal ALT. Human NK (90–96% purity) and NKT cells (75–85% purity) were magnetically isolated from peripheral blood mononuclear cells and cultured with LX2 human hepatic stellate cells (HSC). NK and NKT cells were further phenotyped by Tim-3, NKG2A, NKG2D, NKp46, FasL and TRAIL expression. Induction of LX2 apoptosis was analysed by caspase-3 activation. Intracellular cytokine production (IFN-α and TNF-α) and CD107a degranulation were used to determine NK and NKT cell functional activity. HSC collagen production was determined by the Sircol assay.
Results: 15 patients were recruited: 6 IA HBV, 4 IC HBV and 5 healthy controls (HC) [serum ALT (IU/ml): 260.83±232 vs 24.25±8.93 and 24±5.42 respectively, $p = 0.007$]. Median HBV DNA viral load was higher in IA compared to IC (6.29 log10 IU/ml, IQR: 4.8–7.49 vs 2.26 log10 IU/ml, IQR: 1.73–2.88; $p = 0.019$). NK and NKT cells from IA HBV were significantly more effective in HSC apoptosis induction than similar cells from IC HBV or HC (16.15% ± 13.8 vs 5.17% ± 2.31 and 2.67% ± 0.85, respectively; $p < 0.0001$). HSC caspase-3 expression correlated with serum ALT [Spearman's rho (ρ) = 0.66, $p < 0.0001$], reduced proline incorporation ($\rho = -0.62$, $p < 0.0001$) and increased NKp46 expression on NK^{Bright} cells ($\rho = 0.56$, $p = 0.04$) and NKG2D expression on NKT cells ($\rho = 0.54$, $p = 0.03$). There was no significant difference in cytokine production, TRAIL or FasL expression.
Conclusions: NK and NKT cells from immune active HBeAg negative patients effectively induce HSC apoptosis, which is associated with reduced collagen production. NK and NKT cells may exert an anti-fibrotic effect during the immune active phase of CHB through upregulation of the activating receptors NKp46 and NKG2D.

P0495

PATHOLOGICAL LIVER CONDITIONS ABROGATE INTRAHEPATIC MYELOID CELL TOLERANCE TO BACTERIAL PRODUCTS

A. Tan-Garcia[1], A.T. Tanoto[1], J. Jo[2], M. Hong[1], A. Chia[1], K.C. Tan[3], K.H. Lee[3], C.-A. Dutertre[1], A. Bertoletti[1,4]. [1]*Program Emerging Infectious Diseases, Duke-NUS Graduate Medical School,* [2]*Program of Immunology, Danone Nutricia Early Life Nutrition,* [3]*Asian American Liver Centre, Gleneagles Hospital,* [4]*Singapore Institute of Clinical Sciences, A*STAR, singapore, Singapore*
E-mail: tgalfonso@gmail.com

Background and Aims: Despite their tolerogenic properties, intrahepatic myeloid cells (macrophages and monocyte-derived macrophages) are an important defensive barrier against bacteria dissemination and play a role in chronic liver injury. Whether this functional heterogeneity is altered by pathological liver conditions has not been analyzed in humans. We therefore studied the impact of pathological liver conditions on the composition and function of human liver-resident myeloid cells.
Methods: Intrahepatic myeloid cells were purified from cold perfusates of healthy (living donor liver transplants, n = 8) and pathological (HBV- or HCV-related cirrhosis n = 6) livers. Their phenotypic composition, immune gene profile and functional ability to produce pro-inflammatory, suppressive, antiviral and pro-angiogenic factors *ex vivo* and after activation with live bacteria and TLR agonists were analyzed.
Results: Despite a similar phenotypic composition, the immune gene profile of myeloid cells (CD14+) purified from healthy livers differs from that of the peripheral blood. We detected a constitutively low pro-inflammatory (IL-1b, IL-6, TNF-alpha, PLAU, PLAUR and PTGS2) immune gene expression in healthy intrahepatic myeloid cells compared to those in peripheral blood. Healthy intrahepatic myeloid cells trigger a robust antibacterial response (activation of MAIT and NK-bright cells through IL-12 and IL-18 production) when stimulated with whole bacteria and TLR-8 agonist (ssRNA40) but are hyporesponsive to TLR agonists (TLR-1/2, 2, 2/6, 4 and5) that mimic bacterial products. Pathological livers are instead enriched in (HLA-DRhi CX_3CR1hi) CD14+ CD16+ intermediate monocytes and contain myeloid cells which express a classical inflammatory gene profile producing high levels of pro-inflammatory cytokines (IL-1b, IL-6 and TNF-alpha), chemokines (CCL-3 and CCL-4) and angiogenic factors (VEGF) directly *ex vivo* and after activation with bacterial TLR ligands.
Conclusions: Pathological liver conditions shape the composition and function of intrahepatic myeloid cells. Myeloid cells from healthy human livers trigger an efficient immune response against whole bacteria but are tolerant to bacterial products. This functional profile is reversed in myeloid cells during pathological conditions. These results suggest that translocation of bacterial products from the gut can sustain liver inflammation in pathological livers.

P0496

IMPAIRED NEUTROPHIL FUNCTION CONTRIBUTES TO LIVER INJURY AND POSITIVELY CORRELATES WITH CLINICAL SEVERITY INDICES IN ACUTE-ON-CHRONIC LIVER FAILURE

A. Khanam[1], N. Trehanpati[1], P. Riese[2], A. Rastogi[1], C. Guzman[2], S.K. Sarin[1]. [1]*Institute of liver and biliary sciences, New Delhi, India;* [2]*Helmholtz Centre for Infection Research, Braunschweig, Germany*
E-mail: trehanpati@gmail.com

Background and Aims: Impaired neutrophil function has been demonstrated in acute liver failure and serves as a biomarker involved in organ dysfunction. However, its role in acute-on-chronic liver failure (ACLF) is not known. We assessed functional alterations of neutrophils associated with hepatic injury in 17 hepatitis B virus-related ACLF (HBV-ACLF), 19 alcohol-related ACLF (alcoholic-ACLF), and 42 chronic hepatitis B (CHB) patients in comparison to 18 healthy controls (HC).
Methods: Neutrophil phagocytic activity (NPA) was determined by uptake of opsonized *Escherichia coli* and reactive oxygen species (ROS) with or without *E. coli* stimulation. CXCR-1 and CXCR-2 expression was analyzed by flowcytometry, RT-PCR and immunohistochemistry. Role of neutrophils in hepatic injury was determined by co-culturing of LPS stimulated neutrophils or their supernatant with HepG2 cells.
Results: Neutrophils percentage and absolute neutrophil count (ANC) was significantly higher in both HBV and alcoholic-ACLF patients than CHB and HC. Importantly, ACLF patients having MELD score more than 30 had higher ANC ($p < 0.04$) than those with lower MELD score. In ACLF, NPA was highly impaired ($p < 0.02$, 0.007) and significantly associated with MELD ($p < 0.04$) and CTP score ($p < 0.007$). ROS was also increased ($p < 0.05$, 0.005) and showed positive correlation with inflammatory cytokines, IL-6 ($p < 0.05$), IL-17 ($p < 0.05$) and CXCL-8 ($p < 0.008$). Significant up-regulated CXCR-1 and 2 expressions were seen in ACLF; more so near necrotic areas of liver tissue revealing more infiltration of neutrophils on sites of injury in ACLF. CXCR-1 and 2 expressing neutrophils from ACLF patients significantly induced early apoptosis and necrosis of HepG2 cells by direct contact and cytokine/ROS dependent mechanisms. Further we also found higher gene expression of apoptosis (caspase-3 $p < 0.02$, 0.008) and necrosis marker (receptor interacting protein-3 $p < 0.008$, 0.003) in the liver of ACLF patients which may indicate neutrophil induced cell death in these patients. ACLF also had significant increased inflammatory cytokines (IL-6, IL-17, IL-23, CXCL-8, CCL-20 and GM-CSF).
*Shiv K. Sarin: Corresponding author
Conclusions: ACLF patients have increased neutrophils with high CXCR1/CXCR2. These neutrophils have impaired phagocytic activity with high ROS and pro-inflammatory cytokines propagating hepatic injury by necrosis/apoptosis which may further induce organ dysfunction. Neutrophil markers present a powerful tool for drug targets and clinical management of ACLF.

P0497

SECRETORY LEUKOCYTE PROTEASE INHIBITOR (SLPI) SUPPRESSES INNATE IMMUNE RESPONSES AND PROMOTES RESOLUTION OF INFLAMMATION IN AN AUTO/PARACRINE MANNER DURING ACUTE LIVER FAILURE (ALF)

E. Triantafyllou[1,2,3], E. Liaskou[3], W. Khamri[2], O.T. Pop[1], S. Davies[3], C. Bernsmeier[1], Z. Stamataki[3], R.D. Goldin[2], Y. Ma[1], A. Quaglia[1], M.R. Thursz[2], J. Wendon[1], S.M. Curbishley[3], C.J. Weston[3], D.H. Adams[3], C.G. Antoniades[1,2,3]. [1]*Institute of Liver Studies, King's College Hospital, King's College London,* [2]*Section of Hepatology, St Mary's Hospital, Imperial College London, London,* [3]*NIHR Biomedical Research Unit and Centre for Liver Research, University of Birmingham, Birmingham, United Kingdom*
E-mail: evangelos.triantafyllou@kcl.ac.uk

Background and Aims: Monocytes/macrophages (Mo/h-Mφ) orchestrate resolution responses during acute liver failure (ALF). We recently identified Secretory Leukocyte Protease Inhibitor (SLPI) as a pivotal mediator that suppresses NF-kB-dependent pro-inflammatory responses in ALF. Our aim was to determine the effects of SLPI on both innate immune and resolution responses in human ALF.
Methods: Immunophenotyping of Mo/h-Mφ from liver explants was performed by flow cytometry using a panel of 15 surface markers (n = 30). Immunohistochemistry/multispectral imaging analysis (# cells/high power field [HPF]) was used to examine the h-Mφ phenotype in ALF/control tissue (n = 10). Effects of recombinant human (rh)-SLPI (0.5 ug/ml) on Mo/h-Mφ, neutrophil and NK cell phenotype, function (LPS-stimulated cytokine secretion, uptake of apoptotic neutrophils/hepatocytes; n = 5) and migration across hepatic sinusoidal endothelial cells (HSECs) (n = 3), were examined using confocal microscopy, flow cytometry and ELISA.

Neutrophil survival and LPS-stimulated cytokine secretion were determined in culture with (rh)-SLPI and anti-SLPI neutralizing antibody in healthy control/ALF Mo-derived supernatants (n = 10).
Results: Compared to normal and cirrhotic liver tissue, h-Mφ in ALF exhibit a pro-resolution phenotype (HLA-DRlowCD163highMerTK++) [Fig. A], detected within areas of hepatic necrosis (34vs428 CD163+MerTK+ cells/10HPF; p = 0.0002). Whilst neutrophil and NK cell survival and pro-inflammatory cytokine secretion were not modulated directly by (rh)-SLPI administration, SLPI induced a pro-resolution phenotype in Mo/h-Mφ (CD163high MerTKhigh CCR5low) [Fig. B], which were functionally characterised by: (i) decreased pro-inflammatory cytokine secretion (TNF-α, IL-6, IL-8 and IFN-γ; all p < 0.05), (ii) reduced Mo recruitment across HSECs [Fig. C(i)] and (iii) enhanced uptake of apoptotic neutrophils and hepatocytes [Fig. D]. Importantly, neutrophils cultured in ALF Mo-derived supernatants [Fig. E] showed reduced survival (26.15% vs 21.3% apoptotic cells) and levels of pro-inflammatory cytokine production [TNF-a; 9.8% vs 14.2% cells], which was reversed by inhibiting the activity of SLPI (1 ug/ml a-SLPI).
Conclusions: We reveal that SLPI is a pivotal mediator of resolution responses in ALF through an autocrine negative feedback loop in addition to paracrine suppression of neutrophil survival and pro-inflammatory responses, thereby identifying a novel mechanism of innate immune suppression in ALF.

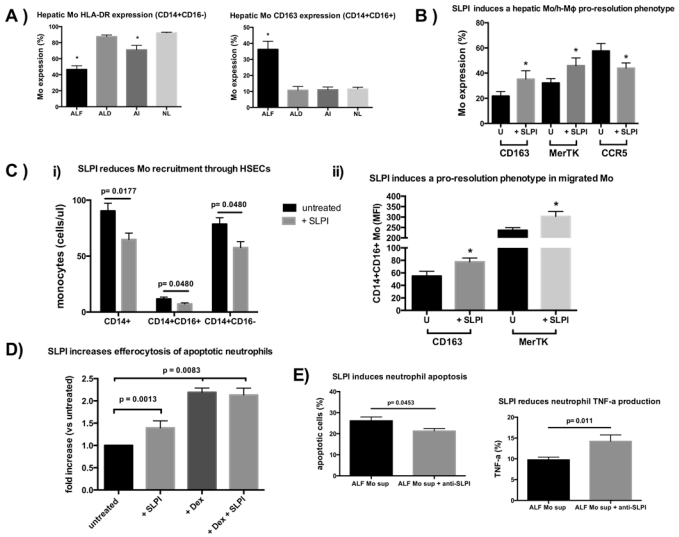

Figure: Secretory Leukocyte Protease Inhibitor (SLPI) suppresses innate immune responses and promotes resolution of inflammation in human acute liver failure (ALF). (A) *Ex vivo* HLA-DR and CD163 expression of hepatic Mo/h-Mφ [acute liver failure (ALF), alcoholic (ALD), auto immune (AI) liver disease and resections (NL)]. Effects of rh-SLPI (0.5 ug/ml) on: (B) hepatic Mo/h-Mφ phenotype (48 h), (C) monocyte migration through HSECs (i) number of migrated monocytes through HSECs/collagen and (ii) CD163 and MerTK migrated monocyte expression, (D) monocyte uptake (6 h) of apoptotic neutrophils after healthy monocyte culture with SLPI and 100nM dexamethasone (48 h). (E) neutrophil survival and TNF-a production of healthy neutrophils cultured in ALF plasma-treated monocyte supernatants +/− anti-SLPI neutralizing antibody (6 h). [*p < 0.05]

DEFINING TISSUE-RESIDENT CD8 T CELLS IN HUMAN LIVERS

A.T. Tan[1], J. Jo[2], X.-Z. Tang[3], E. Sandalova[2], A. Chia[1], K.C. Tan[4], K.H. Lee[4], A. Bertoletti[1]. *[1]DUKE-NUS Graduate Medical School, Singapore; [2]Nutricia Research, [3]Singapore Institute for Clinical Sciences, A*STAR, [4]Asian Unit for Liver Transplantation, Gleneagles Hospital, Singapore, Singapore*
E-mail: anthony.tan@duke-nus.edu.sg

Background and Aims: Tissue resident T cells that behave more like innate rather than classical adaptive effectors cells can provide a rapid immune response upon pathogen encounter, and have been observed in murine skin, lung and intestinal/vaginal mucosa. Our aim was to determine whether a liver resident T cell population with peculiar functional features exists in human livers.
Methods: We performed a comprehensive analysis of immune genes expression, phenotype and function of CD8 T cells obtained from the liver and blood of healthy human donors using Nanostring, flow cytometry and multiplex bead array respectively.
Results: CD8 T cells in the liver have a profile of human immunology gene expression that is distinctly different from their peripheral blood counterparts. They express lower levels of SELL (CD62L) and CCR7, and higher levels of ITGAL (CD11a) and CD69 than blood CD8 T cells, characteristic of tissue-resident memory T cells. Unlike the resting CD8 T cells found in the peripheral blood, these liver-resident CD8 T cells have a reduced TH1 cytokine production, but higher expression of mRNA coding for cytotoxic granules (granzyme B and perforin) upon TCR engagement. Furthermore, they express high levels of STAT4, comparable to that found in effector cells sensitive to cytokine-mediated activation.
Conclusions: We demonstrated the presence of CD8 T cells in human livers with phenotypical and functional features unique to the organ. Their ability to respond to defined cytokines is under investigation.

P0499

FUNCTIONAL ANALYSIS OF GENETIC VARIANTS OF TOLL-LIKE RECEPTOR (TLR) 9 AND INTEFERON REGULATORY FACTOR (IRF) 7 ASSOCIATED WITH THE NATURAL COURSE OF HCV INFECTION

J. Fischer[1], A.N. Weber[2], T. Berg[1]. *[1]Division of Gastroenterology and Hepatology, University Hospital Leipzig, Leipzig, [2]Department of Immunology, Interfaculty Institute for Cell Biology, University of Tübingen, Tübingen, Germany*
E-mail: janett.fischer@medizin.uni-leipzig.de

Background and Aims: Toll-like receptors (TLR) are the main components of the innate immune system and form the first defence line during hepatitis virus C (HCV) infection. The TLRs recognize specific motifs within the virus and trigger downstream via myeloid differentiation primary response gene 88 (MyD88)-dependent signalling cascades to activate the production of interferons, cytokines and chemokines. HCV RNA is usually detected by the intracellular TLR3 and TLR7. TLR9 seems to take part in HCV recognition, although viral RNA is no typical substrate of this receptor. Previously, we were able to show associations of polymorphisms (SNPs) within the promoter of the TLR9 gene and within the interferon regulatory factor (IRF) 7 gene with spontaneous viral clearance and with the severity of liver disease. In this study we investigated the functional impact of those SNPs on the signalling pathway in cell culture.
Methods: Reporter constructs of TLR9 gene (wild type, −1486/C and −1237T/C) and expression plasmids of IRF7 protein (wild type and K192E variant) were generated. The TLR9 plasmids were transfected in Nawalma R20 B-cell culture and the constitutive and stimulated TLR9 promoter activity was measured via the Dual-Luciferase reporter assay. Analysis of the interaction of the IRF7 plasmids with possible partners was performed via LUMIER method in HEK293T cells.

Results: In Nawalma R20 B-cells significant differences in basal promoter activity were observed between TLR9 wild type promoter and the genetic variants. The homozygous CC genotypes of the two SNPs showed higher activities (−1486T/C $p < 0.01$; −1237T/C $p < 0.001$) than the wild type. The presence of homozygous minor variants in both SNPs was associated with a significant reduction of promoter activity as compared to the activity observed in carriers of a single SNP. Stimulation of the TLR9 promoter with CpG ligands suppressed the activity independent of genotype. LUMIER analysis revealed significantly weaker binding of the IRF7 K192E variant with MyD88, IRAK1, TRAF6 and TBK1.
Conclusions: Variants of the TLR9 which are associated with spontaneous HCV clearance showed higher promoter activity and may contribute to enhanced induction of type 1 interferons and pro-inflammatory cytokines. In contrast, the IRF7 K192E variation may promote HCV chronicity due to an impaired binding to partners of the MyD88-depending signalling cascade.

HIV AND HEPATITIS DELTA – THE LAST CHALLENGE IN THE VIRAL HEPATITIDES?

K. Childs[1,2], I. Carey[1], J. Clough[1], S. Hughes[3], M. Bruce[4], A. Suddle[3], M. Nelson[5], C. Taylor[6], K. Agarwal[1]. *[1]Institute of Liver Studies, King's College Hospital, [2]King's College London, London, United Kingdom; [3]Institute of Liver Studies, King's College London, [4]Institute of Liver Studes, King's College Hospital, [5]Kobler Clinic, Chelsea and Westminster Hospital, [6]Dept of Sexual Health, King's College Hospital, London, United Kingdom*
E-mail: kate.childs@nhs.net

Background and Aims: Liver disease in HIV remains a significant clinical issue, predominantly related to BBV. Hepatitis Delta (HDV) is under-ascertained with little data on clinical outcomes. The aim of this cohort study was to compare the clinical outcomes of HDV in HIV-positive HDV with HIV-negative HDV in an ethnically diverse South London environment.
Methods: Retrospective data on pts who had a positive HDV total Ab test (HDV IgG) from Jan 2000 to Aug 2014 were collated. Pts referred for transplant assessment or HCC were excluded as not part of our natural cohort. A cohort of HIV-positive HDV pts from another London HIV centre were included.
Results: 241 pts had positive HDV Ab. 50 were excluded from the analysis as they were tertiary referrals. Of the 191 remaining pts, 17 were HIV positive, 112 HIV negative, 62 HIV status not documented. 90 patients had cleared HDV at the time diagnosis. This was defined by HDV IgM and RNA negativity or only HDV IgM negative alone if pre 2009. 4/17 HIV-positive pts cleared HDV at baseline, 66/112 HIV-negative pts cleared HDV at baseline ($p = 0.009$). 8 pts with HIV-positive HDV from another clinic were included. 2 had evidence of active HDV infection, giving a total of 15 HIV-positive pts with active HDV.
The analysis focuses on the 15 HIV-positive HDV pts and the 46 HIV-negative HDV pts. HIV-positive patients were 80% male, 53% black African, HIV-negative pts were 59% male, 58% black African.
The first available median HDV RNA levels were higher in HIV-positives, 8.3E5 cps/ml (6.6E5–9E6) compared to 2.3E4 (1.9E3–6.8E5) in HIV-negatives ($p = 0.04$).
Of HIV-positive HDV pts, 4/17 were treated with peg-interferon, 1 cleared HDV after 2× therapy, 2 relapsed, 1 discontinued treatment and was lost to FU. Of HIV-negative HDV pts, 15 were treated, 8 cleared HDV, 4 non response, 2 relapsed, 1 stopped.
8/15 HIV-positive HDV pts had cirrhosis at diagnosis vs 6/46 HIV-negative HDV pts ($p = 0.003$). Of the 8/15 HIV-positive HDV cirrhotic pts, 2 died of liver causes, 2 decompensated, 2 were lost to FU. Of the 6/46 HIV-negative HDV cirrhotic pts, there was 1 decompensation and 2 liver deaths. Using a composite endpoint of death, decompensation and cirrhosis, HIV was the only factor associated in univariate analysis ($p = 0.002$); age, risk factor, HDV RNA level and AST were not. With a composite endpoint of death or decompensation, HIV, risk factors and age were all significant but in the final model, only HIV status was predictive ($p = 0.006$).
Conclusions: Compared to HIV-negative HDV pts, those with HIV-positive HDV infection were less likely to spontaneously clear HDV. Patients with HIV-positive HDV suffered significant morbidity and mortality. Better ascertainment and therapies for HDV are urgently needed.

P0501

REDUCED T CELL ACTIVATION, REGULATORY T CELL MEDIATED SUPPRESSION AND COMPROMISED NATURAL KILLER CELL FUNCTION CHARACTERIZE IMMUNE TOLERANT PHASE OF CHRONIC HBV INFECTION

M. Nandi[1], S. Pal[1], G. Ray[2], K. Das[1], S. Ghosh[1], S. Banerjee[1], A. Santra[1], A. Chowdhury[1], S. Datta[1]. *[1]Department of Hepatology and Centre for Liver Research, School of Digestive & Liver Diseases, [2]Department of Pediatric Gastroenterology, School of Digestive & Liver Diseases, Institute of Post Graduate Medical Education and Research, Kolkata, India*
E-mail: madhuparna1986@gmail.com

Background and Aims: Chronic HBV infection (CHI) acquired perinatally or early in life and typified by HBeAg positivity, high viral replication, but normal serum aminotransferases and minimal/no liver inflammation represent the Immune-tolerant (IT) phase of CHI. We investigated potential roles of various arms of host immune system that contribute towards immune tolerance as compared to their functions during chronic Immune-active hepatitis (IA).
Methods: Phenotype and function of $CD8^+$T cell, natural killer (NK) cells and classical regulatory T (Treg) cells was evaluated using standard flow cytometric assays in IT and IA patients and healthy controls.
Results: T cells were similar in percentages in IT and IA but varied significantly in phenotype and function. IT, unlike IA, had significantly higher $CD28^+$T cells but lower PD-1^+T cells denoting absence of T cell exhaustion. While a large fraction of circulating T cells from IT expressed CD69, suggestive of early immune activation, significantly lower numbers of T cells expressing late activation marker HLADR was noted that depict ineffectively primed and inconsistent T cell response. Hence, T cells in IT although transiently activated could not maintain sustained activation status, consequently delaying viral clearance and simultaneously restraining tissue damage. Moreover, memory $CD45RO^+$T cells were greatly decreased in IT that may negatively impact recall response on antigen reencounter. However, upon invitro stimulation, global and HBV specific T cells of IT, retained greater potential to produce IL-2 and IFN-γ suggesting that T cells in IT are capable of mounting antiviral response following adequate stimulation. Conversely, NK cells were quantitatively and qualitatively defective in IT with significantly lower incidence of NK cells expressing NKG2C, NKp44, TRAIL, Perforin, CD107a as well as IFN-γ. Surprisingly, both groups displayed comparable Treg suppressive potential as appraised by similar expression pattern of CTLA-4, CD39, FOXP3, TGF-β and IL-10. Thus reduced ability of NK cells to release IFN-γ and enhanced IL-10 secretion by Treg cells seems to hinder prolonged T cell activation in IT.
Conclusions: Collectively, our data imply that lesser magnitude of T cell activation, smaller memory T cell pool along with enhanced Treg activity and compromised NK cell function limit immunological reactivity to high levels of HBV during IT phase.

P0502

RECOMBINANT NEUROLIGIN 4 (NLG4) ACTIVATES NK CELLS AND ATTENUATES FIBROGENESIS IN NONALCOHOLIC FATTY LIVER DISEASE

J. Amer[1], A. Salhab[1], R. Safadi[1]. [1]*Liver & Gastroenterology Units, Hadassah Hebrew University Medical Center, Jerusalem, Israel*
E-mail: johnnyamer@hotmail.com

Background and Aims: Among the anti-fibrotic responses NK cells induce hepatic stellate cell (HSCs) apoptosis (J Hep 2004). NK cell lose their killing effects in advanced fibrosis and cirrhosis (Gut 2011). NK cells from nonalcoholic fatty liver disease (NAFLD) patients exert high expressions of neuroligin-4 receptors (NLG4) and are thought to interfere with NK functionality (AASLD 2011 and EASL 2013). NLG4 receptor immune synapse interactions with its ligand β-neuroxin (cell-adhesion molecules) are thought to play an important step in fibrogenesis. We aimed to develop NK activation tool to ehance anti-fibrotic effects via NLG4 pathway in an *in vitro* co-culture condition.
Methods: NK cells isolated form peripheral blood of NAFLD patients lacking metabolic syndrome were incubated with 10 nM of recombinant NLG4 for 3 hours prior to incubations with HSCs; LX2- cell line. Following 24 hours, cells were trypsinized and analyzed by flow-cytometry for NK activity by CD107a [Lysosomal-associated membrane protein 1 (LAMP1) – degranulation marker – a marker for NK activation] and LX2 activities (a-smooth-muscle intensities). Interleukin-4 (IL4) quantity expressions were also assessed in NK cells.
Results: LX2 cell line express 75% of β-neuroxin. In co-cultures, recombinant NLG4 significantly increased lysosomal-associated membrane protein-1 (CD107a, NK activation marker) from 10% to 48% ($P < 0.01$). Compared to LX2 mono-cultures, elevations of NK cells CD107a activity was associated with increased LX2 killing; as aSMA mean fluorescence intensities of HSCs decreased from 3938 in cultures without the recombinant to 2432 with the recombinant ($P < 0.01$). NK cells pre-treated with the recombinant NLG4 showed decreased in IL-4 secretions by the flow cytometry technique (1.8-folds, $P = 0.02$).
Conclusions: NLG4-β-neurexin recognition mediates HSCs-NK immune synapse to control release of NK vesicles. Recombinant NLG4 activates NK cells to promote anti-fibrotic effects through increased HSCs killing. These effects were associated with decreased expression of the pro-fibrogenic marker IL4 in the NAFLD NK cells. NLG4 immune modulation of CD107a activity of NK cells extends the understandment and therapeutic strategies in fatty liver disease.

DENDRITIC CELL SUBSETS AND EXPRESSION OF DC-SIGN IN PROGRESSION OF HEPATITIS B INFECTION FROM ACUTE TO CHRONIC INFECTION: A NOVEL INSIGHT THROUGH TLRS AND RELATED INTRACELLULAR SIGNALLING MOLECULES

S. Sukriti[1], N. Trehanpati[1], M. Kumar[1], S. Hissar[1], S.K. Sarin[1].
[1]*Research, Institute of Liver and Biliary Sciences, New Delhi, India*
E-mail: shivsarin@gmail.com

Background and Aims: DC-specific intercellular adhesion molecule 3-grabbing nonintegrin (DCSIGN) and Toll-like receptors (TLRs) which are pathogen recognition receptors (PRRs), present on Dendritic cells (DC) to promote pathogen recognition, uptake and presentation of antigen and potentiates the interaction with T cells. We hypothesize, insufficient generation of immune surveillance in chronic hepatitis B might be because of impairment of frequencies and functional ability of DC's and PRR's. We aimed to monitor temporal changes in DC's during acute phase in comparison to chronic hepatitis B infection.
Methods: Twenty-eight subjects were included; acute viral hepatitis B (AVH-B, n = 8) were serially followed up; chronic hepatitis B (CHB, n = 10) and healthy controls (HC, n = 10). PBMCs were immunostained before and after stimulating with polyI:C, CpGODN and LPS with flourochrome labelled antibodies. The frequency of myeloid DC's (mDC) (CD11c+, BDCA1+), plasmacytoid DC's (pDC's) (CD123+, BDCA1+), intracellular IFN-γ production and expression of DCSIGN, TLR2,3,4 and TLR9 was evaluated. mRNA levels of adaptor molecules of TLR pathway; Myd88, TRAF6 and cytokines IL-2, IL-6, TNF-α, IFN-α was measured by RT-PCR.
Results: Frequencies of both subsets of DC's i.e. mDC's and pDC's, were found significantly higher in acute and naïve chronic HBV patients than healthy controls ($p < 0.00$, $p < 0.01$) but no difference among AVH-B vs CHB. Functionally impaired DC's were seen with significant low IFN-γ production and low DCSIGN expression ($p < 0.04$, 0.00) in CHB patients. Even after stimulations by TLR agonist, no changes were found. The adaptor molecule of TLR's, the MyD88 mRNA levels were also downregulated along with the cytokines IL-6, IFN-α. On follow-up of AVH-B patients, found temporal changes in DC's while mDC's frequency was significantly highest at wk 4, whereas pDC's at wk 6, than wk0 ($p < 0.02$, 0.01) along with the DCSIGN on mDC's expression increased linearly from wk 0 to wk 4 during acute phase (wk 0 28% to wk 4 72%, $p < 0.00$).
Conclusions: (i) Subsets of dendritic cells are phenotypically intact but functionally impaired in CHB compared to seroconverted AVH-B patients. (ii) During acute phase pDC's comes late in generation of effective immune response. (iii) DC SIGN expression is temporally increased in acute phase HBV infection, while is significantly low in CHB, indicating its key role in persistent infection. These novel observations would pave way for prognostication and development of antiviral strategies for chronic HBV infection.

	mDC	pDC	IFN-Y
HC	12.2	11.9	11.2
AVHB	30.5	32.8	40.1
CHB	28.7	33.5	26.5

Figure 1. INF-γ production was significantly low in persistent CHB patients. No significant difference was found in frequency of mDC's and pDC's in acute and chronic HBV infection.

P0504

DE NOVO NUCLEOTIDE BIOSYNTHESIS PATHWAY TIGHTLY REGULATES HEPATITIS E VIRUS INFECTION

Y. Wang[1], W. Wang[1], X. Zhou[1], D. Sprengers[1], M.J. Herold[1], M.P. Peppelenbosch[1], Q. Pan[1]. [1]*Department of Gastroenterology and Hepatology, Erasmus MC-University Medical Center, Rotterdam, Netherlands*
E-mail: y.wang.2@erasmusmc.nl

Background and Aims: Despite an emerging global health issue, no approved drug is available for treating hepatitis E virus (HEV) infection. Since nucleotides are key components involved in host cell metabolism and virus infection, inhibitors of nucleotide synthesis enzymes may be potential drugs against HEV. Biosynthesis of purine nucleotides requires guanosine, which can

be phosphorylated into GMP, GDP and GTP. Pyrimidine nucleotides synthesis requires uridine, which can be catalyzed into UDP and UTP. We thus investigated the effects and mechanism-of-action of targeting de novo nucleotide synthesis in cell culture models of HEV infection.

Methods: A subgenomic HEV replication model expressing luciferase reporter gene and a full-length infectious model were used.

Results: Supplementation of exogenous guanosine, but not uridine, promoted HEV replication in both subgenomic (2.6-fold) and infectious (2.0-fold) models. We thus focused on sequentially targeting key enzymes involved in purine synthesis pathway. Surprisingly, 6-thiohuanine, an inhibitor of Amido phosphoribosyltransferase (APRTase), stimulated HEV replication by 3.6±0.87 folds (Mean±SEM, n = 10, P < 0.0001). Lometrexol, an inhibitor of GAR Transformylase, also promoted HEV replication in both models. ATIC is a bifunctional protein that exerts AICAR transformylase activity and IMP cyclohydrolase activity in this pathway. Methotrexate (MTX) and Fludarabine (FA) are inhibitors of AICAR transformylase and IMP cyclohydrolase, respectively. Both compounds potently increased HEV genome RNA by 5.01±1.4-fold and 5.06±0.3-fold, respectively (n = 5, P < 0.05). Consistently, silencing of ATIC resulted in dramatic increase of HEV RNA by 4.2±2.5-fold and abolished the ability of MTX to activate HEV. This demonstrated that ATIC has anti-HEV activity, which explains the proviral effects of MTX and FA. However, Mycophenolic acid (MPA), an inhibitor of inosine monophosphate dehydrogenase (IMPDH), could effectively inhibit HEV replication by 65% (10 ug/ml).

Conclusions: Purine but not pyrimidine synthesis pathway regulates HEV infection. Unexpectedly, targeting the early steps of this pathway led to enhancement of HEV infection. Whereas targeting the late step (IMPDH enzyme) resulted in potent antiviral activity against HEV.

IDENTIFICATION OF IL-17 POSITIVE INTRAHEPATIC NK CELLS IN HUMAN LIVER AND RELATIONSHIP WITH CHRONIC LIVER DISEASES

Z. Macek Jilkova[1,2], H. Marche[1,2], C. Gierczak[2], V. Leroy[1,2,3], J.-P. Zarski[1,2,3], T. Decaens[1,2,3], P.N. Marche[1,2], N. Sturm[1,2,4], E. Jouvin-Marche[1,2]. *[1]INSERM U823, [2]Univ. Grenoble Alpes, IAB, [3]Département d'Hépato-Gastro-Entérologie, [4]Département d'Anatomie et de Cytologie Pathologiques, CHU-Grenoble, Grenoble, France*
E-mail: zuzana.mjilkova@gmail.com

Background and Aims: The production of pro-inflammatory IL-17 cytokine plays an important role in many inflammatory diseases and is not restricted to Th17 cells. However, in liver diseases, it has not yet been investigated if intrahepatic (IH)-natural killer (NK) cells, the major subset of innate immune cells, produce IL-17 and thereby contribute to liver inflammation.

Methods: To analyze production of IL-17 by IH-immune cells, we performed flow cytometry analyses of fresh liver biopsies from 54 patients: NASH, HCV and HBV-infected and non-inflammatory subjects. Localization of IL-17$^+$ NK cells was studied by double immunohistochemical and triple immunofluorescence analyses. Frequency of IL-17 producing NK cell was compared with INFγ production and correlated with clinical parameters.

Results: Flow cytometry analyses revealed that, in addition to T lymphocytes, IH-NK and IH-NKT cells produced IL-17 cytokine with frequency from 0.1% to 6.0%, depending on liver environment. The population of IL-17$^+$IH-NK cells was significantly higher compared to IFNγ producing IH-NK cells (p = 0.009) and mainly specific to the NKp46$^+$ NK cells subset (p < 0.001). Immunohistology of livers showed that 85% of IL-17$^+$NKp46$^+$ IH-NK cells were localized in septal or portal fibrous area. Finally, the proportion of IH-NK cells producing IL-17 increased during the critical A2 Metavir necro-inflammatory grade, suggesting a specific role of IL-17$^+$ IH-NK cells in the development of liver inflammation.

Conclusions: Our study provides evidence that in human liver, NK cells produce IL-17$^+$ and thus play an active role in shaping the local inflammatory response, in addition of their cytotoxic and regulatory functions.

P0506

IMPAIRED HCV-SPECIFIC CYTOTOXIC T CELL REACTIVITY DUE TO 4-1BB SIGNALLING ADAPTER (TRAF1) DOWN-REGULATION DURING PERSISTENT HCV INFECTION IS RESTORED BY IL-7 PLUS 4-1BBL TREATMENT

E. Moreno-Cubero[1], E. Sanz-de-Villalobos[1], J. Míquel[1], R. Borobia[1], S. García-Garzón[1], A. Lázaro[1], A. González-Pretorious[1], C. Perna[1], M. Torralba[1], T. Hocine[1], J.R. Larrubia[1]. *[1]Translational Hepatology Unit, Guadalajara University Hospital. University of Alcalá, Guadalajara, Spain*
E-mail: elia.morenocubero@gmail.com

Background and Aims: During persistent hepatitis C virus (HCV) infection, HCV-specific cytotoxic T cell (CTL) response is impaired and featured by IL-7 receptor (CD127) down-regulation. IL-7 could impact on T cell reactivity by regulating 4-1BB signalling adapter (TRAF1). In this study, TRAF-1 expression on HCV-specific CTL according to viral control and, the role of IL-7 on TRAF-1/4-1BB signalling and CTL reactivity were addressed.

Methods: Peripheral blood mononuclear cells (PBMC) from 6 healthy donors (HD), 12 HLA-A2$^+$ genotype-1 HCV$^+$ sustained viral responders after treatment (SVR) and 16 HLA-A2$^+$ chronic naïve genotype-1 HCV$^+$ (CHC) patients were obtained. In HD, TRAF1 expression on CD8$^+$ cells according to CD45RO/CCR7 phenotype was tested after either αCD3/αCD28 or IL-7 stimulation. On HCV-specific CTLs from SVR and CHC, directly *ex-vivo* TRAF1/CD127 expression was tested and proliferation ability and TRAF1 level after specific stimulation without any treatment and in presence of IL-7 and/or 4-1BBL was checked. HCV-specific CTLs were visualised by staining with labelled HLA-A2/epitope multimeric complexes (Pentamer) and CD8 mAb. TRAF1/CD45RO/CCR7/CD127 labelling was performed by staining with different mAb. Flow-cytometric analysis was carried-out.

Results: On total CD8$^+$ cells from HD, TRAF1 expression was significantly higher on naïve and central memory T cells than in RA and RO effector memory T cells after αCD3/αCD28 *in-vitro* challenge (p < 0.05). Interestingly, IL-7 *in-vitro* treatment increased TRAF1 expression on all CD8 populations (p < 0.05). HCV-specific CTLs (CD8$^+$/Pentamer$^+$) from CHC showed lower CD127 and TRAF1 expression than in SVR (p < 0.01 and p < 0.05, respectively). A positive correlation between CD127 and TRAF1 on CD8$^+$/Pentamer$^+$ cells was observed (r = 0.7, p < 0.05). HCV-specific CTL proliferation after specific *in-vitro* challenge was lower in CHC than in SVR (p < 0.05). Specific *in-vitro* simulation in presence of IL-7/4-1BBL improved HCV-specific CTL proliferation ability in CHC, showing a similar post-treatment TRAF1 expression than SVR, while treatment with either IL-7 or 4-1BBL alone induced a lower effect (p < 0.05).

Conclusions: TRAF1 expression is down-regulated on exhausted T cells but IL-7 can induce its up-regulation. In CHC, there is a TRAF1/CD127 down-regulation associated to low reactivity on HCV-specific CTLs. IL-7/4-1BBL treatment can improve HCV-specific CTL response in CHC by TRAF1/4-1BB signalling enhancement.

Non-invasive markers of liver fibrosis

P0507
EFFECTS OF VITAMIN D SUPPLEMENTATION ON LIVER STIFFNESS IN PATIENTS WITH CHRONIC LIVER DISEASES

A. König[1], C.S. Stokes[1], M. Krawczyk[1], F. Lammert[1], F. Grünhage[1].
[1]*Medical Department II, Saarland University Hospital, Homburg, Homburg, Germany*
E-mail: frank.gruenhage@uks.eu

Background and Aims: Vitamin D deficiency is common in patients with chronic liver diseases (CLD) and unfavorable genetic polymorphisms of genes controlling vitamin D metabolism have been associated with increased liver stiffness in patients with CLD (Grünhage et al. Hepatology 2012; 56: 1883–91). No data on the effect of vitamin D supplementation on liver stiffness is available. Our aim was to analyse patients with CLD with respect to vitamin D and liver phenotypes.
Methods: Patients were randomly retrieved in our hospital data management system and included if they fulfilled the characteristics of at least one of the following groups. Group 1 consists of patients with vitamin D deficiency (<20 ng/ml) who received vitamin D supplements; group 2 was defined as patients with deficiency who did not receive any supplementation, and group 3 comprised patients without vitamin D deficiency (vitamin D levels >20 ng/ml). Patient characteristics such as age, gender, etiology of liver disease as well as baseline parameters (liver stiffness, AST, ALT, GGT) and follow-up parameters were analysed in pairwise comparisons.
Results: We included 100 patients in groups 1 and 2 but we were only able to identify 33 patients with CLD who presented with normal vitamin D levels without supplementation, reflecting the increased incidence of vitamin D deficiency in this population. In all three groups, patients with chronic hepatitis C virus infection represented the largest subgroup (41%, 55%, 64%). The supplementation of vitamin D for at least 6 months resulted in a significant rise of vitamin D levels in group 1 (10.6±5.2 vs 32.9±14.8). Interestingly, these patients also presented with a significant decrease in median liver stiffness (16.0±19.9 kPa vs. 12.9±11.7 kPa; $P = 0.02$), while no significant changes were detected in pairwise comparisons in groups 2 and 3 (both $P > 0.05$). Interestingly, ALT declined significantly in patients with supplementation (66±74 U/L vs. 49±41 U/L, $P = 0.01$), but also in patients of group 2 (67±80 U/L vs. 49±49 U/L; $P = 0.03$) but patients without vitamin D deficiency and without supplementation showed no change ($P > 0.05$).
Conclusions: Our data indicate that vitamin D supplementation might have an influence on liver stiffness in patients with CLD independent from improvement of liver function tests, consistent with our findings in preclinical models (Hochrath et al. 2014). Prospective trials are mandatory to assess the therapeutic potential of vitamin D in patients with chronic liver diseases.

P0508
BIOPSY FINDINGS, ACE LEVELS AND APRI ARE SIMILAR IN PATIENTS WITH SARCOIDOSIS WITH AND WITHOUT PORTAL HYPERTENSION

B. John[1], S. Nagpal[1], T. Plesec[1], R. Jegadeesan[1], R. Lopez[1], N. Alkhouri[1], K. Highland[1], D. Culver[1]. [1]*Cleveland Clinic, Cleveland, United States*
E-mail: johnb@ccf.org

Background and Aims: *Background:* Sarcoidosis of the liver is a cause of portal hypertension both in the in the presence of cirrhosis as well as its absence (pre-sinusoidal portal hypertension). There are no prospective studies evaluating portal hypertension in hepatic sarcoidosis and its correlation with histology and non-invasive markers of fibrosis.
Methods: We prospectively evaluated 21 consecutive patients with hepatic sarcoidosis seen at the Cleveland clinic referral center for sarcoidosis. All patients were evaluated for portal hypertension by imaging as well as percutaneous or trans-jugular liver biopsies. Biopsies were scored blindly by a single liver pathologist. Various non-invasive markers of portal hypertension were evaluated.
Results: Twenty-nine percent (n = 6) of subjects had evidence of portal hypertension (2 had intrahepatic collaterals and 4 had pressure gradient >5 mmHg), four of whom had non-cirrhotic portal hypertension. There was no difference in liver enzymes, Angiotensin Converting Enzyme (ACE) levels or AST to Platelet ratio (APRI) between patients with and without portal hypertension.
Conclusions: In a prospective study of patients with hepatic sarcoidosis, 21% had evidence of portal hypertension and 14% had non-cirrhotic portal hypertension. There was no difference in liver enzyme abnormalities, ACE levels or APRI between patients with and without portal hypertension.

P0509
DIAGNOSTIC AND PROGNOSTIC STAGINGS ARE IMPROVED BY MULTI-TARGETING BIOMARKERS. APPLICATION TO LIVER FIBROSIS TESTS

P. Cales[1], S. Bertrais[1], J. Boursier[1], F. Oberti[1], V. Moal[2], I. Fouchard Hubert[1], G. Hunault[3], M.C. Rousselet[4], and multicentric groups (SNIFF 12 17, ANRS HC 23). [1]*Hepatology,* [2]*Biochemistry, CHU,* [3]*HIFIH laboratory, University,* [4]*Pathology, CHU, Angers, France*
E-mail: paul.cales@univ-angers.fr

Background and Aims: Construction of diagnostic tests is usually limited by a unique diagnostic target, e.g. significant liver fibrosis in chronic liver diseases. Our aim was to improve diagnostic accuracy of diagnostic tests by simultaneously targeting biomarkers for different diagnostic targets in the context of liver fibrosis tests.
Methods: A total of 3247 patients were included: 1688 patients with chronic hepatitis C in two diagnostic populations with Metavir fibrosis stages (F) on liver biopsy as reference, and 1559 patients with miscellaneous chronic liver diseases with prognostic outcome (liver related death) as reference. We tested 12 biomarkers provided by different published single-targeted blood tests. Construction of new multi-targeted test included the four following steps: classical construction of four single-targeted tests corresponding to four Metavir targets; three single-targeted tests were independent predictors of fibrosis level; fibrosis classifications were then derived from the three test scores; test classifications were segmented and the three most accurate parts were aggregated in a new unique classification of a multi-targeted test called MFM.
Results: In the derivation diagnostic population, the accuracy of multi-targeted MFM test classification was (predominant/minority F stage): F0/1: 96.0%, F1/2: 85.7%, F1/2/3: 95.7%, F2/3/4: 86.6%, F3/4: 86.3%, F4: 96.0%. The overall accuracy of MFM test classification was 92.7% vs. 87.6% for reference published single-targeted test ($p < 0.001$). MFM sensitivity for cirrhosis of the 3 classes including F4 was 91.3% and MFM positive predictive value for cirrhosis of F4 class was 96.0%. In the validation diagnostic population, overall diagnostic accuracy of MFM test was 88.2% vs. 83.6% for published single-targeted test ($p < 0.001$). In the prognostic population, multi-targeted MFM classification well predicted liver related death (log rank test for Kaplan–Meier plots: $p < 10^{-5}$), especially better between early (F3/4) and definitive cirrhosis (F4, $p = 0.0003$) than with published single-targeted test ($p = 0.0034$).
Conclusions: The classical way to construct a diagnostic test can be significantly improved by multi-targeting biomarkers. Applied to

fibrosis tests, this improves accuracy – up to 93% – and prognostic discrimination especially between early and definitive cirrhosis.

P0510

DIRECT COMPARISONS OF FIBROTEST, APRI, FIB-4, AND TRANSIENT ELASTOGRAPHY (TE) FOR THE DIAGNOSIS OF CIRRHOSIS AND FIBROSIS, IN PATIENTS WITH CHRONIC HEPATITIS C (CHC) AND B (CHB) USING INTENTION TO DIAGNOSE AND BAYESIAN METHODS. A SYSTEMATIC REVIEW

M. Houot[1], Y. Ngo[1], M. Munteanu[1], S. Marque[2], T. Poynard[3].
[1]*BioPredictive,* [2]*Capionis,* [3]*APHP, Paris, France*
E-mail: tpoynard@teaser.fr

Background and Aims: The diagnostic performances of non-invasive tests for the diagnosis of cirrhosis (F4) or clinically significant fibrosis (METAVIR stages F2F3F4) in chronic liver disease (CLD) have been assessed using indirect comparisons and "per-protocol" (PP) analysis, that is, without taking into account the applicability (failure or non reliability) of tests, ["intention-to-diagnose" (ITD)]. As for drugs, indirect comparisons between tests are limited by the spectrum effect and PP analysis by applicability effect. The aim was to compare the performance of the four most validated tests (FibroTest, TE, APRI and FIB-4) in patients with chronic liver diseases using only direct comparison, ITD and Bayesian methods.
Methods: Direct comparisons using biopsy as reference were searched (MEDLINE) from 2001 to 2014; four methods were used for AUROCs' difference (AUC-D) in ITD: the descriptive AUC-D (Chou 2013), pooled indirect AUC-D, pooled direct AUC-D and pooled direct Bayesian AUC-D (BayesAUC-D).
Results: Among 1279 biomarker studies identified, 71 studies with 77 groups of patients were included (37 with CHC only, 28 CHB only, and 12 "MixedCB" defined as CHC-CHB >49% of CLD) allowing 185 direct comparisons between the 4 tests' AUROCs; 99 for F2F3F4 (12,725 patients) and 86 for F4 (10,929 patients). The significant (credibility interval) BayesAUC-D were 0.06 in favor of FibroTest vs TE and 0.05 vs APRI; for cirrhosis BayesAUC-D were 0.07 in favor of TE vs APRI and 0.04 for FIB4 vs APRI. Non-applicability rate (median/range) was 0% (0–8%) for FibroTest lower ($P < 0.0001$) than for TE 8% (0–41.8); APRI and FIB4 have no rules for applicability.

Table: Fibrosis biomarkers' performances in CHC and CHB, assessed by direct comparisons, intention to diagnose and Bayesian methods

Stage of fibrosis	Test A	Test B	Studies n	Median AUROC A/B	Descriptive ADC Median difference (range)	Pooled Bayesian AUROC difference [$CI_{95\%}$]	Bayesian Credible Conclusion
F2F3F4	FibroTest	TE	15	0.79/0.77	0.04 (−0.10; 0.14)	0.06 [0.02; 0.09]	FibroTest > TE
	FibroTest	APRI	21	0.80/0.73	0.05 (−0.06; 0.18)	0.05 [0.03; 0.07]	FibroTest > APRI
	FibroTest	FIB-4	5	0.79/0.74	0.03 (−0.01; 0.08)	0.02 [−0.05; 0.10]	
	TE	APRI	17	0.82/0.78	0.01 (−0.14; 0.25)	0.04 [0.00; 0.09]	
	TE	FIB-4	6	0.81/0.74	0.04 (−0.13; 0.15)	0.03 [−0.08; 0.15]	
	APRI	FIB-4	35	0.74/0.75	−0.01 (−0.13; 0.10)	−0.01 [−0.03; 0.01]	
F4	FibroTest	TE	13	0.85/0.83	0.01 (−0.18; 0.07)	0.00 [−0.04; 0.04]	
	FibroTest	APRI	14	0.83/0.78	0.08 (−0.13; 0.35)	0.05 [0.00; 0.11]	
	FibroTest	FIB-4	6	0.83/0.81	0.05 (−0.03; 0.11)	0.05 [−0.03; 0.12]	
	TE	APRI	18	0.87/0.81	0.08 (−0.07; 0.37)	0.07 [0.02; 0.13]	TE > APRI
	TE	FIB-4	7	0.87/0.77	0.13 (−0.01; 0.25)	0.12 [0.00; 0.24]	
	APRI	FIB-4	28	0.78/0.82	−0.04 (−0.24; 0.10)	−0.04 [−0.05; −0.02]	FIB4 > APRI

Conclusions: This overview, the first focusing on direct comparisons in ITD and using Bayesian meta-analysis, permitted to compare fibrosis biomarkers without the limitations of meta-analyses not taking into account the tests' applicability, and of indirect comparisons. FibroTest had better performance than TE for the diagnosis of F2F3F4, in CHC and CHB, which was not observed by indirect and per-protocol previous meta-analyses.

P0511

DIRECT COMPARISON OF 3 ELASTROMETRY DEVICES (FIBROSCAN, ACOUSTIC RADIATION FORCE IMPULSE, SUPERSONIC SHEARWAVE IMAGING) FOR THE NON-INVASIVE DIAGNOSIS OF LIVER FIBROSIS IN CHRONIC LIVER DISEASES

J. Boursier[1], V. Cartier[1], J. Lebigot[1], F. Oberti[1], I. Fouchard-Hubert[1], S. Bertrais[1], P. Cales[1], C. Aube[1]. [1]*University Hospital, Angers, France*
E-mail: JeBoursier@chu-angers.fr

Background and Aims: Liver stiffness measurement using elastography allows for a non-invasive diagnosis of liver fibrosis with immediate results at bedside. The first elastography device developed was Fibroscan (FS) using transient elastography with mechanical impulse on the skin. Then, acoustic-based elastographic methods, Acoustic Radiation Force Impulse (ARFI) and more recently Supersonic Shearwave Imaging (SSI), have been developed using ultrasound pulses. We aimed to evaluate and compare the feasibility and the diagnostic accuracy of FS, ARFI, and SSI for the non-invasive diagnosis of liver fibrosis.
Methods: 192 patients with chronic liver disease, liver biopsy, FS, ARFI and SSI were included. Metavir F staging on biopsy was taken as the reference for liver fibrosis. Result for each elastographic device was the median of 10 valid measurements. Diagnostic cut-offs were calculated to maximize the sum of sensitivity + specificity.
Results: Cause of chronic liver disease was NAFLD in 55.7% of cases, viral hepatitis: 16.1%, alcohol: 16.7%, and others: 11.5%. Fibrosis stage prevalence was: F0: 23.4%, F1: 37.0%, F2: 19.3%, F3: 13.5%, F4: 6.8%. Failure of liver stiffness measurement (no valid measurement) occurred in 18 patients (9.4%) with FS, no patients with ARFI, and 3 patients (1.6%) with SSI ($p = 0.001$ between FS and SSI). Results for the 3 devices were available in 171 patients. Obuchowski indexes were: FS: 0.855±0.018, ARFI: 0.761±0.027, SSI: 0.789±0.025 (FS vs ARFI or SSI: $p \leq 0.020$). AUROC for significant fibrosis (Metavir F≥2) were: FS: 0.863±0.027, ARFI: 0.749±0.039, SSI: 0.781±0.036 ($p = 0.006$; FS vs ARFI or SSI: $p \leq 0.021$). Diagnostic cut-offs for F≥2 were: FS: 8.0 kPa, ARFI: 1.29 m/s, SSI: 1.85 m/s. Using this cut-offs, diagnostic accuracy for F≥2 was: FS: 76.0%, ARFI: 70.2%, SSI: 77.2% ($p = 0.204$). AUROC for cirrhosis were: FS: 0.941±0.027, ARFI: 0.895±0.048, SSI: 0.870±0.035 ($p = 0.011$; FS vs SSI: $p = 0.010$). Diagnostic cut-offs for cirrhosis were: FS: 16.6 kPa, ARFI: 1.87 m/s, SSI: 1.93 m/s. Using this cut-offs, diagnostic accuracy for cirrhosis was: FS: 90.6%, ARFI: 79.5%, SSI: 75.4% ($p < 0.001$, FS vs others: $p \leq 0.001$).
Conclusions: ARFI and SSI have better feasibility and similar accuracy for the diagnosis of significant fibrosis than FS. However, FS has the best accuracy for the diagnosis of cirrhosis.

P0512

LIVER STIFFNESS MEASURMENTS USING FIBROSCAN AFTER THREE MONTHS OF IFN-BASED ANTIVIRAL THERAPY IS UNLIKELY TO PREDICT VIRAL RESPONSE IN CIRRHOTIC PATIENTS

N. Gamal[1], L. Brodosi[1], A. Scuteri[1], G. Simonetti[1], C. Cursaro[1], M. Mastroroberto[1], M. Bernardi[1], P. Andreone[1]. [1]*Department of Medical and surgical sciences, University of Bologna, Bologna, Italy*
E-mail: nesrine.gamal@gmail.com

Background and Aims: Chronic HCV infection (CHC) is the leading cause of mortality from liver cirrhosis and hepatocellular carcinoma. Antiviral therapy can prevent disease progression. Transient Elastografy (TE; Fibroscan) is an accurate surrogate marker to liver fibrosis, by measuring liver stiffness (LS). LS decrease has been associated with sustained virologic response (SVR). In this study we aimed to assess the changes of LS measurments in CHC patients during and one year after Interferon (IFN)-based antiviral therapy (IFN/ribavirin) or (telaprevir+IFN/ribavirin).
Methods: This is an ongoing study, in which consecutive 69 CHC patients (53.6% females, mean age 57.9±11.4) who underwent

antiviral therapy for at least 20 weeks were enrolled. LS was measured using Fibroscan at baseline, after three months, at the end of treatment and one year after treatment discontinuation. Fibrosis was graded using METAVIR score.
Results: Twenty patients were treated with triple therapy and 49 with IFN/ribavirin. Fifty patients had SVR and 19 were non-responders. LS changed significantly in all patients and independently from the initial fibrosis stage, genotype, type of treatment, basal ALT and BMI. Twelve months after treatment discontinuation, we found that in SVR patients: F0–F1, F2 and F3 patients (39.1%, 7.2% and 17.4%; respectively) showed no significant LS decrease (P = 0.186, 0.068 and 0.075; respectively). Conversely, in F4 patients (36.2%) LS was significantly decreased (P = 0.015) after one year of treatment completion. In all patients with no SVR, no significant decrease in LS was observed. Interestingly, all Patients with F4 fibrosis (even non-responders) showed an initial significant decrease in LS (P = 0.024) at 3 months after the start of treatment. However, this decrease was not predictive of SVR; area under the ROC curve 0.369 (CI %: 0.145–0.592) P = 0.265.
Conclusions: Performance of LS measurements for fibrosis assessment confirmed results from previous studies. Our preliminary data suggest that LS changes significantly in CHC patients treated with IFN-based antiviral therapy (standard and triple therapy with telaprevir) and it decreases significantly in responders with high initial LS measurements independently from the type treatment. Initial significant decrease in LS measurements in such patients is unlikely to predict an SVR.

P0513
DIAGNOSTIC ALGORITHM FOR IMPLEMENTATION OF NON-INVASIVE SCORES FOR LIVER FIBROSIS IN CLINICAL PRACTICE IN CHILDREN WITH CHRONIC HEPATITIS C
S.H. Barakat[1], W. El-Gandy[2], M. Salem[3], N. Ahmed[1]. *[1]Pediatrics, [2]Clinical pathology, [3]Pathology, Alexandria University, Faculty of Medicine, Alexandria, Egypt*
E-mail: barakat_sana@yahoo.com

Background and Aims: Considering that most noninvasive scores for evaluating liver fibrosis have been validated only in adults and taking into account that liver biopsy is less accepted in children. there is a clear need to assess these scores in childrenn. the aim of our study was to assess the diagnostic performance of 3 of the non-invasive fibrosis scores with limited expense and simple calculation and then combined them with the aim of defining an algorithm of higher diagnostic accuracy (DA) in Egyptian children with chronic hepatitis C (CHC).
Methods: 117 children with CHC aged 5–15 years were evaluated for Forns score, FIB-4 and APRI at the time of liver biopsy and a combination algorithm for discriminating non-significant (F0–F1) versus significant (F2, F3F4) fibrosis were developed. Liver fibrosis staging were assessed according to the METAVIR scoring system. The performance of each scores is expressed by the area under the receiving-operating-characteristic (AUROC). Positive and negative predictive values (PPV, NPV) were calculated using cut-off generated for each score according to the highest Youden index to provide the best DA.
Results: Fibrosis stages were: F0: 47%, F1: 39% and F2: 14%. The studied scores had a similar diagnostic performance (AUROCs 0.79–0.76). All scores showed excellent NPV (>93%) to exclude significant fibrosis, while PPV was quite low for all scores (30–40%), so that significant fibrosis cannot be reliably predicted in HCV studied children. Several combinations were tested and the best algorithm was to first calculate APRI in all children followed by Forns score in children classified F2 by APRI. The algorithm we have developed was based on the NPV of the scores, identifying children with non-significant fibrosis. In this algorithm APRI (cut-off <0.68) correctly classified 86% of children with non-significant fibrosis, in the second step Forns score (cut-off <0.97) correctly classified another 6% of children with non-significant fibrosis and restricting liver biopsy to children classified F2 by both scores.
Conclusions: Studied non-invasive scores, when combined, may reduce by 85% the number of liver biopsies needed for correctly classifying hepatic fibrosis in children. Being non-invasive, they can be repeated every year to monitor liver fibrosis progression in those children with non-significant fibrosis. However, liver biopsy cannot be completely avoided but should be considered when significant fibrosis is predicted by the non-invasive scores.

THE CORRELATION BETWEEN 25-HYDROXYVITAMIN D LEVEL AND LIVER FIBROSIS ASSESSED BY TRANSIENT ELASTOGRAPHY IN PATIENTS WITH COMPENSATED CHRONIC LIVER DISEASE
Y.S. Kim[1], S.G. Kim[1], B.J. Ko[1], S.W. Jeong[2], J.Y. Jang[2], Y.D. Kim[3], G.J. Cheon[3], H.S. Kim[4], B.S. Kim[1], S.M. Kim[1]. *[1]Soonchunhyang university Bucheon hospital, school of medicine, Bucheon, [2]Soonchunhyang university Seoul hospital, school of medicine, Seoul, [3]Gangneung Asan hospital, Ganggeung, [4]Soonchunhyang university Cheonan hospital, school of medicine, Cheonan, Korea, South*
E-mail: mcnulty@schmc.ac.kr

Background and Aims: 25-hydroxyvitamin D [25(OH)D_3] deficiency has been known to be prevalent in chronic liver disease (CLD). Low 25(OH)D_3 serum levels were correlated with an increase of liver fibrosis. The purpose of this study was to evaluate correlation between 25(OH)D_3 level and liver fibrosis assessed by transient elastography (TE) in patient with compensated CLD.
Methods: From January 2013 to June 2014, the measurement of 25(OH)D_3 serum levels and liver stiffness using TE were done in 260 CLD patients. Among them, 207 CLD patients were enrolled in this study after excluding the patients with decompensated liver disease.
Results: The mean age of patients was 48 years and 151 (72.9%) patients were male. The most common etiology was chronic hepatitis B (110, 53.1%), followed by chronic hepatitis C (15, 7.2%), non-alcoholic fatty liver disease (25, 12.1%), alcohol (41, 19.8%) and others (16, 7.7%). The median liver stiffness value was 6.8 kPa (Inter-quartile range: 5–11.5) and mean 25(OH)D_3 level was 12.68 ng/ml (standard deviation: 9.1–18.57). The number of patients with 25(OH)D_3 deficiency (<20 ng/ml), severe 25(OH)D_3 deficiency (<10 ng/ml) were 94 (45.4%) and 72 (34.8%) respectively. Advanced liver fibrosis defined by TE (9.5 kPa) was 75 (36.2%). There was a significantly correlation between 25(OH)D_3 deficiency and liver stiffness ($r = -0.204$, $p < 0.003$). On the multivariate analysis, associated with advanced liver fibrosis severe 25(OH)D_3 deficiency [adjusted odds ratio (aOR) 3.92, 95% confidence interval (CI) 1.70–9.01, $p = 0.001$], Gamma GT [aOR 1.004, 95% CI 1.00–1.007, $p = 0.041$], and FIB4 [aOR 2.01, 95% CI 1.43.-2.83, $p < 0.001$] were independently significant factors.
Conclusions: In patients with compensated CLD, there was a close correlation between 25(OH)D_3 level and liver stiffness assessed by TE. Severe vitamin D deficiency was independently associated with advanced liver fibrosis.

P0515

BIOLOGICAL STABILITY AND DIAGNOSTIC ACCURACY OF ELF® (ENHANCED LIVER FIBROSIS TEST) TO IDENTIFY LIVER FIBROSIS IN PATIENTS WITH CHRONIC HEPATITIS C USING CRYOPRESERVED SERUM SAMPLES DURING 25 YEARS

M. Puigvehí[1], J. Hernández[2], N. Cañete[1], T. Broquetas[1], M. García-Retortillo[1], S. Coll[1], B. Cabrero[1], M. Garcia[3], D. Giménez[1], F. Bory[1], M. Salvadó[2], R. Solà[1], J.A. Carrión[1]. *[1]Liver Section, Gastroenterology Department, Hospital del Mar, Universitat Autònoma de Barcelona, IMIM, [2]Laboratori de Referència de Catalunya, [3]Pathology Department, Hospital del Mar, Barcelona, Spain*
E-mail: 95565@parcdesalutmar.cat

Background and Aims: Applicability of liver fibrosis serum markers is higher than other non-invasive methods. Moreover, cryopreservation of serum samples is a routine procedure in reference centers.
To evaluate the biological stability of serum markers and their diagnostic accuracy to identify significant fibrosis using HCV infected frozen serum samples during the last 25 years.
Methods: We evaluated 225 frozen serums samples of patients with chronic HCV infection and their liver biopsy during 5 periods: 1990–94 (n = 25), 1995–99 (n = 50), 2000–04 (n = 50), 2005–09 (n = 50) and 2010–14 (n = 50). Thirty-four patients with low quality biopsies (<6 portal tracts) or more tan 2 years between biopsy and serum sample were excluded. Hyaluronic acid (HA), N-terminal propeptide of type III procollagen (PIIINP) and tissue inhibitor of metalloproteinases 1 (TIMP-1) were measured to determine ELF® (Enhanced Liver Fibrosis) using ADVIA Centaur® immunochemical analyzer. We evaluated the diagnostic accuracy (AUROC) of ELF® to identify significant fibrosis (F2–4).
Results: Seventy-six patients (39.8%) had mild fibrosis (F0–1), 37 (22%) moderate (F2) and 82 (38.2%) advanced liver fibrosis (F3–4). Length of biopsy (median) for 1990–94 (14 mm) was lower than the rest of periods (18 mm) ($p < 0.001$). Values of HA, PIIINP and TIMP-1 were similar during all periods (1990–2014) without a decline of their levels. We did not found differences of ELF® values (median) between periods (1995–2014) in patients with mild fibrosis (8.4–8.7), moderate (9.8–10) or advanced fibrosis (10.4–11.2) (p = ns between periods and fibrosis stages). The AUROCs of ELF® to identify significant fibrosis were from 0.86 to 0.91 for the different periods (1995–2014).
Conclusions: Biological stability of direct serum markers (HA, PIIINP and TIMP-1) and diagnostic accuracy of ELF® to identify significant fibrosis was very high using HCV infected frozen serum samples during the last 20 years.

P0516

QUALITY CONTROL OF QUANTIFICATION OF ARFI MEASUREMENTS – PHANTOM STUDY IN COMPARISON WITH FIBROSCAN

R. Kubale[1], T. Fuhrmann[1], A. Arslanow[2], P. Minko[1], F. Frenzel[1], F. Grünhage[2]. *[1]Department of Diagnostic and Interventional Radiology, [2]Hospital for Internal Medicine II, Saarland University Hospital Center, Homburg, Germany*
E-mail: kubale@mac.com

Background and Aims: A precise and reproducible non-invasive assessment of the progression of liver fibrosis is important for the estimation of prognosis and treatment decisions. Alternative approaches include transient elastography (FibroScan®) and shear wave measurements (ARFI technique). Although there are reports demonstrating high correlations with histology and between different techniques, absolute values and reproducibility are still under discussion. The aim of our study was to evaluate the reproducibility and factors influencing the absolute values using a standardized phantom.
Methods: For validation, all examinations were correlated with the CIRS shear wave phantom (039) made of Zerdine with values for Young's modulus between 3 and 48 kPa (attenuation 0.5 dB/cm/MHz, speed 1560–1600 m/s, density 1.03 g/cc). Homogeneity of the phantom was proved by CT and 2D shear wave imaging. ARFI measurements were performed with S2000 and S3000 machines (Siemens) using different scan heads (9 MHz, 4 and 6 MHz), depths, pressures and angles in at least 10 repeated measurements. The ARFI values (m/s) were correlated with transient elastography (kPa) and the expected SVI values of the CIRS phantom. Because the first series showed an underestimation of all modalities, the phantom was redesigned by CIRS with values of 3.5, 10.0, 24.7 and 44.8 kPa.
Results: Although the correlation in the first series was 0.89, there was an underestimation of shear wave velocities and stiffness values with all ultrasound machines by 15–40%. Using the redesigned phantom, the correlation improved to 0.96. The underestimation of transient elastography ranged from 14 to 31%; the underestimation of ARFI values was in the range of 0.3 to 10.2% with lowest errors when using the 4 MHz scan head. Critical factors are examination pressure (ARFI) and depth of measurement (Figure 1).
Conclusions: Although there was a significant correlation between phantom values and ARFI measurements, there was a systematic underestimation of the absolute values. The best results for measurements in liver-equivalent depths were achieved at 4 MHz. Depth causes a significant reduction of the shear wave velocity measurements with low errors in the range of 3–6 cm depth. Our experimental results provide evidence that there is still a problem in defining the gold standard for non-invasive liver stiffness measurements.

FEASIBILITY OF TRANSIENT ELASTOGRAPHY IN OVERWEIGHT AND OBESE PATIENTS

R. Şirli[1], I. Sporea[1], R. Mare[1], A. Popescu[1], M. Danila[1], C.S. Ivaşcu[1]. *[1]Department of Gastroenterology and Hepatology, "Victor Babes" University of Medicine, Timisoara, Romania*
E-mail: roxanasirli@gmail.com

Background and Aims: Liver stiffness measurement (LSM) using transient elastography (TE) is a non-invasive technique that evaluates liver fibrosis. However reliable elasticity measurements are difficult to obtain in overweight (BMI≥25 kg/m^2) and obese (BMI≥30 kg/m^2) patients with the M probe. The XL probe was meant to improve the feasibility of TE in this category of patients. *The aim* of our paper was to assess the feasibility of the TE in daily practice in overweight and obese patients.
Methods: Our study included 2046 successive overweight and obese patients with chronic hepatitis and cirrhosis of various

etiologies in which TE measurements were made either with the M (3.5 MHz) probe or with XL (2.5 MHz) between January 2012 and October 2014. In patients in which reliable measurements could not be obtained by M probe, XL measurements were performed in the same session. In each patient 10 valid LSM were acquired with each probe, a median was calculated expressed in kiloPascals (kPa). Reliable measurements were defined as: median value of 10 valid LSM with a success rate (SR) ≥60% and an interquartile range interval (IQR) <30%. Unreliable TE measurement were considered the following situations: fewer than 10 valid shots; SR <60% and/or IQR ≥30%.

Results: A total of 2046 patients were examined, 1156 (56.5%) overweight and 890 (43.5%) obese. In the 1156 overweight patients reliable LSM were obtained in 979 (84.7%) cases: in 729 (63.1%) by the standard M probe and in 250 (21.6%) by the XL probe. In the 890 obese patients, reliable measurements were obtained in 744 patients (83.6%), in 165 (18.5%) by the M probe, and in 522 (58.6%) by using the XL probe. Thus, by using both probes, reliable measurements were obtained in 1723 (84.2%) of the 2046 examined cases.

Conclusions: By using both M and XL probes, reliable LSM by TE can be obtained in the majority of the obese and overweight patients (84.2%).

P0518

ARTERIAL PRESSURE SUFFICES TO INCREASE LIVER STIFFNESS INDEPENDENT OF CENTRAL VENOUS PRESSURE

F. Piecha[1], T. Peccerella[1], H.-K. Seitz[1], V. Rausch[1], S. Mueller[1]. *[1]Dept. of Medicine and Center for Alcohol Research, Salem Medical Center and University of Heidelberg, Heidelberg, Germany*
E-mail: vanessa.rausch@uni-heidelberg.de

Background and Aims: Liver stiffness (LS) is not only increased by matrix deposition (fibrosis stage) but also in response to an elevated central venous pressure (liver congestion) and many other more complex conditions such as inflammation or food intake. We here study whether arterial or portal pressure is able to modulate LS.

Methods: LS was measured in 25 male Wistar rats using transient elastography (Microfibroscan, Echosens, Paris) during single i.v. injections of Epinephrine (0.05 mg), Norepinephrine (4 μg), Dobutamine (50–150 mg) and sodium chloride (1–4 ml, control). Pressures in all liver-relevant compartments (abdominal aorta, caval and portal vein) were invasively measured in real time using the Powerlab device and analyzed with Labchart software (AD Instruments, New Zealand).

Results: Initial normal LS values in rats were comparable to those in humans with a mean of 4.1 kPa. Epinephrine and Norepinephrine drastically increased systolic arterial pressures from 120 to >210 mmHg while LS doubled from 4 to 8 kPa. In the same time, central venous pressure (CVP) remained unchanged while portal pressure slightly increased by a mean of 3 mmHg. In confirmation, LS correlated highly with arterial pressures ($r = 0.811$) and portal pressure ($r = 0.599$) but not with CVP. Real-time monitoring clearly demonstrated that the slight elevation of portal pressure followed the increase of LS with a lack phase of 8 seconds. Both Dobutamine and volume challenge with sodium chloride of up to 4 ml failed to increase LS.

Conclusions: We here show that an increase of the arterial pressure is sufficient to elevate LS independent of the central venous pressure and prior to the portal pressure. Thus, elevated arterial pressure could be an important cofactor for the observed increase of LS e.g. during inflammation or food intake.

LIPIDOMICS REVEALS THAT LOW PLASMA UNSATURATED TO SATURATED FAT RATIOS ARE BIOMARKERS OF NAFLD AND LIVER DAMAGE

M. Gaggini[1,2], C. Saponaro[1,3], C. Rosso[4], E. Buzzigoli[1], F. Carli[1], D. Ciociaro[1], L. Mezzabotta[4], E. Vanni[4], R. Gambino[4], F. Saba[4], S. Carenzi[4], G.P. Caviglia[4], M.L. Abate[4], A. Smedile[4], M. Rizzetto[4], M. Cassader[4], E. Bugianesi[4], A. Gastaldelli[1]. *[1]Cardiometabolic Risk Unit, Institute of Clinical Physiology, CNR, [2]Dipartimento di Patologia Chirurgica, Molecolare Medica e di Area Critica, Università di Pisa, Pisa, [3]Dottorato Pegaso Regione Toscana in Biochimica e Biologia Molecolare, Università di Siena, Siena, [4]Dept. of Medical Sciences, University of Turin, Division of Gastroenterology and Hepatology and Lab. of Diabetology, Turin, Italy*
E-mail: mgaggini@ifc.cnr.it

Background and Aims: Alterations in lipid metabolism and insulin resistance (IR), have been associated with development and progression of NAFLD. Increased de novo lipogenesis (DNL) and low activity of Stearoyl-CoA desaturase-1 (SCD1) result not only in fatty liver but also in unbalanced production of unsaturated vs. saturated fat, ultimately determining lipotoxicity. Other classes of fat, e.g., ceramides, have been associated with organ inflammation and lipotoxicity. Thus, we measured plasma lipidomic profile and evaluated the association with NAFLD and liver fibrosis.

Methods: We studied 54 subjects, 45 non obese NAFLD with liver biopsy and 9 controls (CT) without fatty liver and measured different plasma lipid classes (i.e., FFA; lysophosphocholine, Lyso-PC; Ceramides, Cer) by mass spectrometry (GC-MS and LC-MS QTOF). We evaluated unsaturated to saturated fat ratio in FFA (PUFA/SFA) and Lyso-PC, hepatic TG (by MRI), indexes of adipose tissue IR (AT-IR= fasting lipolysis x insulin); hepatic IR (Hep-IR=EGPxInsulin); de novo lipogenesis index (DNL=16:0/18:2); SCD1 activity (16:1/16:0); MCP-1; oxidized LDL (ox-LDL), adiponectin, tryglicerides and GSG-index [= glutamate/(glycine + serine)] that we recently developed and found associated with presence of oxidative stress and glutathione demand, but also with TCA cycle turnover

Results: PUFA/SFA (in both FFA and Lyso-PC) were decreased in NAFLD vs CT particularly in NAFLD with fibrosis score F3–F4 ($p < 0.05$ vs F0 and CT). Fatty acid PUFA/SFA were inversely associated with hepatic TG ($r = -0.56$), AT-IR ($r = -0.37$), Hep-IR ($r = -0.28$), DNL ($r = -0.93$), SCD1 ($r = -0.38$), GSG ($r = -0.52$), and MCP-1 ($r = -0.42$, all $p < 0.05$). Lyso-PC PUFA/SFA were inversely associated with hepatic TG ($r = -0.44$), GSG ($r = -0.42$) and ox-LDL ($r = -0.30$). Total ceramides were increased in NAFLD vs CT, and Cer(d18.0/18:1) and Cer(d18:0/24:0) were also increased in F3–F4 vs F0 and CT ($p < 0.05$). Cer(d18:0/24:0) and Cer(d18.0/18:1) were positively associated with hepatic TG ($r = 0.43$, $r = 0.30$), DNL ($r = 0.34$, $r = 0.39$), plasma TG ($r = 0.42$, $r = 0.41$), AT-IR ($r = 0.46$, $r = 0.31$) and oxLDL ($r = 0.51$, $r = 0.40$).

Conclusions: Decreased PUFA/SFA ratio and increased ceramides are markers of metabolic derangement (i.e., increased lipotoxicity, hepatic fat accumulation and de novo lipogenesis) and severe liver fibrosis in NAFLD.

ACCEPTABILITY, RELIABILITY AND APPLICABILITY OF LIVER BIOPSY AND NON-INVASIVE METHODS FOR ASSESSMENT OF HEPATIC FIBROSIS AND CIRRHOSIS AMONG HEPATOLOGISTS; A WEB BASED SURVEY

M. Alboraie[1], M. Khairy[2], A. Elsharkawy[2], N. Asem[3], M. El Kassas[4], F. Elghamry[1], F. Hassan[5], G. Esmat[2], Egyptian Liver Fibrosis Study Group. *[1]Department of Internal Medicine, Al-Azhar University, [2]Endemic Medicine Department and Hepatology Unit, [3]Department of Public Health and Community Medicine, Faculty of Medicine, Cairo University, [4]Endemic Medicine and Hepatology Department, Faculty of Medicine, Helwan University, Cairo, Egypt; [5]Department of Internal Medicine, Faculty of medicine, Kuwait University, Al-Jabriya, Kuwait*
E-mail: m.alboraie@hotmail.com

Background and Aims: Liver biopsy is the standard reference for staging hepatic fibrosis. Non-invasive methods for assessment of hepatic fibrosis and cirrhosis are becoming increasingly popular. We aimed at exploring the change in practice regarding the use of liver biopsy and non-invasive methods for staging hepatic fibrosis and cirrhosis.
Methods: A 56 questions survey was designed and hosted on an online survey's hosting website. Invitations sent to practicing physicians interested in hepatology via e-mails and through major international hepatology societies' social media walls (Twitter, Facebook and LinkedIn). Questions covered different aspects of practice regarding the use of liver biopsy, serum fibrosis biomarkers and radiological methods for assessment of hepatic fibrosis and cirrhosis.
Results: 444 physicians from 28 countries completed the survey (70% hepatologists and gastroenterologists, 69% experts or consultants). Liver biopsy is still considered the gold standard for assessment of hepatic fibrosis and cirrhosis by 85% of participants. Liver biopsy was accepted by 76.33% of their patients, 97.6% of participants thought that liver biopsy result was reliable and 60.84% admitted that liver biopsy was applicable for all patients. 94.23% reported the need of a more practical alternative to liver biopsy to assess disease progression or response to treatment. 91.89% of participants knew serum biomarkers, 93.36% reported they were acceptable by patients, 85.26% thought they were reliable and 57.9% applied them. 95.4% were familiar with radiological methods of non-invasive assessment of hepatic fibrosis, 97.81% reported that radiological methods were acceptable by their patients, 94.96% thought that they were reliable and 96.28% reported they were applicable in clinical practice. 86.72% thought that combining non-invasive methods was better than using a single method and 39.41% of them thought that radiological methods were cheaper than biomarkers (35.59%), combination of both (24.55%) or liver biopsy (0.45%). 96.17% of them agreed that we are in need of a guideline for using non-invasive methods for assessment of liver fibrosis.
Conclusions: Acceptability of non-invasive methods for assessment of hepatic fibrosis by patients was better than liver biopsy. Physicians trusted liver biopsy more than radiological methods or serum biomarkers and applied non-invasive radiological methods easily to their patients than liver biopsy or serum biomarkers.

E-mail: paloma_march@hotmail.com

Background and Aims: Chronic hepatitis C (CHC) progression deeply influences hepatic vascular homeostasis leading to significant functional and anatomical alterations of the liver. As a consequence of CHC advancement, patients show diverse grades of inflammation, fibrosis and angiogenesis which confer an important risk of cirrhosis and hepatocellular carcinoma (HCC) development. Evolution of CHC is highly variable among patients depending on a broad set of host factors, highlighting the importance of patient's genetic profile. Therefore, the assessment of the overall contribution of certain genetic variants related to main vascular mediators on CHC progression might be crucial for treatment decision making and personalized management of CHC.
Aims: To test and validate the impact of angiogenic-related genetic variants on CHC progression to cirrhosis and HCC.
Methods: 364 SNPs were selected by their potential effects on gene expression or functionality from 76 candidate genes (angiogenic factors, receptors and signalling effectors) and subsequently genotyped in 384 patients with fibrosis (F0–1=112, F2=43 and F3=49), cirrhosis (F4=45) and HCC (134) of CHC-etiology. Genotyping also included 20 additional SNPs previously related to CHC progression ($p < 0.01$) in an independent cohort ($n = 384$, 49th annual meeting of EASL, 2014) for their validation. Association of disease stages (F0–1 vs. F2–4, F0–1 vs. CHC and F2–4 vs. CHC) with genetic variants was analyzed by PLINK software and Bonferroni multiple test correction was applied.
Results: 13 SNPs located in 8 angiogenic genes were significantly associated with CHC progression ($p < 0.01$). Of those, 6 SNPs were related to significant fibrosis (F0–1 vs. F2–4), 2 to HCC progression (F2–4 vs. HCC) and 5 to the evolution from F0–1 to HCC. Interestingly, 2 of those SNPs associated with mild to significant fibrosis remained significantly associated even after Bonferroni correction ($pcB < 13 \times 10^{-5}$). Remarkably, 4 of the 20 SNPs previously associated with CHC progression by our group were independently validated in present study. Interestingly, one of those SNPs was related to significant fibrosis (F0–1 vs. F2–4) and HCC (F2–4 vs. CHC), 2 SNPs were associated with significant fibrosis (F0–1 vs. F2–4) and one SNP to HCC (F2–4 vs. HCC).
Conclusions: The influence of characterized and validated genetic variants on CHC progression to HCC might serve as a valuable tool for the clinical management of CHC patients and the early diagnostic of HCC.

P0522

VALID LIVER STIFFNESS MEASUREMENT CAN BE OBTAINED IN MORE THAN 99% OF PATIENTS WITH VIRAL HEPATITIS BY REPEATING THE EXAMINATION IN CASE OF INITIAL FAILURE

B. Staugaard[1], J.F. Hansen[1], P.B. Christensen[1]. [1]*Department of Infectious Diseases, Odense University Hospital, Odense, Denmark*
E-mail: b_staugaard@hotmail.com

Background and Aims: Liver Stiffness Measurement (LSM) with Fibroscan (Echosens) has become a standard tool for detecting liver fibrosis in patients with chronic viral hepatitis (CVH). Initially invalid LSM was reported in 10–20%. Since the introduction of a special XL-probe for obese patients and the new quality criteria for a valid LSM, the proportion of invalid LSM has decreased. The aim of this study was to investigate the value of performing additional LSM in patients with invalid LSM.
Methods: We evaluated the outcome of initial and repeated LSM at subsequent visits in two populations of patients with CVH, one with initial LSM before and one with initial LSM after the introduction of the XL probe. We determined the number of invalid scans according to the 2014 criteria for poorly reliable LSM: <10 valid measures or, IQR/Median >30% if LSM >7.1 kPa (Boursier J et al. Hepatology 2013).
Results: In the 3 years prior to the XL-probe we performed 1757 LSM among 746 patients with CVH. Overall 89.1% (1566/1757) of the LSM were valid using the new criteria and 91.3% (681/746) of the patients had a valid first LSM. At the second LSM 51.1% (23/45) of those with an initial invalid LSM had a valid examination. At subsequent examinations among patients with two invalid LSM, only 20% had a valid LSM. In the 4 years after introduction of the XL-probe in 2010, we performed 2701 scans among 970 patients (19.3% with the XL-probe). Overall 96.6% (2610/2701) of all the LSM were valid by new criteria and 96.3% of patients had a valid first LSM. Among 36 patients with an initial invalid LSM, 78.1% (25/32) had a valid scan at the second examination (4 were lost to follow-up). Of the 7 patients with two successive invalid scans, all examined (5) had a valid LSM at a later visit and the remaining 2 are awaiting examination. After the introduction of the XL-probe a valid LSM was obtained in 100% (21/21) who previously had only invalid examinations.
Conclusions: The success rate of LSM among patients with CVH is close to 100% when combining the use of the M- and/or XL-probe with repeated examination in patients with initial invalid LSM.

MODIFICATION OF EXPRESSION OF MIR-20A, MIR-92A AND MIR-122 DURING FIBROSIS IN PATIENTS WITH CHRONIC HEPATITIS C

K. Appourchaux[1], E. Estrabaud[1], P. Broet[2], M. Lapalus[1], M. Martinot-Peignoux[1], N. Boyer[1], M. Vidaud[3], P. Bedossa[4], P. Marcellin[5,6], T. Asselah[1,6]. [1]*UMR1149, INSERM, Paris,* [2]*UMR669, INSERM, Villejuif,* [3]*UMR745, INSERM, Paris,* [4]*Service d'anatomie pathologique, INSERM, Clichy,* [5]*U1149, INSERM, Paris,* [6]*Service d'Hépatologie, Hôpital Beaujon, Clichy, France*
E-mail: kevin.appourchaux96@gmail.com

Background and Aims: The high stability of Micro-RNAs (MiRNAs) make them interesting as circulating biomarkers. They are released in the blood stream via cellular apoptosis and secretion. Patients with chronic hepatitis C (CHC) have a liver necrosis that can be detected by measuring transaminases. Thus, the relevance of studying microRNAs as biomarkers could be challenged in patients with CHC. In this study, we aimed to evaluate the potential of miRNAs as biomarkers of liver fibrosis in patients with CHC.
Methods: Serum samples and liver biopsies were available for respectively 86 and 40 patients. HCV-G1 were the more represented (58%). Among patients with available serum samples, the mean viral load was 1300×10^3 UI/mL. Fibrosis distribution was F1 (31.4%), F2 (20.9%), F3 (23.3%) and F4 (24.4%). Among patients with available biopsies, the mean viral load was 820×10^3 UI/mL and fibrosis distribution was F1 (27.5%), F2 (17.5%), F3 (27.5%) and F4 (27.5%). Fibrosis was staged according to the Metavir score system (F0 to F4). We also studied patients for whom paired biopsies (4–9 years) were available and progressed from mild fibrosis (F1) to significant fibrosis (F2 to F4). We selected miR-20a, miR-92a, miR-122 because of their implication in liver fibrosis. Their expression was assessed by RT-qPCR.
Results: Transaminases were higher in patients with severe fibrosis compared to patients with mild and moderate fibrosis ($p < 0.001$). In serums, while circulating mir-122 was correlated with transaminases ($p < 0.02$), no such association was found for mir-92a and mir-20a. Circulating miR-122 was increased in F3–F4 patients compared to F1–F2, but no difference was observed for mir-92a and mir-20a. No association was found between necroinflammatory activity and circulating miR-20a, miR-92a, and miR-122. In liver biopsies, a higher expression of hepatic miR-122 ($p < 0.0001$), miR-92a ($p = 0.026$) and miR-20a ($p = 0.024$) was observed in patients with mild (F1) and moderate fibrosis (F2) compared to those with severe fibrosis (F3–F4). This result was confirmed in patients whose fibrosis stage increased from mild to moderate fibrosis.
Conclusions: The expression of hepatic miR-122, miR-92a and miR-20a was higher in patients with mild and moderate fibrosis as compared to those with more advanced fibrosis. However, the expression of those 3 miRNAs was not different in the serum. Only miR-122 was associated with transaminases and no association was found with necro-inflammation.

P0524

IMPACT OF NUMBER OF MEASUREMENTS ON DIAGNOSTIC PERFORMANCE OF REAL TIME SHEAR-WAVE ELASTOGRAPHY: A BIOPSY-CONTROLLED STUDY

M. Thiele[1], B.S. Madsen[1], A. Krag[1]. [1]*Department of Gastroenterology and Hepatology, Odense University Hospital, Odense C, Denmark*
E-mail: majath@dadlnet.dk

Background and Aims: Real time shear-wave elastography (SWE) is a novel technique with excellent diagnostic accuracy for liver fibrosis and cirrhosis. However, there is no consensus on how many measurements should be obtained to gain the best diagnostic accuracy, or whether to use the mean or median when reporting results. To assess the most optimal reporting of SWE results, we compared diagnostic accuracies of seven methods of reporting, using liver biopsy as gold standard.
Methods: During 6 months we consecutively recruited patients from an ongoing biopsy-controlled study on the performance of elastography for the diagnosis of liver fibrosis. Five SWE measurements, transient elastography (TE) and liver biopsy were performed on the same day. We applied two SWE quality criteria: Q-box ≥15 mm in diameter and a standard deviation of less than 30% of the mean. SWE results were reported by seven methods: A: one measurement, B: the mean of two, C: three, D: four and E: five measurements, and F: the median of three or G: five measurements. We used AUROC comparisons to compare the diagnostic accuracies of the seven methods. We also assessed which reporting method best correlated with TE.
Results: Of 71 patients evaluated, five valid SWE measurements were obtained in 67 patients (failure rate 6%). The majority had alcoholic liver disease (51 ALD, 16 HCV) and 61% were men. Our cohort represented a broad spectrum of liver disease (METAVIR F0/1/2/3/4 = 16/16/11/5/19). The mean liver stiffness was 14.0 ± 10.8 kPa with a mean difference between the five measurements of 3.7 ± 4.2 kPa (range 0.3–26). The mean difference between the seven reporting methods were 1.6 ± 1.7 kPa (range 0.2–8.6).
The diagnostic accuracy for significant fibrosis (≥F2) was excellent when using any of the seven reporting methods. AUROCs ranged from 0.961 (A) to 0.942 (G). There was no difference in diagnostic

accuracy between the seven methods (P = 0.58). The diagnostic accuracy for cirrhosis (F4) was also excellent, without differences across methods (P = 0.87), and AUROCs from 0.952 (D) to 0.942 (A). All seven SWE reporting methods correlated highly with TE [Spearman's rho, range 0.91 (D) to 0.89 (G)], without any one reporting method correlating better with TE than the others.
Conclusions: The diagnostic performance of SWE does not increase with the number of measurements. Applying a set of quality criteria ensure a low variability between measurements. One measurement is enough to gain excellent diagnostic accuracy for both significant fibrosis and cirrhosis.

P0525
N-ACETYLATED ALPHA SMOOTH MUSCLE ACTIN LEVELS ARE INCREASED IN HEPATIC FIBROSIS BUT DECREASED IN HEPATOCELLULAR CARCINOMA

M.J. Nielsen[1,2], S.H. Nielsen[1], N.U.B. Hansen[1], J.H. Kristensen[1,3], M.A. Karsdal[1], D.J. Leeming[1]. *[1]Biomarkers and Research, Nordic Bioscience, Herlev, [2]Department of Gastroenterology, Odense University Hospital, University of Southern Denmark, Odense, [3]Department of Systems Biology, Technical University of Denmark, Kgs. Lyngby, Denmark*
E-mail: mju@nordicbioscience.com

Background and Aims: Alpha Smooth Muscle Actin (α-SMA) is upregulated together with extracellular matrix (ECM) during activation of Hepatic Stellate Cells (HSCs) in fibrosis. Histone deacetylase (HDAC) remove acetylations and regulate the expression of genes, which is associated with cancers. There is a close relationship between cirrhosis and hepatocellular carcinoma (HCC), and markers enabling identification of patients in risk of developing HCC with cirrhosis is a major unmet clinical need. We developed an ELISA for the assessment of acetylated α-SMA (Ac-α-SMA) in serum. The objective was to investigate the ability of this marker to non-invasively diagnose hepatic fibrosis and assess the influence of HDAC in hepatocellular carcinoma (HCC).
Methods: We generated a monoclonal antibody towards the N-terminus of α-SMA containing acetylation of the third amino acid, N-acetyl-glutamic acid. A competitive ELISA was developed and tested for robustness and the presence of acetylation of the third amino acid on the synthetic peptides was analyzed by mass spectrometry. The biological relevance of the Ac-α-SMA marker was tested in serum and tissue cultures from a Carbon tetrachloride (CCl_4) liver fibrosis rat model and a diethylnitrosamine (DENA) cancer rat model.
Results: Mass spectrometry analysis confirmed the presence of N-acetylation of the peptide compared to a non-acetylated α-SMA peptide. The assay was found to be technical robust including intra- and inter-variations below 10% and 15%, respectively, and showed no reactivity towards the non-acetylated peptide. Ac-α-SMA was significantly increased in serum from CCl_4 induced rats compared to healthy controls (p = 0.002) whereas the level of Ac-α-SMA was significantly decreased in DENA rats compared to healthy controls (p = 0.002). Similar results were found for western blot analysis showing increased expression of Ac-α-SMA in CCl_4 livers compared to controls.
Conclusions: We developed a technical robust serum marker specific for Ac-α-SMA. The level of Ac-α-SMA was increased in hepatic fibrosis, and decreased in HCC. This suggests that acetylations could be the discriminating factor in identification of those patients who progress to HCC.

P0526
ACCURACY OF POINT SHEAR WAVE ELASTOGRAPHY TECHNIQUE (ELASTPQ) IN THE NON-INVASIVE ASSESSMENT OF LIVER FIBROSIS IN VARIOUS LIVER DISEASES

M. Garcovich[1], M. Pompili[1], E. Di Stasio[1], M.E. Ainora[1], L. Riccardi[1], B.E. Annicchiarico[1], M. Siciliano[1], A. Grieco[1], G. Rapaccini[1], A. Gasbarrini[1], M.A. Zocco[1]. *[1]Catholic University of Sacred Hearth, Rome, Italy*
E-mail: matteogarcovich@yahoo.it

Background and Aims: Point shear wave elastography (PSWE) is a novel non-invasive technique that assesses liver fibrosis by measuring liver stiffness (in kPa) with few studies published so far. The purpose of this study was to determine the efficacy and the feasibility for the assessment of hepatic fibrosis as compared with the histological grade in patients undergoing liver biopsy (LB) for various etiologies.
Methods: Consecutive patients scheduled for LB were studied by using the iU22 Philips ultrasound system with ElastPQ technique. The correlations between laboratory findings, liver stiffness and the Metavir score were analyzed using Spearman correlation and ROC curve analyses were performed to calculate AUC for F > 2, F > 3, and F = 4.
Results: We enrolled 172 patients (113/59 males/females) who underwent LB for viral or non-viral chronic hepatitis (HCV 46%; NASH 23%; AIH/PBC 14%; other 17%). Liver stiffness measurements performed on the right lobe were reliable in all cases but one (due to morbid obesity). After univariate and multiple regression analysis PSWE showed a strong correlation with the fibrosis stage; no correlation was found with the degree of necroinflammation or steatosis. Mean kPa values in the whole cohort were 3.62 (range 2.81–4.69) for F0, 4.94 (range 2.81–9.68) for F1, 7.74 (4.16–20.79) for F2, 12.32 (6.25–19.78) for F3 and 23.32 (18.91–32.40) for F4 in the right lobe. AUROCs were 0.92 (±0.17), 0.97 (±0.11) and 0.98 (±0.03), when comparing F0–F1 vs F2–F4, F0–F2 vs F3–F4 and F0–3 vs F4, respectively. When analyzing PSWE values according to different etiologies, AUROCs were 0.93 (±0.31) and 0.97 (±0.29) for F > 2, 0.99 (±0.03) and 0.97 (±0.30) for F > 3, 0.99 (±0.03) and 0.99 (±0.03) for F > 4 in HCV and NASH patients, respectively.
Conclusions: PSWE with ElastPQ appears to be a useful tool for non-invasive evaluation of fibrosis not only in patients with viral chronic hepatitis, but also for patients with different liver diseases. In order to validate such a non-invasive technique these findings need to be confirmed in larger studies.

P0527
PERFORMANCE OF FIBROSCAN XL PROBE WITH ADAPTED MEASUREMENT DEPTH FOR LIVER STIFFNESS MEASUREMENT IN MORBIDLY OBESE PATIENTS

Y. Liu[1,2,3], F. Surroop[3], P. Bedossa[4], J. Aron-Wisnewsky[1,2], L. Sandrin[3], J. Tordjman[1,2], K. Clément[1,2], M. Sasso[3], V. Miette[3]. *[1]Institute of Cardiometabolism and Nutrition, Pitié-Salpêtrière Hospital, [2]Inserm UMR U1166, équipe 6, Nutriomique, UPMC, Cordeliers Research Center, [3]Echosens, Paris, [4]Pathology Department, Beaujon Hospital, Assistance, Publique-Hôpitaux de Paris, Clichy, France*
E-mail: yuejun.liu@inserm.fr

Background and Aims: The XL probe of transient elastography (FibroScan®) was recently developed to evaluate liver stiffness measurements (LSM) in overweight and obese patients. However overlying fat layers in morbidly obese patients (BMI ≥40 kg/m^2) are much thicker and present a major inter-individual variability and thus could lead to an overestimation of stiffness. In this study, we evaluated the diagnostic performance of XL probe after adapting LSM depths in morbidly obese candidates for bariatric surgery.
Methods: From 09/2010 to 04/2014, 119 morbidly obese patients (69.7% female; age 41±11 years; BMI 46.9±7.3 kg/m^2) candidates for bariatric surgery were recruited and underwent LSM using

XL probe before surgery. Per-operative liver biopsy (LB) samples were collected and evaluated by a single anatomo-pathologist using Kleiner's classification for fibrosis. Valid LSM was considered for who had at least 5 valid measurements. Probe performance for diagnosing ≥F2 and ≥F3 fibrosis versus biopsy were examined using AUROC.

Results: In 94 patients who had valid LSM, 26% had significant fibrosis (14% F2, 10% F3, 3% F4). AUROC of standard XL LSM (35–75 mm) for significant fibrosis (F≥2) was 0.84 (0.75–0.94), for F ≥3 was 0.84 (0.71–0.97). To recalculate LSM, three adapted measurement depths were selected according to fat layer: 35–75 mm, 40–75 mm and 45–80 mm. AUROC of adapted LSM for significant fibrosis (F≥2) was 0.85 (0.75–0.94); AUROC for F≥3 was 0.92 (0.83–1). 10 patients who had overestimated LSM using standard depth were significantly more obese (BMI 51.8±6.0 kg/m^2 versus 44.5±5.9 kg/m^2, $p = 0.001$).

Conclusions: FibroScan allows the early diagnosis of significant fibrosis in morbidly obese patients before bariatric surgery. This study demonstrates that fat layer thickness superior to 40 mm in such patients requires an adaptation of the LSM calculation but the measurements are feasible and accurate. FibroScan appears as a reliable and noninvasive tool for screening chronic liver disease severity in morbidly obese patients. Further studies are needed to confirm these results.

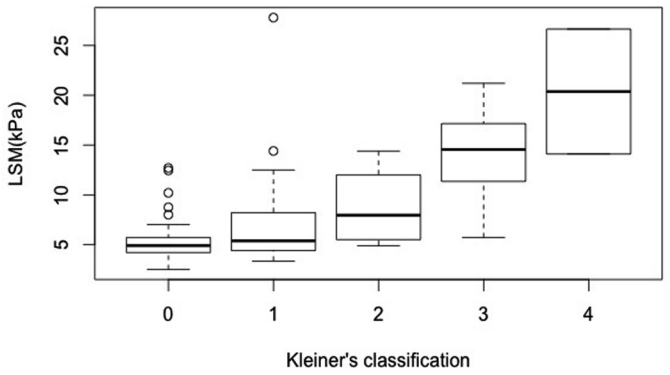

Figure: Boxplot of adapted LSM of FibroScan XL.

TRANSIENT ELASTOGRAPHY IS SAFE IN PATIENTS WITH PACEMAKERS AND IMPLANTABLE CARDIOVERTER-DEFIBRILLATORS

F. Schoelzel[1], S. Linzbach[2], F. Seeger[2], J. Bojunga[1], S. Fichtlscherer[2], J. Rey[3], E. Herrmann[3], A.M. Zeiher[2], S. Zeuzem[1], M. Friedrich-Rust[1].
[1]Department of Internal Medicine 1, [2]Department of Internal Medicine 3, J.W. Goethe-University Hospital, [3]Institute of Biostatistics and Mathematical Modelling, Faculty of Medicine, J.W. Goethe-University, Frankfurt am Main, Germany
E-mail: fabian.schoelzel@stud.uni-frankfurt.de

Background and Aims: Transient elastography (TE) is widely used for non-invasive assessment of liver fibrosis and is recommended by EASL Clinical Practice Guidelines for chronic hepatitis C. However, TE is not accredited in patients with pacemaker (PM) and implantable cardioverter-defibrillator (ICD) devices, since side effects on PM and ICD are unknown. Therefore, studies in these patients are missing. The aim of the present study was to evaluate whether liver stiffness measurement (TE) using FibroScan® effects safety and function of such devices.

Methods: In a prospective study between January 2012 and October 2014 patients with PM or ICD receiving TE underwent two PM/ICD check-ups, one immediately before and one after TE. At least 10 TE-measurements were performed with the FibroScan® M-Probe (3.5 MHz; shear wave frequency 50 Hz; depth of measurement 25–65 mm) using the FibroScan® 502 touch device (Echosens, Paris, France). During PM/ICD check-ups stimulation thresholds, electrode impedance and sensing were recorded and changes after TE-performance as compared to the check prior to TE were documented and analyzed.

Results: Thirty-four patients [82% male; mean age 73±10 years; median body mass index 27.8 kg/m^2 (range 17.8–43.0 kg/m^2)] with PMs (n = 16) or ICDs (n = 18) were enrolled in the present study. In none of these 34 patients changes in stimulation thresholds, electrode impedance and sensing of PM or ICD were detected. Furthermore, none of the probed devices recorded any cardiac events during TE-examination. All patients reported well-being throughout the whole study period.

Conclusions: Our findings support the assumption that transient elastography can be performed safely in patients with implanted pacemakers and implantable cardioverter-defibrillators.

Viral hepatitis: Hepatitis B & D – a. Experimental

ANTI CAPSID DRUGS HAP12 AND AT130 TARGET HBV CORE PROTEIN NUCLEAR FUNCTIONS

L. Belloni[1,2], G.A. Palumbo[2], L. Lupacchini[2], L. Li[3], S. Reddy Chirapu[4], L. Calvo[2], M.G. Finn[4], U. Lopatin[5], A. Zlotnick[3,5], M. Levrero[1].
[1]Center for Life Nano Science (CLNS), IIT-Sapienza University, [2]Dept of Internal Medicine – DMISM, Sapienza University, Rome, Italy; [3]Dept of Molecular & Cellular Biochemistry, Indiana University, Bloomington, [4]Dept Chemistry, Georgia Institute of Technology, Atlanta, [5]Assembly Bioscience, Bloomington, United States
E-mail: massimo.levrero@uniroma1.it

Background and Aims: HBV Core protein (Cp) represents an attractive new therapeutic target for HBV chronic infection. In addition to their role in capsid assembly, pgRNA packaging and reverse transcription, Cp has been shown to bind the nuclear cccDNA mini-chromosome as well as a number of cellular genes promoters. Several compounds that target Cp and HBV capsids assembly, including the Hetero-aryl-dihydropyrimidines (HAPs) and the phenyl-propenamide derivatives AT61 and AT130, have been shown to inhibit HBV replication in vitro and in vivo. HAPs and AT130 enhance the rate and the extent of Cp assembly leading to non-functional capsids and, at high concentration, stabilize preferentially non-capsid polymers of Cp. Here we investigated the ability of the Core protein Assembly Modulators (CaMPs) HAP12 and AT130 to affect both nuclear (cccDNA structure and transcription) and cytoplasmic (capsid maturation and replication) Cp functions as part of their antiviral activity against HBV.

Methods: HAP12 and AT130 effects on capsid-associated HBV-DNA (TaqMan real-time PCR), cccDNA (TaqMan real-time PCR) and pgRNA levels (quantitative real-time PCR with specific primers), were assessed in: (a) HBV-infected NTCP-HepG2 cells; (b) AD38 inducible HBV stable cell line. Recruitment of HBc and histone modifications on the viral minichromosome were assessed using the cccDNA ChIP assay in AD38 cells.

Results: CaMPs treatments started at day 6 post-infection (NTCP-HepG2) or day 6 post-induction (AD38 tet-off cells) resulted in a very strong inhibition of HBV replication (>95%) and a significant but incomplete reduction of the stable cccDNA pool. A strong effect on cccDNA-dependent HBeAg production (AD38 tet-off) and pgRNA transcription (AD38 tet-off / tet-on and NTCP-HepG2 infected cells) was also demonstrated. The ability HAP12 to target cccDNA transcription was confirmed by the reduced cccDNA-bound H3 histone acetylation and the descreased HBc occupancy on the

cccDNA in induced AD38 cells. Importantly, when CaMPs treatment was started during infection, cccDNA formation/accumulation was completely inhibited (>95%) and viral replication was blunted.
Conclusions: Anti-capsid compounds (CpAMs) have an impact on Cp nuclear functions at multiple levels: block of new cccDNA formation / accumulation, reduction of an established cccDNA pool and inhibition of HBc occupancy and histone acetylation on the cccDNA that translate into a reduced pgRNA transcription.

MYRCLUDEX-B INHIBITS ESTABLISHMENT OF HDV SUPER-INFECTION IN HBV INFECTED MICE AND REDUCES HDV VIREMIA IN STABLY HBV/HDV CO-INFECTED MICE

T. Volz[1], K. Giersch[1], L. Allweiss[1], O.D. Bhadra[1], J. Petersen[2], A.W. Lohse[1,3], M. Lütgehetmann[1,4], S. Urban[5,6], M. Dandri[1,3]. *[1]I. Department of Internal Medicine, University Medical Center Hamburg Eppendorf, [2]IFI Institute for Interdisciplinary Medicine, Asklepios Clinic St. Georg, [3]Hamburg and Heidelberg Sites, German Center for Infection Research, [4]Institute of Microbiology, Virology and Hygiene, University Medical Center Hamburg Eppendorf, Hamburg, [5]Department of Infectious Diseases, Molecular Virology, University Hospital Heidelberg, [6]Hamburg and Heidelberg Sites, German Center for Infection Research, Heidelberg, Germany*
E-mail: t.volz@uke.de

Background and Aims: 15 million people are infected with the hepatitis Delta virus (HDV) worldwide. Therapeutic strategies specifically targeting HDV infection are not available but urgently needed. We previously demonstrated prevention of de novo HBV/HDV co-infection using the entry inhibitor Myrcludex-B in naïve human liver-chimeric uPA/SCID mice (Lütgehetmann, Hepatology 2012). Aim of the study was to assess (I) whether treatment with Myrcludex-B can hinder infection establishment and spreading of HDV also in humanized mice already infected with HBV, and (II) whether long-term entry inhibition can affect viremia levels in stably HBV/HDV co-infected mice.
Methods: Humanized uPA/SCID mice were first stably infected with HBV, then super-infected with HDV and treated with Myrcludex-B (2 mg/kg; daily) 2 days before until 5 weeks after HDV inoculation (I), while stably HBV/HDV co-infected mice received Myrcludex-B daily for 9 weeks (II). Viral loads were quantified in serum and liver by qRT-PCR and visualized by immunohistochemistry.
Results: (I) In HBV-infected mice, which received Myrcludex-B during the first 5 weeks of HDV super-infection, HDV viremia, intrahepatic HDV RNA and HDAg remained below detection levels. However, one mouse showed development of HDV viremia 3 weeks after treatment cessation, demonstrating that Myrcludex-B strongly hindered but did not completely abrogate establishment of HDV infection in humanized mice. (II) In stably HBV/HDV co-infected mice, 9 weeks of Myrcludex-B treatment induced 1-log reduction of HDV, while HBV viremia was similar in untreated and treated mice. However, no significant intrahepatic viral changes could be determined by comparing treated and untreated animals. The ratio of HDV RNA quasi-species encoding for the small and large HDAg was also maintained after 9 weeks of Myrcludex-B administration.
Conclusions: Myrcludex-B significantly inhibited HDV infection establishment also in the presence of a productive HBV infection. However, continuous drug administration was necessary to prevent HDV spreading from the very few initially infected human hepatocytes. Long-term treatment of HBV/HDV co-infected mice with the entry inhibitor was needed to detect HDV viremia decrease. The high infection efficiency and great survival capacities of HDV shown in this study highlight the difficulties encountered in treating HBV/HDV co-infected patients.

Background and Aims: Hepatitis B virus carrying the rtA181T/sW172* mutation conferred cross-resistance to adefovir and lamivudine. Cell-based and epidemiological studies indicated that hepatitis B virus pre-S/S proteins carrying this mutation had an increased oncogenic potential. Here we created transgenic mice models to study this issue.
Methods: Transgenic mice were generated by transfer of hepatitis B virus pre-S/S gene (genotype A) together with its own promoter into C57B6 mice.
Results: Four lines of transgenic mice were created. Two of them carried wild type pre-S/S gene and produced high and low levels of HBsAg (TgWT-H and L). The other two carried mutant type pre-S/S gene containing the rtA181T/sW172* mutation (TgSW172-H and L). Western blot/IHC analysis detected high and low levels of intrahepatic truncated pre-S/S proteins respectively in TgSW172-H and L mice. The former had detectable low level of HBsAg in the serum, while the latter was negative for serum HBsAg (secretion failure). All mice were sacrificed 18 months after birth. None of the TgWT mice developed hepatocellular carcinoma (HCC), whereas 6/26 (23.1%) TgSW172-H and 2/24 (8.3%) TgSW172-L mice developed HCC. Molecular analysis of liver tissues revealed significantly increased expression of GPR78 and phosphorylated ERK1 in TgSW172 mice versus TgWT mice; and decreased expression of Bcl-XL in TgSW172-H mice versus TgSW172-L and TgWT mice. Higher proportion of apoptotic cells assessed by TUNEL assay was found in TgSW172-H than in TgWT mice, but both showed increased cyclin E levels, suggesting increased hepatocyte turnover and regeneration. Combined analysis of cDNA microarray and microRNA array showed reduced expression of the CUB and Sushi multiple domains 3 (CSMD3) protein, a putative tumor suppressor, in TgSW172 but not TgWT mice.
Conclusions: Transgenic mice experiments confirmed that the pre-S/S gene carrying rtA181T/sW172* mutation had an increased oncogenic potential in development of liver cancer. Increased ER stress with more rapid hepatocyte turnover as well as decreased expression of CSMD3 contributed in part to hepatocarginogenesis.

P0532
HBx–DLEU2 lncRNA COMPLEX AFFECTS TRANSCRIPTION OF NEW TARGET PROMOTERS

F. Guerrieri[1], L. Chiodo[2], S. Jeddari[3], D. D'Andrea[4], G. Ruocco[1], A. Tramontano[4], M. Levrero[3]. *[1]CLNS@SAPIENZA, Istituto Italiano di Tecnologia (IIT), Rome, [2]CLNS@SAPIENZA, Istituto Italiano di Tecnologia (IIT), IIT, [3]Dept of Internal Medicine, Sapienza University, [4]Biocomputing Lab, Department of Physics, Sapienza University of Rome, Rome, Italy*
E-mail: fraguerrieri@gmail.com

Background and Aims: HBx affects HBV mini-chromosome transcription, by preventing HDACs and PMRT1 recruitment on the cccDNA, and cellular genes expression, by favoring the recruitment of positive and negative chromatin modifying enzymes. A ChIPSeq analysis of HBx genome wide recruitment identified 39 long non coding RNAs (lncRNAs), including DLEU2, as direct HBx transcriptional targets in HBV replicating cells. DLEU2 lncRNA overlaps the first exon of the TRIM13 gene in the opposite orientation and the pri-Mir of the miR-15a/16–1 cluster. Up-regulation of specific DLEU2 splicing variants correlates with tumors. TRIM13 induces autophagy and increase ectopic levels of p53.

Methods: Anti-HBx ChIP were performed in HepG2 cells replicating wt and HBx-mt HBV. HBx ChIPed DNA and lncRNA/gene expression levels were analysed by TaqMan RT-PCR using specific primers. Specific LNA™ longRNA GapmeRs (Exiqon) were used for highly efficient inhibition of DLEU2 lncRNA function. I-Tasser was used for *ab initio* prediction of HBx protein structure. RNA secondary and tertiary structures were predicted with the *RNAfold* and *3dRNA* softwares, respectivly. Protein-RNA interactions were calculated by *Hex*.
Results: We show that HBx binding to the DLEU2 promoter leads to increased H4 acetylation, a different DLEU2 splicing profile, down-regulation of miR-15a/16–1 cluster and up-regulation of the antisense autophagic gene TRIM13, in the absence of HBx binding to the TRIM13 promoter. GapmeR-mediated selective degradation of DLEU2 RNA results in reduced TRIM13 promoter H4 acetylation and a ~50% reduction of TRIM13 expression in HBV replicating cells. These results directly link DLEU2 RNA species with TRIM13 transcriptional regulation in the presence of HBx. The interaction between HBx and DLEU2 was confirmed by RIP (RNA Immune Precipitation) experiments. We further characterized the HBx-DLEU2 complex *in silico* by coupling *ab initio* modeling of HBx protein and DLEU2 RNA tertiary structures and we constructed a docking model of DLEU2-HBV complex. Finally, we found that DLEU2 inactivation has a profound impact on pgRNA transcription, suggesting a functional relevance of DLEU2-HBx interaction for HBV replication.
Conclusions: HBx targets the DLEU2 promoter leading to a different DLEU2 splicing profile and its binding to DLEU2 RNA species affects cellular genes transcription and HBV replication.

P0533
THE EFFICACY OF ZINC FINGER ANTIVIRAL PROTEIN AGAINST HEPATITIS B VIRUS TRANSCRIPTION AND REPLICATION IN TRANSGENIC MOUSE MODEL

E.-Q. Chen[1,2], H. Tang[1,2], J. Dai[1,2], L. Bai[1,2]. [1]*Center of Infectious Diseases, West China Hospital of Sichuan University,* [2]*Division of Infectious Diseases, State Key Laboratory of Biotherapy, Sichuan University, Chengdu, China*
E-mail: htang6198@hotmail.com

Background and Aims: The zinc finger antiviral protein (ZAP) is a mammalian host restriction factor, and it could inhibit HBV RNA synthesis in vitro experiments. However, the role of ZAP against HBV in vivo environment is unclear. This study aimed to investigate whether ZAP could act against HBV transcription and replication in ZAP tansgenic mouse model.
Methods: HBV-replication-competent plasmid pHBV4.1 was transferred to ZAP transgenic ICR mice via the tail vein, using a hydrodynamic in vivo transfection procedure. HBV RNA and HBV DNA replication intermediates in the liver were respectively analyzed by Northern blotting and Southern blotting. The expression of hepatitis B surface antigen (HBsAg) and hepatitis B core antigen (HBcAg) in the liver tissue was detected by immunohistochemical staining.
Results: As compared to control ICR mouse, the level of HBV RNA in ZAP transgenic mouse liver tissue was only decreased by 8.4%; while the level of HBV DNA replication intermediates was decreased by 82%. In addition, the expression levels of HBsAg and HBcAg in ZAP transgenic mouse liver were both significantly less than that of control ICR mouse.
Conclusions: Our findings suggest that ZAP could inhibit HBV replication in vivo in mice, which offers a new target for anti-HBV drug development.

P0534
HEPATITIS E VIRUS RNA REPLICATION IS ENSURED BY UNPROCESSED ORF1 PROTEIN

V. Loan Dao Thi[1], S.U. Emerson[2], T. Ahola[3], D. Moradpour[1], J. Gouttenoire[1]. [1]*Division of Gastroenterology and Hepatology, Centre Hospitalier Universitaire Vaudois – University of Lausanne, Lausanne, Switzerland;* [2]*2Molecular Hepatitis and Hepatitis Viruses Sections, Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, United States;* [3]*Institute of Biotechnology, University of Helsinki, Helsinki, Finland*
E-mail: Jerome.Gouttenoire@chuv.ch

Background and Aims: Hepatitis E virus (HEV) infection is believed to be the most common cause of acute hepatitis and jaundice in the world. HEV is a non-enveloped positive-strand RNA virus whose genome encodes 3 open reading frames, namely ORF1, ORF2 and ORF3. The aim of this study was to clarify whether the HEV ORF1 protein, which harbors the viral genome replication functions, is processed into distinct functional proteins.
Methods: ORF1 from HEV genotypes 1 and 3 was expressed in different experimental systems, including (i) a wheat germ-based cell-free expression system, (ii) a T7 polymerase-based cellular expression system, (iii) newly established human cell lines inducibly expressing HEV ORF1, as well as (iv) selectable subgenomic HEV replicons derived from the Kernow-C1 strain, followed by immunoblot and immunofluorescence analyses using antibodies directed against different ORF1 domains, i.e. the methyltransferase, helicase and RNA-dependent RNA polymerase.
Results: The product of HEV ORF1 was detected only as single a protein of ~190 kDa in the four experimental systems investigated, including in a context of authentic viral RNA replication. In addition, the different ORF1 domains perfectly colocalized at an as yet undefined cellular compartment. Collectively, these results indicate that no or only very inefficient processing of the polyprotein encoded by ORF1 occurs during viral RNA replication.
Conclusions: Our results indicate that HEV RNA replication is ensured by unprocessed ORF1 protein. Efforts are ongoing to validate these findings in a fully infectious system. Our findings yield a number of intriguing questions regarding the functional organization, structure and cell biology of the polyprotein encoded by HEV ORF1.

DIRECT ANTIVIRAL EFFECTS OF VARIOUS PATTERN RECOGNITION RECEPTOR (PRR) AGONISTS IN HBV-REPLICATING HEPATOCYTES

J. Lucifora[1,2], S. Maadadi[2,3], O. Floriot[1,2], S. Daffis[4], S. Fletcher[4], F. Zoulim[1,2,5], D. Durantel[1,2]. [1]*U1052, INSERM,* [2]*UCBL, University of Lyon,* [3]*INSERM, U1052, Lyon, France;* [4]*Gilead Sciences, Foster City, United States;* [5]*Liver unit, Hospices Cilvils de Lyon, Lyon, France*
E-mail: david.durantel@inserm.fr

Background and Aims: Current therapies for chronic hepatitis B virus (HBV) infection are effective at suppressing viral replication and improve long-term outcome, but have only low rates of HBsAg loss and anti-HBs seroconversion. There is an urgent need to identify new antiviral therapies to achieve functional cure and so decrease the risk of end-stage liver disease. Studies with the oral TLR7 agonist GS-9620 in animal models of chronic hepatitis B (CHB) have recently highlighted the potential of therapeutic immune modulation by small molecule agonists of innate immunity. To further explore the potential of PRR agonists to induce efficient and durable immune control against HBV, we tested the direct anti-HBV effect of different PRR agonists in cell culture models of natural infection.
Methods: Primary human hepatocytes (PHH) and differentiated HepaRG cells (dHepaRG), which are both innate immune competent cells, were infected with HBV for 7 days, and then treated with

various concentrations of different PRR agonists for 7 days. Antiviral activity was evaluated by quantifying HBeAg and HBsAg secretion (ELISA), HBV RNA (qRT-PCR) and total intracellular HBV DNA and cccDNA (qPCR), and toxicity measured by MTS assay and ApoB ELISA. Cytokine production was evaluated by ELISA 24 hours (h) post-stimulation.

Results: The cytokines IP-10 and/or IL-6 were secreted by both PHH and dHepaRG 24 h after stimulation with TLR1/2, TLR3, TLR4, TLR5, TLR2/6, RIG-I/MDA5, and AIM2 agonists, which correlated with a strong and dose-dependent antiviral effect in the absence of toxicity. The maximal antiviral effect was induced by Pam3CSK4 (i.e. TLR1/2-L), which induced sustained reduction in all viral parameters, including levels of cccDNA. Stimulation with TLR7, TLR8 and TLR9 agonists did not significantly induce IP-10 or IL-6 production and, with the exception of imiquimod, did not inhibit HBV replication. Interestingly, the antiviral response induced by imiquimod was independent of innate immune activation, suggesting an additional mode of action that should be further investigated.

Conclusions: Our data highlight the potential of direct innate immunity activation in hepatocytes in the control of HBV replication, and support the recent interest in the development of PRR-based antiviral strategies against HBV. In addition, our data suggest that elucidation of the mode of antiviral action of imiquimod may lead to the identification of a novel target for the treatment of CHB.

P0536
OSTEOPONTIN IS INVOLVED IN CHRONIC HBV INFECTION AND ENHANCES HBV REPLICATION AND HBsAg SECRETION

S. Phillips[1], J. Coombes[1], S. Mistry[1], R. Williams[1], W. Syn[1], S. Chokshi[1]. [1]*Foundation for Liver Research, Institute of Hepatology, London, United Kingdom*
E-mail: s.phillips@researchinliver.org.uk

Background and Aims: Hepatitis B virus (HBV) requires host cellular machinery such as cyclophilins to support its ongoing propagation (Phillips et al, Gastroenterology 2014), these host proteins represent ideal candidates for therapeutic interventions as they are generally expected to have a lower frequency of drug-resistance and antiviral efficacy across genotypes. We have also recently described a role for the host protein Osteopontin (OPN), a pro-fibrogenic downstream effector of the Hedgehog pathway, in enhancing HCV replication (Choi et al, Clinical Sciences 2014). Whilst increased levels of blood OPN have similarly been reported in chronic Hepatitis B (CHB), its role in viral replication remains unknown. This study aimed to evaluate the role of OPN in HBV replication, HBsAg secretion and HBV-driven liver injury.

Methods: Stably (HepG2215), transiently (HUH-7) transfected and infected (HepaRG) cell lines, producing full HBV virions and HBsAg particles were cultured over 72 h in the presence/absence of several concentrations of recombinant OPN (recOPN). In addition, secreted OPN was neutralized using OPN-specific aptamers. Cells and supernatants were harvested at baseline, 24, 48 and 72 hours. Intracellular OPN mRNA and HBV-DNA levels were quantitated by Real-Time qPCR. HBsAg levels were measured by ELISA. OPN levels were also measured by ELISA in cell culture supernatants and in sera of controls and HBeAg(+) CHB patients who were either treatment naive or treated with potent antiviral agents. In addition, expression of OPN was assessed in explanted livers from healthy and HBV-cirrhotic patients.

Results: Serum levels and intrahepatic expression of OPN were significantly increased in CHB patients compared to controls (up to 7 fold; $p < 0.05$). In vitro, mRNA and protein levels of OPN were highly correlated with intracellular HBV-DNA ($r = 0.858; p < 0.001 / r = 0.997; p = 0.003$), secreted HBV-DNA ($r = 0.968; p < 0.001 / r = 0.818; p = 0.047$) and secreted HBsAg ($r = 0.738; p = 0.001 / r = 0.89; p = 0.018$). The relationship between OPN and HBV replication was further confirmed following treatment with recOPN which showed a significant increase in intracellular and secreted HBV-DNA by an additional 1.3 Log10 copies/mL and amplified HBsAg secretion rates by 2 fold.

Conclusions: These data confirm that OPN is upregulated in the blood and livers of CHB patients. We also show that OPN directly augments HBV replication, thus identifying a novel therapeutic target.

DATING THE ORIGIN OF HBV USING FULL-LENGTH SEQUENCES

D. Paraskevis[1], K. Angelis[1], G. Magiorkinis[2], E. Kostaki[1], S. Ho[3], A. Hatzakis[1]. [1]*Department of Hygiene, Epidemiology and Medical Statistics, Medical School, University of Athens, Athens, Greece;* [2]*Department of Zoology, University of Oxford, Oxford, United Kingdom;* [3]*School of Biological Sciences, University of Sydney, Sydney, Australia*
E-mail: dparask@med.uoa.gr

Background and Aims: The origin of HBV has been debated. Our previous analyses based on the overlapping S/P region suggested that HBV has followed major expansion of modern humans, with its origin to be estimated 22,000–47,000 years ago [1]. Our aim was to test the hypothesis of co-expansion between HBV and humans and to propose a new approach for dating based on full-length genomic sequences.

Methods: Analyses were performed on 105 HBV sequences from all major genotypes. We initially tested the co-expansion hypothesis performing a Bayesian molecular clock analysis calibrated at the origin of the F/H genotypes from Amerindians. To date the origin and evolution of HBV we use five calibration points at the origin of F/H genotypes, D_4, C_3 and B_6 from indigenous populations in Pacific and Arctic, respectively, and A_5 from Haiti. We translated anthropological, genetic and archaeological time estimates into statistical distributions, taking uncertainty of those estimates into account, to be used as calibration densities on an HBV phylogeny estimated with ML. Bayesian dating analyses were performed using the MCMCTree program. The analyses were based on three partitions across the genome.

Results: The molecular clock analysis using a calibration on the most recent common ancestor (MRCA) of F and H genotypes estimated the origins of C_3 and D_4 at 5,910 and 10,558 years ago, which coincide with genetic estimates of the timing of human population movements (5,100–8,100 and 6,200–12,000 years, respectively). The estimated time for the origin of HBV was 34,103 (95% HPD CI: 27,623–41,347) years ago, coinciding with the origin of modern non-African humans. Moreover, the time estimates of HBV lineages had significantly narrower credibility intervals than in a previous analysis of the overlapping S/P region [1]. The substitution rates for the different partitions were estimated at 2.6×10^{-6}, 4.4×10^{-6} and 4.4×10^{-6} substitutions/site/year.

Conclusions: Our study, using for the first time full-length sequences, provides an estimate of the timescale of HBV epidemic that coincides with dates of migrations of modern humans. The hypothesis of co-expansion of the pathogen and the human host was supported by our findings. Our study provides a new approach for dating HBV based on the most informative full-genomic HBV alignment.

E-mail: dparask@med.uoa.gr

Background and Aims: HBV genotypes have a distinctive distribution in the Arctic: B_6 is unique to Inuit populations of North America and Greenland; D_3 and D_4 circulate primarily among the First Nations (Na-Dene) population in northern Canada and D_1/D_2 is found among Inuit in Greenland. Our aim was to estimate the origin and dispersal of HBV infection in indigenous Arctic populations and understand better the global mobility of the HBV epidemic.
Methods: We used a phylogenetic approach to study the dispersal of HBV genotype D (*N*=81 sequences) using all sequences available (*N* = 2,965) in the overlapping P/S region. To estimate the date of HBV origin we performed a Bayesian dating analysis using 128 sequences and five calibration points at the origin of F/H genotypes, D_4, C_3, B_6 and A_5. Based on anthropological, genetic and archaeological time estimates of human migrations, we calibrated the HBV molecular clock. We estimated the timescale of HBV evolution using the program MCMCTree.
Results: Phylogenetic analyses suggest that subgenoypes D_4 and D_1/D_2 from Canada and Greenland are monophyletic, whereas D_3 strains from Na Dene are dispersed within the D_3subgenotype. The D_1/D_2sequences were more closely related to viral strains from Central Asia (Turkey, India), but their exact origin is not evident. The time of origin of B_6 was estimated at 5,904 (95%HPD CI: 5,180–6,470), of D_4 in the Arctic at 2,948 (1,120–5,510) and of D_1/D_2 4,104 (1,860–5,880) years ago. Subgenotype D_4 (tMRCA: 6,579; 95%HPD: 4,650–11,150) formed two major clades: one from Qinghai-Tibet (tMRCA: 3,393; 95%HPD: 1,170–5,930) and another from the Pacific, the Arctic and the Americas. This suggests that HBV D_4 has followed a long dispersal through Central Asia in Tibet, and then took two distinct routes in Remote Oceania and North Eastern Asia from where it migrated to Americas.
Conclusions: Our analysis, based on one of the largest HBV datasets from Arctic indigenous populations, provided evidence that in addition to B_6, D_4 and D_1/D_2 are inherent to these populations. In contrast, D_3 was the result of multiple introductions. The distinct ages of HBV subgenotypes could suggest that introduction of HBV in the Arctic might have occurred at different time periods. Notably our study provides evidence that D_1/D_2 found at low prevalence in Greenland probably originated from Central Asia, where D_1/D_2 is circulating. To our knowledge this is one of the few studies showing genetic evidence for a Central Asian-Greenlandic HBV association.

P0539

EXPRESSION PROFILE OF Tim-3 INDUCED BY MULTIPLE CYTOKINES AND ANTIGENS IN PATIENTS WITH CHRONIC HEPATITIS B

J. Dong[1], X. Yang, R. Zhao, H. Shen, Y. Zhao, Y. Zhang, C. Huang, J. Lian. *[1]Infectious Diseases, Tangdu Hospital, Fourth Military Medical University, Xi'an, China*
E-mail: 903913505@qq.com

Background and Aims: Previous studies have demonstrated HIV-1 could not directly induce the expression of T cell immunoglobulin- and mucin-domain-containing molecule-3 (Tim-3) on $CD4^+$ and $CD8^+$T cells, However, Tim-3 could be markedly enhanced by the common gamma-chain (γc) cytokines. Thus, the aim of the study was to investigate whether the expression of Tim-3 on the $CD4^+$ and $CD8^+$ T cells in HBV infection was closely related to the gamma-chain cytokines and HBV associated antigens.
Methods: Peripheral blood mononuclear cells was obtained from chronic hepatitis B (CHB) patients (n = 108) and healthy volunteers (n = 30). PBMCs were stimulated by HBV Ag, HBV Pep or gamma-chain cytokines, respectively. The expression of Tim-3 on peripheral $CD4^+$ and $CD8^+$ T cells was determined by flow cytometry.
Results: Under the stimulation of HBV Ag and HBV Pep, The Tim-3 expression by HBV Pep stimulated was elevated on peripheral $CD4^+$ and $CD8^+$ T cells from CHB patients compared to those from the healthy controls. After the gamma-chain cytokines stimulation, the increased-expression of TIM-3 was also detected on peripheral $CD4^+$ and $CD8^+$ T cells of CHB patients compared to that of the healthy controls. Given the combined stimulation of the gamma-chain cytokines and HBV Pep, there are also a enhanced expression of Tim-3, as well as the results of their alone stimulation.
Conclusions: The current results suggest that the HBV Ag, HBV Pep, and the gamma-chain cytokines could induce the over-expression of Tim-3 in the HBV patients, which may indicate that the inhibition of these cytokines can not only decrease the expression of Tim-3, but also may enhance the cytotoxic function of $CD8^+$T cells in patients with CHB.

P0540

THE SUBSTITUTION AT rt269 IN HEPATITIS B VIRUS POLYMERASE IS ASSOCIATED WITH THE MULTI-DRUG RESISTANCE AS A COMPENSATORY MUTATION

Sung Hyun Ahn[1], D.H. Kim[1], B.K. Kim[2], A.R. Lee[1], Sang Hoon Ahn[2], Y.K. Park[3], E.-S. Park[3], K.-H. Kim[1], Y.K. Park[1], Sung Hyun Ahn[1], E.-S. Park[1], D.H. Kim[1], A.R. Lee[1]. *[1]Pharmacology, Konkuk University, Seoul, [2]Internal Medicine, Yonsei University, Seoul, [3]Konkuk University, Seoul, Korea, South*
E-mail: khkim10@kku.ac.kr

Background and Aims: The emergence of compensatory mutation in polymerase gene of drug resistant hepatitis B virus (HBV) is associated with treatment failure. We previously identified a multi-drug resistant HBV mutant which showed resistant to lamivudine (LAM), clevudine (CLV), and entecavir (ETV) with strong replication ability. The aim of this study was to identify the previous unknown compensatory mutation and to search the clinical relevance of this mutation during antiviral therapy.
Methods: In vitro mutational analysis and drug susceptibility assay were performed to characterize the function of rtL269I mutation.
Results: The point mutation of rtL269I showed about 2- to 7-fold higher replication ability in wt or YMDD mutation back-bone regardless of drug treatment. The rtL269I mutation by itsefl did not show the resistance to LMV, CLV, ETV, adefovir (ADV), and tenofovir (TDF) treatment. However, when the rtL269I was combined with YMDD mutation, it enhanced the replication ability by several folds under LMV or ETV treatment. Molecular modeling study predicted that rtL269I mutation may affect the negative antiviral action of nucleos(t)ide drugs and incoming dNTP binding.
To investigate the clinical relevance of rtL269I mutation, we analyzed a total of 22 patients who showed suboptimal response or treatment failure during antiviral monotherapy and found that 16 patients had the YMDD mutation. Among them, 7 (43.8%) patients harbored the rtL269I mutation. We further analyzed so-called the "difficult-to-treat" cases who experienced the complex history of antiviral therapy. Among 14 "difficult-to-treat" patients, the 13 patients had rtL269I mutation during the follow-up.
Conclusions: Collectively, our study suggests that the substitution at rt269 in HBV polymerase is associated with the multi-drug

resistance and may serve as a novel compensatory mutation for replication defect of multi-drug resistant HBV.

P0541

SMALL INTESTINAL PERMEABILITY IS ELEVATED IN CHRONIC VIRAL HEPATITIS PRIOR TO THE DEVELOPMENT OF CIRRHOSIS, AND IS ASSOCIATED WITH THE DEGREE OF FIBROSIS

A.S. Raj[1,2], G. Holtmann[1,2], L. Fletcher[1,2], P. Bhat[2], C. Tran[3], M. Black[1], K. Nath[1], W. Jao[1], D. Vesey[4], G.A. Macdonald[1,2]. *[1]Gastroenterology and Hepatology, Princess Alexandra Hospital, [2]School of Medicine, University of Queensland, Brisbane, [3]Gastroenterology, Womens and Childrens Hospital, Adelaide, [4]Centre for Kidney Disease Research, University of Queensland, Brisbane, Australia*
E-mail: ashok.raj@uq.edu.au

Background and Aims: Small intestinal permeability may play a role in fibrosis progression in chronic liver disease. However portal hypertension itself is likely to contribute to increased permeability measurements. Few data exist in patients with chronic viral hepatitis prior to the development of portal hypertension.
Aim: To determine if small intestinal permeability is associated with hepatic fibrosis in non-cirrhotic patients with chronic viral hepatitis.
Methods: Subjects with chronic viral hepatitis without cirrhosis were prospectively recruited and compared to healthy volunteer controls. Small intestinal permeability was assessed by determining the ratio of plasma concentrations of lactulose and rhamnose (expressed as log L:R ratio), 90 minutes after oral ingestion of 5g lactulose and 1g rhamnose. Hepatic fibrosis was assessed by Transient Elastography (kPa) and hepatic steatosis by the Controlled Attenuated parameter (CAP). The limulus-amebocyte lysate assay was used to detect endotoxaemia in peripheral blood. Subjects were excluded if they had a liver stiffness measurement >11 kPa and platelet count $<150\times10^9$, drank alcohol within 24 hours of testing or had known gastrointestinal pathology. Statistical analysis was performed utilising SPSS.
Results: 39 subjects with chronic viral hepatitis (23 chronic hepatitis B, 16 with chronic hepatitis C) and 29 healthy volunteers completed evaluation. Small intestinal permeability was significantly higher in chronic viral hepatitis vs controls (2.78 ± 0.13 vs. 2.21 ± 0.18, $p=0.01$) (mean±SEM). In the chronic viral hepatitis group, there was a positive correlation between permeability and hepatic stiffness (Pearson's correlation $r=0.40$, p-value 0.01). There was no correlation between permeability and age ($p=0.46$), renal function ($p=0.26$) or CAP value (0.73), and no difference between those with and without the metabolic syndrome (p 0.61). The proportion of endotoxin-positive subjects was similar between chronic liver disease and healthy controls (2/39 vs 1/29, $p=1.0$).
Conclusions: Small intestinal permeability is increased in non-cirrhotic patients with chronic viral hepatitis and is associated with the degree of fibrosis. These data suggest that permeability is elevated prior to the development of portal hypertension.

THERAPEUTIC EFFECT AGAINST HEPATITIS B OF VARIOUS NUCLEIC ACID POLYMERS IN THE CHRONIC DHBV INFECTION MODEL

C. Brikh[1], C. Jamard[1], J. Quinet[1], C. Bouchareb[1], I. Roehl[2], A. Vaillant[3], L. Cova[1]. *[1]CRCL, INSERUM U1052, University Lyon 1, Lyon, France; [2]Axolabs GMBH, Kulmbach, Germany; [3]REPLICor Inc., Montreal, Canada*
E-mail: availlant@replicor.com

Background and Aims: Nucleic acid polymers (NAPs) block the release of HBsAg from infected hepatocytes and can effectively clear the blood of HBsAg in human subjects with chronic HBV infection. When used in combination with immunotherapy, NAPs can achieve higher SVR rates in patients than when immunotherapy is used alone. The goal of this preclinical study was to examine the effect of various NAP modifications on their tolerability, liver accumulation and antiviral effect in vivo in the chronic DHBV infection model.
Methods: Three-day-old Pekin ducklings were infected with infectious duck serum (2×10^{11} VGE/ml of DHBV). NAP treatment was started in 14 day old animals via intraperitoneal injection with 10 mg/kg of NAPs 3 times / week for three weeks followed by autopsy analysis. All five NAPs used (REP 2055, REP 2139, REP 2163, REP 2165 and REP 2166) had the same sequence composition ([AC]20) but each comprised different modifications impacting the tolerability and stability of oligonucleotides. Tolerability was assessed by monitoring weight during treatment, injection site reactivity and findings at autopsy. NAP levels in the liver at the end of treatment were assessed by fluorescence-HPLC using a fluorescent PNA probe-based hybridization assay. Antiviral activity was assessed by monitoring serum DHBsAg and anti-DHBpreS antibodies by ELISA and serum and liver DHBV DNA by quantitative PCR.
Results: No significant changes in weight gain or injection site reactions were observed for any NAP. All NAPs tested reduced serum DHBsAg and this effect was more pronounced with REP 2055, REP 2139, REP 2163 and REP 2165. The most significant stimulation of anti-DHBpreSAg antibody response was observed in the REP 2139 and REP 2165 groups. Substantial reductions in serum DHBV DNA were found in all NAP groups. Drastic decrease in liver DHBV DNA was observed for four groups treated with REP 2055, REP 2139, REP 2163 and REP 2165. Importantly, liver accumulations for some NAPs that were less resistant to nuclease attack (REP 2055 and REP 2165) were 6–7 fold less at the end of treatment than for REP 2139 yet showed comparable antiviral activity.
Conclusions: The tolerability and liver accumulation of NAPs can be modulated significantly without affecting their overall ability to reduce serum DHBsAg and elicit other crucial antiviral responses in DHBV-carriers, suggesting important ways in which NAPs can be altered to minimize side effects and liver accumulation in human subjects receiving NAP therapy.

P0543

COMPARATIVE EVALUATION OF THE ARTUS HBV QS-RGQ ASSAY AND THE ROCHE COBAS AMPLIPREP/COBAS TAQMAN V.2 HBV TEST FOR THE QUANTIFICATION OF HBV DNA IN PLASMA

S. Brichler[1], S. Dziri[1], A. Duhant[1], G. Faleu[1], E. Gordien[1]. *[1]Virology department, associated with the National Reference Center for Viral Hepatitis B, C and Delta, Avicenne Hospital, Bobigny, France*
E-mail: segolene.brichler@avc.aphp.fr

Background and Aims: Hepatitis B Virus (HBV) infection is a major cause of chronic liver disease. Virological monitoring of HBV DNA is essential for the diagnosis, follow-up and treatment of infected patients. HBV viral load (VL) quantification on plasma samples is based on viral DNA extraction, followed by real-time PCR amplification. VL are standardized and expressed in International Units (IU)/mL. Numerous commercial kits are now available. Evaluation of a new assay should ideally be performed on diverse clinical populations.
The goal of this study was to evaluate the performances of the artus HBV QS-RGQ kit from QIAGEN.
Methods: We analyzed 230 samples from HBV-infected patients, and 12 negative samples (HBsAg negative patients). Patients were informed; plasma samples were taken for routine follow-up, and stored at −80°C until testing; VL were routinely quantified with Ampliprep/Cobas Taqman v.2 Assay (Roche), used as predicate device for method comparison analysis. Repeatability and reproducibility were evaluated using 3 VL levels of 2 samples (genotype A and D), analyzed 8 and 7 times respectively. DNA extraction was performed with the DSP Virus/Pathogen Midi Kit

on a QIASymphony SP/AS system, using 1 mL of plasma, and DNA elution in 60 μL buffer.
Results: Intra-assay and inter-assay coefficients of variation of the artus HBV QS-RGQ kit ranged from 0.4% to 2.8% and 0.3% to 8.1%, respectively. No negative sample was found positive. 52 samples were undetectable or below the lower limit of quantification, and 7 above the upper limit. 171 VL were within the linear quantification range for both techniques [1.5–7.3 log IU/mL]. Linear regression analysis showed an R2 value of 0.89. Bland-Altman analysis showed a good level of agreement with a median difference (Roche-QIAGEN) of +0.1 log IU/mL. 77% VL were within a −0.5/+0.5 log IU/mL difference range. A total of 20 samples were discordant between the two tests. The potential influence of gender, age, viral co-infections, ongoing treatments, as well as HBV genotype, on HBV quantification is currently evaluated.
Conclusions: In conclusion, the QIAGEN artus HBV QS-RGQ assay is specific, reproducible, and accurately quantifies HBV VL in chronically infected patients. Differences in technical protocols may explain the discrepancies observed. While the quantification range is a bit narrower than that of other available assays, these data suggest that the artus HBV QS-RGQ assay is suitable in monitoring HBV DNA levels according to current clinical practice guidelines.

INNATE AND ADAPTIVE IMMUNE RESPONSES CORRELATE WITH PEGINTERFERON ALFA TREATMENT EFFICACY IN CHRONIC HEPATITIS B PATIENTS (THE OSST IMMUNOLOGY STUDY)

W. Yan[1], D. Wu[1], X. Wang[1], Q. Lai[2], Q. Zheng[2], J. Jiang[3], J. Hou[2], M. Han[1], Q. Ning[1]. *[1]Department and Institute of Infectious Disease, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, [2]Hepatology Unit and Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, [3]Department of Liver Diseases Research Center, First Affiliated Hospital of Fujian Medical University, Fuzhou, China*
E-mail: tj_hu@126.com

Background and Aims: The aim of this study was to characterize the immunological features responsible for improved treatment responses in 77 patients with chronic hepatitis B (CHB) treated with peginterferon (Peg IFN) alfa-2a after switching them from entecavir (ETV) therapy.
Methods: Peripheral natural killer (NK) cells, Toll-like receptors (TLRs), T cells, regulatory T cells (Tregs) and programmed death 1 (PD-1) were evaluated dynamically by flow cytometry. Response was defined as hepatitis B e antigen (HBeAg) seroconversion, hepatitis B surface antigen (HBsAg) loss, and HBsAg seroconversion (either as singular events or in combination at week 48)
Results: From week 12 to week 24, compared with ETV responders or Peg IFN alfa non-responders, Peg IFN alfa responders exhibited a significant decline in Treg proportions as well as a diminished negative regulation of $CD8^+$ T cells by Tregs. Those HBeAg-negative patients at baseline treated with Peg IFN alfa also showed significantly decreased Treg proportions and a higher rate of HBsAg seroconversion. Moreover, Peg IFN alfa responders showed a significantly higher increase in the $NKG2C^+$ NK cell proportions from baseline to week 12 and of $TLR2^+$ monocytes at week 12 than Peg IFN alfa non-responders.
Conclusions: Successful response to Peg IFN alfa correlates with an early significant restoration of impaired immune responses. Although antiviral treatment response can be achieved by both IFN and ETV, the underlying immunological features vary which may explain the generally observed difference in off-treatment durability of response between the two treatments, as well as effects on HBsAg.
negative regulation of $CD8^+$ T cells by Tregs. Those HBeAg-negative patients at baseline treated with Peg IFN alfa also showed significantly decreased Treg proportions and a higher rate of HBsAg seroconversion. Moreover, Peg IFN alfa responders showed a significantly higher increase in the $NKG2C^+$ NK cell proportions from baseline to week 12 and of $TLR2^+$ monocytes at week 12 than Peg IFN alfa non-responders.

TARGETING VIRAL DNA WITH CRISPR/Cas9 ROBUSTLY SUPPRESSES HEPATITIS B VIRUS

A. Shlomai[1,2,3], V. Ramanan[4], D.B. Cox[4,5,6], R.E. Schwartz[7,8,9], E. Michailidis[1], A. Bhatta[1], F. Zhang[4,5,10], S.N. Bhatia[5,7,8,11,12], C.M. Rice[1]. *[1]Virology and Infectious Disease, Rockefeller University, New-York, United States; [2]The Liver Institute, Rabin Medical Center, Beilinson hospital, Petah Tikva, [3]Sackler School of Medicine, Tel-Aviv University, Tel-Aviv, Israel; [4]Department of Health Sciences and Technology, Massachusetts Institute of Technology, [5]Broad Institute, [6]Department of Biology, Massachusetts Institute of Technology, [7]Department of Health Sciences and Technology, MIT, Cambridge, [8]Department of Medicine, Brigham and Women's Hospital, Boston, [9]Division of Gastroenterology and Hepatology, Weill Cornell Medical College, New-York, [10]Department of Brain and Cognitive Science, [11]Department of Electrical Engineering and Computer Science, [12]Koch Institute for Integrative Cancer Research, Massachusetts Institute of Technology, Cambridge, United States*
E-mail: shlomaiamir@gmail.com

Background and Aims: Hepatitis B virus is a 3.2kb DNA virus that infects the liver. Current anti-viral drugs efficiently suppress viral replication but do not clear viral episomal DNA (cccDNA). As a result, lifelong treatment is often needed to control viremia, underscoring the need for drugs or strategies that can effectively eliminate cccDNA and lead to a durable cure. The recent discovery of CRISPR (clustered regularly interspersed short palindromic repeat) as a bacterial adaptive immune system, and subsequent engineering of this system to precisely cleave DNA, provides a potential approach for direct targeting of HBV DNA in infected human hepatocytes.
Results: We first engineered a set of CRISPR/Cas9 guide RNAs targeting conserved regions in the HBV genome and screened for their utility *in-vitro* and *in-vivo*. Hepatoma cells were co-transfected with HBV expressing as well as CRISPR/Cas9 encoding plasmids and animals were hydrodynamically injected with those plasmids to analyze the effect on HBV gene expression and replication. We identified three guide RNAs highly potent for HBV inhibition that were further tested in HepG2215 cells, which stably express HBV from an integrated transgene and also maintain a stable pool of cccDNA. A kinetic analysis revealed a robust reduction in HBV replicative forms as well as in cccDNA levels over time. Analysis of CRISPR-mediated DNA cleavage revealed substantial cleavage presence in integrated HBV DNA but much less in residual cccDNA. This suggests that that cccDNA targeted by CRISPR/Cas9 may be rapidly degraded upon cleavage rather than repaired. Importantly, predicted off-target gene loci were not cleaved, further supporting the mechanism and specificity of this approach. Finally, hepatoma cells over expressing the HBV receptor NTCP and selected for the expression of HBV specific CRISPR/Cas9 guide RNAs were infected with HBV. A large attenuation of HBV infection was observed in CRISPR/Cas9 expressing cells, confirming the utility of this system in the context of natural infection, as well
Conclusions: The CRISPR/Cas9 system suppresses HBV replication and possibly eliminates cccDNA. Our study provides a proof of concept for targeting DNA viruses with CRISPR/Cas9 and highlights the possible utility of this approach as a curative anti-HBV therapy.

P0546

IN VIVO IMPACT OF PRECORE MUTATIONS OF HBV ON VIRAL REPLICATIVE CAPACITY, VIRAL PROTEIN PROCESSING, AND VIRION ASSEMBLY. MOLECULAR CORRELATES OF HISTOLOGIC AND IMMUNOHISTOCHEMICAL ASPECTS IN LIVER TISSUE FROM PATIENTS WITH CHRONIC HEPATITIS B

C. Minosse[1], A. Baiocchini[1], S. Coen[1], P. Zaccaro[1], U. Visco Comandini[1], R. Lionetti[1], M. Montalbano[1], F. Del Nonno[1], M. Vivarelli[2], G. D'Offizi[1], M.R. Capobianchi[1], S. Menzo[1,2]. [1]*National Institute for Infectious Diseases "L. Spallanzani", Rome,* [2]*Università Politecnica delle Marche, Ancona, Italy*
E-mail: menzo@univpm.it

Background and Aims: In chronic hepatitis B (CHB), ccc- and total intrahepatic DNA are the best markers of viral hepatic colonization and replicative capacity. Another interesting marker of viral colonization is histochemical staining of viral antigens. Such staining also reveals the intracellular localization pattern of viral antigens. In particular, HBsAg can be found either on intracytoplasmatic membranes or on the cell membrane in different patients. The molecular mechanisms determining this difference, and its pathogenetic or clinical implications are presently unknown
Methods: 35 consecutive untreated CHB patients have been enrolled for this study. In addition to classical virological and clinical parameters, intrahepatic cccDNA, total DNA (by real-time PCR) and intrahepatic viral antigen distribution (by immunohistochemical staining of HBcAg and HBsAg) were evaluated in bioptic liver tissue from these patients. Nucleotide sequencing of the pre-core and pre-s regions of viral genome was performed on intrahepatic and on peripheral blood virus
Results: A strong correlation between the frequency of HBcAg positive cells in the liver tissue and cccDNA molecules /10^5 cells was found. HBcAg positive cells also correlate with viral DNA load, HBsAg and especially HBeAg load in peripheral blood. By contrast, intrahepatic HBsAg positive cells did not significantly correlate with any of the different molecular parameters, but only with peripheral HBsAg. The different patterns of intracellular localization of HBsAg correlates significantly with viral replicative capacity (intrahepatic totalDNA/cccDNA). More insight into this aspect emerged by sequencing the pre-core region, which identified pre-core mutations (but not being HBeAg negative *per se*) as a strong correlate of intracytoplasmatic localization of HBsAg. In addition, a patient with grade 3 steatosis harbored a virus with a frameshifting deletion in the pre-core region which determined the expression of a 51 residues long peptide replacing HBeAg
Conclusions: This study indicates that pre-core mutations in the HBV genomes, in addition to abrogating HBeAg expression, lead to a significant reduction of viral replicative capacity, alter intracellular processing of viral proteins and virion assembly. Unexplained hepatic steatosis, a rare event in the natural history of CHB, might be a result of peculiar genetic determinants imposed by the immune system on the virus

P0547

PHYLOGEOGRAPHY OF GLOBAL HBV GENOTYPE D REVEALS THE CENTRAL ROLE OF CENTRAL ASIA IN DISSEMINATING THE EPIDEMIC

D. Paraskevis[1], E. Kostaki[1], G. Magiorkinis[2], S. Ho[3], A. Hatzakis[1]. [1]*Department of Hygiene, Epidemiology and Medical Statistics, Medical School, University of Athens, Athens, Greece;* [2]*Department of Zoology, University of Oxford, Oxford, United Kingdom;* [3]*School of Biological Sciences, University of Sydney, Sydney, Australia*
E-mail: dparask@med.uoa.gr

Background and Aims: HBV genotype D shows a global expansion including Indigenous populations in Tibet and the Arctic. The aim of the current study was to estimate the pattern of dispersal of HBV genotype D using full-length genomic sequences.
Methods: We studied all full-length non-recombinant sequences of genotype D (N = 926) available on public databases. The migration events were inferred from viral phylogenies by character reconstruction using parsimony. This formed the basis of a metric that we used to determine whether a geographical unit (country or region according to WHO criteria) is actively spreading ("hub") or passively receiving ("sink") viral migrations.
Results: Based on combined statistical phylogeographic and additional analysis using the newly developed metric, we found that Turkey, Russia (mostly sampled from the C. Asian part of Russia), C. Asia, and L. America acted as hubs suggesting that they exported viral infections at a higher rate than the corresponding imported. On the other hand, India, Lebanon and New Zealand were sinks (higher rate for importing versus exporting viral migration) and Africa, E. Europe and Oceania/Pacific were classified both as sinks and hubs (no significant difference in importing versus exporting). For Greenland, S.E. Asia and Tunisia we found no significant migration, suggesting that they provide isolated areas ("islands") for viral dispersal. Finally for China, Belgium, Japan, W. Europe and Syria, we found no statistical evidence for their epidemic dispersal. Notably, all hubs apart from L. America exported within Eurasia, whereas for L. America we found significant dispersal on a global scale. We show similar patterns for C. Europe, whereas Oceania/Pacific exported to New Zealand and Africa to Tunisia and Europe.
Conclusions: We show that C. Asia and European areas have played a major role in disseminating genotype D epidemic within Eurasia. These patterns are probably due to expansion of Neolithic farmers from C. Asia westwards. On the other hand, exporting migration from L. America on a global scale was probably more recent than the C. Asian/European exports, given the recent introduction of genotype D in L. America as a result of the colonization of Americas by Europeans. Our study highlights the importance of westward patterns of viral dispersal mirroring the significant routes of human migrations during the Neolithic. One of the potential limitations is the non-uniform availability of sequences across different regions.

P0548

IMPAIRED ANTI-HBV VACCINE RESPONSE IN NON-CIRRHOTIC CHRONIC HCV PATIENTS COMPARED TO HEALTHY CONTROLS

M.G. Pessoa[1], R.P. Medeiros[1], M. Lopes[1], D. Mazo[1], C.P. Oliveira[1], P.M. Zitelli[1], J.R. Pinho[1], F.J. Carrilho[1]. [1]*Gastroenterology, University of Sao Paulo School of Medicine, Sao Paulo, Brazil*
E-mail: mgpessoa@usp.br

Background and Aims: Some immunogenicity studies of anti-HBV vaccine in patients with chronic HCV infection have demonstrated a diminished response ranging from 63.6% to 72.9% on seroconversion rate, compared to 90.9% to 93.9% in healthy controls. Aims: To evaluate the anti-HBV vaccination response in treatment naive chronic HCV patients without cirrhosis and compare them to healthy controls.
Methods: 110 chronic HCV adult patients without cirrhosis were randomized to receive anti-HBV vaccination regimen at standard 3 doses (0, 1 and 6 months) of 20ug, or higher dose of 40ug. Response to vaccination was measured by titers of anti-HBs 1 and 6 month after the last dose of anti-HBV vaccine. Healthy controls were negative to anti-HCV, anti-HBc, HBsAg and anti-HBs antibodies, and received standard 3 doses of 20ug at intervals of 0, 1 and 6 months, and were also evaluated for anti-HBs titers.
Results: Of the 110 HCV vaccinated patients, the seroconversion rate (anti-HBs ≥10 IU/mL) was 74.5% (82/110). Out of the 45 healthy controls vaccinated with standard dose, we observed a seroconversion rate of 93.3% (42/45).
Conclusions: Our study had demonstrated that chronic HCV patients without cirrhosis presented impaired anti-HBV vaccine

response compared to healthy controls, similar to data previously demonstrated in the literature. This impairment is apparently not overcome by exposure to double-dose anti-HBV vaccination regimen.

P0549

THE USEFULNESS OF CLIF-SOFA SCORE FOR PREDICTING SHORT-TIME MORTALITY OF PATIENTS WITH HBV-RELATED ACUTE-ON-CHRONIC LIVER FAILURE IN CHINA

C. Li[1], Z. Wan[1], S. You[1], H. Liu[1], S. Xin[1]. [1]*Beijing 302 hospital, Beijing, China*
E-mail: xinshaojie302@163.com

Background and Aims: Chronic liver failure (CLIF)-SOFA score was introduced to the diagnostic criteria for acute-chronic liver failure (ACLF) in recent by the European Association for the Study of the Liver (EASL)-CLIF Consortium. However, there were no relevant studies between CLIF-SOFA score and the patients who met Chinese diagnostic criteria for HBV-related ACLF. In this study, we investigated whether CLIF-SOFA score could predict 12-week mortality of patients with HBV-related ACLF in China.
Methods: The prospective study was conducted between 1 August 2013 and 1 August 2014. A total of 167 patients who met Chinese diagnostic criteria for HBV-related ACLF were recruited. At admission, CLIF-SOFA score was calculated according to the criteria from EASL-CLIF Consortium for each patient. All of the patients were followed up for at least 12 weeks. The predictive value of CLIF-SOFA score for short-term mortality was evaluated by receiver operating curve (ROC) curve. Kaplan–Meier survival curve and Cox's proportional hazards regression model were used to estimate survival rates and the risk factors for mortality.
Results: One hundred sixty-five cases completed the 12-week clinical follow-up. The overall mortality rate was 44.8%. According to the CLIF-SOFA score at admission, the patients were further divided into high score (CLIF-SOFA ≥10), medium score (CLIF-SOFA ≥8, but ≤9) and low score group (CLIF-SOFA <8). Kaplan–Meier survival curve showed that 12-week survival were significantly different among the three groups ($c2 = 18.460$, $P = 0.000$). The mortality rate showed a significant ($P < 0.05$) stepwise increase in the order of low score (30.5%), medium score (45.9%) and high score group (68.8%). The Cox proportional hazards regression model identified CLIF-SOFA score [$P = 0.006$, HR = 1.267, 95% CI (1.071–1.498)], MELD score [$P = 0.000$, HR = 1.107, 95% CI (1.049–1.169)], and total bilirubin [$P = 0.009$, HR = 1.044, 95% CI (1.011–1.078)] were independent factors significantly ($P < 0.05$) associated with survival. ROC curve showed that the predictive value of CLIF-SOFA was significantly higher than CTP ($P < 0.05$).
Conclusions: CLIF-SOFA score could distinguish the patients with HBV-related ACLF who had different outcomes. It might be used for predicting short-term mortality of patients who met Chinese criteria for HBV-related ACLF.

P0550

THE IMPACTS OF BASELINE CLINICAL CHARACTERISTICS AND HEPATITIS B VIRUS MUTATIONS ON CURATIVE EFFECTS OF CHRONIC HEPATITIS B TREATED WITH NOVAFERON

W. Daxian[1], T. Deming[1]. [1]*Department of Infectious Diseases, Xiangya Hospitalo of Central South University, Changsha, China*
E-mail: ling7080@126.com

Background and Aims: Novaferon, which is a new type of IFN, had approved by State Food and Drug Administration (SFDA) for clinical trials of new drugs on CHB therapy in 2009. To assess the impacts of baseline clinical characteristics of patients with chronic hepatitis B (CHB) and baseline hepatitis B virus (HBV) gene mutations on curative effects of CHB treated with Novaferon.
Methods: Enrolled patients accepted Novaferon monotherapy for 24 weeks and follow up for 12 weeks. Body mass index (BMI) of patients, genotype, basal core promoter (BCP) and precore (PC), reverse transcriptase (RT), S region variants of HBV were determined prior to Novaferon treatment. Aminotransferase (ALT), Hepatitis B e antigen (HBeAg), HBV DNA, Hepatitis B surface antigen (HBsAg) were determined at the beginning of treatment and 12 weeks after treatment. Then the present study evaluated the influence of age, gender, genotype, BMI, baseline ALT, HBeAg, HBV-DNA, HBsAg titer as well as BCP, PC, RT and S region variants on curative effects of chronic hepatitis B treated with Novaferon.
Results: Results In total of 126 CHB patients who finished the treatedment and follow-up, 38.9% obtained virological response and 32.5%, 25.4%, 44.4%, 23.8% obtained HBeAg clearence, HBeAg seroconversion, biochemical response and combined response respectively. The baseline DNA level of virological response group was significantly lower than no-virological response group; the baseline ALT level were significantly higher in HBeAg clearence group and HBeAg seroconversion group; female and lower BMI level was prone to acquired biochemical response. Stepwise logistic regression analysis showed that PC-P159T (ntC2288A), BCP-N118T (ntA1726C), BCP-L134L (ntA1775C/G/T) were independent influence factors for virological response. The frequencies of PC-G182C (ntG2357T) was significantly higher in groups with HBeAg clearance group and PC-S64A/T (ntT2003G/A), PC-W28STOP (ntG1896A) was significantly higher in HBeAg seroconversion groups, combined response respectively.
Conclusions: Conclusions Novaferon was an effective therapeutic drug for CHB patients, different response type was influenced by different clinical characteristics and mutations. Baseline mutations screening could predict curative effect of Novaferon efficiently and offered the optimal drugs for CHB patients.

P0551

THE CRISPR/Cas9 SYSTEM BEING AS A CUTTER FOR COVALENTLY CLOSED CIRCULAR DNA OF HEPATITIS B VIRUS

X.-B. Pan[1], X.-L. Zhao[1], L. Wei[1]. [1]*Peking University People's Hospital, Peking University Hepatology institute, Beijing, China*
E-mail: pxbdxq@hotmail.com

Background and Aims: Current therapeutics block the production of new hepatitis B virus (HBV) DNA, but do not eliminate pre-existing viral reservoir of covalently closed circular DNA (cccDNA), thus curing less than 50% of patients.
Methods: We totally designed 20 CRISPR plasmids targeting at whole HBV genome, HBV DNA-integrated cell lines HepG2.2.15, HepAD38 and HepDES19 were tested as cell culture models. In HepDES19 cells, HBV e antigen was only produced from the enriched-HBV cccDNA but not integrated HBV DNA in chromosome. The system was also tested in HBV chronic infection mice, in which C57/BL6 mice was infected with PAAV8-HBV1.3 virus at least six months ago.
Results: When the cells were infected with HBV DNA-targeting CRISPR/Cas9 lenti viruses, HBV e antigen was decreased to ~91%, 84% and 51% in HepG2.2.15, HepAD38 and HepDES19, respectively. 18 of the 20 CRISPR/Cas9 systems had similar efficiency of inhibition except one was invalid and one was significantly higher efficiency. The inhibitory effect was significantly enhanced in combination of 3 cleavage sites. Sequence analysis confirmed that this CRISPR/Cas9 system efficiently cleaved and mutated HBV DNA target sites. CRISPR/Cas9 system exhibited a significant inhibition of production of viral proteins in HBV-infected mice as well
Conclusions: Although this system was able to remove internal viral genes from the host cell chromosome; it has higher efficiency to cleave extrachromosome HBV cccDNA. Our results suggest that the CRISPR/Cas9 system may be a useful tool for curing HBV infection.

P0552

VITAMIN D HAS NO DIRECT EFFECT ON HEPATITIS B VIRUS REPLICATION AND TRANSCRIPTION

N. Gotlieb[1,2], M. Sultan[1], M. Safran[1], Z. Ben-Ari[1,3,4]. *[1]Liver Research Laboratory, [2]Internal Medicine F, [3]Liver Disease Center, chaim Sheba medical center Tel-Hashomer, Ramat Gan, [4]The Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel*
E-mail: gbenari@bezeqint.net

Background and Aims: Vitamin D is an important immune modulator that plays an emerging role in inflammatory and metabolic liver diseases, including infection with hepatitis C virus. In contrast, the relationship between vitamin D metabolism and hepatitis B virus (HBV) infection is less well characterized. Recently it has been demonstrated that low 25(OH)D3 serum levels are associated with high levels of HBV replication in patients with HBV (Farnik H, et al. [1]). Our aim was to determine in vitro the potential of vitamin D or its active metabolite calcitriol to directly affect HBV transcription and production.
Methods: HBV-transfected HepG2 cells (HepG2 215) and HBV-Luc construct (the luciferase ORF cloned downstream the HBV enhancer II and the core promoter) were used to assess the level of HBV transcription by determining the HBVRNAs level. In addition, the level of HBV replication was evaluated by determining the concentrations of HBsAg levels in the cell culture medium HepG2 215 (using specific enzyme-linked immunosorbent assay), the HBV-RNA by quantitative real-time PCR and by quantifying the level of cccDNA (using qRT-PCR on DNA extracted from HepG2 215 cells). The level of HBV transcription and replication were both assessed before and after treatment with vitamin D (0–200μM) or calcitriol (0–100 nM) for 48 and 72 hours.
Results: In HBV-transfected HepG2 cells, the administration of vitamin D or calcitriol did not suppress the secretion of HBsAg, the cccDNA expression, the replication of HBV and the HBVRNAs level. Increasing the dose of both vitamin D and clacitriol did not affect the findings.
Conclusions: Our results indicate that in HBV-transfected HepG2 cells there is no direct effect of either vitamin D or its active metabolite calcitriol on neither the transcription nor the replication of HBV. Vitamin D may be involved in HBV replication by other immune-mediated mechanisms.

POLO-LIKE-KINASE 1, A POSITIVE EFFECTOR IN HEPATITIS B VIRUS REPLICATION: THERAPEUTIC IMPLICATIONS

A. Diab[1,2,3,4], A. Foca[3,4], P. Jalaguier[3,4], L. N'guyen[3,4], N. Isorce[3,4], F. Zoulim[3,4,5], O. Andrisani[1,2], D. Durantel[3,4]. *[1]Basic Medical Sciences, [2]Center for Cancer Research, Purdue University, West Lafayette, United States; [3]INSERM U1052, CNRS UMR 5286, Cancer Research Center of Lyon, [4]University Claude-Bernard Lyon 1 (UCBL), University of Lyon, [5]Department of Hepatology, Croix-Rousse Hospital, Hospices Civils de Lyon, Lyon, France*
E-mail: adiab@purdue.edu

Background and Aims: Polo-like-kinase 1 (PLK1), which plays pivotal roles in mitosis and is over-expressed in many human cancers, represents a promising druggable target in oncology. The X protein (HBx) of hepatitis B virus activates PLK1, which in turn induces degradation of chromatin regulating proteins SUZ12 and ZNF198, observed in human hepatocellular carcinoma. Whether PLK1 has a role in HBV replication remained to be determined, and represented the main objective of this study. Moreover we aimed at exploring if PLK1 inhibition could serve as a novel antiviral strategy against HBV.
Methods: Primary human hepatocytes (PHH) and differentiated HepaRG cells (dHepaRG) were primarily employed in this study as our HBV infection models, while initial studies employed HepAD38 cells. We generated and characterized HepaRG cells lines expressing in a tetracycline-dependent manner either individual HBV proteins or the constitutively active PLK1 mutant (i.e. T210D) for performing gain of function studies. Conversely, various commercially available Plk1 inhibitors and PLK1 siRNAs were utilized to inactivate PLK1, in loss of function studies, in order to determine the role of PLK1 in HBV replication.
Results: Firstly, we showed PLK1 activation in HBV infected cells, and that both HBx and HBc contribute to this activation. Gain- and loss-of-function studies for PLK1 demonstrated that PLK1 positively regulates HBV replication in differentiated hepatocytes. Next, antiviral properties of PLK1 inhibitors were investigated in HBV-infected hepatocytes. A 50% reduction (EC_{50}) in the accumulation of intracellular HBV DNA was quantified with a single administration of PLK1 inhibitor BI2536 at 5.0 nM. At this concentration, no effect on nuclear cccDNA, viral RNA synthesis, HBs/HBeAg secretion, was observed, indicating a post-transcriptional mechanism. BI2536 was not toxic in non-dividing cells up to 5000 nM. Interestingly, HBc accumulation was impaired in PLK1 inhibitor-treated cells, suggesting PLK1 targets HBc stability. In this respect, *in vitro* PLK1 kinase assays demonstrated that PLK1 phosphorylates HBc, although endogenous interaction between PLK1 and HBc was not detected in HepaRG cells. However, PLK1/HBc interaction was detected by co-IP in the HepAD38 model.
Conclusions: We have shown that HBV requires PLK1 activity to replicate efficiently in hepatocytes. PLK1 inhibition may therefore represent a novel antiviral therapeutic strategy for suppressing HBV replication.

HEPATITIS E VIRUS INFECTION INDUCES AN INNATE IMMUNE RESPONSE IN HUMAN CHIMERIC MICE

L. Allweiss[1], S. Gass[1], T. Volz[1], K. Giersch[1], J. Kah[1], A.W. Lohse[1,2], J. Petersen[3], S. Polywka[4], S. Pischke[1], M. Dandri[1,2], M. Lütgehetmann[1,4]. *[1]I. Department of Internal Medicine, University Medical Center Hamburg Eppendorf, [2]Hamburg and Heidelberg Sites, German Center for Infection Research, [3]IFI Institute for Interdisciplinary Medicine, Asklepios Clinic St. Georg, [4]Institute of Microbiology, Virology and Hygiene, University Medical Center Hamburg Eppendorf, Hamburg, Germany*
E-mail: t.volz@uke.de

Background and Aims: Hepatitis E Virus (HEV) is recognized as important pathogen in developing and industrialized countries leading to acute and chronic infections with considerable morbidity and mortality. Since our knowledge about the molecular biology and pathogenicity of HEV is still rudimental, we employed humanized uPA/SCID/beige (USB) mice to investigate viral host interactions.
Methods: Viremia and induction of human interferon stimulated genes (ISGs) and cytokines were determined by qRT-PCR and immunohistochemistry in humanized mice infected with HEV (genotype 1) and compared to uninfected chimeric animals.
Results: HEV viremia developed rapidly with up to 1×10^7 IU/ml within 4 weeks and remained stable for up to 35 weeks. HEV-infected human hepatocytes could be visualized by immunofluorescence using HEV orf2 specific antibodies and 1–5% of the human hepatocytes stained positive. Of note, although only a minority of the human hepatocytes stained HEV-positive, a clear induction of classical human ISG's (i.e. hMXA, hOAS, hISG15 and hSTAT1) was determined in the liver of HEV infected compared to uninfected mice. Pattern recognition factors hTLR2, hTLR3, hTLR4, hIFIH1 and hRig-I were also significantly upregulated (by factor 5–10 fold), indicating enhancement of innate recognition and defense mechanism in human hepatocytes. Furthermore, although human-specific cytokines like IFN-alpha, TNF-alpha and

IL6 were not or only slightly induced (i.e. IFN-beta and IL2; < factor 3), transcriptional levels of pro-inflammatory chemokines, such CXCL10 and CCl20, as well as IRAK2, appeared strongly enhanced (> factor 10) in HEV infected mice. Immunohistochemical staining of MXA and HLA confirmed that not only active HEV infected hepatocytes but also uninfected human hepatocytes could sense the infection.

Conclusions: Establishment of HEV infection provoked a clear enhancement of human innate defence mechanisms in chimeric mice, in the absence of adaptive immune responses. Elevated pre-treatment ISGs, pattern recognition factors and chemokines levels may contribute to liver damage and inflammation, providing a rationale for the severe clinical course of HEV genotype 1 associated liver disease.

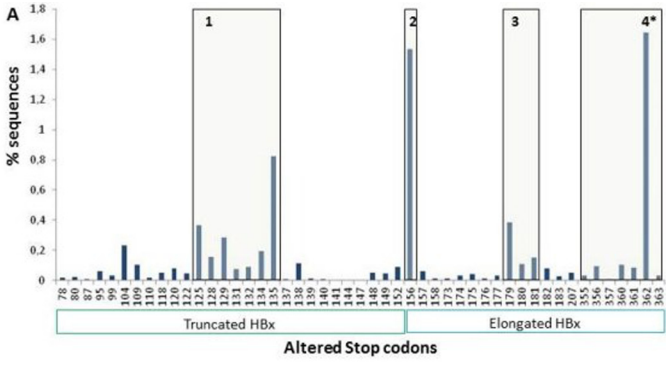
INSERTIONS AND/OR DELETIONS IN THE MAIN REGULATORY REGION OF HEPATITIS B VIRUS SUGGEST MULTICODING OF THE X PROTEIN

A. Caballero[1], J. Gregori[2,3], M. Buti[2,4], D. Tabernero[1,2], J. Quer[2,3], M. Blasi[2], F. Rodriguez-Algarra[5], R. Casillas[4], C. González[1], I. Belmonte[1], L. Nieto[6], X. Costa[7], R. Esteban[4], M. Homs[1,2], F. Rodriguez-Frías[1,2]. *[1]Biochemistry, Vall d'Hebron Hospital, Barcelona, [2]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos III, Madrid, [3]Vall d'Hebron Research Institute, [4]Liver Unit, Vall d'Hebron Hospital, [5]Pompeu i Fabra University, [6]Microbiology, Vall d'Hebron Hospital, Barcelona, [7]Microbiology, Clinic University Hospital of Santiago de Compostela, Santiago de Compostela, Spain*
E-mail: ancaball@vhebron.net

Background and Aims: The hepatitis B virus (HBV) main regulatory region, enhancer II (ENHII), encodes the preCore region and the C-terminal region of the multifunctional transactivating protein X (HBx). Nucleotide (nt) insertions and deletions (Ins-Del) in ENHII that modify HBx are associated with the severity of HBV infection.
Aim: Evaluate the presence of Ins-Del in ENHII and the possible effect of truncation or elongation of HBx on the HBV quasispecies.
Methods: Fifty samples from 50 antiviral-untreated patients with chronic active hepatitis were analyzed. HBV quasispecies from the nt 1596–1912 region was analyzed by ultra-deep pyrosequencing (454, Roche). Ins-Del were studied in the total of sequences (seqs) and variants (haplotypes).



B

	Ins-Del Variants	Nt localization	% Sequencies	% haplotypes
1	8-nt deletion	1754-1777 (TA2/TA3)	0.87	4.43
2	Duplication +/- deletion	1644-1770 (DDB1) 1754-1777	1.5	3.08
3	T insertion	1825	0.38	1.06
4*	T deletion	1825	2.91	4.32

DDB1, multifuntional cellular protein
* Stop codon stimated from the pattern sequence of each genotype

Results: A total of 960921 seqs, median 16734 seqs/patient (1905–57993) and 1039 haplotypes, median 17 haplotypes/patient (4–55) were analyzed. Overall, 128 different Ins-Del were detected in 7.1% of seqs and 27.5% of haplotypes. Ins-Del were observed in 47/50 samples (94%): median, 3.4% seqs with Ins-Del/patient (0–74.5%). Ins-Del changed the standard HBx stop codon (position 155), leading to 49 altered codons and resulting in a premature (truncated HBx) or late (elongated HBx) stop codon (Fig 1A). This occurred in 7.6% of seqs and 29.2% of haplotypes.
Main Ins-Del included (1) deletions between 1754–1777 causing elongated HBx, (2) duplications in 1644–1670 (with or without a deletion in 1754–1777) that modified the HBx interaction motif with the essential cell DNA damage-binding protein DDB1 and duplicated the target for C/EBP transcription factor, and (3) insertion or (4) deletion of a T in 1825, both encoding elongated HBx (Fig. 1B).
Conclusions: The significant presence of genomes that code for truncated or elongated HBx suggest a multicoding mechanism that could potentially affect the transcriptional activity of HBV ENHII and whose clinical relevance should be evaluated in further studies.

P0556
ANTIVIRAL EFFECTS OF NUCLEIC ACID POLYMERS ON HEPATITIS B VIRUS INFECTION

C. Guillot[1], O. Hantz[1], A. Vaillant[2], I. Chemin[1]. *[1]Cancer Research Center of Lyon UMR Inserm 1052 CNRS 5286, Lyon, France; [2]REPLICor Inc., Montreal, Canada*
E-mail: clementguillot84@gmail.com

Background and Aims: Hepatitis B virus (HBV) infection remains a major public health problem worldwide and current therapies are rarely able to cure HBV infection. Nucleic acid polymers (NAPs) have been shown to inhibit duck HBV infection *in vitro* and *in vivo* (Noordeen et al., 2013). NAPs have been shown to eliminate the hepatitis B surface antigen (HBsAg) from the blood (in ducks infected with the duck hepatitis B virus) but the mechanism whereby NAPs achieve the removal of surface antigen from the blood has yet to be clearly elucidated. Due to their phosphorothioate oligonucleotide structure, NAPs are chemically analogous to sulfated polyglycans such as heparin which are known to block entry of hepatitis B virus. In this study we investigated the *in vitro* antiviral activity of NAPs in HBV infected HepaRG cells and primary human hepatocytes.
Methods: NAP uptake into cells was assessed using Cy3 labeled NAPs. In order to evaluate potent effects of NAPs on HBV entry as well as post-entry, HBV infected differentiated HepaRG cells and primary human hepatocytes were treated with NAPs every two days starting at the time of infection or starting two days post-infection. The Elecsys HBsAg II quant automated system was used to quantitatively measure the secreted HBsAg. PreS1 containing particles were also assessed by ELISA and extracellular HBV DNA was measured by real-time PCR.
Results: Fluorescent NAPs were observed to enter into differentiated HepaRG cells and in primary cultures more particularly in hepatocytes rather than biliary cells. 5μM and 1μM NAPs significantly reduced extracellular HBsAg by 80% and 40% respectively as well as PreS1 containing particles when added at the time of infection. Interestingly, 5μM NAPs seems also to decrease extracellular HBsAg by 25% as well as PreS1 containing particles when added two days post-infection, suggesting NAPs exert a post-entry antiviral effect.
Conclusions: In this study, we showed a strong antiviral activity of nucleic acid polymers against HBV infection in HepaRG cells and primary human hepatocytes. Our results suggest that NAPs are able to block entry of HBV but also to have an effect on the replication cycle following entry of the virus which results in a reduction of HBsAg released into the supernatant. These antiviral activities both on virus entry and within the cells promise a strong potential of NAPs alone or in combination with already existing antiviral treatments.

EFFECT OF URSODEOXYCHOLIC ACID ON THE INTERACTION BETWEEN HEPATITIS B VIRUS AND SODIUM TAUROCHOLATE COTRANSPORTING PEPTIDE

J.W. Chung[1], I.Y. Moon[1], H. Cho[1], E.S. Jang[1], S.-H. Jeong[1], J.-W. Kim[1]. [1]*Seoul National University Bundang Hospital, Seongnam, Korea, South*
E-mail: jjungwha@snubh.org

Background and Aims: Ursodeoxycholic acid (UDCA) had long been used for the management of chronic hepatitis B before potent oral nucleos(t)ide analog therapy was available. Recently, sodium taurocholate cotransporting peptide (NTCP) has been identified as a functional receptor of hepatitis B virus (HBV), and several *in vitro* studies reported that UDCA decreased expression of HBV in NTCP-expressing HepG2 cells, presumably via competitive inhibition of HBV-NTCP binding by UDCA. However, the effect of UDCA in HBV replication with respect to NTCP has not been fully known. In this study, the effect of UDCA on the interaction between HBV and NTCP was examined in non-neoplastic human liver cell line (PH5CH8). For *in vivo* study, the short-term effect of UDCA on the serum HBV DNA titers was examined in a retrospective cohort of chronic hepatitis B.
Methods: HBV was collected by ultracentrifugation of conditioned culture medium of HepAD38 cells. HBV precipitate was directly inoculated in the culture supernatant of PH5CH8 cells at various concentrations with or without UDCA NTCP mRNA and HBV rcDNA were quantified by real-time PCR. A cohort of 793 chronic hepatitis B patients without oral NA therapy was constructed from electronic medical record system of our hospital. Changes in HBV DNA levels after UDCA therapy were compared to control CHB group without UDCA therapy.
Results: Contrary to previous reports, UDCA pre-treatment increased intracellular HBV rcDNA in the direct inoculation model in a dose-dependent manner, whereas UDCA did not have significant effect on HBV replication when treated after HBV inoculation UDCA pre-treatment significantly up-regulated NTCP expression. UDCA did not affect serum HBV DNA levels in 42 CHB patients compared to 751 CHB patients without UDCA therapy.
Conclusions: UDCA up-regulated NTCP expression in non-neoplastic human liver cells with natural NTCP promoter, which might in turn induce internalization of HBV. Clinical use of UDCA did not affect serum HBV DNA levels in CHB patients, suggesting that UDCA has no significant effect on viral replication in CHB.

E-mail: oliver.bhadra@live.de

Background and Aims: The sodium taurocholate cotransporting polypeptide NTCP represents the main transporter for conjugated bile salts in hepatocytes and mediates HBV entry by serving as the binding site for the pre-S domain of the hepatitis B virus (HBV) envelope protein. Recently, HBV binding to NTCP was shown to limit its function, which in turn led to reduced nuclear translocation of the bile acid sensor farnesoid X receptor (FXR). Consequently, and possibly to maintain bile acid homeostasis, expression of genes involved in bile acid metabolism, such as CYP7A1 and SHP, were significantly altered in HBV-infected human hepatocytes in vivo (Oehler, Hepatology 2014). Since NTCP is also involved in drug uptake, HBV-mediated impairment of its function may limit response to certain drugs. *Aim* of this study was (I) to determine whether the induction of FXR activity mediated by the administration of FXR agonists may interfere with HBV replication and (II) to analyse their effectiveness on expression levels of genes involved in bile acid metabolism in HBV-infected human hepatocytes in vivo.
Methods: HBV stably infected (median viremia of 4.4×10^8 HBV-DNA/ml) and uninfected humanized uPA/SCID mice were treated for 3 weeks with PX20606 FXR agonist (0.2 mg/day, oral feeding), while vehicle fed infected and uninfected mice served as controls. Serological and intrahepatic viral loads, as well as human gene expression profiles, were determined by qRT-PCR.
Results: Despite modest enhancement of hSHP (0.2 log), induction of FGF19 (1.6 log) and reduction of hCYP7A1 (−0.9 log) transcriptional levels determined in HBV-infected mice after 3 weeks of PX20606 administration, no significant changes in HBV replication levels (both serum and intrahepatic) were observed. Remarkably, uninfected mice receiving the FXR agonist displayed more pronounced induction of hSHP (0.9 log), the transcriptional target of FXR and corepressor of hCYP7A1 transcription, stronger induction of hFGF19 (3 log), an inhibitor of hCYP7A1 transcription through FGFR4 activation, and a dramatic reduction of hCYP7A1 RNA levels (3 log), while FXR and NTCP expression levels remained comparable among all groups.
Conclusions: Although the gene expression changes induced by the FXR agonist on bile acid homeostasis had no significant impact on viral productivity, HBV infection appeared to limit the capacity of human hepatocytes to respond to FXR agonists that mostly mediate their effects through NTCP.

E-mail: Rinker.Franziska@mh-hannover.de

Background and Aims: HBsAg consists of three proteins called large (L-), middle (M-) and small (S-) HBs that differ in amino-terminal sequences and glycosylation status. Commercial HBsAg assays currently quantify the total amount of HBsAg. LHBs contains the preS1 domain which is necessary for entry and the preS-domains contain B and T cell epitopes, reflecting targets for specific host responses. So far there are no systematic data on HBs proteins but this may be relevant for the development of biomarkers, i.e. to predict treatment response to immune based therapies aiming at HBsAg loss.
Methods: Serum samples of 106 HBeAg positive patients, from two phase III/IV PegIFNα-2a trials were retrospectively analysed. Clinical and laboratory patient data was obtained from the completed trials and provided by Roche. We quantified the amount and the proportions of the three HBs proteins using a quantitative ELISA and well-defined monoclonal antibodies against the S-domain (total HBsAg), the preS1-domain (LHBs) and the N-glycosylated preS2-

domain (MHBs) of the HBs protein. SHBs was indirectly quantified by subtracting LHBs and MHBs from total HBsAg. The proportions were calculated in relation to total HBsAg.

Results: Baseline HBsAg levels measured with a commercial assay strongly correlated with our ELISA results for total HBs ($r = 0.97$, $p < 0.0001$), as well as the three individual HBs proteins. LHBs (median 1017 ng/ml) and MHBs levels (median 293 ng/ml) represent 8.3% and 2.8% of total HBs, respectively, whereas SHBs (median 10415 ng/ml) accounts for 88%. Interestingly, patients with genotype B showed significantly higher proportion of LHBs compared to genotype C (14% vs. 5.2%, $p < 0.0001$). Number of genotype A and D patients were insufficient for further genotype comparison.

Conclusions: The results validate an ELISA method for quantification of HBs proteins in sera from HBeAg positive patients with chronic hepatitis B. SHBs represents the commonest protein subtype, accounting for 88% of total HBsAg, with LHBs and MHBs accounting for 8% and 3%. The ratio of HBs proteins appears to be genotype specific: LHBs levels are significantly higher in patients with genotype B compared to genotype C. HBs subtypes represents a novel biomarker which deserves further investigation, particularly comparing genotypes and during administration of CHB treatments.

ASSOCIATION OF SINGLE NUCLEOTIDE POLYMORPHISM rs2296651 IN SLC10A1 WITH HEPATOCELLULAR CARCINOMA AND LIVER CIRRHOSIS

H.-H. Hu[1], J. Liu[1], Y.-L. Lin[1], W.-S. Luo[1], Y.-J. Chu[1], C.-L. Chang[1], C.-L. Jen[1], M.-H. Lee[2], S.-N. Lu[3], L.-Y. Wang[4], S.-L. You[1], H.-I Yang[1], C.-J. Chen[1,5]. *[1]Genomics Research Center, Academia Sinica, [2]Institute of Clinical Medicine, National Yang-Ming University, Taipei, [3]Department of Gastroenterology, Chang-Gung Memorial Hospital, Kaohsiung, [4]MacKay College of Medicine, [5]Institute of Epidemiology and Preventative Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan*

E-mail: andrea.hu1712@gmail.com

Background and Aims: Chronic hepatitis B virus (HBV) infection increases the risk for liver cirrhosis (LC) and hepatocellular carcinoma (HCC). Sodium taurocholate co-transporting polypeptide (NTCP), encoded by *SLC10A1*, was recently identified as a receptor for hepatocyte entry of HBV. The SNP rs2296651 [A/G] has only been reported among Chinese populations, and the resulting NTCP p.S267F variant was shown to exhibit loss of bile acid uptake, and could neither bind to the HBV preS1 region, nor support HBV infection in cell cultures. Therefore, we aimed to assess the association of rs2296651 with HCC and LC.

Methods: The rs2296651 SNP was genotyped by the TaqMan platform in 3994 individuals with chronic HBV infection. Among 3994 individuals, 3470 were from the REVEAL-HBV study and 524 were patients with HBV-related HCC from the Taiwan Liver Cancer Network (TLCN). REVEAL-HBV is a community-based cohort recruited during 1991–1992 and followed-up every 6–12 months. The TLCN cohort is comprised of HCC patients from 5 major medical centers across Taiwan. Clinical and pathological information of patients were collected. DNA samples were obtained after approval by the research committee. The association of the SNP with HCC and LC was assessed by multivariate-adjusted odds ratios (OR_{adj}) with 95% confidence intervals (CI).

Results: The rs2296651 SNP was heterozygous (GA) in 678 (16.98%) and homozygous (AA) in 6 (0.15%) individuals with a minor allele frequency of 8.64%. The variant was observed in a subset of 100/781 (12.8%) HCC cases and 540/2945 (18.3%) non-HCC, non-cirrhotic controls ($P < 0.001$). After adjustment for age, gender, and serum ALT and HBV DNA levels, there was a significant association between the rs2296651 variant and HCC (OR_{adj} [95% CI] 0.57 [0.44–0.75], $P < 0.001$). In another subset, the variant was also lower in LC patients (86/607, 14.2%) than in healthy controls (559/3054, 18.3%) ($P = 0.01$). The variant was significantly associated with LC (OR_{adj} [95% CI] 0.64 [0.49–0.85], $P = 0.002$) after adjustment for other LC risk factors. There was no significant association between the rs2296651 variant and HBsAg seroclearance (OR_{adj} [95% CI] 0.88 [0.67–1.15], $P = 0.89$).

Conclusions: The rs2296651 SNP plays an important role in the development of LC and HCC. This finding is in accordance with previous reports on the function of p.S267F in HBV entry and infection, which is involved in the hepatocarcinogenic potential of the virus.

P0561

DIFFERENCES IN QUANTITATIVE COMPOSITION OF LARGE, MIDDLE AND SMALL HEPATITIS B VIRUS (HBV) SURFACE ANTIGEN (HBsAg) IN ACUTE AND CHRONIC HBV INFECTION

M. Grossmann[1], S. Böhm[1], D. Glebe[2], T. Berg[1], F. van Bömmel[1]. *[1]Division of Gastroenterology and Hepatology, University Hospital Leipzig, Leipzig, [2]Institute for Medical Virology, University Hospital Giessen, Giessen, Germany*

E-mail: Maria.Grossmann@medizin.uni-leipzig.de

Background and Aims: Quantification of HBsAg has been used as a marker to predict the course of HBV infections and response to antiviral treatment. The viral surface antigen consists of three components, large (L-), middle (M-) and small (S-) HBsAg, which differ in amino-terminal sequences and glycosylation status. In different ratios, all HBsAg components are part of infectious virions and non-infectious subviral particles. Quantitative analysis of HBsAg composition in serum can be a potential marker to assess the relative proportion of infectious virions. Additionally, there are evidences indicating that the L-HBsAg plays an important role in viral entry of hepatocytes. However, the clinical value of determining HBsAg components has not been established yet. In this study, we established a sensitive ELISA for quantitative detection of the different HBsAg components and determination of the HBsAg composition in patients with either acute or chronic HBV infections.

Methods: Microtiter plates were coated with specific antibodies and blocked with different reagents to optimize the test. L-, M- and S-HBsAg were quantified in serum samples of 23 patients (11 acute and 12 inactive chronic HBV infections) without antiviral therapy and a wide range of known HBsAg in total (mean 14.490 IU/ml, range 1.68–124,000 IU/ml) measured by a commercial assay (Abbott Architect). Three healthy patients served as negative control.

Results: Detection of lowest quantities (2–40 ng/ml) of all three HBsAg components was possible. The mean serum levels of HBsAg in patients with acute and chronic HBV infection were $4.81 \pm 4.82 \log_{10}$ ng/ml (range, $0.67 \log_{10}$ to $5.47 \log_{10}$ ng/ml) and $4.31 \pm 4.20 \log_{10}$ ng/ml (range, $1.63 \log_{10}$ to $4.76 \log_{10}$ ng/ml; $p = 0.128$). The mean ratios of L-, M- and S-HBsAg in patients with acute and chronic HBV infections were 25% versus 17% ($p = 0.073$), 8% versus 4% ($p = 0.016$) and 66% versus 78% ($p = 0.021$), respectively.

Conclusions: Different phases of HBV infection may be characterized by different ratios in HBsAg components. Quantitative analysis of HBsAg composition in serum can be a potential marker to characterize the course of HBV infections and the response to antiviral treatment.

P0562

MICRORNA-99 FAMILY MODULATES HEPATITIS B VIRUS REPLICATION BY TARGETING THE PHOSPHOINOSITIDE 3-KINASE/ Akt/mTOR SIGNALING PATHWAY

Y. Lin[1], W. Deng[1], J. Pang[1], T. Kemper[1], M. Lu[1]. [1]*Institute of Virology, University Hospital Essen, Essen, Germany*
E-mail: linyong1027@163.com

Background and Aims: MicroRNA (miRNA) is a class of highly conserved small noncoding RNAs participating in regulation of various cellular processes like cell proliferation, differentiation, apoptosis, autophagy and viral replication. Evidently, miRNAs are able to modulate the host gene expression and thereby inhibit or enhance hepatitis B virus (HBV) replication. It was reported that the level of miRNA-99 family in peripheral blood corresponds with HBV DNA loads. Thus, we asked whether miR-99 family regulates HBV replication by targeting the specific cellular gene expression.
Methods: The level of miR-99 family members miR-99a, miR-99b, and miR-100 in primary human hepatocytes (PHHs) and hepatoma cells was determined by miScript RT-PCR. HepG2.2.15 cells were transfected with miR-99 family mimics and harvested at 4 days post transfection. HBV progeny, HBsAg and HBeAg from supernatant were separately determined by realtime PCR and chemiluminescence microparticle immunoassay (CMIA). The level of HBV replication intermediates (RI) from intracellular core particles was determined by Southern blot. HBV transcripts were detected by northern blot hybridization. And HBV promoter activity was also measured by using luciferase report vectors. Further, relative total or phosphorylated proteins were determined by western blot.
Results: Compared with primary hepatocytes, the level of miR-99 family members was down-regulated in hepatoma cells. Transfection of miR-99 family members resulted in a marked increase of HBV replication, progeny secretion, and antigen expression in HepG2.2.15 cells. To determine whether miR-99 family regulates HBV transcription or promoter activity, the results showed that transfection with miR-99 family members had no effect on them, suggesting that miR-99 family members regulate HBV replication through a posttranscriptional mechanism. Bioinformatic analysis and recent reports indicated that phosphoinositide 3-kinase (PI3K)/Akt/mTOR pathway was targeted by miR-99 family. Etopic expression of miR-99 family attenuated Akt/mTOR signaling pathway and could repress insulin-stimulated activation. Modulation of Akt/mTOR signaling by insulin or specific chemical inhibitors led to decrease or enhancement of HBV replication accordingly.
Conclusions: Our results thus demonstrate that miR-99 family promotes HBV replication through the PI3K/Akt/mTOR signaling pathway by regulation of a post-transcriptional process.

RNAi-BASED GENE THERAPY FOR CHRONIC HEPATITIS B: EVALUATION IN A MURINE MODEL

T. Michler[1], S. Grosse[2], S. Mockenhaupt[2], M. Heikenwaelder[1], D. Grimm[2], U. Protzer[1]. [1]*Institute of Virolgy, Technische Universität München/Helmholtz Zentrum München, Munich,* [2]*Bioquant, University of Heidelberg, Heidelberg, Germany*
E-mail: protzer@tum.de

Background and Aims: Current therapeutic options for chronic hepatitis B patients are unsatisfying, as nucleoside-analogs don't eliminate the virus and often need to be given life-long. A new therapeutic approach is to directly target viral mRNA transcripts for degradation by RNA interference. Long-term suppression of the viral transcripts can be achieved by a single dose of a vector encoding for a short-hairpin RNA (shRNA) and may allow restoration of antiviral immunity.
Methods: We designed recombinant Adeno-associated-virus (AAV) vectors to specifically address each of the proposed mechanisms by: (1) Co-expression of the shRNA with Ago2; (2) co-expression of the shRNA with a decoy RNA to neutralize the sense-strand; and (3) expression of the siRNA-sequence from a microRNA backbone using a liver specific polymerase III promoter. Vectors were injected i.v. into HBV-transgenic mice and compared head to head for efficacy of HBV-suppression and signs of toxicity.
Results: The conventional approach of a polymerase III promoter driven shRNA led to reduction of HBV-parameters by up to 97% but was accompanied by elevated ALT levels and loss of body mass. Co-expression of Ago2 with the shRNA from a single-stranded AAV reduced signs of toxicity with similar efficacy of HBV-suppression. Liver specific expression of the microRNA mimic showed ameliorated toxicity but was less efficient in suppressing HBV-replication. Co-expression of the sense-strand decoy with the shRNA not only prevented sense-strand off-target activity as revealed by transcriptome-analysis of liver RNA, and generally improved markers of toxicity. Most noteworthy, it also significantly enhanced HBV-suppression with long-term reduction by 99%.
Conclusions: We conclude that enhanced antiviral efficacy is due to the fact that the siRNA antisense-strand is more likely to be loaded into Ago2 in absence of the sense-strand. This underlies how understanding the mechanisms of RNAi-related toxicity and the rational design of new expression vectors can lead to the development of safe and efficient RNAi-based therapeutics for chronic hepatitis B.

P0564

INCREASED IL-17, TNF α SECRETION BY TFH AND THEIR SUBTYPE (TFH17) (CD4+CXCR5+CCR6+) CELLS HELP IN HBV SEROCONVERSION

A.K. Vyas[1], S. Sharma[1], P. David[1], A. Bhardwaj[2], N. Trehanpati[1], S.K. Sarin[2]. [1]*Research,* [2]*Hepatology, Institute of liver and biliary sciences, New Delhi, India*
E-mail: trehanpati@gmail.com

Background and Aims: The incidence of HBsAg spontaneous seroconversion is only 0.5%. Host immunity is mainly responsible for clearing the virus spontaneously. T follicular helper cells (TFH) are a special subpopulation of T helper cells that regulate B cell maturation and antibodies production through IL-21. On stimulation, TFH cells release pro-inflammatory cytokines, which help viral clearance. We investigated the role of TFH cells in HBV clearance, circulating CD4+ CXCR5+ (TFH) cells and their subsets; TFH1, TFH2 and TFH17 were studied.
Patients and Methods: *Inclusion criteria:* Patients with spontaneous seroconversion (group A, n = 11) were taken within 6 months of HBsAg loss and appearance of anti HBs >10 IU/ml (seroconversion) with negative HBV DNA. Patients in group B were treatment naïve, HBeAg+ve and persistently normal ALT (<40 wIU/ml) for >12 months. Serum HBsAg, Anti HBc (T), anti-HBs, quantitative HBV DNA, AST and ATL levels were determined for each patient in groups A (n = 11) and B (n = 20). Phenotypic expression of circulating TFH cells and their subtypes (TFH 1, 2 and 17) was analyzed by Flow cytometry. HBV specific response of TFH cells secreting TNF-α, IL-17A were determined by stimulating PBMC's with HBV surface pooled peptides (207–339) and HBV core pooled peptides (340–388) of HBV genotype D and PMA/Ionomycin. Data were analyzed using the non-parametric Mann–Whitney U test for comparing two groups.
Results: Spontaneously seroconversion of HBsAg was observed within 3–5 months of acute infection and patients showed anti-HBs titers in the range of 12 to 1000 mIU/ml. CD4+CXCR5+ (TFH) cells were significantly increased in group B compared to group A (43.3% vs. 34.7%, P = 0.01). There was HBV specific functional impairment of TFH1, TFH17 cells in group B compared

to group A patients. The peptide stimulation of TFH cells in group A compared to group B showed significantly increased frequencies of CD4+CXCR5+CCR6+TNFα+ and IL17+ cells producing pro-inflammatory cytokines, TNF-α (8.96% vs. 1.29%, p = 0.02) and IL-17A (15% vs 1.37%, p = 0.014).
Conclusions: Significantly increased IL-17A and TNF-α production by CD4+CXCR5+CCR6+ TFH17 cells may play a major role in HBV clearance and HBsAg seroconversion

P0565
CYTOKINE PATTERNS OF PATIENTS WITH HCV/HBV CO-INFECTION
S.B. Wiegand[1,2], A. Wranke[1,2], J. Jaroszewicz[3], A. Potthoff[1], K. Deterding[1], M.P. Manns[1,2], H. Wedemeyer[1,2], M. Cornberg[1,2]. *[1]Department of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, [2]German Center for Infectious Disease Research (DZIF), partner site Hannover-Braunschweig, Hannover, Germany; [3]Department of Infectious Diseases and Hepatology, Medical University of Bialystok, Bialystok, Poland*
E-mail: wiegand.steffen@gmail.com

Background and Aims: In the natural course of HBV/HCV co-infection, different patterns of viral dominance have been documented based on HBV DNA and HCV RNA quantification. In the majority of cases, HCV seems to dominate and suppress HBV replication. The mechanisms are poorly understood but immune mechanisms may be one reason. It is known that HCV infection is associated with induction of ISG and high IP-10 levels. The aim of this study was to analyze immunological serum markers of HBV/HCV co-infected patients revealing an association with different dominance pattern.
Methods: In this cross-sectional retrospective study we analyzed 61 serum cytokines, chemokines and angiogenetic factors in 50 patients with respect to different serological patterns of HBV/HCV co-infection. Four pattern of viral dominance have been defined according to (Raimondo et al., 2006): (A) HBV dominance with HBV DNA >2,000 IU/mL and HCV RNA <600 IU/mL, (B) HCV dominance with HCV RNA >600 IU/mL and HBV DNA <2,000 IU/mL, (C) both viruses dominant with HBV DNA >2,000 IU/mL and HCV RNA >600 IU/mL, (D) no virus dominant with HBV DNA <2,000 IU/mL and HCV RNA <600 IU/mL. Univariate and Multivariate analyses were performed.
Results: Group A and B differ in concentration of FGFb, IFNg, VEGF, IL1a, IL2Ra, IL12p40, IL16, IL17a, IL25 p = *; MCSF, SCF, IP10 p = **; CTACK p = ***. All but one marker are higher in HBV dominant patients, while only IP10 is higher in HCV dominant patients (4,785 pg/mL vs. 1,820 pg/mL; p = **). Multivariate analyzes revealed that VEGF p = *, IP10 p = ** and CTACK p = *** differ independently. Comparing group A and C showed only a difference considering IP10 concentration, which was higher in group C (5,887 pg/mL vs. 1,820; p = *). Group B and C discern in concentration of IL1b, IL7, GCSF, PDGFbb, MIP1b, VEGF, IL1a, CTACK, MIF, TGFb2, TGFb3, IL17a, IL31 p = *; IL4, IL10, FGFb, IFNg, IL25 p = ** and IL12p70 p = ***, but not in IP10 concentration. Multivariate showed differences in IL1a and VEGF concentration p = *.
Conclusions: Host responses in form of cytokines, chemokines and anigogenetic factors show remarkable differences between different dominance pattern of HBV/HCV co-infection. For example, HCV dominance is associated with IP-10, which may help to explain the inhibitory effect on HBV. The pattern of immunological marker may also help to better understand the pathogenesis of HBV/HCV co-infection. Longitudinal analyzes are needed to evaluate the predictive value for endpoints like HBsAg loss, cirrhosis or HCC.

P0566
AUTOPHAGY OF CD4+T CELLS: A NEW MECHANISM OF SELF-REGULATION IN THE PROCESS OF CHRONIC HEPATITIS B VIRUS INFECTION
Y. Liu[1], L. Cheng[1], W. Jiang[1]. *[1]Department of Gastroenterology, Zhongshan Hospital, Shanghai, China*
E-mail: liuyun2008294@163.com

Background and Aims: In the previous researches, we proved $CD4^+$T cells play important roles in regulating hepatitis B virus (HBV)-related inflammation and fibrosis. Recently, $CD4^+$T cells are found to achieve immune homeostasis via the autophagy. This study was designed to investigate the significance of $CD4^+$T autophagy in the process of chronic HBV infection.
Methods: Patients diagnosed as the inactive HBV carrier (n = 28), HBeAg-positive CHB (n = 48) and HBV-related cirrhosis (n = 55) were enrolled in this study. The autophagosomes of purified peripheral $CD4^+$T cells were observed under electron microscopy. The expressions of light chain 3 II (LC3II, specific marker for the autophagy) in $CD4^+$T cells were detected by immunofluorescence and flow cytometry. The autophagy associated signal proteins were tested by western blot. The *in vitro* stimulation experiments were also designed to determine the role of high mobility group box 1 (HMGB1) in the activity of $CD4^+$T autophagy and the associated downstream signal pathways.
Results: The mean number of autophagosomes in each $CD4^+$T cell was dramatically increased after chronic HBV infection compared to healthy subjects. The autophagy associated proteins in peripheral $CD4^+$T cells including LC3II, Atg5, Atg7 and Beclin-1 were all significantly upregulated when inflammation and fibrosis progressed after chronic HBV infection. Besides, the significantly positive correlations were found in HBeAg-positive CHB patients between serum HMGB1 levels and peripheral LC3II/CD4 ratios. Also, recombinant HMGB1 (rHMGB1) showed a strong ability to enhance the autophagy of $CD4^+$T from CHB patients *in vitro*, simultaneously with a dramatic up-regulation of RAGE expression on $CD4^+$T cells, rather than TLR2 or TLR4. Moreover, the intracellular phosphorylated JNK and ERK (not AKT or p38) proteins in $CD4^+$T cells were dramatically upregulated by rHMGB1 stimulation. Finally, the autophagy activity of $CD4^+$T cells could be significantly downregulated by either JNK inhibitor (SP600125) or ERK inhibitor (U0126).
Conclusions: The exacerbated autophagy of peripheral $CD4^+$T cells in the process of chronic HBV infection may prove to be an important mechanism of self-regulation which also indicates the inflammation degree.

P0567
GLOBAL PATTERNS OF HBV GENOTYPE D EPIDEMIC DISPERSAL
E. Kostaki[1], D. Paraskevis[1], K. Angelis[1], A. Hatzakis[1]. *[1]National Retrovirus Reference Center, Department of Hygiene, Epidemiology and Medical Statistics, Medical School, University of Athens, Athens, Greece*
E-mail: ekostakh@med.uoa.gr

Background and Aims: Genotype D is the only HBV genotype having a global expansion. This is reflected mainly by the subgenotypes D_1, D_2 and D_3 which are dominant in N. Africa, E. Europe and W. Asia. In contrast, D_4, D_5 and D_6 circulate mainly in indigenous populations in India, Oceania and Arctic. The aim of the current study was to estimate the levels of regional clustering for HBV subtype D in order to shed light on how the virus has been disseminated within different geographic areas over time.
Methods: We used 926 full-length non-recombinant genotype D sequences available on public databases. The number of sequences available for different regions (according to WHO criteria) were as follows: N. Africa and Middle East: 394, S. Asia: 157, W. Europe: 74, C. Asia: 44, Australasia: 40, Asia-Pacific: 36, E. Asia: 35, E.

Europe: 27, L. America: 25, Oceania: 23, Sub-Saharan Africa: 20, N. America: 16, C. Europe: 14, Caribbean: 11 and S.E. Asia: 10. Phylogeny reconstruction with bootstrap evaluation was conducted by the maximum likelihood method.
Results: The phylogenetic analysis suggests that HBV genotype D sequences form regional clusters at different percentages according to their geographic origin. Specifically 90% of the Australasian sequences form a single monophyletic cluster, followed by sequences from S.E. Asia (80%), Oceania (78%), Asia-Pacific (75%), Caribbean (64%), L. America (56%) and N. America (50%). Sequences from E. Asia (80%) and Sub-Saharan Africa (55%) form several monophyletic clusters while sequences from W. Europe (37%), S. Asia (26%), E. Europe (19%) and N. Africa and Middle East (16%) revealed the lowest monophyly levels. The C. Europe and C. Asia did not reveal any monophyletic pattern. Country-wise analyses showed the following monophyly patterns: Greenland: 100%, New Zealand: 97%, Japan: 75%, Tunisia: 66%, China: 61% and India: 27%. Absence of monophyly patterns was observed for Iran, Syria, Turkey, Belgium, Lebanon, and Russia (mostly sampled from the C. Asian part of Russia).
Conclusions: Our analysis suggests considerable differences in the patterns of HBV genotype D regional clustering around the globe. Notably for Eastern Mediterranean we found very low levels of regional clustering suggesting high levels of viral mobility. This pattern was distinct for Eastern Mediterranean in contrast to several areas in Africa, Asia and the Americas and it is indicative for the central role of this region for genotype D dissemination.

P0568

TGF-β SIGNALING IS ACTIVATED IN PATIENTS WITH CHRONIC HEPATITIS B AND IS REPRESSED BY SMAD 7 OVER EXPRESSION DURING LONG TERM ANTIVIRAL TREATMENT

G. Germanidis[1], N. Argentou[2], P. Hytiroglou[3], E. Apostolou[4], T. Vassiliadis[5], K. Patsiaoura[6], P. Sideras[4], A. Germenis[2], M. Speletas[7]. *[1]First Department of Internal Medicine, AHEPA Hospital, Aristotle University of Thessaloniki, School of Medicine, Thessaloniki, [2]Department of Immunology and Histocompatibility, University of Thessaly, School of Health Sciences, Faculty of Medicine, Larissa, [3]Department of Pathology, AHEPA Hospital, Aristotle University of Thessaloniki, School of Medicine, Thessaloniki, [4]Center for Immunology and Transplantation, Biomedical Research Foundation, Academy of Athens, Athens, [5]Third Department of Internal Medicine, Papageorgiou Hospital, Aristotle University of Thessaloniki, [6]Department of Pathology, A. Pavlos Hospital, Thessaloniki, [7]Department of Immunology and Histocompatibility, University of Thessaly, School of Health Sciences, Faculty of Medicine, Larissa, Greece*
E-mail: geogerm@auth.gr

Background and Aims: Recently the contribution of TGF-β signaling in hepatic injury has been extensively studied. Although animal studies demonstrated that Smad7 induction ameliorates TGF-β/SMAD-mediated fibrogenesis, its role in human hepatic diseases is rather obscure. Our study was designed to explore the activation status of TGF-β/activin pathway in patients with chronic HBV hepatitis/cirrhosis (CHB) at diagnosis and the effect of successful antiviral treatment.
Methods: Liver biopsies from 37 HBeAg-negative CHB patients, (19 with active disease-CHB/d, 14 completely responders on 5 years antiviral treatment-CHB/r and 4 relapsers after treatment withdrawal-CHB/nr) were studied. Biopsies from 18 patients with chronic HCV hepatitis, 12 with non-alcoholic fatty liver disease (NAFLD), and three normals were also studied and served as controls. Liver mRNA levels of CTGF, all TGF-β isoforms and activins, their receptors and intracellular mediators (SMADs), were quantified using qRT-PCR and were compared and correlated with the intensity of liver inflammation and fibrosis staging. The expression and localization of pSMAD2 and pSMAD3 were also assessed by immunohistochemistry.
Results: CHB/d patients displayed a remarkable increased expression of *SMAD2* and *SMAD3* compared to CHB/r patients ($p < 0.001$). We observed an extensive nuclear positivity of pSMAD2 and pSMAD3 of the inflammatory infiltrates in both CHB/d and steatohepatitis patients, as well as variable nuclear positivity of the hepatocytes and biliary epithelial cells. Noteworthy, CHB/r patients displayed an approximately 3-fold increase of SMAD7 expression compared to CHB/d patients ($p < 0.001$). SMAD7 mRNA levels were significantly increased in patients with minimal inflammation, followed by a decrease as inflammation became severe. We observed that TGFB1, INHBB and SMAD4 mRNA levels are also significantly correlated with fibrosis grade, following a similar expression pattern ($p = 0.039$, $p = 0.006$ and $p = 0.008$, respectively). SMAD7 overexpression was also observed in NAFLD patients, despite activation of TGF-b/activin signaling, indicating that SMAD7 upregulation might effect in limiting the fibrotic process.
Conclusions: Molecular and immunohistochemistry data clearly demonstrate that TGF-β signalling is activated in CHB patients with active disease, while SMAD7 is up-regulated during the resolution of inflammation after successful antiviral treatment. SMAD7 overexpression might represent a mechanism limiting TGF-β-mediated fibrogenesis in CHB.

P0569

LIVER INFLAMMASOME EXPRESSION SIGNALING MAY BE ACTIVATED IN PATIENTS WITH CHRONIC HEPATITIS B AND REPRESSED DURING LONG TERM ANTIVIRAL TREATMENT

G. Germanidis[1], A. Molyvdas[2], N. Lasaridis[3], T. Vassiliadis[4], A. Voumvouraki[5], E. Laspa[3], A.E. Germenis[2], M. Speletas[2]. *[1]First Department of Internal Medicine, AHEPA Hospital, Aristotle University of Thessaloniki, School of Medicine, Thessaloniki, [2]Department of Immunology and Histocompatibility, University of Thessaly, School of Health Sciences, Faculty of Medicine, Larissa, [3]First Department of Internal Medicine, AHEPA Hospital, Aristotle University of Thessaloniki, School of Medicine, [4]Third Department of Internal Medicine, Papageorgiou Hospital, Aristotle University of Thessaloniki, [5]First Department of Internal Medicine, AHEPA Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece*
E-mail: geogerm@auth.gr

Background and Aims: Inflammasomes are molecular platforms activated upon cellular infection or stress that trigger the maturation of pro-inflammatory cytokines such as interleukin-1b to engage innate immune defenses. The NLRP3 inflammasome is a cytosolic protein complex required for the development of sterile inflammation, that can further increase organ damage. Many liver diseases such as alcoholic steatohepatitis, non-alcoholic steatohepatitis, and drug-induced liver injury have sterile inflammation as a major component. Our study aimed to explore, for the first time, the liver NLRP3 inflammasome pathway activation status in patients with chronic hepatitis B (CHB) at diagnosis, and how it is affected during long term antiviral treatment.
Methods: Twenty HBeAg-negative CHB naive patients with active disease before treatment, 12 patients on complete virological remission after long-term 5 years antiviral treatment and 9 patients with chronic HCV hepatitis were enrolled in our preliminary study. Liver mRNA levels of NLRP3 (NACHT, LRR, and PYD domains-containing protein 3/cryoporin), IL (interleukin)1b, IL1Ra (interleukin-1 receptor antagonist), ICE (interleukin 1 converting enzyme or Caspase-1) and ASC (apoptosis-associated speck like CARD-domain containing protein), were quantified using qRT-PCR and correlated with histological liver inflammation and fibrosis. Cell-specific inflammasome expression in the liver by immuno-histochemistry was also performed.

Results: Molecular data suggest that liver NLRP3 inflammasome pathway signaling may be activated in CHB patients with active untreated disease: NLRP3 (p = 0.012), IL1Ra (p = 0.024) and ASC (p = 0.028) liver mRNA expression is significantly up-regulated in comparison with CHB patients on remission after antiviral treatment. No statistical difference was observed between active CHB and CHC, with only a trend of higher expression of IL1Ra (p = 0.082) in CHB.
Conclusions: Our preliminary study suggests for the first time that liver NLRP3 inflammasome pathway signaling may be activated in CHB patients with active untreated disease. This up-regulation could represent an additional mechanism of liver damage in CHB. Its repression may represent a candidate for novel therapeutic approaches.

Viral hepatitis: Hepatitis A, B, D, E – b. Clinical (except therapy)

P0570
OCCULT HEPATITIS B INFECTION IN COMPLETELY IMMUNIZED INDIVIDUALS NEGATIVE FOR ANTI-HEPATITIS B CORE ANTIBODY

M.-W. Lai[1], T.-Y. Lin[2], C.-T. Yeh[3]. [1]*Pediatric Gastroenterology,* [2]*Pediatric Infectious Disease,* [3]*Hepato-gastroenterology, Chang Gung Memorial Hospital, Linko, Taoyuan, Taiwan*
E-mail: mingweilai@gmail.com

Background and Aims: Positive anti-hepatitis B virus (HBV) core antibody (anti-HBc) was considered a stigma of HBV infection. Here we challenged this dogma by investigating the prevalence of occult HBV infection (OBI) in anti-HBc-negative, complete vaccinees in Taiwan.
Methods: 705 participants of an epidemiology study for vaccine-preventable diseases in Taiwan had completed ≥3 doses of HBV vaccine in infancy and were negative for anti-HBc. Of them, 460 carried isolated anti-HBV surface antibody (anti-HBs) (HBsAg-negative, anti-HBs-positive, and anti-HBc-negative) and 245 tested negative for all 3 markers (triple seronegative). All samples were submitted for PCR detection targeted against HBV S and X/pre-C genes.
Results: Of the 460 samples carrying isolated anti-HBs, 26 (5.65%) were positive for two-target PCR detection (diagnosed as OBI). Of the 245 triple seronegative samples, 12 (4.90%) were positive. In the former group, prevalence of OBI significantly increased in individuals aged 6–10 years (P = 0.004), accompanied by a significant reduction of the anti-HBs titers (P < 0.001). Of the 38 OBI patients, 7 had HBV DNA >60 IU/mL (ranged from 280 to 18,820 IU/mL). Sequence analysis of the S gene revealed vaccine-escape like mutations with predominantly genotype A. Clinical importance of recognizing OBI in anti-HBc-negative vaccinees was illustrated by a case receiving stem cell transplantation.
Conclusions: OBI could occur in anti-HBc-negative, completely vaccinated individuals. In individuals carrying isolated anti-HBs, the highest prevalence of OBI was observed in 6–10 years of age, associated with age-dependent reduction of anti-HBs titer.

P0571
LIVER HISTOLOGY IN IMMUNE TOLERANCE PHASE PATIENTS WITH CHRONIC HEPATITIS B VIRUS INFECTION ACCORDING TO DIFFERENT ALANINE TRANSAMINASE LEVEL

D. He[1], Q. Shang[1], Y. Zhang[1], Y. An[1], Q. Yi[1], W. Zhang[1], M. Ding[1]. [1]*The 88th hospital of PLA, Tai'an, China*
E-mail: hedengming@gmail.com

Background and Aims: A normal alanine transaminase (ALT) levels does not mean normal liver inflammation. We aimed to observe the difference of liver inflammation in immune tolerance phase chronic HBV infection according to two upper limits of normal ALT standards (30 U/L for males and 19 U/L for females vs. 40 U/L).
Methods: 202 patients were divided into low ALT group (≤30 U/L for males and ≤19 U/L for females) and high ALT group (31–40 U/L for males and 20–40 U/L for females). Ishak and Metavir system were used to evaluate liver inflammation and fibrosis.
Results: Significant difference of Ishak inflammation score and fibrosis score were seen between low ALT group and high ALT group. Positive correlation was seen between ALT levels and Ishak inflammation score or fibrosis staging score. The proportion of mild inflammation was 97.9% in low ALT group and 65.7% in high ALT group. Metavir fibrosis staging in all cases of low ALT group is F0 and F1. In high ALT group, the proportion of F0, F1, F2, F3, and F4 was 51.4%, 39.0%, 7.6%, and 1.9%, respectively. Different distribution of Metavir mild, moderate, and severe or fibrosis staging was seen in age and sex, but not in HBV DNA levels.
Conclusions: For immune tolerance phase patients, the lower ALT ULN is better than the current one in evaluating liver histology. Sex and age are associated with the degree of liver histology for ALT levels >30 in males or >19 in females.

P0572
THE IMPACT OF HEPATITIS B VIRUS (HBV) INFECTION ON PROGNOSIS OF PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA AND THE OCCURRENCE OF HEPATITIS FLARES AFTER WITHDRAWAL OF PROPHYLACTIC ANTIVIRAL TREATMENT ON COMPLETION OF CHEMOTHERAPY

M.F. Law[1], H.N. Chan[2], H.K. Lai[3], C.Y. Ha[3], C. Ng[3], Y.M. Yeung[3], S.F. Yip[3]. [1]*Department of Medicine, Prince of Wales Hospital, Shatin,* [2]*Department of Medince,* [3]*Department of Medicine, Tuen Mun Hospital, Tuen Mun, Hong Kong, China*
E-mail: mflaw99@yahoo.com.hk

Background and Aims: It is important to understand the impact of hepatitis B virus (HBV) infection on prognosis of patients with lymphoma receiving treatment. There is also no consensus on the duration of prophylactic antiviral treatment after cessation of chemotherapy. We analyzed the characteristics and clinical outcomes of diffuse large B-cell lymphoma (DLBCL) patients with HBV infection and compare with those without HBV infection. We also assessed the occurrence of hepatitis flares after withdrawal of prophylactic antiviral treatment on completion of chemotherapy.
Methods: Patient records were reviewed retrospectively from all patients aged 18 or above, with untreated DLBCL who had received chemotherapy between January 1996 and December 2010 in Tuen Mun Hospital, Hong Kong. The hepatitis B surface antigen (HBsAg) positive patients were given prophylactic lamivudine until 6 months after finishing chemotherapy. After chemotherapy and withdrawal of antiviral therapy, patients were followed up regularly to examine for hepatitis flare.
Results: 81 patients were recruited with 16 in the HBsAg positive group and 65 in the HBsAg negative group. The prevalence of hepatitis B among DLBCL patients was 20% in our cohort. The clinical characteristics were similar in both groups of patients. There was no statistically significant difference in overall survival between the two groups (p = 0.23). 4 of the 16 HBsAg positive patients (25%) had hepatitis after cessation of chemotherapy and prophylactic

lamivudine. One patient was given CHOP (cyclophosphamide, doxorubicin, vincristine and prednisolone) therapy and the other three were given R-CHOP treatment previously. The onset of hepatitis ranged from 2 to 4 months (mean 3 months) after stopping lamivudine. These four patients had normal ALT levels before chemotherapy and stopped lamivudine 6 months after completion of chemotherapy. Lamivudine was resumed in these four patients and one patient required addition of adefovir because of the presence of the YMDD mutant. The liver enzymes gradually normalized in all these patients.

Conclusions: HBV infection did not appear to affect the clinical outcomes and prognosis of DLBCL patients given prophylactic antiviral treatment. A significant number of hepatitis flares occurred after 6 months of antiviral prophylaxis upon finishing chemotherapy. It is reasonable to consider prophylactic antiviral therapy to extend to at least one year on completion of chemotherapy.

A STRATEGY TO FAVOR THE ACCESS OF IRREGULAR AND REFUGEE MIGRANTS TO A SCREENING PROGRAM FOR HBV, HCV AND HIV INFECTION

N. Coppola[1], L. Alessio[1], L. Gualdieri[2], M. Pisaturo[1], C. Sagnelli[3], N. Caprio[4], R. Maffei[2], M. Starace[2], I.F. Angelillo[4], G. Pasquale[1], E. Sagnelli[1]. *[1]Department of Mental Health and Public Medicine, Section of Infectious Diseases, [2]Internal Medicine, [3]Department of Clinical and Experimental Medicine and Surgery, [4]Pediatric, Second University of Naples, Naples, Italy*
E-mail: nicola.coppola@unina2.it

Background and Aims: In recent decades, Italy has become land of immigration from countries with intermediate or high HBV, HCV and HIV endemicity. Half immigrants are irregular or refugee frequently excluded from social life by linguistic, cultural and socioeconomic barriers also limiting their access to the healthcare services. The aim is to analyze the use of strategies favoring the access of irregular or refugee migrants to a screening program for HBV, HCV and HIV infection.

Methods: A screening to identify subjects with HBV, HCV or HIV infection was proposed to 926 migrants by a team (doctors, nurses and cultural mediators) skilled in managing problems of vulnerable groups. The screening, free of charge and with no bureaucracy, was accepted by 882 (95.2%) migrants, 625 irregular and 257 refugee, and performed at 4 territorial medical centers in Campania region, southern Italy. None of these 882 had been vaccinated against HBV.

Results: 78 (8.7%) migrants were HBsAg positive, 35 (3.7%) anti-HCV positive, 11 (1.3%) anti-HIV positive and 7 (0.8%) had a multiple infection. These 131 patients were addressed to Department of Infectious Diseases for further investigation and treatment. Of the 801 HBsAg negative patients, 373 (40.2%) were anti-HBc positive. All migrants with a detectable marker of HBV, HCV or HIV infection were unaware of their serological status. The HBsAg positivity rate was high (13.9%) in migrants from sub-Saharan Africa and intermediate in those from eastern Europe (6.1% of 194 cases), northern Africa (2.5% of 80 cases) and Indian–Pakistani area (3.2% of 126 cases). Anti-HCV was more frequent in migrants from eastern Europe (6.2%) and Indian–Pakistani areas (7%) than in those from sub-Saharan (3.8%) and northern Africa (2.5%). Anti-HIV was detected in 17 (3.8%) migrants from sub-Saharan Africa, in 5 (2.4%) from eastern-Europe, in 1 (0.8%) from Indian–Pakistani area and in none from northern Africa. Regarding single countries, the highest positivity rate was found in Burkina Faso subgroup for HBsAg (28.6%), in Ukraine and in Pakistani subgroups for anti-HCV (11.6%) and in Nigeria subgroup for anti-HIV (4.5%).

Conclusions: This investigation identified 131 migrants with HBV, HCV or HIV infection unaware of their serological status, suggesting the need of a strong action of Healthcare Authorities of Italy, may be using our model, to favor the access of migrant populations to healthcare services and to support screening and educational programs.

P0574

A SIGNATURE OF ELEVATED IMMUNE ACTIVATION IS OBSERVED IN THE PERIPHERAL BLOOD OF VIRALLY SUPPRESSED, HBeAg-NEGATIVE CHRONIC HBV PATIENTS

C. Frey[1], A. Palazzo[1], L. Li[2], Menashe Elazar[3,4], E. Pham[3,4], B. Fram[3,4], T. Nguyen[3,4], H. Han[3,4], Monica Elazar[3,4], J. Glenn[3,4], A. Ahmed[3], S. Pflanz[1]. *[1]Immunology Department, [2]Biomarker Department, Gilead Sciences, Inc., Foster City, [3]Department of Medicine, Division of Gastroenterology and Hepatology, [4]Department of Microbiology and Immunology, Stanford University School of Medicine, Stanford, United States*
E-mail: christian.frey@gilead.com

Background and Aims: In the natural history of chronic HBV infection (CHB) loss of HBeAg and anti-HBeAg seroconversion precedes loss of HBsAg and anti-HBsAg seroconversion, the latter being considered the equivalent of achieving immunological control and functional cure. However, patients who achieve HBeAg-negative status with nucleos(t)ides (Nuc) therapy rarely achieve HBsAg loss and seroconversion. This suggests that host immunity to HBV might be compromised even with complete viral suppression under Nuc treatment. This study compares the immunological profiles in peripheral blood of healthy donors and virally suppressed CHB patients.

Methods: Whole blood, serum and peripheral blood mononuclear cells (PBMC) were isolated from healthy donors (HD) and virally suppressed, HBeAg-negative CHB patients (CHB). Transcriptional profiling of the whole blood was performed by RNA-sequencing (n = 6, HD; n = 8, CHB) and cytokine secretion profiles were assessed in PBMC cultures and directly ex vivo in matched serum samples (n = 12, HD; n = 8, CHB).

Analyte	IFN-α	IL-29	IL-12	TRAIL	MIP-1β
PBMC					
HD	3.6 (±5.5)	19.8 (±26.8)	0.59 (±0.96)	16.6 (±27.8)	7991 (±17682)
CHB	41.1 (±24.4)	149.6 (±69.3)	6.51 (±3.94)	139.7 (±48.0)	84982 (±31830)
P-value	<0.001	<0.001	<0.001	<0.001	<0.001
Serum					
HD	4.6 (±6.2)	7.5 (±4.6)	0.33 (±0.22)	9.7 (±3.2)	216 (±82)
CHB	27.1 (±39.0)	15.6 (±4.0)	0.96 (±0.91)	23.9 (±9.1)	682 (±361)
P-value	0.06	<0.001	<0.05	<0.001	<0.001

Mean (±SD) shown for each analyte in supernatants of un-stimulated 24 h PBMC cultures (upper part), and directly ex vivo in serum (lower part); units are pg/ml. Statistical significance was calculated using an unpaired, 2-tailed T-test.

Results: Principal component analysis of the transcriptome data showed segregation of CHB versus HD. Gene set enrichment analysis identified an IL-12/T cell receptor-related signature that was induced in CHB but not HD. In vitro culture of isolated PBMC revealed significantly elevated secretion of several cytokines in CHB compared to HD, including type I and III IFN, and also IL-12. Of note, elevated levels of some but not all of those cytokines were also detected in corresponding CHB serum samples.

Conclusions: These data suggest that an activated immune signature is maintained in peripheral immune cells of virologically suppressed CHB patients. Continuous low level cytokine production may mediate enhanced feedback inhibition mechanisms in the signaling cascades of key anti-viral mediators, and hence contribute to overall suboptimal anti-HBV immunity.

P0575

LIVER FIBROSIS IN TREATMENT-NAÏVE HIV-INFECTED AND HIV/HBV-COINFECTED PATIENTS: ZAMBIA AND SWITZERLAND COMPARED

E-mail: gwandeler@ispm.unibe.ch

Background and Aims: Differences in HBV transmission, environmental exposures and other hepatotoxic coinfections between sub-Saharan Africa and Europe may influence the development of HBV-related liver fibrosis. We compared the impact of HBV-coinfection on the prevalence of liver fibrosis in HIV cohorts in Zambia and Switzerland.

Methods: We included all participants with available measurements of HBsAg, ALT, AST and platelets at ART initiation in the Zambian IeDEA-SA hepatitis cohort and the Swiss HIV Cohort Study. Hepatitis C-coinfected patients were excluded. Liver fibrosis was evaluated using the AST to Platelet Ratio Index (APRI), with a ratio >1.5 defining significant fibrosis. Baseline characteristics were compared between HBsAg-positive and negative individuals in both cohorts with the Chi-square test. We used multivariable logistic regression to evaluate the association between HBsAg-positivity and significant liver fibrosis. The analyses were repeated using HBV DNA >20 IU/ml as the marker for HBV activity.

Table: Risk factors for significant liver fibrosis, by cohort

	Zambia (n = 689)		Switzerland (n = 2,057)	
	No. (%) with significant fibrosis	Multivariable analysis (95% CI)	No. (%) with significant fibrosis	Multivariable analysis (95% CI)
HBV-coinfection				
No	23/600 (3.8)	1	87/1962 (4.4)	1
Yes	9/89 (10.1)	2.96 (1.29–6.80)	14/95 (14.7)	3.68 (1.97–6.87)
Gender				
Female	7/358 (2.0)	1	6/466 (1.3)	1
Male	25/331 (7.6)	3.41 (1.40–8.34)	95/1591 (6.0)	5.18 (2.16–12.41)
Age, y				
16–40	20/503 (4.0)	1	45/1126 (4.0)	1
>40	12/186 (6.5)	1.65 (0.77–3.53)	56/931 (6.0)	1.38 (0.91–2.10)
African origin				
No	0	1	88/1727 (5.1)	1
Yes	32/689 (4.6)	1	13/330 (3.9)	1.38 (0.72–3.65)
High alcohol intake				
No	25/577 (4.3)	1	85/1875 (4.5)	1
Yes	7/112 (6.3)	0.97 (0.39–2.40)	16/182 (8.8)	1.60 (0.90–2.84)
Advanced HIV disease				
No	12/376 (3.2)	1	83/1834 (4.5)	1
Yes	20/298 (6.7)	1.70 (0.79–3.67)	18/223 (8.1)	1.58 (0.88–2.83)
CD4+ count, cells/μL				
≥200	14/378 (3.7)	1	61/1445 (4.2)	1
<200	18/311 (5.8)	1.32 (0.63–2.79)	40/612 (6.5)	1.39 (0.89–2.19)

Results: Among 689 ART-naive patients in Zambia (52.0% female, median age 34 years) and 2,057 in Switzerland (22.7% female, median age 39 years), 89 (12.9%) and 95 (4.6%) were HBsAg positive, respectively. Overall, 90.3% (131/145) of those with an available HBV viral load at ART initiation had detectable HBV DNA. Age, sex, alcohol consumption, and HIV disease markers were similar between HIV and HIV/HBV-coinfected groups in both countries. Median APRI score was 0.37 [95% confidence interval (CI) 0.26–0.57] in Zambia and 0.40 (0.30–0.60) in Switzerland and differences in APRI between HIV and HIV/HBV-coinfected individuals were similar across cohorts. In both countries, HBV-coinfected patients were more likely to have an elevated ALT (grade 1 or higher) at ART initiation (Zambia: 18% vs 9%, p = 0.01; Switzerland: 26% vs. 11%, p < 0.001). In adjusted analyses, HBV-coinfection and male sex were independent predictors of significant liver fibrosis in both countries (Table). The association between HBV-coinfection and significant liver fibrosis was similar when active HBV replication was used instead of HBsAg-positivity.

Conclusions: HBV-coinfected patients had approximately 3 times the odds of significant liver fibrosis at ART initiation compared to HBsAg-negative ones in Zambia and Switzerland. Despite the known differences in HBV natural history between these settings, the degree of liver fibrosis and the role played by other risk factors were similar.

P0576

IMPACT OF ORGAN AND NON-ORGAN-SPECIFIC AUTOANTIBODIES ON THE TREATMENT OUTCOME OF PATIENTS WITH HEPATITIS D VIRUS INFECTION

K. Zachou[1,2], C. Yurdaydin[3], U. Drebber[4], V. Schlaphoff[2], H.P. Dienes[4], M.P. Manns[2], H. Wedemeyer[2], G.N. Dalekos[1], HIDIT-1 Study Group. *[1]Department of Medicine and Research Laboratory of Internal Medicine, Medical School, University of Thessaly, Larissa, Thessaly, Greece; [2]Department of Gastroenterology, Hepatology and Endocrinology, Hanover Medical School, Hanover, Germany; [3]Gastroenterology Section, University of Ankara Medical School, Ankara, Turkey; [4]Institute of Pathology, University of Cologne, Cologne, Germany*
E-mail: zachoukalliopi@gmail.com

Background and Aims: Chronic hepatitis delta virus (HDV) infection has been associated with the production of autoantibodies. However, their clinical significance has not been investigated. We reevaluated the production of organ and non-organ specific autoantibodies in a large cohort of patients with chronic HDV infection who participated in the Hep-Net/International Delta Hepatitis Intervention Trial (HIDIT-1), as well as their impact in treatment outcome.

Methods: We investigated the presence of antinuclear (ANA), antimitochodrial (AMA), anti-smooth muscle (SMA), anti-liver kidney microsomal (anti-LKM) and anti-parietal cell (PCA) antibodies by indirect immunofluorescence on HEp2 cells and rat liver-kidney-stomach sections and anti-LKM-3 antibodies by western blot using recombinant UGT 1.1, at baseline and at week 48 of treatment, in the sera of 87 patients with chronic HDV infection. Quantitative determination of HDV-RNA, HBsAg and HBV-DNA was performed by real-time PCR, the Architect HBsAg assay and Cobas TaqMan HBV test, respectively, at baseline, week 48 (end of treatment) and week 72.

Results: At baseline, ANA, SMA, AMA, anti-LKM, PCA and anti-LKM-3 were detected in 29/87 (33%), 24/87 (27%), 2/87 (2.3%), 3/87 (3.4%), 4/87 (4.6%) and 21/87 (24%) of patients, respectively. At least 1 autoantibody was detected in 56/87 (64.4%). At week 48, positive were 29/74 (39%), 20/74 (27%), 3/74 (4%), 5/74 (7%), 18/74 (24%) and 20/74 (27%) respectively, while at least 1 autoantibody was detected in 54/74 (73%) of the patients. ANA presence at baseline was associated with increased probability of HDVRNA negativity at week 72 (p = 0.04). The absence of SMA at baseline tended to be associated with lower HDVRNA levels at week 72 (p = 0.057) and amelioration of fibrosis in liver biopsy at week 48 compared to fibrosis at baseline (p = 0.05). The absence of PCA at week 48 was associated with lower HBsAg levels at weeks 48 (p = 0.01) and 72 (p = 0.01), biochemical response (p = 0.04) and amelioration of inflammation in liver biopsy at the end of treatment (p = 0.03). Finally, the presence of at least 1 autoantibody at baseline was

associated with increased probability of HDVRNA negativity at week 48.
Conclusions: We found increased incidence of anti-LKM-3 as well as of other autoantibodies in patients with chronic HDV infection. Although anti-LKM-3 antibodies do not seem to affect response to treatment, others may play a role in the virological, biochemical or histological response.

P0577
VACCINE EFFICACY OF COMBINATION VERSUS MONOVALENT HEPATITIS B VACCINES IN INFANTS AT HIGH RISK OF VERTICAL TRANSMISSION

L.Y. Lee[1], C. Ong[2], M. Aw[3], G.H. Lee[4], K.C. Thoon[2], K.B. Phua[2].
[1]Neonatology, National University Hospital, [2]Pediatrics, Kandang Kerbau Women and Children's Hospital, [3]Pediatrics, [4]Medicine, National University Hospital, Singapore, Singapore
E-mail: le_ye_LEE@nuhs.edu.sg

Background and Aims: There are concerns with regards to the efficacy of combination (DTaP-IPV-HiB-HBV) vaccine, especially in infants with high risk of vertical transmission, and there has been no study comparing the vaccine efficacy in those receiving three doses of monovalent HBV vaccine versus two doses monovalent plus one dose of combination vaccine in infants of chronic HBV-infected mothers. The aim of this study is to examine the anti-HBs antibody levels of both vaccine regimens in a cohort of these high-risk infants.
Methods: An observational cohort of term neonates was recruited from June 2009 to June 2014 from multiple primary to tertiary centres in Singapore. Anti-HBs antibody levels were measured at 9 months of age. Vaccine regimen administered were based on the individual institutions' practice.
Results: All term neonates received monovalent hepatitis B vaccine with hepatitis B immunoglobulin at birth with a repeat dose of monovalent hepatitis B vaccine at 1 month. They received either monovalent (n = 111) or combination vaccine (n = 95) at 6 months. Baseline maternal age (31.3 year vs 32.9 years), hepatitis B e-antigen positivity (24% vs 28%, p = 0.78) and birth characteristics, including gestational age (38 weeks versus 38weeks, p = 0.34), birth weight (3.13 kg vs 3.16 kg, p = 0.62) were similar between groups. The mean anti-HBs antibody were both not statistically different (478 IU/L vs 469 IU/L, p = 0.88). Vaccine failure rate (anti-HBs antibody <10 IU/L) was 4.5% vs 4.7% (p = 1.00). Vertical transmission rate (HBsAg or HBV DNA positive) was 1.8% vs 2.3% (p = 0.78).
Conclusions: For term neonates delivered by chronic HBV-infected mothers, both 3-dose monovalent and combination vaccine regimen showed similar vaccine efficacy, with no increased risk of vertical transmission.

P0578
HBsAg NEGATIVE ANTI-HBC POSITIVE SEROLOGY INCREASES THE RISK OF HCC IN CHRONIC HEPATITIS PATIENTS: A META-ANALYSIS

N. Coppola[1], L. Onorato[1], C. Sagnelli[2], E. Sagnelli[1], I.F. Angelillo[3].
[1]Public Health and Public Medicine, [2]Clinical and Experimental Medicine, [3]Experimental Medicine, Second University of Naples, Naples, Italy
E-mail: nicola.coppola@unina2.it

Background and Aims: We performed a meta-analysis to ascertain at which extend patients with chronic hepatitis (CH) of different etiology and positivity for anti-HBc are at a higher risk to develop hepatocellular carcinoma (HCC) than those anti-HBc negative
Methods: Included in the meta-analysis were 26 studies meeting these criteria: investigating on the relationship between HBsAg-negative/anti-HBc-positive serology and occurrence of HCC, being a case–control or cohort study, providing relative risk or odds ratios and 95% confidence intervals, being available as full text written in English, being published and indexed up to September 2014.
Results: Twenty-six original studies met inclusion criteria, allowing a meta-analysis on 14,558 patients: the rate of HCC was higher in the 5,581 anti-HBc positive subjects than in the 8,977 negative (RR = 1.58; 95% CI: 1.49–1.69, $p < 0.0001$). The results were similar when groups of patients with a different stage of liver disease were singularly analyzed: RR = 1.30; 95% CI: 1.12–1.51, $p = 0.001$, in the 1,932 patients with cirrhosis and RR = 1.44; 95% CI: 1.18–1.87, $p < 0.0001$, in the 778 with chronic hepatitis. An independent association of anti-HBc positivity with HCC was similar both in the 16 studies carried out in Asia (RR = 1.62; 95% CI: 1.50–1.74, $p < 0.0001$) and the 10 studies in other countries (RR = 1.50; 95% CI: 1.35–1.70, $p < 0.0001$). Regarding the etiology, the relationship between anti-HBc positivity and HCC was investigated in HCV-related chronic liver diseases (RR = 1.52; 95% CI: 1.41–1.63, $p < 0.0001$). In 9 studies the data are presented according also to both anti-HBc- and anti-HBs-positivity. Compared to the 4198 anti-HBs/anti-HBc negative patients the rate of HCC was significantly higher in both the 935 anti-HBs/anti-HBc positive patients (RR = 1.17; 95% CI: 1.01–1.35, $p = 0.030$) and in the 719 anti-HBs negative/anti-HBc positive ones (RR = 1.75; 95% CI: 1.56–1.96, $p < 0.0001$). Besides, the 935 anti-HBs/anti-HBc positive subjects showed a risk of HCC significantly lower than those anti-HBs negative/anti-HBc positive (RR = 0.63; 95% CI: 0.55–0.72, $p < 0.0001$).
Conclusions: This meta-analysis show that in HBsAg negative CH patiens "isolated" anti-HBc is strongly associated with the presence of HCC, an association observed in all subgroups established by the stage of the disease, aetiology and ethnicity.

EPIDEMIOLOGICAL, CLINICAL AND VIROLOGICAL FEATURES OF HEPATITIS DELTA VIRUS INFECTION IN FRANCE

S. Brichler[1], F. Roudot-Thoraval[2], D. Samuel[3], P. Marcellin[4], O. Chazouilleres[5], T. Poynard[6], V. Thibault[7], F. Zoulim[8], P. André[9], N. Ganne[10], H. Fontaine[11], Z. Benabdesselam[12], R. Layese[2], E. Gordien[1], D. Roulot[13], The Delta study group. *[1]Laboratoire de bactériologie, virologie, hygiène, associé au Centre National de Référence des hépatites B, C et Delta, AP-HP, Hôpital Avicenne, Bobigny, [2]Département de Santé Publique, AP-HP Hôpital Mondor, Paris, [3]Service d'hépatologie, AP-HP Hôpital Paul Brousse, Villejuif, [4]Service d'hépatologie, AP-HP Hôpital Beaujon, Clichy, [5]Service d'hépatologie, AP-HP Hôpital Saint-Antoine, [6]Service d'hépatologie, [7]Laboratoire de virologie, AP-HP Groupe hospitalier Pitié-Salpetriere, Paris, [8]Service d'hépatologie, Hôpital Hotel-Dieu, Lyon, [9]Laboratoire de virologie, Hôpital de la Croix Rousse, Lyon, [10]Service d'hépatologie, AP-HP Hôpital Jean Verdier, Bondy, [11]Service d'hépatologie, AP-HP Hôpital Cochin, Paris, [12]Unité d'Hépatologie, AP-HP, Hôpital Avicenne, Bobigny, [13]Unité d'Hépatologie, AP-HP, Hôpital Avicenne, Bobigny, France*
E-mail: dominique.roulot@avc.aphp.fr

Background and Aims: Hepatitis Delta Virus (HDV) infection often causes severe chronic liver disease. Epidemiology of HDV has changed in developed countries, because of sanitary improvement on one hand, and of population migrations on the other hand. Comprehensive data on HDV and on its societal burden are currently lacking in France.
Methods: HDV-infected patients were identified from the French National Reference Centre database. Epidemiological clinical and virological data, including HBV and HDV viral load and HDV genotyping, were collected on a standardized form from initial diagnosis to the last recorded follow-up.
Results: 1112 HDV/HBV co-infected patients were included in the study. The mean age was 37±10 years. Patients were predominantly male (69%) and migrants (86%), originating from sub-Saharan Africa

(53%), southern and eastern Europe (19%), Middle East (5%) Asia (7%), northern Africa (2%) and South America (0.3%).
16% were IV drug users, 19% were co-infected with HIV and 24% with HCV; 46% had a history of past or persistent excessive alcohol consumption, and 37% were overweight. 88% showed detectable HDV viral load (median value: 165000 copies/mL) and 47% detectable HBV viral load (median value: 400 IU/mL).
HDV-1 was the predominant genotype (76%) followed by genotypes typical of the sub-Saharan area: HDV-5 (18%), HDV-7 (3%), HDV-6 (2%) and HDV-8 (2%).
At first referral 28% of the patients showed histological cirrhosis, 15% one episode (or more) of hepatic decompensation and 2.7% hepatocellular carcinoma (HCC).
During the median follow-up of 4.4 years [1.4–8.9], 47% of the patients were treated for HDV, and 70% remained HDV-RNA positive; 20%, 10% and 6.5% of the patients developed cirrhosis, liver decompensation and HCC, respectively. Liver transplantation was performed in 14% of all initial patients and 5% died. Overall, the 10-year risk of cirrhosis, decompensation, HCC, liver transplantation, and death was 40%, 31%, 15%, 16% and 7%, respectively.
Conclusions: HDV infection in France is predominantly observed in migrants, mostly from sub-Saharan Africa. Genotype HDV-1 is largely predominant. Anti-viral treatment was effective in 30% of the cases. HDV is currently the most severe among the chronic viral hepatitis causes, being associated with very high risk of cirrhosis and related complications

P0580
GENETIC SIGNATURES SPECIFICALLY CLUSTERED IN IMMUNE ACTIVE HBsAg REGIONS CORRELATE WITH IMMUNOSUPPRESSION-DRIVEN HBV REACTIVATION: AN EXTENSIVE ANALYSIS OF HBV GENOME

E-mail: rsalpini@yahoo.it

Background and Aims: To investigate genetic features along HBV genome underlying immunosuppression-driven HBV reactivation.
Methods: This study includes 127 patients (pts) (all genotype D): 47 with HBV reactivation (defined by Hwang, 2013), and 80 with chronic HBV infection, drug-naïve, as control. Genetic distance (using genotype D as reference and expressed as mean±SE) is used to estimate the extent of genetic variability in sequences of Pre-S1/S2 (aa: 1–163), HBsAg (aa: 1–226), RT (aa:1–344), Basal Core Promoter (BCP) (nt: 1–72), and PreCore/Core (aa: 1–112) obtained by population-sequencing. HBsAg ultra-deep sequencing (UDPS) is performed for 30 HBV-reactivated pts and 23 controls.
Results: The pre-reactivation HBV status is: 63.7% anti-HBc pos ± anti-HBs, 21.3% inactive carriers, 6.4% isolated anti-HBs, 4.3% active carriers, and 4.3% negative to all HBV markers. 53.2% of HBV-reactivated pts was treated with rituximab for hematologic malignancies, 14.9% with corticosteroids for chronic inflammatory diseases, 27.7% with other immunosuppressive chemotherapeutics. In 51.1% of pts, HBV reactivation occurs after completing immunosuppressive therapy (range: 1–48 months).
HBsAg genetic variability is significantly higher in HBV-reactivated pts than in controls (0.025±0.006 vs 0.018±0.005, $P < 0.001$). Such increase is not observed in pre-S1/S2, RT and BCP/PreCore/Core, suggesting that HBsAg variability gives a specific contribution of to HBV reactivation.
In particular, 78.7% of HBV-reactivated pts (vs 6.3% of controls, $P < 0.001$) carries mutations localized in immune-active HBsAg regions. Among them, 14 (M103I/T, L109I, T118K, P120A, Q129H/R, Y134H, S143L, D144E, G145A/R, S154P, E164D) reside in major hydrophilic loop (target of antibodies). Most of them are known to act as immune-escape. The others (C48G, V96A, L175S, G185E) reside in Class-I T-cell epitopes.
By UDPS, these mutations occur with an intra-patient prevalence >50% in 81.8% of HBV-reactivated pts indicating their fixation as predominant species. In controls carrying such mutations, their intra-patient prevalence ranges from 0.4% to 21.3% ($P = 0.003$).
Conclusions: HBV reactivation occurs in various clinical settings, often after completing immunosuppressive therapy, and correlates with a high genetic heterogeneity specifically clustered in immune active HBsAg regions. This supports the need to carefully monitor all pts at reactivation risk, and to assess the best time for the onset and duration of prophylaxis to prevent clinical complications.

Medizinische Klinik und Poliklinik, Mainz, [7]Universitätsklinikum Leipzig, Leipzig, [8]Universitätsklinikum Würzburg, Würzburg, [9]Hepatologische Schwerpunktpraxis, Herne, [10]Ärztezentrum am Nollendorfplatz, Berlin, Germany*
E-mail: viola.knop@kgu.de

Background and Aims: Single-point HBsAg and HBV DNA quantification at baseline were shown to be major predictors of spontaneous clearance of HBsAg during natural course of HBV infection in Asia.
The aim of the present study was to analyze dynamic viral and biochemical parameters within the first and second year of follow-up in order to predict HBsAg seroclearance and HBsAg seroconversion in a cohort of inactive HBsAg carriers from Europe.
Methods: 602 patients with HBeAg-negative HBV infection were prospectively followed. They were considered not to be candidates for antiviral therapy at study inclusion based on international guidelines. Biochemical, virological and non-invasive fibrosis parameters were performed at baseline (BL) as well as during annual follow-up. HBsAg, HBV DNA and biochemical values were compared between the following groups: patients with continuous positive HBsAg (group A), patients with HBsAg loss (group B) and patients with HBsAg seroconversion (group C) within 2 years of study entry.
Results: Data of 1, 2, 3 and 4 years follow-up were available in 288, 184, 101 and 52 patients. 10 patients lost HBsAg within the first 2 years of follow-up and 6 out of 10 achieved HBsAg seroconversion. Patients without HBsAg seroclearance (group A) had higher HBsAg titers at baseline (BL) compared to patients

with loss of HBsAg (group B) ($p < 0.001$) and patients with HBsAg seroconversion (group C) ($p = 0.002$). In group B+C patients log decay rate of HBsAg decline was 2.67 per year compared to 0.002 in the remaining patients (n = 174) without HBsAg loss ($p = 0.0002$). There was no significant difference of annual decline between group B+C patients. Levels of HBV DNA at BL were lower in group A than in group B and C patients ($p = 0.018$ A vs B; $p < 0.001$ A vs C) without difference of annual decay rate. AST values were significantly lower in group A vs C patients ($p = 0.038$). HDL cholesterin levels were higher in group A than group B and lowest in group C patients ($p = 0.038$). In contrast, ALT, GGT, LDL and total cholesterol did not show significant differences between the 3 patient groups during 2 years follow-up.

Conclusions: After 2 years prospective follow-up of 602 patients with low-replicative chronic hepatitis B spontaneous HBs antigen loss and seroconversion rates were low (5.4% and 3.3% respectively). In addition to HBsAg concentration at baseline the annual decay rate was a highly significant predictor for both HBsAg seroclearance and HBsAg seroconversion.

P0582

ADHERENCE TO GUIDELINES: HEPATITIS B SEROLOGY BEFORE STARTING IMMUNOSUPPRESSIVE THERAPY (RITUXIMAB, ANTI-TNF) IN AN URBAN AND RURAL REGION IN NORTH HOLLAND (NETHERLANDS)

J.V.D. Giessen[1], M. Klemt-Kropp[1]. [1]*Gastroenterology, Medisch Centrum Alkmaar, Alkmaar, Netherlands*
E-mail: janinevdgiessen@gmail.com

Background and Aims: The risk of reactivation of a chronic hepatitis B or an occult hepatitis B (OBI) during treatment with certain immunosuppressive medication is relevant with a significant morbidity and even mortality. Therefore national guidelines of different medical specialties advice to screen for hepatitis B virus prior to starting therapy. The aim of this study was to assess the adherence to these guidelines in patients with gastrointestinal, rheumatic and hematologic diseases in a urban and rural region in North Holland, a province in the Northwest of the Netherlands with a relatively low prevalence of hepatitis B.

Methods: A retrospective cohort study was conducted. 508 patients, who received rituximab, adalimumab, infliximad or etanercept (biologicals) in 2013 and 2014, were included using the record list of the hospital pharmacy. Many of these patients received their first biological earlier. The medical records and laboratory results were screened. When a patient was screened for hepatitis B one year prior to the start of treatment, this was accepted as screening according to the guidelines. Prior to the start of the study a survey was send to all medical specialist involved in the treatment with above mentioned substances to obtain information about the personal knowledge and application of the guidelines.

Results: 35% of all patients were screened for hepatitis B prior to starting a biological. A difference was found between specialty. The gastroenterologist tested in 68.9%, the hematologist-oncologist in 15.6% and the rheumatologist in 28.4% of the cases. We also looked at testing rate prior to the start of other immunosuppressant (azathioprine, 6-mercaptopurine, methotrexate en prednisolone), this was very low (3.9%).

There were no cases of reactivation in the whole study group.

When we look at testing, before a biological, through the years we see a significant positive trend from 2000 until 2014 with a steep increase of screening from 2009 (5% in 2009 and 67% in 2014, $P = 0.000$). These are the years were divers guidelines concerning this issue were published (2008–2014).

Conclusions: In conclusion, 35% of the patients were tested for hepatitis B before starting a biological. There was no case of reactivation in our low-prevalance region. With precaution we conclude that in a low prevalence area not following the guidelines is possibly without clinical consequences and can safe costs. Further research in high prevalence areas has to be done.

P0583

AN ANALYSIS OF RISK FACTORS OF SECONDARY INFECTION OF PATIENTS WITH HBV RELATED ACUTE-ON-CHRONIC LIVER FAILURE AND ITS IMPACT ON PROGNOSIS

K. Ma[1], P. Li[1], M. Han[1], T. Chen[1], D. Yang[1], J. Huang[1], Y. Huang[1], X. Zhao[1], J. Song[1], J. Qi[1], Q. Ning[1]. [1]*Department and Institute of Infectious Disease, Tongji Hospital, Tongji Medical College, University of Science and Technology, Wuhan, China*
E-mail: tj_hu@126.com

Background and Aims: Hepatitis B related acute-on-chronic liver failure (HBV-ACLF) has a poor prognosis with high mortality. Secondary infection is frequently occurred in these patients. The aim of this study is to evaluate its impact on clinical outcome and identify the potential risk factors for its development in these patients.

Methods: In this retrospective and case controlled analysis, ninety-eight patients with HBV-ACLF were enrolled and divided into two groups (infected 48 and non-infected n = 50). Clinical features and biochemical markers of these patients were collected (Table 1). Univariate analysis was performed by chi-square test using SPSS 19.0 software.

Results: The average time duration to occurance of secondary infection was (12.40±9.61) days after patients administration. Sites infections were occurred: abdominal infections (including spontaneous bacterial peritonitis) 13 cases (27.08%), respiratory infections 10 cases (20.83%), blood-borne infection 3 cases (6.25%), biliary tract infection 2 cases (4.17%), urinary tract infection 1 case (2.08%), skin infections 1 case (2.08%), location unknown 8 cases (16.67%), more than two and two parts of the infection 10 cases (20.8%). Patients survival in infected group were 25%, significantly lower than that in non-infected group (96%, $P < 0.001$). Univiarate analyses indicated that risk factors for secondary infection include age >45 years ($P = 0.046$), ascites ($P = 0.003$), hepatic encephalopathy ($P < 0.001$), hepatorenal syndrome ($P < 0.001$), serum total bilirubin >400 μmol/L ($P = 0.029$), serum alanine aminotransferase >410 U/L ($P = 0.029$), serum total protein <62 ($P = 0.027$), serum globulin <25 g/L ($P = 0.01$), platelet count $<100 \times 10^9$/L ($P = 0.026$).

Table 1. Baseline characteristics of patients with HBV-ACLF

	Overall (n = 98)	Infected (n = 48)	Non-infected (n = 50)	P value
Age (mean±SD)	40.83±12.21	43.19±13.85	38.88±9.84	0.046
Sex (M:F)	89:9	45:3	44:6	0.487
Liver cirrhosis	22 (22.45%)	8 (16.67%)	14 (28.00%)	0.228
Ascites	56 (57.14%)	31 (64.58%)	25 (50.00%)	0.159
HRS	10 (10.20%)	8 (16.67%)	2 (4%)	0.049
Bleeding esophageal varices	2 (2.04%)	1 (2.08%)	1 (2.00%)	1
HE	32 (32.65%)	24 (50.00%)	8 (16.00%)	<0.001
Albumin (g/L)	32.08±4.59	31.23±4.39	32.89±4.67	0.073
Albumin <35 g/L	76 (77.55%)	39 (81.25%)	37 (74.00%)	0.471
Globulin (g/L)	30.57±7.78	29.94±9.02	31.18±6.40	0.432
Total protein (g/L)	62.65±8.70	61.16±9.04	64.07±8.19	0.099
ALT (IU/L)	641.90±781.95	532.19±782.17	747.22±774.9	0.175
AST (IU/L)	473.30±563.55	446.35±632.87	499.16±493.07	0.645
Total bilirubin (μmol/L)	287.74±130.15	307.02±151.22	269.24±104.32	0.152
Serum sodium (mmol/L)	137.79±4.38	137.05±4.95	138.52±3.65	0.660
Prothrombin activity (%)	38.04±12.16	38.52±14.11	37.6±10.00	0.51
INR for prothrombin time	2.06±0.56	2.10±0. 70	1.99±0.38	0.216
Serum urea (mmol/L)	5.36±6.00	6.01±5.70	4.72±6.28	0.255
Serum creatinine (μmol/L)	71.11±41.49	78.16±50.82	64.21±28.55	0.072
Platelet count (10^3/μL)	107.71±40.81	100.89±35.26	114.25±44.89	0.105
WBC (10^3/μL)	6.63±2.21	7.07±2.34	6.21±2.12	0.052
Hemoglobin (g/dL)	124.94±21.37	120.40±21.33	131.34±20.01	0.174
MELD scores	21.27±5.90	22.36±5.79	20.1±5.95	0.062
CTP scores	10.21±1.67	11.16±1.42	9.26±1.32	0.878
HBV DNA (lg copies/mL)	5.77±1.71	5.97±1.64	5.56±1.77	0.099
HBeAg positive	11 (11.22%)	4 (8.33%)	7 (14.00%)	0.525

Conclusions: Secondary infection including SBP and pneumonia frequently occurred in patients with HBV-ACLF and significantly increased mortality. Early identification and intervention of the risk factors may improve the survival.

P0584

GENDER DIFFERENCES IN HEPATOCELLULAR CARCINOMA (HCC) SURVEILLANCE ADHERENCE PATTERNS IN PATIENTS WITH CHRONIC HEPATITIS B (CHB) IN A MULTICENTER ACADEMIC AND COMMUNITY COHORT STUDY

L. Nguyen[1], C. Wang[1], J. Hoang[2], H.N. Trinh[3], J. Li[4], J.Q. Zhang[5], M. Nguyen[2]. *[1]Stanford University, Stanford, [2]Division of Gastroenterology and Hepatology, Stanford University, Palo Alto, [3]San Jose Gastroenterology, San Jose, [4]Gastroenterology, Palo Alto Medical Foundation, Mountain View, [5]Chinese Hospital, San Francisco, United States*
E-mail: mindiehn@stanford.edu

Background and Aims: HCC surveillance is associated with improved survival of CHB patients. Although HCC risk is higher in males than females, it is not known if there are gender differences in HCC surveillance adherence. Our goal is to examine HCC surveillance adherence in males versus females and to determine surveillance adherence predictors.
Methods: We performed a retrospective cohort study of 1098 consecutive CHB patients without prior history of HCC and at least 12 months follow-up at a university medical center and 3 community gastroenterology and primary care sites in the U.S from 10/98–10/13. Patients were identified using ICD-9 diagnosis codes. Adherence to HCC screening by AASLD 2010 guidelines was categorized by imaging: optimal (every 6 months), suboptimal (6–12 months), poor (>12 months) and none.

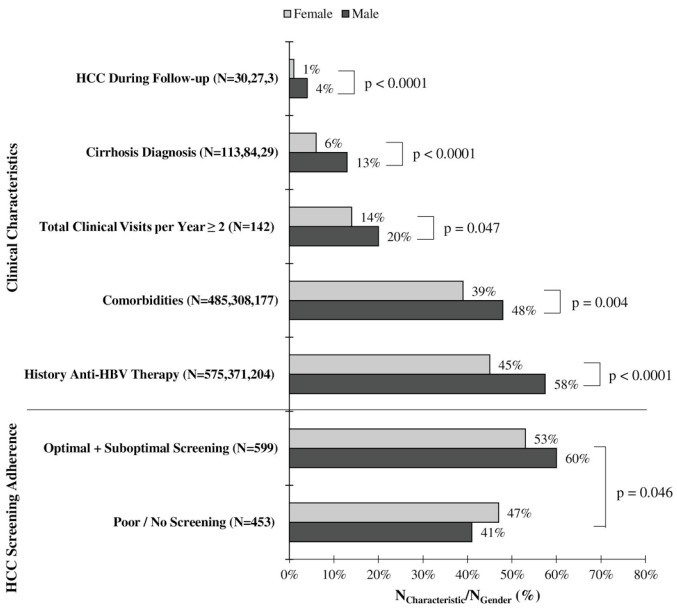

Figure: Clinical characteristics and screening adherence patterns of cohort by gender.

Results: The overall cohort was 51% male, 96% foreign-born, 97% medically insured, 92% Asian, and 61% from community practices. Males were slightly older (51.7 vs. 50.7, p = 0.17), had longer mean follow-up time (62.5 vs. 58.9, p = 0.11) but these differences were not statistically significant; however, and males were significantly more likely to receive anti-HBV treatment for CHB (57.5% vs. 45.0%, p < 0.001). Males had more severe progression of CHB such as cirrhosis diagnosis (13% vs. 6.4%, p < 0.0001) and HCC incidence (4.2% vs. 0.7%, p < 0.001) during follow-up compared to females. Males were also more likely to have two or more clinic visits per year (20% vs. 14%, p = 0.047) compared to females. According to AASLD HCC screening guidelines, males were more likely to undergo optimal or suboptimal screening (60% vs. 53%, p = 0.046) compared to females. On multivariate logistic regression also inclusive of age, sex, cirrhosis status, independent predictors for optimal screening adherence were anti-HBV therapy (OR = 2.3, p < 0.0001) and more frequent clinical visits per year (OR = 13.4, p < 0.0001).
Conclusions: In this large multicenter cohort study consisting of consecutive CHB patients followed at either academic or community practices, males were significantly more likely to have more severe progression of CHB, to receive antiviral treatment for CHB, to have more frequent clinic visits for CHB, and to have better HCC screening adherence relative to females. More frequent clinical visits may improve HCC screening adherence in both male and female patients with CHB, which ultimately can improve survival for HCC in patients of both genders.

P0585

DIFFERENCE OF SERUM CYTOKINES EXPRESSION BETWEEN HBeAg-POSITIVE AND HBeAg-NEGATIVE CHRONIC HEPATITIS B

D. He[1], S. Guo[2], M. Li[2], X. Zeng[2], H. Huang[2], Z. Tan[2], Y. Wang[2]. *[1]The 88th hospital of PLA, Tai'an, [2]The third military medical university, Chongqing, China*
E-mail: hedengming@gmail.com

Background and Aims: The pattern of cytokines in sera was consistent with the level of inflammation during chronic hepatitis. By observing the difference of cytokines expression between HBeAg-positive and HBeAg-negative chronic hepatitis B (CHB), we aimed to explore the immune pathogenesis of HBeAg-negative CHB.
Methods: We investigated the expression of 30 cytokines (IFN-γ, IL-1β, IL-2, IL-4, IL-6, IL-7, IL-9, IL-10, IL-12p40, IL-12p70, IL-15, IL-17A, IL-17C, IL-21, IL-22, IL-23p19, IL-28A, IL-29, CCL5, CCL16, CCL20, CCL22, CXCL9, CXCL10, CXCL11, TNFRSF8, TNFRSF18, IL-6R, gp130, and TGF-β1) associated with HBV immune in sixty treatment-naïve CHB (30 with HBeAg-positive and 30 with HBeAg-negative) by a protein array. Cytokines expression among different ALT levels group and the correlation between cytokines and ALT levels were observed. Protein-protein interactions were analyzed by STRING.
Results: IFN-γ, IL-29, IL-7, IL-9, IL-15, and IL-6 with significant difference among different ALT groups in HBeAg-positive patients were not found significant difference among ALT groups in HBeAg-negative patients. IL-21 was the opposite. IFN-γ, TNFRSF18, IL-12p40, IL-17C, IL-1β, IL-12p70, IL-6, IL-15, and IL-10 with significant correlation in HBeAg-positive patients were not found significant correlation in HBeAg-negative patients. IL-21 and TGF-β1 were the opposite. Protein-protein interactions indicated that a close relationship between IFN-γ and STAT1, IL-6 up-regulating SOCS3, a close relationship between IL-21 and STAT3, IL-29 up-regulating Mx1.
Conclusions: Defection of IFN-γ, IL-29, and IL-6 expression and compensatory up-regulation of IL-21 is the characteristic of HBeAg-negative CHB and may be associated with the immune pathogenesis of HBeAg-negative CHB.

P0586

INFLUENCE OF HEPATITIS B e-ANTIGEN ON THE OUTCOME OF TWO NOSOCOMIAL OUTBREAKS OF HEPATITIS B IN NURSING HOMES IN GERMANY

P.L. Seiz[1], H. Slanina[1], J. Ziebuhr[1], W.H. Gerlich[1], D. Glebe[1], C.G. Schüttler[1]. [1]*Justus Liebig University Giessen, National Reference Center for Hepatitis B and D Viruses, German Center for Infection Research, Biomedical Research Center Seltersberg, Institute of Medical Virology, Giessen, Germany*
E-mail: dieter.glebe@viro.med.uni-giessen.de

Background and Aims: Hepatitis B virus (HBV) causes acute or chronic hepatitis B. Outbreaks of HBV infections occur increasingly in skilled nursing homes in developed countries.
Methods: We investigated two recent outbreaks of hepatitis B in two nursing homes in Germany using serological tests, in addition to PCR, cloning and sequencing of associated HBV strains.
Results: The outbreak at location A included severe acute and fatal fulminant cases, while the outbreak at location B led mostly to asymptomatic or mild hepatitis B with very high viremia. Sequence analysis revealed at each location a different, but unique HBV strain that was able to induce high viremia of $>10^9$ virions/mL. At location B, a wildtype strain of HBV genotype A2 was found which is common in Central Europe. All viral isolates of the affected patients showed nearly 100% sequence identity and encoded HBV e protein (HBeAg) that serves as an immunemodulator during the incubation phase or chronic HBV infection. The severe acute and fulminant hepatitis B cases at site A were caused by a variant of HBV genotype D2 that was unable to express HBeAg, resulting in strong pathogenic immune reactions and high sequence variability. All patients had type 2 diabetes mellitus that is regarded as a risk factor for healthcare-associated transmission of HBV.
Conclusions: Transmission of HBeAg-negative HBV strains can lead to severe outcomes during local outbreaks of HBV. Improved hygiene, testing for HBsAg and active hepatitis B vaccination of residents in nursing homes, especially for persons with diagnosed diabetes should be taken into consideration to avoid the tragedy of hepatitis B transmission with fulminant outcome.

P0587

CAN HEPATITIS B SURFACE ANTIGEN LEVEL PREDICT SEVERITY OF LIVER DISEASE IN GENOTYPE E PATIENTS?

G. Chakrabarty[1], S. Verma[1], R. Basuroy[1], V. Audimoolam[1], M. Horner[1], M. Bruce[1], T. Cutino[1], A. Suddle[1], K. Agarwal[1], I. Carey[1]. [1]*Institute of Liver Studies, King College Hospitals NHS Trust, London, United Kingdom*
E-mail: chakrabartyg@hotmail.com

Background and Aims: HBeAg negative chronic hepatitis B (CHB) infection is heterogeneous disease. CHB patients with persistently active hepatic necroinflammation (NI) and viraemia have higher rate of disease progression and complications related to liver disease. Surface antigen (HBsAg) level defined low replicative phase of CHB in genotype D patients. Higher HBsAg level predicts progression of liver disease and development of HCC in HBeAg negative CHB in genotype B and C patients. Correlation between HBV DNA and HBsAg level was noted in genotype D but not in genotype A patients. In this single centre cross-sectional observational study we aimed to evaluate whether HBsAg levels can predict severity of liver disease in genotype E HBeAg negative patients.
Patients: 259 HBeAg negative CHB genotype E patients underwent liver biopsy for assessment of liver disease (all HBV DNA >2000 IU/ml and/or abnormal ALT) between 2006–2014, median age 38 y, 61% males.
Methods: Demographic characteristics, viral and biochemical markers were evaluated near the time of liver biopsy. HBsAg levels (Abbott ARCHITECT®) were measured at same time-point. APRI and Kings (= age·AST·INR/Platelet) score were calculated. Patients were divided into 3 groups according to severity of fibrosis scoring on liver biopsy, Mild (F0–1), Moderate (F2–4), Severe (5–6) liver disease. The results are presented as median, ranges.
Results: The demographic, virological and biochemical parameters in 3 groups of patients according to severity of fibrosis are summarised in Table 1.
Patients were also divided into 2 groups based on their NI score, 0–3 and ≥4. There were significant differences in the ALT, HBV DNA, APRI, Kings Score and HBsAg/DNA ratio, but no difference in the HBsAg levels. Similarly in patients with APRI score (<1.5 and ≥1.5), HBV DNA was significantly higher in the group with APRI ≥1.5, but there was no difference in HBsAg levels. There was no correlation between the HBsAg and HBV DNA level in this cohort.

Table 1. The demographic, virological and biochemical parameters in 3 groups of patients according to severity of fibrosis

Parameter	Mild (n = 151)	Moderate (n = 84)	Severe (n = 24)
Age, years	38 (19–61)	39.2 (21–62)	41 (25–71)
Gender, male (%)	84 (55.6)	60 (71.4)	15 (62.5)
ALT, U/L (mean±SD)	40.7±76.8	69.2±136.9	130.3±187.7**
HBV DNA $\log_{10}$	3.51 (2.14–7.36)	3.63 (1.00–9.00)	5.59 (2.08–9.04)**
HBsAg level $\log_{10}$	3.90 (2.16–5.35)	3.80 (2.13–4.74)	3.53 (0.43–4.16)**
HBsAg/DNA ratio	1.06 (0.50–1.73)	1.00 (0.49–3.43)	0.60 (0.21–1.94)**
Knodell NI score	3 (0–6)	4 (1–9)	6 (3–9)**
APRI score	0.31 (0.13–12.78)	0.44 (0.14–7.53)	1.07 (0.19–2.68)**
King's score	4.71 (0.00–269.89)	6.84 (2.07–187.27)	18.82 (1.96–66.41)**

Comparison between 3 groups, *P < 0.05, **P < 0.001.
Kruskal–Wallis and chi-square test.

Conclusions: In our population, HBsAg level was lower in patients with more severe liver disease in CHB genotype E patients. Severe fibrosis was associated with higher HBV DNA and ALT level but lower HBsAg level and HBsAg/DNA ratio. There was no correlation between the HBsAg and HBV DNA level in this cohort. This probably highlights a differential HBsAg expression in genotype E patients with more advanced liver disease. The study population is small, hence further studies are required for confirmation of the above findings.

P0588

IMMUNE RESPONSE TO HEPATITIS B VACCINATION IN HIV INFECTED INDIVIDUALS WITH ISOLATED ANTIBODIES TO HBV CORE ANTIGEN

G. Morsica[1], L. Della Torre[1], S. Bagaglio[1,2], S. Salpietro[1], E. Messina[1], M. Merli[1], H. Hasson[1], M. Maillard[1], S. Nozza[1], V. Spagnuolo[1], A. Castagna[1], A. Lazzarin[1,2], C. Uberti-Foppa[1]. [1]*Infectious Diseases Department, Ospedale San Raffaele, Scientific Institute,* [2]*Vita Salute University, Milan, Italy*
E-mail: morsica.giulia@hsr.it

Background and Aims: About 10% of HIV infected individuals are coinfected with HBV and about 15–45% have isolated antibodies to HBV core antigen (anti-HBc). Anti-HBc in absence of HBsAg may be encountered as a false positive result, as past infection with decrease of anti-HBs at undetectable levels or loss of anti-HBs. In this latter case the patients are not protected by HBV infection. We aimed to evaluate the anamnestic or primary response to standard HBV vaccination in HIV positive individuals with isolated anti-HBc.
Methods: Twenty-five HIV infected patients were included in this prospective study. They received a 3-doses HBV vaccination with recombinant HBV vaccine if they did not elicite an anamnestic response (anti-HBs >100 U/L) at week (w) 4 after the first dose of vaccine. Individuals with an anamnestic response were not vaccinated further. Clinical and laboratory data were evaluated at baseline, w 4, w 24, w 29.
Results: At baseline evaluation, the median CD4+ cells count was 562 (IQR 381–764); 13 patients were anti-HCV positive, 10 individuals had sexual risk factor for HIV infection and 15 were ex-IVDU. All patients were anti-HBe negative, had HIV-RNA

levels <50 copies/mL; 14/25 individuals were on ART including drugs active against HIV/HBV. Two of 25 patients (8%) elicited an anamnestic response. Eleven of 23 (48%) elicited a primary response. In total, the response to vaccine was obtained in 52% of individuals. Comparison of clinical characteristics showed that age, CD4+ cells count, transaminases, risk factors for HIV infection, and anti-HCV positivity were similar in the two groups. The responders were older than non-responders, a higher number of females females elicited humoral immune response; these data showing a trend towards significance P = 0.08 and P = 0.06, respectively. HBV-DNA measured at baseline by standard laboratory assay (real time-PCR) was negative in all individuals.

Conclusions: We found a low frequency of anamnestic response (8%) in this group of HIV infected patients, suggesting that the majority of individuals with isolated anti-HBc lost or did not form anti-HBs. This finding suggests also that testing for anti-HBc alone may not be the reliable assessment of protection from HBV infection.

P0589

IS HBV GENOTYPE PLAYING A ROLE IN PREDICTING POST-PREGNANCY ALT FLARE?

I. Carey[1], M. Horner[1], M.-A. McLeod[1], T. Bowyer[1], M.J. Bruce[1], K. Oakes[1], T. Al-Chalabi[1], S. Verma[1], K. Agarwal[1]. *[1]Institute of Liver Studies and Transplantation, King's College Hospital, London, United Kingdom*
E-mail: ivana.kraslova@kcl.ac.uk

Background and Aims: Pregnancy in chronic hepatitis B (CHB) patients represents a unique dynamic challenge for the host-immune interface. This cross-sectional, observational single-centre cohort study evaluated the importance of HBV genotypes on predicting post-pregnancy flares comparing virological (HBV DNA), serological (HBsAg levels) and immunological markers (plasma IP10 levels) markers during pregnancy (2nd trimester).

Patients: 312 CHB patients (median age 31.1years) were assessed at 2nd pregnancy trimester (1st visit median gestation week 26); 10 patients were treated with tenofovir (TDF) prior to pregnancy and 21 patients started TDF from gestation week 28 to minimise HBV transmission. 193 untreated patients (8% HBeAg+) were followed post-delivery (median 65days).

Methods: Plasma IP10, HBsAg, ALT and HBV DNA levels were measured by ELISA [pg/ml], Abbott ARCHITECT® assay [log10 IU/ml], AutoAnalyser [IU/l] and real-time TaqMan PCR [log10 IU/ml] respectively at 2nd pregnancy trimester and 1st post-pregnancy visit. The results were compared in 193 untreated patients based on ALT levels post-pregnancy: hepatic flares (ALT >40 IU/l and two-fold pregnancy level) (HF) (n = 46) vs. normal ALT post-delivery (n = 147). HBV genotypes were evaluated by direct sequencing in patients with HBV DNA >50 IU/ml. Fibroscan LSM was measured in all patients post-pregnancy (median 3.9 kPa).

Results: Patients with HF (24%) were more likely HBeAg+ (OR 11.2), had high IP10 (>200 pg/ml) (OR 9.3), HBV DNA (>10000 IU/ml) (OR 2.4) and low HBsAg/HBV DNA ratio (<0.85) (OR 6.2) at 2nd pregnancy trimester. The HBV genotypes distribution was following: A 10%, B 6%, C 7%, D 10%, E 41% and not typeable (NT) due to low HBV DNA in 26% patients. Post-pregnancy flares were more frequent in patients infected with genotypes B (40%), C (47%) and D (47%) than genotypes A (27%), E (20%) and NT (12%) ($p < 0.05$). When individual parameters were assessed only high pregnancy IP10 levels were significantly higher across all genotypes in patients with HF in comparison to normal ALT patients (median: 234 vs. 143, $p < 0.05$). Only in genotype B patients higher pregnancy HBV DNA (median: 4.93 vs. 2.87, $p = 0.01$) and HBsAg (median: 4.1 vs. 2.96, $p = 0.01$) were predictive of ALT flares.

Conclusions: Post-pregnancy flares were more frequent in genotypes B, C and D chronic hepatitis B patients and high pregnancy IP10 level was predictive of flares across genotypes.

P0590

MODIFIED MODEL FOR END STAGE LIVER DISEASE SCORE ACCURATELY PREDICTS DEATH OR LIVER TRANSPLANTATION IN ACUTE FLARES OF CHRONIC HEPATITIS B

J. Fung[1,2], F. Lam[1], K. Chok[2], W.-K. Seto[1], T. Wong[2], A. Chan[2], S.-C. Chan[2], C.-L. Lai[1], C.-M. Lo[2], M.-F. Yuen[1]. *[1]Medicine, [2]Surgery, The University of Hong Kong, Hong Kong, Hong Kong, China*
E-mail: jfung@gastro.hk

Background and Aims: For patients chronically infected with hepatitis B virus, acute flares of chronic hepatitis B (AFOCHB) can be severe and fatal. The decision on whether to transplant or not is often a difficult one. The current study aims to determine the predictive value of short-term outcomes using the MELD score and its modified counterpart in AFOCHB patients.

Methods: Patients admitted with AFOCHB with ALT >5× upper limit of normal and HBV DNA of at least 4 logs IU/mL were included. Laboratory data was collected at the time of admission, at day 7, and at day 14. The MELD-ALT-Platelet (MAP) score was derived by additional points to the MELD score according to the ALT level (+1, +2, and +4 points for ALT ≤2000, 2000–3000, and >3000 respectively) and platelet level (+1, +2, +3, and +7 points for platelets ≥150, 100 to <150, 50 to <100, and <50 respectively).

Results: A total of 210 patients with AFOCHB were included. The outcome measured was either death or liver transplantation. Within 30 days, 25 (11.9%) patients died and 91 (43.3%) underwent liver transplantation. The AUROC of INR, MELD, and the MAP score at the time of admission to predict day 7 outcome was 0.935, 0.945, and 0.950 respectively. At day 7, 179 patients survived without the need for liver transplantation. The AUROC of INR, MELD, and MAP score at day 7 to predict day 14 outcomes were 0.869, 0.867, and 0.871 respectively. By day 14, 159 patients remained alive without the need for liver transplantation. The AUROC at day 14 for INR, MELD and MAP to predict day 30 outcomes was 0.834, 0.878, and 0.912 respectively. Although a high AUROC was observed for day 0, 7, and 14 MAP to predict day 7, 14, and 30 events respectively, the accuracy was reduced when day 0 MAP was used to predict events at day 14 and 30, with AUROC of 0.819 and 0.764 respectively. A similar trend was observed when day 7 MAP was used to predict day 30 events, achieving an AUROC of 0.772 (compared to 0.871 for day 14 events). A MAP score of <25 at day 0, day 7, and at day 14 was associated with no events at day 7, 14, and 30 respectively. For those presenting with MAP ≥35, the rate of events by day 7, 14 and 30 was 72%, 88%, and 96% respectively.

Conclusions: Severe AFOCHB can be associated with high rates of mortality and LT. The MAP score at different time points can accurately predict short-term outcome to provide useful prognosis and determine the urgency of LT workup.

P0591

HBV VACCINATION STATUS IN PATIENTS WITH END STAGE PULMONARY DISEASE EVALUATED FOR LUNG TRANSPLANTATION

E-mail: johannes.wiegand@medizin.uni-leipzig.de

Background and Aims: In times of limited donor resources, anti-HBc positive organs can be accepted for lung transplantation in order to increase the number of donors. Transplant recipients should be vaccinated against hepatitis B during transplant evaluation to prevent HBV infection. However, response after HBV vaccination has not been evaluated in patients with end stage pulmonary disease.

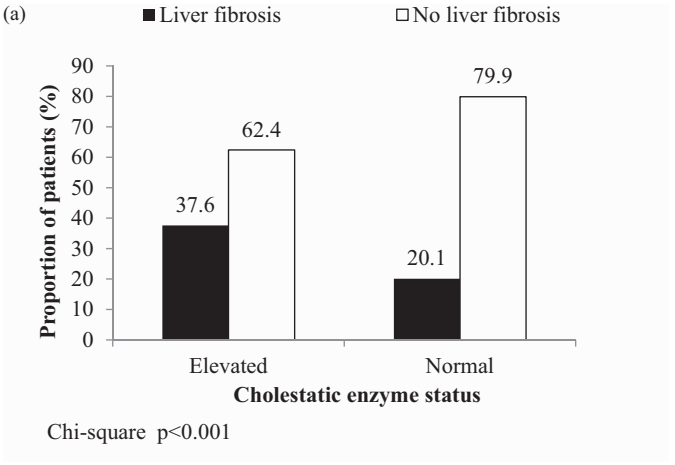
Methods: Anti-HBs titers of anti-HBc negative patients with end stage pulmonary disease evaluated for lung transplantation

were analyzed with the Architect® system (Abbott, Germany). Responders, partial responders, or non-responders after HBV vaccination were defined by anti-HBs titres >100 IU/L, 10–100 IU/L, and <10 IU/L, respectively.
Results: 28 patients were analyzed (46% female, age 57±8 years, COPD n = 18/28, long-term prednisolone therapy n = 5/28, history of smoking n = 24/28) and vaccinated at baseline either with Engerix® (n = 11), Twinrix® (n = 11), or HBVAXpro® (n = 1). Three and more or two vaccinations were performed in 14 (50%) and nine (32%) of cases. Five individuals (18%) were not vaccinated. Response, partial response, and non-response after vaccination were observed in 5/23 (22%), 7/23 (30%), and 11/23 (48%) of patients, respectively. Individuals with three or more vaccinations did not develop anti-HBs titres >100 IU/L more frequently than patients with two vaccinations (n = 4/14 vs. n = 1/9). Response to vaccination did not correlate with gender, pulmonary disease (COPD vs. non-COPD), long-term prednisolone therapy, or smoking status.
Conclusions: Only 5/28 (18%) of patients evaluated for lung transplantation showed anti-HBs titres >100 IU/L. Thus, serological control of anti-HBs titres after vaccination should be mandatory prior to transplantation. In case of transplantation of an anti-HBc positive donor organ, the majority of recipients needs therapy with a nucleos(t)ide analogue to prevent HBV reactivation after surgery.

P0592
A CROSS-SECTIONAL STUDY ON INTRAHEPATIC CHOLESTASIS INDICATORS OF VIRAL HEPATITIS PATIENTS

J. Cheng[1], J. Wang[2], W. Zhang[3], X. Yang[4], Y. Cao[5]. *[1]Beijing Ditan Hospital of Capital Medical University, Beijing, [2]China-Japan Union Hospital of Jilin University, Changchun, [3]Huashan Hospital Affiliated to Fudan University, Shanghai, [4]Sichuan Provincial Peopls's Hospital, Chengdu, [5]Guangzhou Eighth People's Hospital, Guangzhou, China*
E-mail: chengjunditan@163.com

Background and Aims: Intrahepatic cholestasis (IHC) is a hepatocellular or cholangiocellular disorder which can be caused by viral hepatitis. The cut-off levels of serum alkaline phosphatase (ALP) and gamma glutamyltransferase (GGT) in diagnosing IHC are still debated. Although the patients are clinically asymptomatic, ALP or GGT can or remain abnormal. This study is to investigate the abnormality of IHC indicators (ALP, GGT) for in-patients with viral hepatitis when they are being discharged, and to explore the correlation between IHC indicators and liver fibrosis.
Methods: It is a multi-center, cross-sectional study. A total of 1000 hospitalized patients with viral hepatitis were recruited from five big hospitals. Demographic characteristics, clinical and laboratory data including IHC indicators and liver fibrosis indicators (hyaluronic acid and type IV collagen) were collected. Chi-square and multivariate logistic regression were performed to determine the correlation between abnormal IHC indicators and liver fibrosis.
Results: 998 of 1000 patients were included in the analysis (Table 1). 560 patients (56.17%) had abnormal IHC indicators at discharge. Comparing to patients with normal IHC indicators, patients with abnormal IHC indicators had significantly more abnormal liver fibrosis indicators (hyaluronic acid and type IV collagen; severer Child–Pugh Classification. both $p < 0.001$). Multivariate analysis showed that patients with abnormal IHC indicators had significantly higher risk to have abnormal liver fibrosis indicators ($p = 0.0236$, OR = 1.542), and higher trend to have higher Child–Pugh Classification ($p > 0.05$, OR = 1.238).
Conclusions: More than half of the patients with viral hepatitis had abnormal IHC indicators at discharge, which are correlated with liver fibrosis in clinical practice. Therefore, monitoring and following up on IHC indicators after discharge are recommended for viral hepatitis patients.



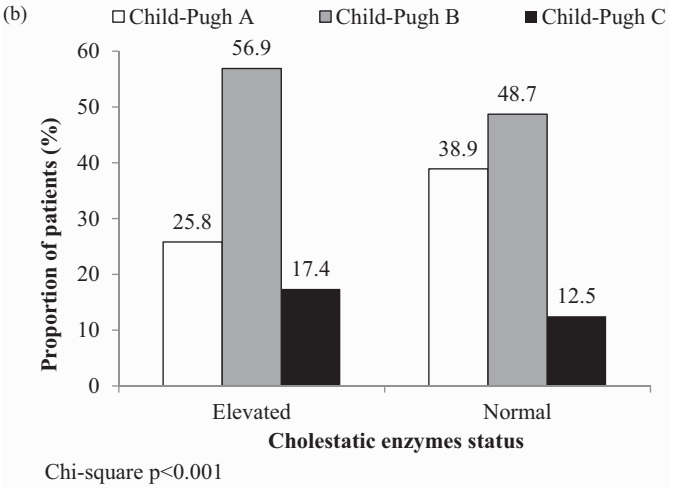


Figure 1. Distribution of (a) liver fibrosis and (b) Child–Pugh Classification according to abnormal IHC indicator status.

Table 1. Multivariate analysis on the correlation between abnormal IHC indicators and liver fibrosis or Child–Pugh Classification B and C

Indicators	ALP or GGT (OR)	p-value
Abnormal hyaluronic acid and Type IV collagen	1.542	0.0236
Child–Pugh Classification B and C	1.238	>0.05

P0593
PREDICTIVE MODEL OF HBsAg NEGATIVIZATION IN INACTIVE HBsAg CHRONIC CARRIERS, MAINLY CAUCASIAN

M.L. González-Diéguez[1], C.A. Navascués[1], G. Albines[1], Mercedes Rodríguez[2], V. Cadahía[1], M. Varela[1], R. Pérez[1], Manuel Rodríguez[1]. *[1]Liver Unit, [2]Microbiology Department, Hospital Universitario Central de Asturias, Oviedo, Spain*
E-mail: luisagondi@hotmail.com

Background and Aims: HBsAg negativization is the last phase of HBV chronic infection and represents its resolution. The aim of this study was to analyze the frequency of HBsAg negativization in HBV inactive carriers (HBV-IC) and to develop a predictive model of it.
Methods: 297 HBV-IC were studied, 51% males, 86% Caucasians, 42% genotype A and 35% genotype D, 67% with liver elastography <6.2 kPa and with a mean age of 45±13 years. HBV-IC diagnosis was based on HBeAg negativity and HBV-DNA <20000 IU/ml, confirmed in several controls. HCV, HDV and HIV coinfection were excluded

in all. Basal determinations of HBV-DNA (RT-PCR, Cobas TaqMan VHB) and quantitative HBsAg (Architect HBsAg; Abbott), with lower limit of detection of 0.05 IU/ml, were performed. Patients were prospectively followed annually or biannually, with a mean follow-up of 52±28 months.
Results: 57/297 (19%) were initially HBV-DNA negative. Mean HBsAg level was 8.852±17.700 IU/ml. During the follow-up, 49 patients (16.5%) became HBsAg-negative. In univariate analysis (Kaplan–Meier), HBsAg negativization was not associated with sex ($p = 0.18$), ALT normal or high values ($p = 0.8$), liver elastography < or ≥6.2 kPa ($p = 0.45$), or race ($p = 0.96$). The probability of HBsAg negativization was significantly higher in patients >30 years ($p = 0.02$), HBV-DNA-negative ($p < 0.001$) and with initial HBsAg <1000 UI ($p < 0.001$). In multivariate analysis, initial HBV-DNA absence (HR 2.37 [95% CI 1.34–4.19], $p = 0.03$) and basal HBsAg <1000 IU/ml (HR 49.4 [95% CI 6.76–361.02], $p < 0.001$) were independently associated with the probability of HBsAg clearance. The presence or absence of these factors allowed to establish three groups of patients with a significant different probability of HBsAg negativization at 5 years: In those without any favorable factor ($n = 151$) such probability was 0%, in those with one factor ($n = 101$) 27.2%, and in patients with both of them ($n = 45$) 53.5% ($p < 0.001$). Isolated use of HBsAg was also useful to distinguish three groups of patients with different probability of HBsAg negativization at 5 years: 0% in those with HBsAg >1000 UI/ml, 15.2% if HBsAg was between 100 and 1000 IU/ml and 53% when it was <100 IU/ml. However, area under the ROC curve was greater in the model using HBsAg and HBV-DNA (0.88 [0.83–0.92]) than in the one based only in HBsAg (0.84 [0.78–0.89]).
Conclusions: In a series of HBV-IC, mainly Caucasians, the combination of HBsAg cuantification and the presence or absence of HBV-DNA is useful to predict the probability of infection resolution at 5 years.

P0594
CAN SERUM LEVEL OF HEPATITIS B SURFACE ANTIGEN (HBsAg) DIFFERENTIATE HBsAg INACTIVE CARRIER STATE FROM CHRONIC HEPATITIS B?

M. Keshvari[1,2], S. Sali[3], H. Sharafi[2], S. Hoda Alavian[4], S. Moayed Alavian[2], F. Etesam[5], S. Salimi[2], M.A. Merza[6]. *[1]Blood Transfusion Research Center, High Institute for Research and Education in Transfusion Medicine, [2]Middle East Liver Disease (MELD) Center, [3]Infectious Diseases and Tropical Medicine Research Center, [4]Faculty of Medicine, Shahid Beheshti University of Medical Sciences, [5]Hepatitis Clinic, Tehran Blood Transfusion Center, Tehran, Iran; [6]Azadi Teaching Hospital, School of Medicine, Faculty of Medical Sciences, University of Duhok, Duhok, Iraq*
E-mail: h.sharafi@meldcenter.com

Background and Aims: HBeAg-negative hepatitis B virus (HBV) infection exerts both inactive carrier (IC) state and chronic hepatitis B (CHB) which are sometimes difficult to be differentiated. Recently, serum HBsAg level has been introduced to evaluate treatment response to interferon and probably help in diagnosis of hepatitis B clinical stages. We aimed to assess the role of HBsAg level in differentiation of IC and CHB among a group of chronic HBeAg-negative HBV-infected patients.
Methods: A total of 251 HBeAg-negative HBV-infected patients were enrolled. Serum alanine transaminase (ALT), HBV DNA and HBsAg levels were determined for each patient. Liver histology was evaluated by liver biopsy using Knodell scoring system. HBV DNA and HBsAg levels were assessed using COBAS TaqMan HBV test and HBsAg II quant assay, respectively.
Results: A total of 243 HBeAg-negative HBV-infected patients including 139 ICs and 104 CHB patients were evaluated. All HBV isolates were identified as genotype D. HBV DNA and HBsAg levels were significantly higher in CHB patients than in ICs. HBV DNA quantification with cutoff value 2,000 IU/mL for diagnosis of CHB had 99.0% sensitivity and 74.1% specificity. A cutoff value of HBsAg level at 1,000 IU/mL was more reliable for diagnosis of CHB with 82.7% sensitivity and 66.2% specificity than other HBsAg level cutoffs. Combination of HBV DNA and HBsAg levels did not increase diagnostic performance of HBV DNA level for differentiation of IC and CHB stages. There was a positive correlation between HBV DNA and HBsAg levels in both IC ($r = 0.43$, $P < 0.001$) and CHB ($r = 0.42$, $P < 0.001$) groups.
Conclusions: Single point HBsAg quantification did not have enough sensitivity and specificity for diagnosis of HBV clinical stages.

P0595
HIGH FREQUENCY OF ACTIVE HCV INFECTION AMONG SEROPOSITIVES IN WEST AFRICA AND EVIDENCE FOR MULTIPLE TRANSMISSION PATHWAYS

J. Layden[1,2], N. Mora[1], R.O. Phillips[3,4], S. Owusi-Ofori[3], F.S. Sarfo[3,4], S. Kliethermes[1,5], D. Owusu[3], K. Nelson[6], L. Dugas[1], A. Luke[1], D. Shoham[1], J.C. Forbi[7], Y.E. Khudyakov[7], R.S. Cooper[1]. *[1]Public Health Sciences, Loyola University Chicago, [2]Division of Infectious Disease, Department of Medicine, Loyola University Medical Center, Maywood, United States; [3]Komfo Anokye Teaching Hospital, [4]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana; [5]Department of Medicine, Loyola University Chicago, Maywood, [6]Epidemiology and International Health, Johns Hopkins School of Public Health, Baltimore, [7]Molecular Epidemiology and Bioinformatics, Centers for Disease Control, Atlanta, United States*
E-mail: namora@luc.edu

Background and Aims: Sub-Saharan Africa (SSA) has among the highest global Hepatitis C Virus (HCV) sero-prevalence estimates. However, reports suggesting high rates of serologic false positives and low levels of detectable viremia has led to uncertainty regarding the burden of active HCV infection in this region. Additionally, little is known about the predominant transmission risk factors and mechanisms in this region. The aims of this study were to determine the frequency of active infection among persons who screened positive for HCV infection and identify risk factors for HCV infection.
Methods: Between May 2013 and January 2014 we recalled 363 blood donors [180 rapid screen assay (RSA) (Accu-Tell HCV) positive and 183 RSA negative at time of donation] to identify the level of active infection and risk factors at Komfo Anokye Teaching Hospital in Kumasi, Ghana. Participants had blood drawn for serologic and virologic testing (HBVsAg Abbott Architect CIA, HIV 4th generation Ab/Ag test, the HCV Advia Centaur HCV CIA, and Abbott RealTime PCR assay for HCV RNA quantitative levels). HCV genotypes were determined by the generated NS5b sequences (SuperScript® VILO™ cDNA Synthesis Kit). A questionnaire on demographics and risk factors was administered.
Results: The frequency of active infection varied based on serologic testing results, but was overall high. In subjects with a positive CIA Serologic Antibody Assay [Signal to Cut-off ratio (S/C) >1], the rate of active viremia was 74.4%, and increased to 88% among the individuals with a CIA S/C ≥11. Individuals were predominantly infected with genotype 2, and the median viral load among actively infected individuals was 5.75 log cp/ml. Blood donors from the northern and upper regions of Ghana had substantially higher risks of infection compared to those from the middle belt. Individual level Odds ratio statistical significant risk factors included: traditional circumcision (3.8), home birth (2.0), tribal scarring (2.2) and HBV co-infection (2.7). See Table 1.
Conclusions: Among serologically confirmed cases, active infection rates were high. Appropriate testing algorithms should be widely implemented to define the true HCV burden in SSA. These data also suggest that several transmission modes, particularly

those associated with cultural skin-piercing practices, are likely contributing to the current HCV epidemic in Ghana, and the distribution of these practices may result in regional variation in prevalence.

Table 1. Multivariable logistic regression model for HCV seropositivity

Variable	OR (95% CI)	*p*-value
Region of Origin		<0.001
Northern vs. Ashanti	6.64 (2.44–18.23)	<0.001
Other vs. Ashanti	1.15 (0.33–3.93)	0.83
Upper vs. Ashanti	18.69 (8.27–42.22)	<0.001
Education level		0.01
Nil/Primary vs. Tertiary	0.42 (0.16–1.11)	0.08
JHS/MSLC/SHS/Tech vs. Tertiary	0.29 (0.12–0.66)	0.003
Marital status	2.31 (0.80–6.70)	0.06
Married vs Single	0.93 (0.45–1.92)	0.83
Other vs. Single	8.04 (1.28–50.35)	0.03
HBsAg positive	3.82 (1.08–13.53)	0.04
Circumcision		0.01
None vs. Hospital	3.46 (1.31–9.12)	0.01
Traditional vs. Hospital	3.26 (1.47–7.21)	0.004

OR, covariate-adjusted odds ratio. CI, confidence interval for estimate.

P0596
ASSOCIATION OF HEPATITIS E VIRUS AND CRYOGLOBULINEMIA

S. Pischke[1], S. Polywka[2], J.H. Schirmer[3], F. Haag[4], M. Sterneck[1], M. Luetgehetmann[2], C. Iking-Konert[5], W. Dammermann[1], S. Lueth[1], F. Moosig[3], A.W. Lohse[1]. *[1]Gastroenterology, [2]Medical Microbiology, University Hospital Hamburg Eppendorf, Hamburg, [3]Rheumatology, Klinikum Bad Bramstedt, Bad Bramstedt, [4]Immunology, [5]Rheumatology, University Hospital Hamburg Eppendorf, Hamburg, Germany*
E-mail: s.pischke@uke.de

Background and Aims: Several extrahepatic manifestations have been observed in the context of acute or chronic hepatitis E virus infections. Recently a case indicated an association between HEV infection and cryoglobulinemia (Pischke et al. Lancet Inf. Dis. 2014), but this observation still needs to be confirmed and clarified.
Methods: Stored serum samples of 68 German patients with cryogluobulinemia were retrospectively tested for anti HEV IgG (Wantai assay). Seroprevalence rates were compared in patients with essential cryoglobulinemia (n = 33) and in patients with cryoglobulinemia secondary to various underlying conditions (n = 35) using chi square test.
Results: Within the group of patients with essential cryoglobulinemia 46% (n = 15) tested positive for anti HEV IgG, while in the group of patients with different underlying conditions 23% (n = 8) tested positive (p = 0.043).
Conclusions: Patients with essential cryoglobulinemia tested positive more frequently for anti HEV than patients with secondary cryoglobulinemia due to well defined causes. This indicates that development of cryoglobulinemia of unknown origin is a relevant extrahepatic manifestation of hepatitis E.

Table 1. Characteristics of patients

	Essential cryoglobulinemia (n = 33)	Cryoglobulinemia of defined origin (n = 35)	p-value
Anti HEV IgG positive	15 (46%)	8 (23%)	0.043
Male	12 (36%)	14 (40%)	ns
Age in years, range (mean±SD)	37–83 (61.7±13.2)	36–76 (57.4±10.8)	ns
OD value of anti HEV IgG	0.004–3.239 (0.686±1.035)	0.000–3.205 (0.326±0.758)	ns

P0597
THE ROLE OF GENOTYPE, PRE-CORE, BASAL CORE PROMOTER AND PRE-S MUTATIONS OF HBV IN PATIENTS OF HEPATOCELLULAR CARCINOMA WITH HEPATITIS C AND OCCULT HEPATITIS B

W.-L. Tsai[1], J.-S. Cheng[1], K.-H. Lai[1], H.-H. Chan[1], P.-I Shu[1]. *[1]Department of Gastroenterology, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan*
E-mail: tsaiwl@yahoo.com.tw

Background and Aims: HBV coinfected with chronic hepatitis C subjects were found to increase the risk to develop advanced liver disease later in their life. In chronic HBV patients, some virological factors such as genotype C, preS deletion and core promoter/precore mutations are found to increase the risk of HCC. However, little was known about the role of the virological risk factors of HBV in chronic HCV patients with occult HBV.
Methods: One hundred and eighty-one HBsAg-negative, HCV-Ab positive HCC patients (group A), 153 HBsAg-negative, HCV-Ab positive chronic hepatitis patients (group B), and 20 HCC subjects with both positive HBsAg and HCV-Ab (group C) were enrolled. The preS, core promoter/precore region and S gene were amplified by nested PCR and direct-sequenced. Viral phylogenetic analysis was also performed.
Results: The occult HBV infection was found for 20.4% (37/181) in the group A, and 34.0% (52/153) in group B. In addition, the genotype C (P = 0.019), BCP mutations (P = 0.004) and 1858 mutation (P < 0.001), 1896 mutation (P = 0.032) were more common in chronic HCV patients with HCC. PreS1 deletion (P = 0.033), BCP (P = 0.014) and precore 1896 mutation (P = 0.008) were more common in chronic HCV patients with overt than occult HBV.
Conclusions: In patients with chronic HCV and occult HBV infection, HBV genotype C, BCP, 1858 and 1896 mutations seemed to be associated with the development of HCC.

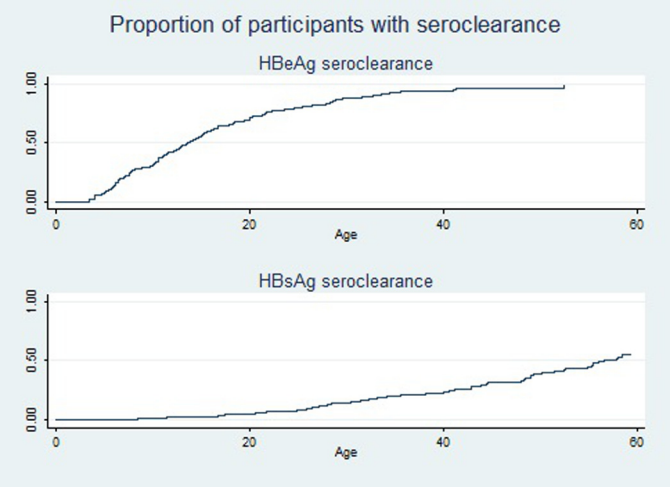
P0598
NATURAL HISTORY OF CHRONIC HEPATITIS B INFECTION IN THE GAMBIA, WEST AFRICA: A LONGITUDINAL POPULATION-BASED STUDY

Y. Shimakawa[1,2,3], M. Lemoine[1,4], C. Bottomley[2], H. Freeya Njai[1], G. Ndow[1], R. Wegmuller[5], S.E. Moore[5,6], U. D'Alessandro[1,2], H. Whittle[2], M. Mendy[7], M. Thursz[4], R. Njie[1,7]. *[1]MRC Unit, The Gambia, Banjul, Gambia, The, [2]Faculty of Epidemiology and Population Health, London School of Hygiene and Tropical Medicine, London, United Kingdom; [3]Emerging Disease Epidemiology Unit, Institut Pasteur, Paris, France; [4]Department of Hepatology, Imperial College, London, London, United Kingdom; [5]MRC International Nutrition Group, MRC Keneba, West Kiang, Gambia, The, [6]MRC Human Nutrition Research, Cambridge, United Kingdom; [7]International Agency for Research on Cancer, Lyon, France*
E-mail: yusuke.shimakawa@pasteur.fr

Background and Aims: The natural history of chronic hepatitis B (CHB) infection in sub-Saharan Africa is poorly documented. This study describes the natural history of CHB in The Gambia, West Africa.
Methods: An open community cohort of treatment-naïve CHB carriers was recruited from rural villages in the West Kiang district, The Gambia between 1974 and 2008. The cohort was used to estimate the rates of hepatitis B e (HBeAg) and surface antigen (HBsAg) clearance and incidence of hepatocellular carcinoma (HCC). In 2012–2013 we invited members of the cohort for a comprehensive liver assessment to estimate the prevalence of chronic liver disease as part of the PROLIFICA study.
Results: 405 chronic carriers were identified in 10 sero-surveys, and the median length of follow up was 28.4 years. Annually, 7.4% (95% CI: 6.3–8.8) and 1.0% (95% CI: 0.8–1.2) of the carriers cleared HBeAg and HBsAg, respectively (Figure). The incidence

of HCC was 55.5/100,000 carrier-years (95% CI: 24.9–123.5). The median age of the CHB carriers assessed in the 2012–13 survey (n = 301) was 38 years, 43.2% were male, 5.6% (95% CI: 3.4–9.1%) had significant fibrosis and 3.7% (95% CI: 2.0–6.5%) required antiviral therapy according to the EASL guidelines. Having an HBsAg-positive mother was associated with higher viral load and ALT levels over time, liver fibrosis, requiring antiviral treatment, and HCC. Among chronic carriers, 63.0% (95% CI: 47.0–74.1%) of the cases requiring antiviral therapy were attributable to perinatal transmission.

Conclusions: The incidence rate of HCC in CHB carriers in The Gambia was higher than Europe but lower than East Asia. Positive maternal HBsAg, a proxy for perinatal mother-to-infant transmission, was associated with an increased risk of liver fibrosis and HCC. Prevention of perinatal HBV transmission through the timely administration of hepatitis B vaccine to infants within 24 hours after birth may reduce the disease burden in sub-Saharan Africa.



P0599
ROLE OF NON-HEPATOTROPIC VIRUSES IN ACUTE SPORADIC VIRAL HEPATITIS IN ADULTS: SHOULD THE SCREENING STRATEGIES BE CHANGED?

E. Gupta[1], M.K. Sharma[2], P. Pandey[1], S.K. Sarin[2]. [1]*Virology,* [2]*Hepatology, Institute of liver and biliary sciences, Delhi, India*
E-mail: ektagaurisha@gmail.com

Background and Aims: Acute viral hepatitis (AVH) is mostly caused by Hepatitis E (HEV) and hepatitis A (HAV) viruses in India. The etiology of AVH has been dynamically changing during the recent years and the viral etiology of acute event in Acute on chronic liver failure (ACLF) patients has rarely being explored.

Methods: We hypothesized that the viral causes of acute hepatitis in AVH and ACLF group would differ hence a retrospective analysis of 295 adult patients of acute sporadic viral hepatitis with the criteria: <3 weeks onset of fever or jaundice, serum alanine transaminase (ALT) 10 times the upper limit of normal and with a definite established viral etiology was done. Patients were further divided into two groups, only AVH and ACLF as per clinical criteria. Serum samples were tested for hepatitis A through E, cytomegalovirus (CMV), and Epstein-Barr virus (EBV).

Results: Viral etiology profile was, HEV in 155 (52.5%), HAV in 43 (14.5%), HBV in 35 (11.8%), HCV in 1 (0.3%), mixed viral etiology in 30 (10.1%) and non-hepatotropic viruses (CMV and EBV) in 31 (10.5%). 206 patients (69.8%) were only AVH and 89 (30.1%) were ACLF. HEV was the commonest cause of infection in both the groups: AVH (n = 95, 46.1%) and ACLF (n = 60, 67.4%) as compared to HAV: AVH (n = 36, 17.4%), ACLF (n = 7, 7.8%), [p < 0.001]. 23 (7.7%) patients died on follow up, mortality was higher in ACLF group (12/89, 13.5%) than in AVH group (4/206, 1.94%) [p < 0.05]. The mortality was higher when HEV was the cause of acute event in ACLF group (20/23, 86.9%). In AVH mixed infection were more common as compared to ACLF (27 vs. 3, p < 0.001). In mixed viral etiology, HBV + HEV and HAV +HEV dual infection was seen in 11 (0.03%), whereas HBV +HAV was seen in 8 (0.02%) cases. Non-hepatotropic viruses like CMV and EBV contributed significantly higher infections in AVH as compared to ACLF (14% vs 2.2%, p = 0.002) patients. Most cases of EBV and CMV infections presented with only abnormal ALT levels and were not associated with any lymphadenopathy (87%).

Conclusions: Non-hepatotropic viruses like CMV and EBV contribute significantly in the etiology of sporadic AVH in adults. Apart from screening for hepatotropic viruses (A-E), all suspected acute hepatitis patients must be screened for non-hepatotropic viruses as well.

E-mail: dominique.roulot@avc.aphp.fr

Background and Aims: Hepatitis Delta Virus (HDV) infection causes more severe chronic liver disease than isolated Hepatitis B virus (HBV) infection, although it remains largely under-diagnosed and under-evaluated in most countries. Factors associated with worse prognosis have not been fully evaluated in France.

Methods: HDV-infected patients were identified from the French National Reference Centre database. Epidemiological clinical and virological data, including HDV viral load and HDV genotyping, were collected on a standardized form, from initial diagnosis to the last recorded follow-up.

Results: 1112 HDV/HBV co-infected patients were included in the study. The mean age was 37±10 years. Patients were predominantly male (69%) and migrants (86%). 46% had a history of past or persistent excessive alcohol consumption, and 37% were overweight. 88% showed detectable HDV viral load (median value: 165,000 copies/mL). At first referral 28% of the patients showed histological cirrhosis, 15% one episode (or more) of hepatic decompensation and 2.7% hepatocellular carcinoma (HCC). During the median follow-up of 4.4 years [1.4–8.9], 20%, 10% and 6.5% of the patients developed cirrhosis, liver decompensation and HCC, respectively. Overall, the 10-year risk of cirrhosis, decompensation, HCC was 40%, 31%, and 15%, respectively.

In multivariate analysis, older age and elevated GGT were independent factors associated with cirrhosis (HR = 1.03 and 2.1 respectively), hepatic decompensation (HR = 1.04 and 2.6 respectively) and HCC (HR = 1.10 and 3.7 respectively). Cirrhosis was also associated with elevated AST (HR = 2.2) and less frequent in sub-Saharan African patients (HR = 0.76) than in European and Asian patients. Decompensation was associated with positive HDV RNA at last evaluation (HR = 2.2), low platelet count <100,000/mm^3

(HR = 3.8), and prothombin time <60% (HR = 6.4), and HCC with BMI >30 kg/m^2 (HR = 2.5) and prothombin time <80% (HR = 6.2).
Conclusions: In chronic HDV-infection, older age and severity of the disease are associated with cirrhosis and complications. Persistent replicative HDV infection is associated with decompensation. Unexpectedly, cirrhosis is less frequent in sub-Saharan African patients than in non African patients. Obesity is an independent factor associated with HCC related to HDV infection.

P0601
ACOUSTIC RADIATION FORCE IMPULSE IN HEPATITIS B VIRUS INACTIVE CARRIERS – A COMPARISON WITH OTHER CONDITIONS
G.S. Gherlan[1], P.I. Calistru[1], C. Voinea[2], C. Szabo[2]. [1]*Infectious Diseases,* [2]*Laboratory, "Dr. Victor Babes" Center for Diagnostics and Treatment, Bucharest, Romania*
E-mail: gherlanus@gmail.com

Background and Aims: Inactive hepatitis B virus (HBV) carriers are defined as HBs antigen positive, HBe negative patients that have persistently normal transaminase levels and low or undetectable HBV DNA levels. Usually they are not subjected to liver fibrosis evaluation (either invasive or noninvasive) especially if their viral load is below 2000 IU/ml. In this study, we tried to compare the differences between the results of Acoustic Radiation Force Impulse (ARFI) measurements in inactive HBV carriers and in patients with other liver diseases or with no known liver afection.
Methods: 159 patients [43 inactive HBV carriers, 52 randomly selected patients with chronic hepatitis C virus (HCV) infection, 25 patients with ultrasound aspect suggesting fatty liver (FL) but normal transaminase and 39 patients with no evidence of any liver disease] were included in the analysis. We performed 10 consecutive ARFI measurements in the right liver lobe of each patient. In all included patients, interquartile range (IQR) was less than 1/3 of the median of the 10 measurements.
Results: In HBV inactive carriers the mean ARFI result was 1.34±0.34 m/s, in HCV patients 1.84±0.77 m/s, in FL patients 1.02±0.24 m/s, and in healthy patients 1.08±0.21 m/s. ARFI results in HBV carriers are significantly higher than in healthy or FL patients (mean differences: 0.262 m/s, 95% CI 0.118–0.407, p = 0.001 respectively 0.321 m/s, 95% CI 0.141–0.502, p = 0.001). The stiffness in HCV patients was significantly higher than in HBV carriers, as denoted by a speed of propagation of shear waves of 0.502 m/s, 95% CI 0.348–1.037, p < 0.001. Transaminase levels were not significantly different between HBV carriers and healthy patients, but they were significantly higher in FL patients (although normal) than in HBV carriers – mean difference 24.84 IU/l for ALT and 14.77 IU/l for AST, with p = 0.001 and 0.013 respectively.
Conclusions: Liver stiffness measured by ARFI is significantly increased in HBV inactive carriers compared to patients with no liver disease or with fatty liver disease and normal transaminase. This fact is probably related to a mild necroinflammatory process that may be sometimes present in "inactive HBV carriers" and is not reflected by ALT elevation.

P0602
SEROLOGIC PROFILE AND REACTIVATION OF HEPATITIS B IN RHEUMATIC AND INFLAMMATORY BOWEL DISEASE PATIENTS TREATED WITH TNF INHIBITORS BOWEL DISEASE
S. Vítor[1], L. Meireles[1], V.C. Romão[2], C. Freitas[3], S. Fernandes[1], M.J. Gonçalves[2,4], M.J. Saavedra[2], H. Canhão[2,4], J.E. Fonseca[2,4], J.A. Pereira da Silva[2], R.T. Marinho[1], J. Velosa[1]. [1]*Gastroenterology and Hepatology,* [2]*Rheumatology, Hospital Santa Maria, Lisbon,* [3]*Gastroenterology, Hospital Dr Nélio Mendonça, Funchal,* [4]*Rheumatology Research Unit, Instituto de Medicina Molecular – Lisbon Academic Medical Centre, Lisbon, Portugal*
E-mail: sivvitor@gmail.com

Background and Aims: TNF inhibitors (TNFi) are widely used in rheumatologic diseases (RD) and inflammatory bowel disease (IBD). However, these drugs have been associated with an increased risk of reactivation of latent infections. The specific risk of hepatitis B (HB) reactivation remains unclear since the low incidence of that infection in the majority of European countries. Our study aims to evaluate the serologic HB profile of patients with RD and IBD who had undergone TNFi therapy in a single centre; and to assess the incidence of HB reactivation in patients with a serological pattern of past HB infection.
Methods: Retrospective study of HB baseline serologic profile in patients with IBD and RD who have started TNFi therapy at our institution. Clinical signs of liver injury and liver injury blood tests were analysed during the treatment in order to identify cases with reactivation. Reactivation was defined as the detection of AgHBs or DNA-VHB.
Results: We analyzed 484 patients with available data on HB serologic profile, 210 men (43.4%) with a mean age of onset of biological therapy of 38±15 years. 258 patients were diagnosed with RD (100 rheumatoid arthritis, 76 ankylosing spondylitis and 82 other RD); 226 patients suffered from IBD (180 Crohn's disease, 41 ulcerative colitis and 5 indeterminate colitis); 273 patients were simultaneously submitted to immunosuppressive treatment with azathioprine, 6-mercaptopurine, corticosteroids or methotrexate, for at least 1 month. At the beginning of the treatment, the HB serologic profile variations were: negative in 63.4%, 31.0% AbHBs+/AbHBc- and 5.8% AbHBc+ (with or without AbHBs+). The 28 AbHBc+ patients did not differ significantly from the overall population in terms of demographic characteristics, diagnosis, follow-up interval and biological therapy. No patient received prophylactic antiviral therapy during the follow-up period (median 8 years and 80 days) and there was only one case of HB reactivation, a Crohn's disease patient treated with infliximab and azathioprine.
Conclusions: In our cohort, there was one case of HB reactivation, corresponding to 3.5% of AbHBc+ patients treated with TNFi. This study highlights the importance of assessing HB serologic profile at the beginning of immunosuppressive therapy. This strategy allows not only the vaccination of serologic negative patients but also the identification of patients at risk of HB reactivation.

P0603
ASSOCIATION OF PRE-S MUTATION WITH OCCULT HBV INFECTION AND RITUXIMAB-RELATED HBsAg REVERSE SEROCONVERSION IN PATIENTS WITH LYMPHOMA
Y.-H. Huang[1,2], I-C. Lee[1,2], S.-T. Kao[2], C.-J. Lee[1,2], H.-C. Lin[1]. [1]*Division of Gastroenterology, Taipei Veterans General Hospital,* [2]*Institute of Clinical Medicine, National Yang-Ming University, Taipei, Taiwan*
E-mail: yhhuang@vghtpe.gov.tw

Background and Aims: Occult HBV infection (OBI) was observed in over one third of patients with lymphoma and resolved hepatitis B in our previous randomized study. Whether the pre-S mutation/deletion and surface region mutation associated with the negativity of HBsAg was unclear.
Methods: Thirty anti-CD20-positive lymphoma patients negative for HBsAg with HBV viremia (occult HBV infection) and 30 age- and sex-matched HBeAg-negative chronic hepatitis B (CHB) patients were enrolled. HBV pre-S and surface regions were sequenced. Site-directed mutagenesis for the hot spot mutations was performed to generate replication-competent mutant HBV plasmids. The expressions of HBsAg by wild and mutant HBV were validated by western blotting. Mutations within the pre-S/S region from serial samples of the resolved hepatitis B patients with rituximab-related HBV reactivation were also compared.
Results: As compared with CHB patients, multiple mutations within the preS1 I84L/Q, preS2 G30E, and surface regions S114T, T131I/N, A184G/V, F220C/L, C221A/G/Y, I226M/S/V were highly associated with OBI. Pre-S deletion was identified only in one patient with OBI. Interestingly, preS2 G30E mutation decreased the amount of HBsAg

secretion but had no impact on the expression of intracellular HBsAg in vitro. Of the patients with HBV reactivation, all cases had pre-S2 G30E mutation before the reactivation and converted to wild type during the event of HBsAg reverse seroconversion.
Conclusions: Multiple mutations in preS/S regions were observed in lymphoma patients with OBI. Pre-S2 mutation is associated with the secretion of HBsAg. Distinct HBV evolution accounts for the rituximab-related HBsAg reverse seroconversion in lymphoma patients with resolved hepatitis B.

P0604

EVOLUTIONARY CHANGES OF HEPATITIS B VIRUS PRE-S MUTATIONS PRIOR TO DEVELOPMENT OF HEPATOCELLULAR CARCINOMA

A. Zhang[1], D.K.-H. Wong[1], F.-Y. Huang[1], W.-K. Seto[1], J. Fung[1], C.-L. Lai[1], M.-F. Yuen[1]. *[1]Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong, China*
E-mail: anyezhang1985@163.com

Background and Aims: Hepatitis B virus (HBV) pre-S deletions/mutations have been associated with hepatocellular carcinoma (HCC). However, the evolutionary changes of pre-S mutations prior to HCC diagnosis remain unexplored.
Methods: HBV pre-S sequences were determined in 74 chronic hepatitis B (CHB) patients with HCC and 146 CHB patients who have been followed up for >3 years with no HCC (HCC-free). Samples collected at the following time points were studied: 1–3 years, 4–6 years, 7–9 years and ≥10 years prior to HCC development and at the same time points for the HCC-free group from last follow-up. HBV pre-S mutations were assessed by comparison with 54 wild-type reference sequences retrieved from the NCBI Genbank.
Results: Pre-S deletions were detected in 31.1%, 25%, 48.5%, and 42.8% of HCC patients at 1–3 years, 4–6 years, 7–9 years, and ≥10 years prior to HCC development, respectively. In the HCC-free group, the frequencies of pre-S deletions at the 4 corresponding time points were lower (9.6%, 7.9%, 8.8%, and 17.6%, respectively; with p values of <0.001, 0.036, <0.001, and 0.096, respectively). At 1–3 years prior to HCC development, higher frequencies of pre-S point mutations at 11 codons (codons 4, 27, 51, 54, 60, 62, 100, 125, 137, 166 and 167) were observed in the HCC patients (range: 14.9–75.7%) than in the HCC-free patients (range: 5.5–26%; all $p < 0.05$). Ten out of these 11 pre-S mutations (except codon 4, which emerged at 4–6 years before HCC) existed ≥10 years before HCC. Among these 11 codons, the number of mutated codons with differential distribution between HCC and HCC-free patients increased with time prior to HCC: a significantly higher frequency of mutations was detected in the HCC patients in 2/11 codons at ≥10 years, in 9/11 codons at 7–9 years, and in 10/11 codons at 4–6 years prior to HCC. The total number of HCC-associated pre-S point mutations increased with time prior to HCC and correlated with the time to HCC development ($r = 0.151$, $p = 0.042$), while no correlation was observed in the HCC-free group ($r = 0.073$, $p = 0.398$). Multivariable logistic regression analysis showed that pre-S deletions and point mutations at codons 27, 51 and 167 were independent factors associated with increased HCC risk (all $p < 0.05$).
Conclusions: High prevalence and cumulative evolution of pre-S mutations preceding HCC development confirmed the carcinogenic role of pre-S mutations. The effect of individual pre-S mutations on HCC development warrants further studies.

P0605

GENOTYPE SPECIFIC VARIATION IN THE BASAL CORE PROMOTER AND PRE CORE REGIONS IMPACTS HBeAg LEVELS DURING IMMUNE CLEARANCE DISEASE

J. Bayliss[1], G. Rosenberg[1], A. Thompson[2], A. Gaggar[3], K. Kitrinos[3], M. Subramanian[3], P. Marcellin[4], E. Gane[5], H.L. Chan[6], X. Li[1], D. Colledge[1], L. Yuen[1], M. Littlejohn[1], R. Edwards[1], K. Jackson[1], S. Bonanzinga[1], R. Hammond[1], S. Bowden[1], S. Locarnini[1], P. Revill[1]. *[1]Molecular Research and Development, Victorian Infectious Diseases Reference Laboratory, Melbourne, [2]Gastroenterology, St Vincent's Hospital, Fitzroy, Australia; [3]Gilead Sciences, Foster City, United States; [4]Hôpital Beaujon, University of Paris, Clichy, France; [5]New Zealand Liver Transplant Unit, Auckland City Hospital, Auckland, New Zealand; [6]Department of Medicine and Therapeutics, Chinese University of Hong Kong, Hong Kong, Hong Kong, China*
E-mail: julianne.bayliss@mh.org.au

Background and Aims: Basal core promoter (BCP) and precore (PC) mutations first emerge prior to HBeAg seroconversion and have been associated with lower HBeAg expression, liver fibrosis and HCC. GS-US-174-0103 is a phase 3 study evaluating tenofovir in HBeAg-positive chronic hepatitis B (CHB). The aim of the current study was to use next generation sequencing (NGS) to evaluate the prevalence and quantitative frequency of key mutations within the BCP and PC regions and evaluate their impact on baseline virological profiles within the 103 cohort.
Methods: Illumina MiSeq full genome NGS was performed on a subset of 94 baseline samples from patients enrolled in study 103, using a threshold for detection of 1%. The results of NGS were analysed against baseline demographic, clinical, and serological data including HBV DNA, HBsAg, and HBeAg levels. In the first instance only mutations in the BCP and PC regions were considered.
Results: Data were available for 94 patients (median: age 32 yrs, 69% male, HBV DNA 8.43 log10 IU/mL, HBeAg 3.30 log10PEIU/mL, HBsAg 4.71 log10 IU/mL, ALT 137.5 IU/mL, METAVIR fibrosis stage 3). BCP and PC variants were detectable in 34% and 15% of patients using population sequencing respectively vs. 43% and 41% using NGS ($p < 0.001$). Differences were seen in the genotype (Gt) distribution of mutations within the BCP and PC regions (Table 1).
The presence of mutation at A1762 and G1764 was associated with significantly lower HBeAg expression at baseline ($p < 0.0001$ for both). Presence of the G1896A mutant alone was not associated with HBeAg expression. HBsAg levels ($p = 0.002$), A1762T ($p = 0.002$) and T/C1858G ($p = 0.02$) were independently associated with HBeAg levels at baseline (model $p < 0.0001$; R2= 0.31). Baseline HBsAg levels were independently associated with HBV DNA ($p < 0.0001$), genotype ($p = 0.005$) and A1762T and G1764SA ($p < 0.0001$ for both) (model $p < 0.0001$; R2= 0.48).

Table 1. Selected BCP/PC mutations detected by NGS

	n	BCP			PC
		A1762T	G1764A	T/C1858G	G1896A
All	94	34 (36%)	34 (36%)	13 (11%)	39 (41%)
Gt A	26	5 (19%)	6 (23%)	2 (8%)	0
Gt B	19	3 (16%)	3 (16%)	0	15 (79%)
Gt C	21	18 (86%)	19 (90%)	8 (38%)	9 (43%)
Gt D	28	8 (29%)	6 (21%)	1 (4%)	15 (54%)

Conclusions: Clinically important HBV variants are frequently present in treatment naïve patients during the immune clearance phase of CHB prior to the initiation of therapy, often below the threshold of detection by population based Sanger sequencing. These include mutations associated with increased risk of disease progression. Our data suggest that molecular differences in the HBV genome, both within and between genotypes may contribute

to variations in disease status among patients and illustrates the power of NGS for detecting clinically important variants.

P0606

TNF-ALPHA SIGNIFICANTLY INHIBITS HEPATITIS E VIRUS REPLICATION

P. Behrendt[1,2], S. Drave[2], S. Pischke[3], H. Wedemeyer[1], E. Steinmann[2].
[1]Department for Gastroenterology, Hepatology and Endocrinology, Medical School Hannover, [2]Experimental Virology, TWINCORE, Centre for Experimental and Clinical Research, Hannover, [3]Health Care Center, University Medical Center Hamburg-Eppendorf, Hamburg, Germany
E-mail: behrendt.patrick@mh-hannover.de

Background and Aims: Several previous reports suggest an involvement of TNF-alpha in hepatitis E virus (HEV) infection. Polymorphisms in the promotor region as well as serum level of TNF-alpha have been identified to influence clinical outcome of HEV. We aim to characterize the influence of TNF-alpha on viral replication in tissue culture.
Methods: We assessed viral replication under treatment with TNF-alpha by transfection of the hepatoma cell-line HepG2 with a previously described genotype 3 clone of HEV (Kernow p6), which harbours a gaussia-luciferase gene in the ORF2 coding region. Additionally, we performed co-treatment experiments with already approved anti-TNF-alpha drugs as well as ribavirin, a potent inhibitor or HEV-replication. We are currently confirming our results by using the full-length clone of Kernow by addressing viral production with detection of HEV-RNA as well as capsid antigen.
Results: TNF-alpha inhibited HEV-replication in a dose-dependent manner with an IC50 of 50 μg/ml. Addition of an TNF-alpha receptor inhibitor (Etanercept) as well as an TNF-alpha blocking antibody (Certulilumab) completely abolished the antiviral activity of TNF-alpha. Co-treatment with TNF-alpha as well as ribavirin revealed an additive antiviral effect.
Conclusions: As suggested by previous clinical observations TNF-alpha directly influences viral replication in vitro. Patients which receive anti-TNF-alpha drugs should be carefully evaluated for liver enzymes and an elevation should prompt for testing of HEV-RNA, in particular.

P0607

PREVENTION OF VERTICAL TRANSMISSION OF HEPATITIS B: AN EVALUATION OF ADHERENCE RATES AND RISK FACTORS FOR FAILURE TO PROVIDE IMMUNOPROPHYLAXIS THERAPY IN A SINGLE AUSTRALIAN CENTRE

L. Sahhar[1], S. Spring[1], P. Ha[1], N. Tan[1], V. Bull[1], W. Birkett[1], E. Lickliter[1], J. Lewis[1], T. Trivedi[1], S. Le[2], A. Dev[2]. *[1]Monash University, [2]Dept of Gastroeneterology, Monash Health, Clayton, Australia*
E-mail: lukas.sahhar@gmail.com

Background and Aims: Immune prophylaxis therapy (IPT) is well established in decreasing perinatal transmission of hepatitis B virus (HBV) and is a key strategy to reduce the prevalence of chronic hepatitis B (CHB) worldwide. Universal guidelines recommend administration of HBV immunoglobulin (HBIg) and HBV vaccine within 12 hours of birth. Immunisation adherence rates and risk factors for failure to provide timely IPT to babies born to CHB mothers remain poorly defined. We conducted a retrospective cohort study to determine compliance with IPT guidelines in routine obstetric practice at Monash Health, Australia.
Methods: 451 mothers with CHB delivered 451 live born infants at Monash Health between 2008 and 2013. There were 3 stillbirths and 3 sets of twin livebirths. Demographic and disease data, referral rates for specialist HBV care, neonatal and maternal morbidity outcomes and timing of HBIg and HBV vaccine administration were extracted from hospital records. Multivariate logistic regression analysis was utilized to identify the risk factors associated with failure to provide timely administration of IPT.
Results: 47.23% of CHB mothers were diagnosed on routine antenatal screening. Mean maternal age was 30.37±5.25 years and mean gestational age was 38.99±2.50 weeks. 55.67% of women received antenatal specialist care for CHB and 4.29% commenced prophylactic antiviral therapy in the third trimester. 79.82% of newborns received HBIg within 12 hours and 8 babies received no HBIg prior to discharge (1 due to withdrawal of parental consent). 97.12% of newborns received HBV vaccine within 12 hours and 1 baby received no HBV vaccination prior to discharge. On multivariate analysis, antenatal care provided by an Obstetrician and or a Specialist for CHB was associated with timely administration of HBIg (OR 1.64, $p = 0.038$, CI:1.03–2.61). The requirement for an interpreter at birth, maternal age and parity, post-partum complications, gestational age and neonatal morbidity were not significantly related to delayed administration of HBIg. There were no predictors for timely HBV vaccine.
Conclusions: The efficacy of IPT in the prevention of HBV vertical transmission has been well documented. However, the adherence rate to these recommendations remains sub-optimal especially for timely HBIg administration in routine obstetric practice. Targeted clinical interventions to improve HBIg adherence rates and serologic follow-up of infants born to CHB mothers is recommended.

P0608

CAN MBL2 GENOTYPES AND ITS POLYMORPHISM PREDICT THE OCCURRENCE OF CIRRHOSIS AND HEPATOCELLULAR CARCINOMA?

R. Ruttala[1], V.K. Karra[1], S.K. Polipalli[1], A. Rai[2], P. Kar[1]. *[1]Medicine, Maulana Azad Medical College, [2]Division of Biochemistry & Biotechnology, National Center for Disease Control, New Delhi, India*
E-mail: premashishkar@gmail.com

Background and Aims: Mannose binding lectin (MBL2) is a central component of the innate immune response and thus polymorphisms are reported to play a crucial role in outcome of hepatitis B virus (HBV) infection. The study was designed to ascertain the association of MBL2 genotypes (codon 52, 54, 57 and promoter −550, −221) and its serum expression levels with reference to different stages of HBV infection in patients of Chronic hepatitis B, cirrhosis of liver and hepatocellular carcinoma.
Methods: The study included 150 patients of liver diseases in various stages of HBV infection and 100 healthy age and sex matched individuals who were negative for hepatitis B infection served as controls. All the samples were processed for quantification of MBL levels using commercially available ELISA kits as per the manufacturer instruction [BIOPORTO Diagnostics, Denmark]. The MBL2 gene polymorphisms (codon 52, 54, 57 and promoter −550, −221) were identified by polymerase chain reaction sequence specific primer method.
Results: Individuals without infection had highest levels of serum MBL2 (1388.74±2697.57 ng/ml) when compared with the individuals with infection especially patients with advanced disease possessing lowest levels (380.35±175.10 ng/ml; p value 0.001) (Figure 1). A clear association between *mbl2* genotype and HBV infection outcome was noted in these groups.
Codon 54 mutation was significantly associated with hepatitis B related decompensated cirrhotic patients [p = 0.001; OR = 3.31 (1.53–7.14)] and hepatocellular carcinoma (HCC) [p = 0.009; OR = 3.00 (1.28–6.99)] compared to controls. Promoter −221, low expression genotype CC (X) rate was high in chronic hepatitis B, decompensated cirrhosis, and HCC patients [p = 0.01, OR = 2.66 (1.190–5.935); p = 0.001, OR = 3.61 (1.641–7.979) and p = 0.01, OR = 3.05 (1.278–7.320)] compared to controls.
Conclusions: The results provide preliminary evidence that inheritance of codon 54 genotypes and promoter −221 genotype X associated with low MBL level substantially determine the outcome

of HBV infection and predicts the likelihood of cirrhosis and hepatocellular carcinoma.

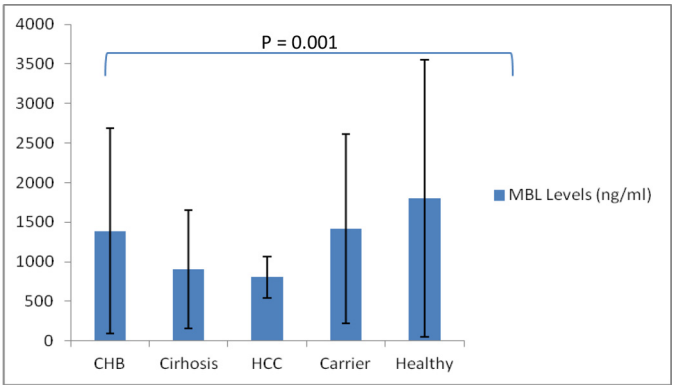

Figure 1. Distribution of serum MBL2 levels.

P0609
RISK PREDICTION OF NON-CIRRHOTIC HEPATOCELLULAR CARCINOMA IN PATIENTS WITH CHRONIC HEPATITIS B VIRUS INFECTION

W.-J. Jeng[1,2,3], H.I Yang[4], J. Liu[4,5], M.-H. Lee[3], C.-L. Jen[4,5], R. Batrla-Utermann[6], S.-N. Lu[7,8], L.-Y. Wang[9], S.-L. You[4], C.-J. Chen[4,5], for the R.E.V.E.A.L.-HBV Study Group. *[1]Department of Gastroenterology and Hepatology, Division of Hepatology, Chang Gung Memorial Hospital, Linkou, [2]College of Medicine, Chang Gung University, [3]Institute of Clinical Medicine, National Yang Ming University, [4]Genomics Research Center, Academia Sinica, [5]Graduate Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan; [6]Roche Diagnostics Ltd., Switzerland, Switzerland; [7]Division of Hepato-Gastroenterology (Department of Internal Medicine), Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, [8]Chang Gung University, Kaohsiung, [9]MacKay Medical College, Taipei, Taiwan*
E-mail: rachel.jeng@gmail.com

Background and Aims: One-third of chronic hepatitis B (CHB) related hepatocellular carcinoma (HCC) patients are non-cirrhotic. This study aimed to investigate the risk factors of HCC in those non-cirrhotic CHB patients
Methods: This analysis included hepatitis B surface antigen (HBsAg)-seropositive participants from the Risk Evaluation of Viral Load Elevation and Associated Liver Disease/Cancer in HBV (R.E.V.E.A.L.-HBV) cohort. Patients with evidence of cirrhosis at entry were excluded. Cirrhosis and HCC were ascertained through regular follow-up ultrasonography, linkage with national health database, and medical chart reviews. Factors included age, gender, HBV e antigen (HBeAg) status, serum levels of HBV DNA, quantitative serum HBsAg levels, Co-infection with HCV, alanine aminotransferase (ALT), habits of smoking, alcohol consumption, family history of HCC, body-mass index, and diabetes mellitus history were analyzed between LC related HCC and non-LC related HCC patients. Multinomial logistic regression was applied for risk factors investigation.
Results: There were 187 patients developed HCC in 3776 CHB patients, 66 of them were non-cirrhotic HCC patients. Older age (>50 vs. <50 year-old, OR: 4.42 [2.15–9.06], P = 0.000), family history of HCC (OR: 3.03 [1.38–6.68], P = 0.006), cigarette smoking habit (OR: 2.02 [1.05–3.86], P = 0.035), alcohol consumption habit (OR: 2.17 [1.16–4.05], P = 0.015), elevated ALT (15–45 vs. <15 U/L, OR: 2.263 [1.279–4.003], P = 0.005; >45 vs. <15 U/L, OR: 3.431 [1.520–7.744], P = 0.003), HBV DNA $>10^6$ copies/mL in HBeAg-seronegative patients (OR: 2.83 [1.081–7.406], P = 0.034 vs. HBeAg-seronegatives with HBV DNA $<10^6$ copies/mL), or HBeAg positivity (OR: 3.679 [1.791–7.558], P = 0.000) are independent risk factors for non-cirrhotic HCC in CHB patients.
Conclusions: Smoking, alcohol drinking, family history of HCC, abnormal LFT, HBV DNA $>10^6$ copies/mL and HBeAg seropositive status are predictors of non-cirrhotic HCC in CHB patients

P0610
DYNAMIC PREDICTION OF INACTIVE CHRONIC HEPATITIS B USING REPEATED HBsAg AND HBV DNA LEVEL MEASUREMENTS THROUGH LONG-TERM FOLLOW-UP

W.P. Brouwer[1], H.L.-Y. Chan[2], M.R. Brunetto[3], M. Martinot-Peignoux[4], P. Arends[1], M. Cornberg[5], B. Cherubini[3], A.J. Thompson[6], Y.-F. Liaw[7], P. Marcellin[4], H.L. Janssen[8], B.E. Hansen[1].

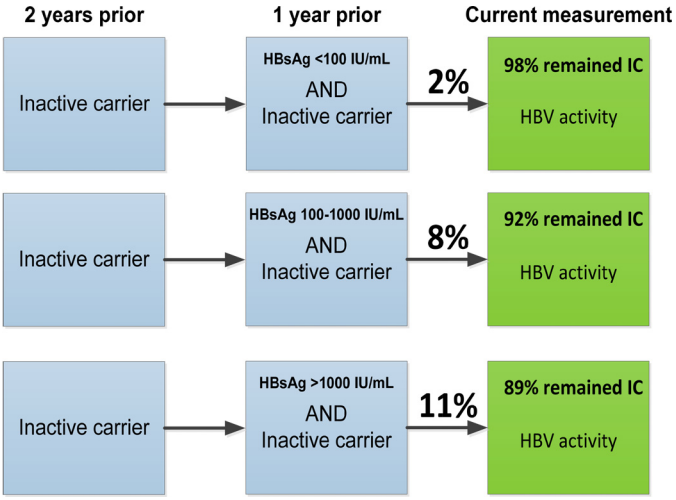
E-mail: w.p.brouwer@erasmusmc.nl

Background and Aims: A single-point hepatitis B surface antigen (HBsAg) level below 1,000 IU/mL combined with low HBV DNA has been shown to identify inactive carriers (IC) after 1 year of follow-up. Our aim was to evaluate the performance of repeated HBsAg measurements through long-term follow-up.
Methods: In this retrospective cohort study conducted at 8 tertiary care centres 293 treatment-naïve non-cirrhotic HBeAg-negative patients with a normal ALT and HBV DNA <20,000 IU/mL were included. HBsAg, HBV DNA and ALT levels were measured at each visit during a median follow-up of 8 years (range 4–9). Patients were defined IC in case of HBVDNA <2,000 IU/mL and persistent normal ALT during a complete follow-up year. A fluctuation >2,000 IU/ml and/or abnormal ALT was defined as HBV activity. Dynamic regression analysis was used to study changes in HBsAg levels and HBV phase.
Results: Of 293 patients, 224 (76%) were IC at inclusion. Mean age was 43±13 years and HBV genotype A/B/C/D was present in 39/42/33/104 patients. Patients with activity in one year and a persistently normal ALT and HBV DNA <2,000 IU/mL during the subsequent year had a 40% chance to have activity again in the year thereafter. By dynamic analysis, the probability to remain IC in the next year given HBsAg levels of <100, 100–1,000 or >1,000 IU/mL was 96%, 86% and 81% (p < 0.001). IC during 2 consecutive years was predictive of IC in the next year, still 10% of patients with HBsAg >100 IU/mL showed disease progression (figure). A single-point HBsAg <100 IU/mL with HBV DNA <2,000 IU/mL could predict IC throughout long-term follow-up with a specificity of 97% and a positive predictive value (PPV) of 95%, while a HBsAg <1,000 IU/mL combined with HBV DNA <2,000 IU/mL had a specificity of 88% and a PPV of 90% for the total cohort. The combined rule of HBV DNA with HBsAg <1,000 IU/mL performed well in HBV genotype D patients (PPV 95%, specificity 92%), still HBsAg levels <100 IU/mL were superior (PPV 99%, specificity 99%). Patients with HBsAg <100 IU/mL also had a high chance of HBsAg loss (HR = 5.1 versus 100–1000 IU/mL, 95% CI: 1.9–13.5, p < 0.001). In those patients with a HBV DNA >2,000–<5,000 IU/mL and a HBsAg decline of ≥0.5 log IU/mL one year prior, 62% became and remained IC.
Conclusions: Both HBsAg levels and declines can be used to identify IC patients. HBsAg levels are predictive of remaining in the IC phase and should be used to define HBV phases.



P0611

TRAJECTORIES OF HEPATITIS B SURFACE ANTIGEN AND ASSOCIATIONS WITH HEPATOCELLULAR CARCINOMA, LIVER CIRRHOSIS, AND HBsAg SEROCLEARANCE AMONG CHRONIC HEPATITIS B CARRIERS WITH LOW VIRAL LOADS

J. Liu[1], H.-I Yang[1], M.-H. Lee[2], R. Batrla-Utermann[3], C.-L. Jen[1], S.-N. Lu[4], L.-Y. Wang[5], S.-L. You[1], C.-J. Chen[1]. *[1]Academia Sinica Genomics Research Center, [2]Institute of Clinical Medicine, National Yang-Ming University, Taipei, Taiwan; [3]Roche Diagnostics, Basel, Switzerland; [4]Gastroenterology, Chang-Gung Memorial Hospital, Kaohsiung, [5]MacKay College of Medicine, Taipei, Taiwan*
E-mail: jessica.b.liu@gmail.com

Background and Aims: Chronic hepatitis B virus (HBV) carriers with low viral loads have significantly decreased risk for hepatocellular carcinoma (HCC) and liver cirrhosis, and are more likely to reach HBsAg seroclearance. Previous studies have shown that baseline serum hepatitis B surface antigen (HBsAg) levels can help to predict HBV-related outcomes, but the role of long-term trajectories of quantitative HBsAg is still unclear. This study aims to examine the role of HBsAg trajectories in predicting HCC, cirrhosis, and HBsAg seroclearance among chronic HBV carriers with low viral loads.
Methods: A total of 1204 individuals from the community-based REVEAL-HBV cohort were included in this study. Participants had viral loads <10,000 copies/mL with normal ALT, and were HBeAg-seronegative, anti-HCV seronegative, and free of cirrhosis at study entry. All participants had >2 measurements of quantitative HBsAg, and trajectories were measured by calculating the decline in HBsAg levels per year of follow-up. The median decrease, 0.059 log iu/mL per year, was used as a cut-off.
Results: Among 1204 individuals with HBV DNA <10,000 copies/mL, the mean (range) baseline HBsAg level was 2.06 (−2.0–4.8) log iu/mL. Compared to those with baseline HBsAg levels <2 log iu/mL, those with HBsAg levels ≥2 log iu/mL had similar rates of HBsAg decline during follow up (P = 0.33). Compared to those without significant declines in HBsAg levels (<0.059 log iu/mL per year) during follow-up, individuals with declines in HBsAg levels ≥0.059 log iu/mL per year had adjusted rate ratios (95% CI, p-value) for HCC, liver cirrhosis, and HBsAg seroclearance of 1.68 (0.66–4.26, p = 0.28), 0.78 (0.48–1.29, p = 0.33), and 1.86 (1.49–2.32, p < 0.001), respectively. Furthermore, compared to those with baseline HBsAg levels ≥100 iu/mL, those with baseline HBsAg levels (iu/mL) and follow-up declines (log iu/year) of <100/<0.059, and <100/≥0.059 had adjusted HBsAg seroclearance rate ratios (95% CI, p-value) of 4.44 (3.43–5.75, p < 0.001), and 7.85 (5.85–10.55, p < 0.001), respectively.
Conclusions: Among chronic hepatitis B patients with low viral loads, decreases in HBsAg levels did not further significantly reduce rates of HCC or cirrhosis, but did significantly predict HBsAg seroclearance. Further clarification of the role of long-term quantitative HBsAg trajectories in the natural history of chronic hepatitis B infection is needed.

E-mail: tkessarin@hotmail.com

Background and Aims: Interferon-γ-inducible protein 10 kDa (IP-10) has an important role for immune regulation. In chronic hepatitis B (CHB) infection, pre-treatment IP-10 levels are associated with HBeAg loss after Pegylated interferon alfa (PegIFN) therapy. The single nucleotide polymorphism (SNP) G-201A in the promoter of IP-10 gene up-regulates IP-10 expression and is associated with disease progression in CHB infection. This study aimed to determine the impact of the SNP G-201A in IP-10 gene on treatment in HBsAg-negative patients treated with PegIFN.
Methods: 115 patients with HBeAg-negative CHB infection treated for 48 weeks with PegIFN from 13 hospitals were prospectively enrolled. The G-201A SNP in promoter of IP-10 gene was genotyped. Response to treatment was assessed at 24 weeks post-treatment and defined as HBV-DNA <2,000 IU/ml.
Results: Eighty-five patients (81.7%) had HBV genotype C infection and five patients (4.6%) had liver cirrhosis. Fifty-four (55.7%) and six (6.3%) patients achieved virologic remission and HBsAg loss at 24 weeks after therapy, respectively. At week 48, HBV-DNA <1 log IU/ml predicted 80% of sustained virologic remission. Age, sex, genotype, HBsAg level and ALT at week 48 were not predictor for virologic response. However, this study found G-201A SNP of IP-10 gene was related to HBsAg levels during treatment period. Patients with non-GG genotype had significant lower HBsAg level at end-of-treatment than GG genotype (p = 0.002) and trended to sustain suppression of HBsAg level after treatment (Figure 1). Eighty-seven patients (93.5%) had HBsAg level <5,000 IU/ml at week 48 and in this group, patients who had non-GG significant achieved more virologic remission than GG genotype (78.9% vs 50.9%, p = 0.033). By multivariate analysis, only −201 IP-10 non-GG genotype was associated with sustained virologic response (adjusted OR: 3.62, 95% CI: 1.06–12.28, p = 0.039). Median rate of HBsAg reduction from pretreatment level to week 48 was not different between responders (−2.87 log IU/ml) and non-responders (−3.19 log IU/ml) (p = 0.08). The SNP −201 was not associated with HBsAg loss and ALT normalization after therapy.
Conclusions: In HBeAg-negative CHB patients treated with PegIFN, combination IP-10 promoter polymorphism with end-of-treatment

HBsAg level strongly predict sustained virologic response. Non-GG genotype of IP-10 gene promoter polymorphism was linked to low HBsAg level at end-of-therapy. Further study on immunopathophysiology is needed to elucidate this association.

E-mail: m.vancampenhout@erasmusmc.nl

Background and Aims: Hepatitis B core related antigen (HBcrAg) is a new serum marker comprised of 3 viral proteins coded by the precore/core region of the covalently closed circular DNA (cccDNA): HBeAg, HBcAg and p22cr. Our aims were to describe HBcrAg kinetics in HBeAg negative chronic hepatitis B (CHB), and to assess if HBcrAg can be used as a marker for immune control in this group.
Methods: We measured serum HBcrAg in patients who participated in an international multicenter RCT (ARES study). In this study, 175 HBeAg positive patients all received entecavir (ETV) treatment for 24 weeks, and were then allocated to either continuation of ETV monotherapy or addition of 24 weeks of peginterferon alpha-2a (PEG-IFN add-on). Only when combined response (CR; HBeAg loss and HBV DNA <200 IU/mL) was achieved at week 48, patients stopped treatment at week 72. For this post-hoc analysis, we focused on HBcrAg decline between week 72 and 96 in patients who were HBeAg negative in this time interval. Also, viral relapse (HBV DNA >200 IU/mL) was assessed. HBcrAg levels were measured using the Lumipulse® G HBcrAg assay (Fujirebio Europe, Belgium).
Results: HBeAg was negative at both week 72 and 96 in 36 patients. In 16/36 patients ETV was stopped at week 72. In this group, HBcrAg levels declined in 10 patients, remained stable in 1 patient and increased in 4 patients (Figure 1). Week 72 HBcrAg was missing in 1 patient. In all 4 patients with HBcrAg increase, viral relapse occurred at week 96. In contrast, viral relapse was observed in only 1/10 patients with HBcrAg decline. In 20 patients who continued ETV between week 72 and 96, HBcrAg declined in 12 patients and increased in 8 patients. No viral relapse occurred in this group. One patient of the PEG-IFN add-on arm who had HBcrAg decline (−0.65 log U/mL) cleared HBsAg at week 96. Overall, mean HBcrAg decline was stronger in patients who previously received PEG-IFN add-on therapy than in patients of the ETV monotherapy arm (−0.29 vs. +0.14 U/mL, p = 0.033).
Conclusions: Serum HBcrAg levels declined in the majority of patients with PEG-IFN add-on induced HBeAg loss. HBcrAg increase was predominantly seen during ongoing ETV treatment of patients with ETV-induced HBeAg loss. Viral relapse after ETV cessation only occurred in patients who had HBcrAg increase or minor decrease. HBcrAg may therefore be useful as a marker for immune control in HBeAg negative CHB, but further analysis in larger patient groups is required.

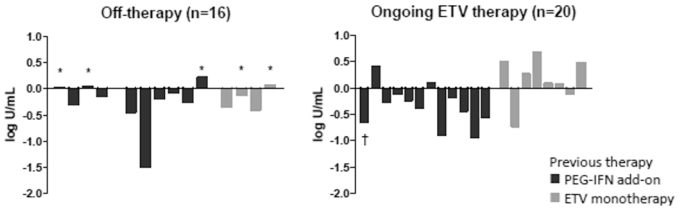

Figure 1. HBcrAg decline between week 72 and week 96. Bars represent individual log HBcrAg declines grouped by previous therapy. All patients were HBeAg negative between week 72 and 96 and had HBV DNA <200 IU/mL at week 72. Patients in the left panel stopped ETV at week 72, patients in the right panel continued ETV. *Viral relapse at week 96. † HBsAg loss at week 96.

E-mail: matteo.surdo@uniroma2.it

Background and Aims: To investigate HBsAg genetic determinants correlated with HBV-induced hepatocellular carcinoma (HCC) and their impact on cell proliferation.
Methods: This study includes 153 HBV chronically infected patients: 15 with HCC (60% D; 33% A, 7% E HBV genotype), and 138 asymptomatic patients as control (58% D, 31% A, 11% E). Mutations were defined according to the reference sequence of each specific HBV genotype. Association of HBsAg mutations with HCC was assessed by Fisher test.

HBsAg mutations were introduced into a 1.3× genome-length HBV genotype D. WT and mutated clones were transfected into Huh7 cells. Lysates and supernatants were harvested in triplicate daily until day 5 post-transfection, and HBsAg (representing 24 hours of accumulation) quantified by Alexxis assay. Mutations were also introduced into a pIRES II plasmid encoding HBsAg and GFP. Cellular cycle was analysed by flow cytometry (DNA propidium iodide-staining) on transfected GFP+ cells at day 7 post transfection (4 experiments in triplicate).

Results: Patients with or without HCC had median (IQR) log serum HBV-DNA of 4.1 (3.2–6.0) and 4.1 (3.1–6.0) UI/ml, respectively. Two HBsAg mutations significantly correlated with HCC: P203Q (27% [4/15] in HCC vs 2% [3/138] in non-HCC, p = 0.002); S210R (40% [6/15] in HCC vs 12% [17/138] in non-HCC, p = 0.012); P203Q+S210R (27% [4/15] in HCC vs 1.4% [2/138] in non-HCC, p = 0.001). Both P203Q and S210R reside in transmembrane C-terminal domain known to be important for HBsAg secretion.

In vitro, the presence of P203Q, S210R and P203Q+S210R reduced the ratio of secreted/intracellular HBsAg compared to wt at each time point. Indeed, this ratio varied as follows: at 3 days P203Q (1.734±0.2; p < 0.005), S210R (2.54±0.7), P203Q+S210R (1.83±0.1; p < 0.005) vs wt (2.99±0.2); at 4 days P203Q (2.22±0.2; p < 0.005); S210R (3.52±0.2; p < 0.05), P203Q+S210R (2.33±0.2; p < 0.01) vs wt (4.42±0.3), and at 5 days P203Q (1.15±0.1; p < 0.005), S210R (1.69±0.1; p < 0.005), P203Q+S210R (1.25±0.1; p < 0.005) vs wt (2.23±0.1).

By flow cytometry, P203Q and P203Q+S210R significantly correlated with an increased percentage of cells in the S phase, indicating cell cycle progression: P203Q (26±13%) and P203Q+S210R (29±14%) compared to wt (18%±9) (p ≤ 0.01).

Conclusions: Key mutations, residing in C-terminal HBsAg domain, are highly correlated with HBV-induced HCC *in vivo*. They affect HBsAg secretion and stimulate cell proliferation *in vitro*, suggesting their potential involvement in HCC development.

P0615

DIAGNOSIS BY SCREENING RATHER THAN SYMPTOMS IN HBV-RELATED HCC IS ASSOCIATED WITH IMPROVED OUTCOMES, REGARDLESS OF CIRRHOSIS STATUS BUT SCREENING HISTORY WAS ONLY PRESENT IN ONE-HALF OF CIRRHOSIS AND ONE-THIRD OF NONCIRRHOSIS CASES

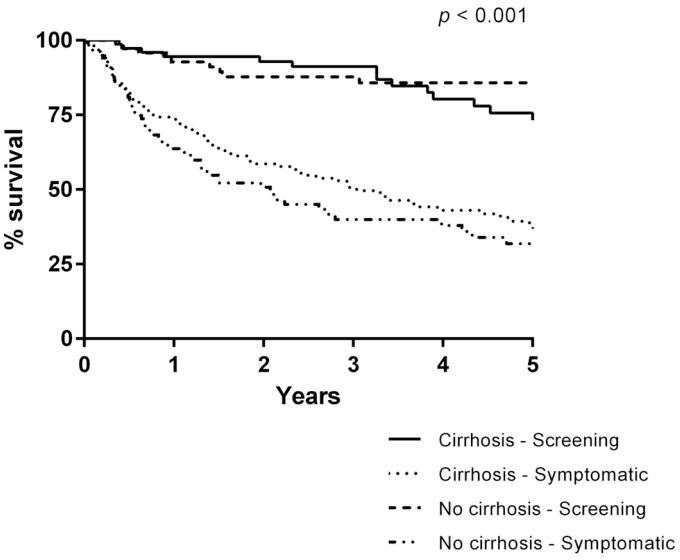
V.L. Chen[1], L. Kim[1], P. Nguyen[1], C. Zhao[1], M.H. Nguyen[1].
[1]*Gastroenterology and Hepatology, Stanford University, Stanford, United States*
E-mail: mindiehn@stanford.edu

Background and Aims: Regular HCC surveillance is recommended by major hepatology societies in patients with chronic hepatitis B (CHB) including those without cirrhosis. However, adherence to surveillance is inconsistent in clinical practice. We investigated the impact of HCC screening on tumor characteristics and patient outcomes in patients with HBV-related HCC with and without cirrhosis.

Methods: We investigated HCC diagnosis scenario (by screening vs. by symptoms) in a cohort of 493 consecutive patients with HBV-related HCC as confirmed by AASLD criteria at a U.S. tertiary care center between 2005 and 2014. "Screening group" patients are those diagnosed by screening imaging in the absence of symptoms while "symptomatic group" patients are those diagnosed with symptoms of HCC. Survival was determined using chart review and/or National Death Index search.

Results: Mean age was 60; 80% were male; 89% were Asian; and 62% had cirrhosis. Patients without cirrhosis were more often diagnosed by symptoms than those with cirrhosis (45% vs. 36%; $p = 0.01$). Compared to those in the symptomatic group, a much greater proportion of screening group patients was eligible for liver transplantation by Milan criteria: 50.6% vs. 22.5% (cirrhosis) and 62.5% vs. 10.5% (no cirrhosis); $p < 0.001$. This difference appeared greater in patients without cirrhosis. Screening group patients were also much more likely to have BCLC stage A/B than symptomatic group patients, especially among those without cirrhosis: 92.6% vs. 59.7% (no cirrhosis) and 84.2% vs. 45.1% (cirrhosis); $p < 0.001$. A greater proportion of screening group patients underwent surgical treatment than did symptomatic group patients: 48.8% vs. 19.1% (cirrhosis) and 58.4% vs. 23.3% (no cirrhosis); $p < 0.001$. Finally, five-year survival was much greater in the screening than in the symptomatic group for patients with and without cirrhosis, though the difference appeared greater in those with cirrhosis (Fig. 1).

Conclusions: HCC diagnosis by routine screening rather than by symptoms is associated with less advanced disease at time of diagnosis, greater likelihood to undergo curative treatment, and improved survival in patients with CHB with and without cirrhosis. Unfortunately, HCC was diagnosed by screening in only half of the patients with cirrhosis and one-third of those without cirrhosis. Further physician and patient education is needed to improve HCC screening adherence in CHB patients, especially in those without cirrhosis.



P0616

DESIGNING ENHANCED PATHWAYS OF CARE FOR PATIENTS WITH CHRONIC HEPATITIS B USING HepBase, A PROPRIETARY DATABASE USED TO STRATIFY PATIENTS

A. Srivastava[1], P. Trembling[1], S. Tanwar[1], J. Catt[1], Z. Mehboob[2], D. Morgan[2], G. Dusheiko[1], W. Rosenberg[1]. [1]*Department of Hepatology, UCL Institute of Liver and Digestive Health, London,* [2]*Health Informatics, Sciensus Health Informatics, Brighton, United Kingdom*
E-mail: ankur.srivastava@nhs.net

Background and Aims: Greater awareness of chronic hepatitis B (CHB), improved therapy and clinical guidelines have all increased patient referrals to liver clinics. Improved understanding of disease progression and fibrosis biomarkers has created the opportunity to redesign pathways of care.

This study aims to use proprietary database software and non-invasive tests to stratify patients attending the Royal Free London (RFL) Hospital for CHB to allow identification of patients who are at low risk of disease progression allowing exploration of alternative follow-up arrangements.

Methods: HepBase, (Sciensus Health Informatics, Brighton) is a real-time clinical and research database, which uses ODBC, SPSS and MATLAB computing programmes to analyse hospital electronic medical record system and pharmacy data to generate patient

cohorts. Patient care pathways were designed in consultation with clinical colleagues based upon EASL clinical care guidelines to identify inactive or pharmacologically controlled CHB who have either (a) mild fibrosis or (b) advanced fibrosis/cirrhosis.
Inclusion criteria included: e-antigen positive or negative, ALT3.25. Patients discharged, transferred, lost to follow up or died were excluded.
Results: Between January 2011 and October 2013 the records of 1796 patients were entered in the RFL HepBase. Of these 867 (48%) satisfied the study's inclusion criteria (Table 1).
Groups 1 and 2 (36%) are considered low risk for disease progression and will be reviewed for allocation to a nurse-led, consultant monitored follow up clinic. 27 patients (FIB4 >3.25) are at risk of advanced fibrosis/cirrhosis. 70% were already diagnosed as cirrhotic. An additional 22% were under close monitoring for advanced liver disease. 9 patients with FIB4 >3.25 were not on treatment with an active decision to withhold treatment documented in five cases.

Table 1.

Group No.	Total	Not on treatment	On treatment
Group 1: HbeAg+, FIB4 <1.45	56	13	43
Group 2: HbeAg−, FIB4 <1.45	584	450	134
Group 3: HbeAg+, FIB4 >3.25	3	0	3
Group 4: HbeAg−, FIB4 >3.25	24	9	15
Unclassified: FIB4 >1.45 and <3.25 or no platelet value	200	127	73
Total	867	602	265

Conclusions: Using an integrated database, 36% of CHB clinic attenders have been identified as inactive or pharmacologically controlled CHB who might be eligible for alternative pathways of care.
Use of HepBase has facilitated redesign of pathways of care for patients with CHB, identifying those who might benefit from less intensive hospital management and those who might benefit from closer monitoring for complications of advanced CHB and consideration of treatment. This approach may also reduce pressure on hospital clinics. We will go on to determine the effectiveness, cost-effectiveness and acceptability of these strategies.

P0617
IS HBeAg SEROCONVERSION A VALID SURROGATE MARKER FOR TRANSPLANT-FREE SURVIVAL IN CHRONIC HEPATITIS B PATIENTS TREATED WITH LAMIVUDINE OR ENTECAVIR?

J. An[1], Y.-S. Lim[1], H.-J. Kim[2], D.J. Suh[1]. *[1]Department of Gastroenterology, [2]Department of Clinical Epidemiology and Biostatistics, Asan Medical Center, Seoul, Korea, South*
E-mail: starlit1@naver.com

Background and Aims: A valid surrogate marker should be predictive of future true clinical outcome of interest to be used to assess the efficacy of disease-modifying interventions. HBeAg seroconversion has been identified as a valid surrogate marker of the survival during the natural course of patients with chronic hepatitis B (CHB). However, the validity of HBeAg seroconversion as a surrogate marker for transplant-free survival during nucleos(t)ide analogue treatment for CHB is not clear.
Methods: We performed a retrospective analysis of data from 5374 consecutive adult patients with CHB, treated with lamivudine (LAM, n = 3374) or entecavir (ETV, n = 2000) at a tertiary referral hospital in Seoul, Korea from 1999 through 2011. Data were analyzed by time-dependent multivariable Cox proportional hazards model.
Results: HBeAg was positive in 3587 (66.7%) patients at baseline; 2419 (71.8%) in the LAM group and 1168 (58.4%) in the ETV group. During the study period, 302 patients (5.6%) died, and 169 (3.1%) received a liver transplant. Multivariable analyses showed that baseline HBeAg-positivity was not an independent risk factor for lower risk of death or transplantation in the entire cohort (hazard ratio [HR], 0.92; 95% confidence interval [CI], 0.78–1.10). Among HBeAg-positive patients at baseline, 1425 (39.7%) achieved HBeAg seroconversion during treatment. In the LAM group, HBeAg seroconversion was significantly associated with a reduced risk of transplant or death (HR, 0.60; 95% CI, 0.48–0.77). On the contrary, HBeAg seroconversion was not associated with the risk of transplant or death in the ETV group (HR, 1.67; 95% CI, 0.78–3.60).
Conclusions: In a large cohort of CHB patients, HBeAg seroconversion was associated with a significantly lower risk of transplant or death during treatment with LAM. However, the significance of HBeAg seroconversion as a surrogate marker for transplant-free survival was not identified during treatment with a more potent antiviral agent, ETV.

P0618
ANTI-HEV IgG SEROPREVALENCE IN EUROPE: A META-ANALYSIS

J. Hartl[1], K.L. Woolson[2], G. Webb[3], M. Saunders[3], A.W. Lohse[4], H.D. Dalton[2], S. Pischke[4,5]. *[1]University Hospital Hamburg Eppendorf, Hamburg, Germany; [2]Royal Cornwall Hospital Trust and European Centre for Environment and Human Health, University of Exeter, Truro, [3]Hepatology, Derriford Hospital, Plymouth, United Kingdom; [4]First Medical Center, University Hospital Hamburg Eppendorf, [5]Hepatobiliary and Transplant Surgery, Universtiy Medical Center Hamburg-Eppendorf, Hamburg, Germany*
E-mail: j.hartl@uke.de

Background and Aims: Hepatitis E is of emerging relevance in Europe. Many early studies showed anti-HEV IgG seroprevalence rates <5%. However, HEV seems to be very common in Europe, as evidenced by high numbers of blood donors who are viraemic at the time of donation. Aim: to compare published anti-HEV IgG seroprevalence estimates in Europe.
Methods: Comprehensive literature review (Pubmed) of English-language anti-HEV IgG seroprevalence surveys in European countries between 01/2004 and 10/2014. Chi square test was used to compare seroprevalence rates.
Results: 82 studies and 1,602,429 individuals (1,592,845 healthy, 3752 HIV-infected, 2742 transplants, 3090 people with contact with swine/wild animals) were included. The most frequently used assays were Wantai (WT), MP-diagnostics (MP) and Mikrogen (MG). Observed seroprevalence rates in healthy populations showed huge differences (WT: 21.2%, MP: 6.5%, MG: 17.8%, WT vs MP, WT vs MG and MP vs MG, $p < 0.0001$ for each comparison). Comparing European nations, the highest seroprevalence rate was found in France (WT: 31.1%, MP: 18.7%) and the lowest in Spain (WT: 4.1%, MP: 3.5%, France vs Spain: WT $p < 0.0000$, MP $p < 0.0000$). Seroprevalence rates in patients with solid organ transplant recipients or HIV-infected patients were not different when compared to healthy controls (table), whereas individuals with contact with swine/wild animals (farmers, veterinarians, forestry workers) showed a significantly higher HEV seroprevalence (WT: $p < 0.0001$, MP: $p < 0.0001$, MG: $p = 0.0153$).
Conclusions: HEV seroprevalence varies considerably and is dependent on the assay employed, geographical location and patient group. None of the assays currently in use have been completely validated with respect to detection of distant infection. However, WT has a sensitivity of 98% in this regard, but its specificity is unknown [1]. Its specificity is probably acceptable, as in some populations seroprevalence estimates using this assay are very low (e.g. Fiji, 2% [2]). A comprehensive validation exercise of existing serology is needed, together with the establishment of WHO reference materials for HEV serology.

ASSOCIATION OF THE GENE POLYMORPHISMS IN SODIUM TAUROCHOLATE COTRANSPORTING POLYPEPTIDE WITH HBV-RELATED HEPATIC FIBROSIS

Z. Su[1], Y. Li[1], Y. Liao[1], B. Cai[1], J. Chen[1], J. Zhang[1], L. Li[1], B. Ying[1], C. Tao[1], L. Wang[1]. *[1]Department of Laboratory Medicine, West China Hospital of Sichuan University, Chengdu, China*
E-mail: wanglanlan_med@163.com

Background and Aims: Progressive hepatic fibrosis with the development of cirrhosis is a feature in the majority of chronic hepatitis B virus (HBV) infection cases. Sodium taurocholate cotransporting polypeptide (NTCP) was newly identified as a HBV receptor and required for efficient viral entry. The aim of the study was to investigate the potential relationship between hepatic fibrosis/cirrhosis and NTCP polymorphisms in HBV patients.
Methods: A total of 581 consecutive patients with chronic HBV infection were retrospectively included for this analysis. Liver fibrosis/cirrhosis was explored by calculating FIB-4 index, the cutoff value were 1.62 and 3.25 for significant fibrosis and cirrhosis, respectively. Three single nucleotide polymorphisms (SNPs) in NTCP were genotyped by high resolution melting (HRM) curve method.
Results: 327 (56.3%) and 150 (25.8%) patients were identified in the study as significant fibrosis and cirrhosis, respectively. Rs4646287 AA genotype was more common in significant fibrosis group (2.1% versus 0.0%, $p = 0.020$ in a recessive model). Furthermore, we found that A allele of rs4646287 was overrepresented in significant fibrosis group as well (11.2% versus 7.3%, $p = 0.025$). No significant differences in frequency distributions of the other two SNP (rs7154439 and rs4646296) alleles or genotypes between case and control groups were found in this study (all $p > 0.05$).
Conclusions: This study suggests that polymorphisms in the NTCP region may be associated with the hepatic fibrosis of HBV infection. The patients with rs4646287 AA genotype may be prone to HBV-related liver fibrosis. However, larger studies, most likely through multicenter collaboration will be needed to fully validate the significance of these findings.

P0620

IMPROVING REFERRAL OF WOMEN WITH CHRONIC HEPATITIS B FROM ANTENATAL SERVICES TO A SPECIALIST HEPATITIS CLINIC – THE NORTHERN IRELAND EXPERIENCE

L.E. Stratton[1], A. McCurley[2], R. Campbell[2], N. McDougall[1]. *[1]Regional Liver Unit, Royal Victoria Hospital, [2]The Northern Ireland Regional Hepatitis B&C Managed Clinical Network, Belfast, United Kingdom*
E-mail: leanne.stratton@doctors.org.uk

Background and Aims: Antenatal screening for hepatitis B in all pregnancies has been recommended in the UK since 1998. Previous Northern Ireland (NI) data showed that only a small proportion of these women were reviewed at a specialist hepatitis clinic[1]. In 2011, a new referral form and referral pathway were introduced to improve follow-up of all pregnant women with a positive HBsAg.
The aim was to re-audit the follow-up of pregnant women with a positive HBsAg in NI.
Methods: Data from NI maternity services, the Regional Virology Laboratory and the NI Hepatitis B&C Clinical Network were reviewed from 2004–2013 to identify all antenatal HBsAg positive patients. Data from 2004–2010 was analysed retrospectively. In 2011 a new referral pathway was introduced by the NI Hepatitis B&C Clinical Network, and data was gathered prospectively, including reason for non-attendance at specialist clinics. All women with an HBV DNA $>10^7$ were considered for oral antiviral treatment in the 3rd trimester.
Results: Table 1 shows the number of HBsAg positive women detected and referred each year. Up until 2010 the number referred to specialist hepatology services was <60%. Following introduction of the new pathway this figure increased to ≥94%.
Review of ethnicity data for 2013 showed that the vast majority of patients were of non-UK origin (19 South-East Asia, 13 Eastern Europeans, 5 Africans, 7 unrecorded and 1 other region). This was similar to the 2004–2010 data.
Conclusions: Intervention by the NI Hepatitis Network in 2011 dramatically improved the rate of referral of HBsAg positive women from maternity services to a specialist hepatitis clinic (from <60% to >90%).

Table 1. Antenatal referral and review of HBsAg positive patients in Northern Ireland

Year	Number of HBsAg positive cases detected	Number (%) of referrals to hepatology	Number (%) seen by hepatology	Patients requiring oral antivirals
2004	25	2 (8%)	N/A	–
2005	36	7 (19%)	N/A	–
2006	29	10 (34%)	N/A	–
2007	46	22 (48%)	N/A	–
2008	39	18 (46%)	N/A	–
2009	36	21 (58%)	N/A	–
2010	45	22 (49%)	N/A	–
2011	35	33 (94%)	27 (82%)	1
2012	37	35 (95%)	31 (89%)	2
2013	45	43 (96%)	36 (84%)	2

E-mail: richie@forfey.com

Background and Aims: In developed countries hepatitis E is a porcine zoonosis caused by HEV genotype 3. In developing countries hepatitis E is mainly caused by genotype 1, and causes increased mortality in patients with pre-existing chronic liver disease which may approach 70%. Aim: determine the role of HEV in patients with decompensated chronic liver disease and/or alcoholic hepatitis.
Methods: Prospective HEV testing of 372 patients with decompensated chronic liver disease and/or alcoholic hepatitis at three UK centres and Toulouse France, with follow-up for 6 months or death. In addition, IgG seroprevalence was compared with 911 controls.
Results: 11/372 patients (2.9%) had acute hepatitis E infection, three died. There were no differences in mortality (27% vs 26%, OR1.1, 95% CI 0.28–4.2), mode of clinical presentation (p = 0.4), bilirubin (p = 0.5), ALT (p = 0.06) albumin (p = 0.5) and INR (p = 0.5) in patients with and without hepatitis E infection. Five cases were PCR positive (genotype 3). Hepatitis E was more common in Toulouse (7.9%) compared to the UK cohort (1.1%, p < 0.001). HEV IgG seroprevalence was higher in Toulouse (OR 17, 95% CI 9.6 to 31) and Truro (OR 2.6, 95% CI 1.4 to 4.7) than in Glasgow, but lower in cases, compared to controls (OR 0.59, 95% CI 0.41 to 0.85).

Case	1	2	3	4	5	6	7	8	9	10	11
Centre	Truro	Truro	Norwich	Toulouse	Toulouse	Toulouse	Toulouse	Toulouse	Toulouse	Toulouse	Toulouse
Age (years)	60	54	60	56	50	59	53	54	75	59	61
Sex	M	M	M	F	M	M	M	M	M	M	M
HEV IgG/IgM	+/+	+/+	+/+	+/+	+/+	+/+	+/+	-/+	+/+	+/+	-/+
HEV PCR	+	-	-	-	+	NA	+	-	+	-	+
Genotype	3				3		3		3		3
Bilirubin (µmol/L)	304	22	45	275	173	61	292	151	797	42	451
ALT (IU/L)	2419	10	70	129	128	129	2060	30	215	126	95
INR	1.5	0.9	1.6	2.1	NA	1.7	NA	1.6	2.3	1.2	NA
Diagnosis	dCLD	dCLD	dCLD	dCLD & AH	dCLD	dCLD	dCLD	dCLD	dCLD	dCLD	dCLD
Cause of liver disease	NASH	Alcohol	Alcohol	Alcohol	Alcohol HBV	HCV NASH	Alcohol	Alcohol	Alcohol	NASH	Alcohol
Child-Pugh	8	5	NA	11	10	10	11	8	14	10	13
Death <3 months	No	No	No	No	No	No	No	Yes	Yes	No	Yes

Conclusions: Hepatitis E occurs in a minority of patients with decompensated CLD and/or alcoholic hepatitis. The mortality is no different to the mortality in patients without hepatitis E infection. The diagnosis can only be established by a combination of serology and PCR, the yield and utility of which vary by geographical location. An early diagnosis is important as patients may respond favourably to anti-viral therapy.

P0622

EFFECTIVENESS OF SEVERAL SIMPLE AND NONINVASIVE MODELS IN ASSESSING LIVER FIBROSIS IN PATIENTS WITH CHRONIC HEPATITIS B

X. Zeng[1], y. Wang[1]. *[1]Institute for Infectious Diseases, Southwest Hospital, Third Military Medical University, Chongqing, China, chongqing, China*
E-mail: wym417@163.com

Background and Aims: The present study was conducted to investigate the influence of hepatic inflammation histologically on liver stiffness measurement (LSM) measured by FibroScan in diagnoses of liver fibrosis.
Methods: Three hundred and twenty-five patients with chronic hepatitis B (CHB), who received liver biopsy and FibroScan, were included. According to Scheuer scoring system, liver fibrosis and inflammation were divided into five stages (S0–S4) and grades (G0–G4).
Results: LSM was correlated positively with fibrosis stage and inflammatory grade (r = 0.479, P < 0.001; r = 0.522, P < 0.001, respectively). Though median value of LSM in the same fibrosis stage increased along with inflammatory grade, no significant difference was found in patients with significant fibrosis (S2–S4) (P > 0.05). In different grades of inflammation (G0/G1/G2/G3), the area under receiver operating characteristic curves of FibroScan in diagnosing significant fibrosis was 0.8267 (P < 0.001), 0.6956 (P < 0.001), 0.709 (P = 0.0012) and 0.6947 (P = 0.137), respectively.
Conclusions: LSM increased as the inflammatory grades increased, but no significant influence of inflammation on LSM in CHB patients with significant fibrosis. As for the diagnoses of significant fibrosis, FibroScan was not suitable for patients with severe hepatic inflammation.

P0623

A COMBINATION OF HEPATOCYTE DEATH BIOMARKER WITH THE MELD SCORE IMPROVES PREDICTIVE ACCURACY OF PROGNOSIS IN PATIENTS WITH HEPATITIS B VIRUS RELATED ACUTE-ON-CHRONIC LIVER FAILURE

Z. Cao[1], H. Wang[1], F. Li[1], Y. Liu[1], Q. Xie[1]. *[1]Department of infectious diseases, Shanghai jiaotong university, school of medicine, Ruijin hospital, Shanghai, China*
E-mail: estherlucifer@163.com

Background and Aims: Survival data from Asia-Pacific on Hepatiis B virus related acute-on-chronic liver failure (HBV-ACLF) patients are urgently needed to develop novel biomarkers or scoring systems to help determining when treatments such as intensive care alone, artificial liver support, or liver transplantation are optimal. Given the increasingly important roles for apoptotic and necrotic cell death in the pathogenesis of HBV-ACLF, we aimed to identify three selected potential hepatocyte death biomarkers that could be of prognostic value in HBV-ACLF patients.
Methods: In a prospective study (3/2013–8/2014), 54 ALF patients were enrolled and followed up for 3 months to identify clinical outcomes. 40 chronic hepatitis B patients and 40 healthy volunteers were recruited as controls. Serum were collected and stored upon admission of 54 ACLF patients or at the enrollment day of controls for subsequent measurements of M30-antigen, M65-antigen and HMGB1. Receiver operating characteristic (ROC) analyses were performed to compare the discrimination abilities of cell death biomarkers, MELD, MELD-sodium (MELD-NA), and Child–Pugh (CP) scores.
Results: M30-antigen, M65-antigen and HMGB1 markedly (P > 0.001 for all) elevated in HBV-ACLF patients compared with controls. The predictive accuracy of M30 (AUC: 0.86) and M65-antigen (AUC: 0.83) for lethal outcome was comparable to the

MELD score (AUC: 0.81) and better than MELD-NA (AUC: 0.78) and CP (AUC: 0.74) scores. In contrast, HMGB1 had no prognostic value (p = 0.681), neither in cirrhotic nor in non-cirrhotic HBV-ACLF patients. In order to accurately predict the clinical prognosis of HBV-ACLF patients, we test the MELD-65 index [MELD-65 = 0.000372×M65-antigen (U/L) + 0.3432×MELD score − 11.17] established by logistic regression analysis with MELD and M65-antigen remaining in the model. The new M65-based MELD score (AUC: 0.92, 95% CI 0.81 to 0.98, youden index: 0.71) provided significantly better predictive values in HBV-ACLF than MELD (AUC: 0.81, youden index: 0.6, P value vs MELD-65, P = 0.03), MELD-NA (AUC: 0.77, youden index: 0.45, P value vs MELD-65, P = 0.01) and CP (AUC: 74, youden index: 0.37, P value vs MELD-65, P = 0.02) scores.

Conclusions: The MELD-65 index, a combination of MELD score and M65-antigen, has superior predictive accuracy to MELD, MELD-NA and CTP scores for the prognosis of HBV-ACLF patients from Asia-pacific. Further prospective clinical studies are warranted to validate its role in predicting ACLF patients with other etiologies.

		AUROC (95% CI)	*p* value vs. MELD-65

ACUTE VIRAL HEPATITIS: EPIDEMIOLOGICAL CHANGE DURING THE LAST 25 YEARS IN SPAIN

M. Riveiro-Barciela[1], E. Mena[2], S. Romero[2], M. Ventura-Cots[1], J. Llaneras[1], F. Rodríguez-Frias[3,4], R. Esteban[1,4], M. Buti[1,4], Liver Unit, Internal Medicine Department, Vall d'Hebron Hospital, Barcelona.
[1]Liver Unit, Internal Medicine Department, [2]Emergency Department, [3]Liver Pathology Unit, Departments of Biochemistry and Microbiology (Virology Unit), Vall d'Hebron Hospital, Barcelona, [4]CIBERehd, Instituto de Salud Carlos III, Madrid, Spain
E-mail: mar.riveiro@gmail.com

Background and Aims: The childhood vaccination programs against hepatitis B virus (HBV) and hepatitis A (HAV) and the improvement in diagnosis of hepatitis E virus (HEV) may have changed the epidemiology of acute hepatitis in Spain. The goal of the present work is to analyze the aetiology of acute hepatitis, and to compare the epidemiologic change with an historic cohort from the same tertiary hospital.

Methods: Patients aged over 18 years old with increased ALT levels (10×ULN) admitted to a universitary hospital within October 2013 to November 2014 were prospectively included. Serological and virological tests (IgM antiHBc, HBsAg, antiHCV, HCV RNA, IgM HEV, IgM HAV) were performed in all patients without biliary obstruction or shock. Acute viral hepatitis cases were contrasted to an historic cohort from 1990 collected in the same hospital [Buti M, *et al.* J Hepatol. 1994].

Results: 124 patients were included. 54% were male, median age 46 years old [IQR 34–65]. 32 (25.8%) were diagnosed with viral hepatitis. The rest of the aetiologies were as follow: biliary obstruction (37.1%), ischemic (13.7%), toxic (10.5%), autoimmune hepatitis (9.7%) and alcoholic (3.2%). Viral hepatitis was caused by HBV (37.5%), HCV (21.9%), HEV (15.6%), EBV (9.4%), HDV (3%), HAV (3%), influenza (3%), measles (3%) and VZV (3%). In the current cohort there were 5 autochthonous cases of hepatitis E in contrast to none in the historic one, and genotype 3 was isolated in those patients with high levels of RNA HEV. In comparison with the cohort from 1990, an increase in the percentage of acute hepatitis due to HBV was observed (18%), in spite of systematic vaccination during childhood since 1992, so outside the range of age that have received HBV vaccination (Figure). There was only one acute hepatitis A, from a traveler from Morocco. 59% of acute viral hepatitis cases were admitted to hospital. 19% developed acute liver injury and 12.5% of cases died.

Conclusions: Acute viral hepatitis remains a frequent cause of admission to hospital, with a mortality rate around 12%. In contrast to 1990, there have been cases due to HEV likely due to the improvement in diagnostic tests, and also an increase in the cases due to HBV, all of them in patients older than 23 years old. This data suggests that patients older than 23 years old may benefit from HBV vaccination.

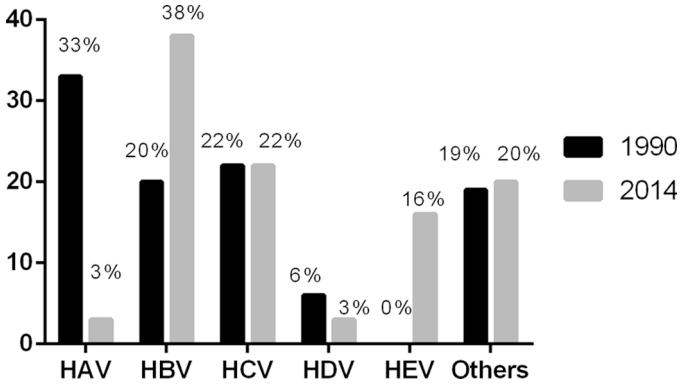

Figure: Comparison of the main causes of acute viral hepatitis.

E-mail: rsalpini@yahoo.it

Background and Aims: To investigate N-linked glycosylation patterns of HBsAg in immunosuppression-driven HBV-reactivation and to evaluate their impact on HBsAg antigenicity.
Methods: Mutations associated with the acquisition of N-glycosylation site were investigated in 127 HBsAg genotype-D sequences from 47 patients with immunosuppression-driven HBV-reactivation (defined as Hwang, 2013), and 80 chronically HBV-infected drug-naïve patients as control.
The impact of N-glycosylation sites on HBsAg antigenicity was analyzed by transfecting HepG2 cells with a plasmid encoding wild-type (wt) and mutated HBsAg-linked to a streptavidin-tag (strep-tag). The strep-tagged HBsAg amount in the supernatants was quantified by a specifically-designed ELISA recognizing the Strep region (thus, not affected by HBsAg mutations), and by two ELISAs directly targeting the HBsAg (Architect Abbott, Monolisa Biorad).
Results: Additional N-glycosylation sites are found in 19.1% (9/47) of HBV-reactivated patients versus 0/80 controls ($P < 0.001$). All of them localize in the major hydrophilic HBsAg region, target of antibodies. In 7 patients, a single additional N-glycosylation site results from the mutations T115N ($n = 2$), T123N ($n = 2$), T131N ($n = 2$), and from the insertion of an N between 114 and 115 position (ins114–115N) ($n = 1$). In the remaining 2 patients, 2 additional glycosylation sites results from the mutations S113N+T131N and ins114–115N+T117N, respectively.
Of note, 5/9 patients with ≥1 additional N-glycosylation sites result HBsAg-negative by diagnostic test at HBV-reactivation ($p = 0.002$).
In vitro, all additional N-glycosylation sites decrease the strep-tagged HBsAg quantification by the 2 ELISAs targeting the HBsAg. In particular, T115N, T123N, ins114–115N determine a >90% decrease in HBsAg quantification by both ELISAs. Similarly, ins114–115N+T117N cause a 90.2% and 75.4% reduction in HBsAg quantification, respectively. No decrease of strep-tagged HBsAg is revealed by ELISA targeting the Strep-tag. Overall results suggest that the additional N-glycosylation sites hamper HBsAg recognition by antibodies without affecting HBsAg release.
Conclusions: Additional N-glycosylation sites in the major hydrophilic HBsAg region correlate with false HBsAg negativity at ELISA despite HBV reactivation, and profoundly affect HBsAg antigenicity *in vitro*. This supports the role of immune escape mutations in HBV reactivation during immune-suppression and the importance of HBV-DNA (more than HBsAg) in the diagnosis of HBV reactivation

P0626

THE ANALYSIS OF THE EXPRESSION OF A2M, COL1A1, MMP2 AND CHI3L IDENTIFIES SIGNIFICANT FIBROSIS IN PATIENTS WITH CHRONIC HEPATITIS B

E. Estrabaud[1], R. Carvalho-Filho[1], O. Lada[1], C. Laouenan[2], A.C. Ferreira Netto Cardoso[1], M. Martinot-Peignoux[1], I. Bieche[3], M. Lapalus[1], M. Vidaud[3], T. Asselah[1,4], P. Marcellin[1,4]. *[1]INSERM UMR1149, [2]INSERM, IAME, UMR 1137, [3]UMR745 INSERM, Université Paris Descartes, Paris, [4]Service d'Hépatologie, Hôpital Beaujon, Clichy, France*
E-mail: emilie.estrabaud@inserm.fr

Background and Aims: Chronic hepatitis B (CHB) remains a major health problem affecting approximately 350 millions people worldwide. Staging liver fibrosis is crucial in patients with CHB because it reflects the progression of the disease. The aim of the study was to identify differential liver gene expression between no and mild fibrosis (Metavir F0–F1) and moderate, severe fibrosis and cirrhosis (F2–F4), in a large cohort of unselected and treatment-naïve patients with CHB.
Methods: The expression of 102 genes was assessed in liver biopsies of 46 patients with CHB. Twenty-nine patients were HbeAg positive. Fibrosis was staged according to the Metavir score system (F0 to F4); 19 patients had no or mild fibrosis (F0 and F1) and 27 had moderate, severe fibrosis or cirrhosis (F2, F3 or F4). Genes with significant difference of expression, were assessed in liver biopsies of 144 patients with CHB (72 F0–F1 and 72 F2–F4), in an independent set of experiment. In this group, 100 patients were HbeAg positive. Gene expression was assessed by RT-qPCR.
Results: From the 102 genes studied, in the first group of 46 patients, 35 and 7 were respectively up-regulated and down-regulated in patients with F2–F4 compared to patients with F0–F1 ($p < 0.05$). In the second set of experiment, from the 42 genes studied, 16 were differentially expressed between F0–F1 and F2–4 ($p < 0.05$) (A2M, CCL4, CDKN1A, CHI3L1, CLDN4, CLL21, COL1A1, COL4A1, SCXL10, IL8, ILB, ITGAV, MMP2, MMP7, TGFB and VIM) In multivariate analysis, A2M ($p < 0.0001$), COL1A1 ($p = 0.060$), MMP2 ($p = 0.0141$) and CHI3L1 ($p = 0.0141$) were all up-regulated in patients with F2–F4 as compared to those with F0–F1. The model combining A2M, COL1A1, MMP2 and CHI3L1 discriminates patients with F0–F1 from those with F2–F4 with and AUC of 0.85 (95% CI: 0.79–0.91), a sensitivity of 70.5% a specificity of 80.8%, a positive predictive value of 79.7% and a negative predictive value of 72.0%. Interestingly, with an OR <1, the over-expression of MMP2 protects against significant fibrosis (F2F4).
Conclusions: We identified a model including 3 genes (A2M, COL1A1 and MMP2) known to play important roles during fibrosis. In patients with CHB, the assessment of A2M, COL1A1, MMP2 and CHI3L1 may help to distinguish patients with F0–F1 from those with F2–F4.

MONOCLONAL GAMMOPATHY IN PATIENTS WITH ACUTE HEPATITIS E AND OTHER CAUSES OF ACUTE VIRAL HEPATITIS

K.L. Woolson[1], A. Forbes[2], R.G. Madden[1], P. Oppong[1], J.G. Hunter[1], R. Martin[1], R.P. Bendall[3], J. Palmer[4], B. Haywood[5], H.R. Dalton[1]. *[1]Cornwall Gastrointestinal Unit, [2]Department of Haematology, [3]Clinical Microbiology, [4]Research, Development and Innovation, Royal Cornwall Hospital, Truro, [5]Virus Reference Department, Microbiology Services, Public Health England, Colindale, London, United Kingdom*
E-mail: kathy.woolson@nhs.net

Background and Aims: Hepatitis E virus (HEV) may be associated with serum monoclonal paraprotein (M-protein) production. It is unknown if M-protein is found in other causes of acute hepatitis.
Methods: We retrospectively compared M-protein prevalence at diagnosis in 46 patients with acute HEV and 54 cases of acute viral hepatitis caused by other agents (hepatitis A, B, C, CMV and EBV)

from 1054 consecutive patients presenting to a fast-track jaundice clinic over a 16 year period.
Results: M-protein was found in 10/39 (25.6%) of patients with HEV, but 0/37 (0%) of other causes of viral hepatitis (p = 0.001). M-proteins were IgG and/or IgM with a median concentration of 2.63 g/L (range from too small for accurate quantitation to 10.6 g/L). Follow up (n = 6, median 42.5 months) showed M-protein disappearance (n = 4), too small for accurate quantification (n = 1) or persistence at 54 months (n = 1). Compared to the comparator group, patients with HEV were older (p < 0.01). None were immunocompromised and all demonstrated HEV genotype 3 (when sequencing data was available) with close sequence homology (figure).
Conclusions: M-protein is commonly associated with acute hepatitis E infection, but not with other causes of viral hepatitis. The clinical significance of this observation remains uncertain and merits further study, particularly with regard to the risk of future lymphoid malignancy.

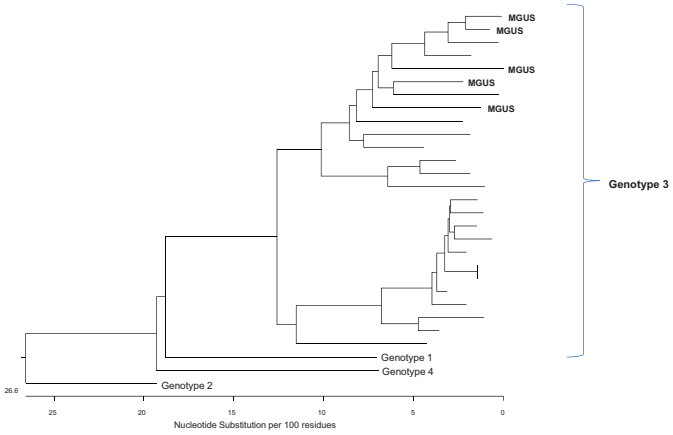

Figure: Phylogenetic tree of sequenced HEV in the patient cohort.

E-mail: marianna.aragri@libero.it

Background and Aims: To characterize HBV RT and HBsAg quasispecies heterogeneity in acute HBV (AHB) infected patients and to define their clinical value.
Methods: 62 HBsAg+ and IgM/anti-HBc+ patients with clinical and biochemical signs of AHB (44 HBV genotype [gen] D and 18 gen A) were enrolled from 2000 to 2010. Plasma samples obtained at first observation were analyzed by Ultra-deep sequencing (UDPS) for drug-resistance (DR) and immune-escape mutations. Shannon Entropy, weighted for intra-patient prevalence of each mutated position (Sn), was used to measure the extent of HBsAg amino acid (aa) variability.
Results: 75.8% of patients were male with median (IQR) age of 36 (29–46) years. Median (IQR) ALT and HBV-DNA were 2,544 (1,938–3,078) U/L and 5.9 (4.5–7.4) log10 IU/ml. 61/62 (98.4%) patients became HBsAg negative with 33/61 (54.1%) developing also anti-HBs.
By UDPS, 8.1% (5/62) of patients carried >1 DR mutation (rtV173L/rtL180M/rtA181T/rtA194T/rtM204I). In particular, A181T was detected with an intra-patient prevalence of 0.1% and 47.5%, while both A194T and M204I were found at a prevalence of 0.2%. Compensatory mutations were detected with an intra-patient prevalence of 10.5% and 63.5% for V173L and, 99.9% for L180M.
Analysing HBsAg a-determinant, 48.4% (30/62) of patients carried /1 immune-escape mutation (intra-patient prevalence range: 0.2–100%). Vaccine-escape mutations were found in 11.4% of patients, all gen D-infected. This is the case of sG145R, sM133L, and sP120S, detected with an intra-patient prevalence ranging from 3.9% to 99.9% for sG145R, from 1.9% to 16.8% for sM133L, and always of 100% for sP120S.
Stop-codons were found in 19.3% patients (intra-patient prevalence range: 1.6–47.5%). They occurred at 11 HBsAg positions including also 172 and 182, known to increase HBV oncogenic potential.
Finally, by Shannon Entropy, specific HBsAg aa positions were associated with the lack of HBsAg seroconversion in gen D. In particular, aa positions 130 and 133 (localized in HLA class II epitope) were found mutated only in patients not developing anti-HBs (Sn, mean±SE:1.98±0.01 vs 0, and 1.95±0.03 vs 0, respectively, P < 0.05).
Conclusions: AHB is characterized by a complex coexistence of viral quasispecies, some of them with reduced antigenicity/immunogenicity, enhanced oncogenic-potential and altered drug-susceptibility. These viral variants may induce severe and/or difficult-to-treat forms of HBV infection (es. HBV reactivation), and might affect the efficacy of current HBV vaccination strategy.

P0629
FIRST DETECTION OF GENOTYPE 3 AND 4 HEPATITIS E VIRUS (HEV) RNA AMONG THE GENERAL POPULATION IN CAMBODIA: FULL-LENGTH SEQUENCE OF HEV ISOLATE, PREVALENCE AND INCIDENCE OF HEV INFECTION WERE CLARIFIED BASED ON THE SERO-EPIDEMIOLOGICAL STUDY
H. Yamada[1], K. Takahashi[2], O. Lim[3], J. Matsuo[1], T. Kaishima[1], T. Fujii[1], K. Katayama[1], S. Svay[3], J. Tanaka[1]. *[1]Department of Epidemiology Infectious Disease Control and Prevention, Hiroshima University Institute of Biomedical and Health Sciences, Hiroshima, [2]Department of Medical Sciences, Toshiba General Hospital, Tokyo, Japan; [3]Ministry of Health, Phnom Penh, Cambodia*
E-mail: jun-tanaka@hiroshima-u.ac.jp

Background and Aims: In Cambodia, one of the developing countries in Asia, hepatitis E virus (HEV) infection might remain an important health problem. However, few data are known about that in the country. Therefore, we investigated the HEV infection on seroprevalence, incidence, and genotypic distribution among the general population in Siem Reap province. Based on the results, we aim to consider the prevention strategy in cooperation with Ministry of Health in Cambodia.
Methods: This study was approved by the Ethics Committee for epidemiological research of Hiroshima University in Japan and that of Ministry of Health in Cambodia. We conducted the survey after obtaining written informed consents from all participants. Sero-epidemiological study, which consisted of questionnaires and taking blood samples for determining hepatitis virus infections, was performed from 2010 to 2014 among the general population in Siem Reap province. New HEV infection among the elementary school students was diagnosed who turned positive for IgG HEV antibody (anti-HEV IgG) during the observation period.
Results: For the prevalence, total participants were 857, comprising 355 males (41.4%) and 502 females (59.8%). Age distribution was from 7 to 90 years old as of 2013. Mean age was 30.7±18.7 years old. The prevalence of anti-HEV IgG was 18.7% (160/857; [95% CI: 16.1–21.3%]) and significantly higher in males (22.3% [17.9–26.6%]) than in females (16.1% [12.9–19.4%]) ($p = 0.0236$). Moreover, it showed the

trend that the older the age, the higher the positive rate ($p < 0.0001$). HEV RNA was detected in 2 (0.23% [0–0.56%]) participants. One of them could be sequenced over the entire genome and classified as genotype 4. This isolate was close to the swine China strain (swGX40) with 95.6% identity, and had the same length of ORF1, ORF2, and ORF3 as swGX40 and coded for 1,705, 674, and 114 amino acids, respectively. Another HEV RNA positive sample was classified as genotype 3 from a partial ORF1 genome sequence. New HEV infection developed in 1 of the 54 subjects (19 males and 35 females) who participated in our survey twice. The incidence of HEV infection was calculated to be 6.43/1,000 person-years [0.16–35.8/1,000 person-years].
Conclusions: Our study showed that the new HEV infection occurred frequently among the general population in Cambodia. This is the first report that HEV genotype 3 and 4 detected from people living in Cambodia.

P0630
VIROLOGIC CHARACTERIZATION AND ASSOCIATION WITH DISEASE PROGRESSION IN CHILDREN WITH HEPATITIS B VIRUS BCP/PC MUTANTS

Y. Zhong[1], H. Zhang[1], S. Zhu[1], Y. Dong[1], Z. Xu[1], D. Chen[1]. [1]*Pediatric Liver Disease Therapy and Research Center, 302 Hospital, Beijing, China*
E-mail: zhongyanwei@126.com

Background and Aims: To investigate the virologic characterization and association with disease progression in children with hepatitis B virus BCP/PC mutants.
Methods: A total of 307 patients with HBV infection, including 88 with hepatitis B related liver cirrhosis and 219 with CHB were enrolled. The HBV genotypes and the oresence of mutations in the BCP/PC regions were determined by direct sequencing. Biochemical and serological parameters as well as HBV DNA levels were routinely performed. Mutations at 11 interested sites of the BCP/PC regions were compared among the two groups of patients.
Results: 46/307 (14.98%) were infected with genotype B and 261/307 (85.02%) with genotype C. LC and CHB patients both had a significantly higher ratio of genotype C to B (81.9% > 18.1% vs 70.1% > 29.9%). The prevalence of BCP/PC wild-type virus was 54.3% in CHB patients in contrast to 4.8% in LC patients. In genotype C patients, the C1653T, T1753C, A1762T, G1764A, G1896A mutations were significantly higher prevalent in LC patients. Genotype B virus had higher 1752 mutation frequency. Genotype C virus had higher prevalence of T1753C, T1758C, A1762T, G1764A, G1896A mutation frequency compared to genotype B virus. CHB patients with BCP/PC mutant virus had higher viral load, whereas LC patients with BCP/PC mutant virus had higher viral load and elevated alanine aminotransferase in comparison with those with the wild type virus.
Conclusions: Children patients with HBV genotype C virus infection, BCP/PC C1653T, A1762T/G1764A, G1896A mutant were more susceptible to develop LC, whereas high prevalence of the BCP/PC mutations was associated with CHB progression.

P0631
THE HEPATITIS E VIRUS GENOTYPE 2 JUNCTION VARIANT RESTORES THE CREX 'STEM-LOOP' STRUCTURAL INTEGRITY, ESSENTIAL FOR VIRAL LIFE CYCLE

M.K. Parvez[1]. [1]*Department of Pharmacognosy, King saud University College of Pharmacy, Riyadh, Saudi Arabia*
E-mail: khalid_parvez@yahoo.com

Background and Aims: Of the human hepatitis E virus (HEV) strains (genotypes 1–4), the Mexican (genotype 2) isolate has two 'double-base' substitutions (5′U5100G5101→CU/3′C5117U5118→GG) flanking the conserved cis-reactive element (CRE) in the ORF1–ORF3 junction sequences. While 'CU' mutations in the 5′ ORF1 coding-region replaces 'Ala' for 'Val', 'GG' resides in the 3′ ORF3 promoter-region. In this study therefore, the evolutionary significance of such tolerable mutations in the conserved sequences was investigated.
Methods: GeneBank sequences (n = 77) of human HEV junction-region (nt. 5099–5121) including CRE and flanking bases (named, CREX) were analyzed in silico. Study sequences of SAR55, Mexican, Swine and T1 strains representing genotypes 1–4, were subjected to RNA structural analysis. Virtual mutations (μ1-U5118G and μ2-C5117A/U5118G) were introduced to break the 'C:G' and 'U:G' parings in the CREX 'stem-loop'. CREX mutants were constructed in SAR55 replicon (pSK-GFP) and tested in S10-3 cells. Further, trans-encapsidation of mutant-RNA in baculovirus-expressed capsid proteins were performed, followed by virion infectivity assay in naïve HepG2 cells. ORF2 productions in S10-cells were confirmed by immune-staining, and GFP +ve cells were scored by FACS to quantify the replication and packaging fitness of mutant RNA.
Results: Analysis of the conserved sequences (nts. 5099–5121) of the four genotypes revealed a stable CREX 'stem-loop' structure. Of these, the Mexican mutant bases 'CU/UG' very interestingly, compensated and complemented themselves (5′C5100:3′G5118 and 5′U5101:3′G5117) in the CREX 'lower-stem'. Substitution of 'GG' in the ORF3 promoter-region however, did not affect its 'optimal-context'. Virtual mutations introduced to break the two base-pairings in the CREX 'lower-stem', completely destabilized the secondary structure. At day 6, FACS analysis scored a remarkable reduction in the GFP +ve cells harboring CREX-μ1 (~62%) and CREX-μ2 (~75%) RNA. Further, the two mutant-virions produced in S10-3 cells when infected to naïve cells, showed a remarkable 3- and 6-fold reduction in GFP production, respectively. While the infectivity of the mutant virions were comparable they were poorly infectious (~33%) compared to the wild-type particles.
Conclusions: The compensatory mutations in the intergenic-junction of Mexican isolate suggest strict conservation of the CREX 'stem-loop' structure, essential for HEV genome replication. This could have a greater regulatory role in viral life cycle, including RNA packaging.

Viral hepatitis: Hepatitis B & D – c. Clinical (therapy, new compounds, resistance)

BISPECIFIC ANTIBODY CONSTRUCTS MEDIATE SPECIFIC RETARGETING TOWARDS AND ELIMINATION OF HBV-POSITIVE HEPATOCYTES AND TUMOR CELLS

F. Bohne[1], J. Hasreiter[1], O. Quitt[1], J.-H. Bockmann[1], F. Momburg[2], U. Protzer[1]. [1]*Institute of Virology, Technische Universität München/Helmholtz Zentrum München, Munich,* [2]*National Center for Tumor Diseases, German Cancer Research Center (DKFZ), Heidelberg, Germany*
E-mail: felix.bohne@tum.de

Background and Aims: Chronic hepatitis B is characterized by exhausted effector cells, incapable of eradicating the virus. To circumvent this limitation, HBV-specific retargeting of immune effector cells using bispecific monoclonal antibody (biMab) constructs is a promising therapeutic approach. In this study, effector cells are supplied with biMab that redirect T cells cells towards HBV infected cells and activate their cytotoxic potential.
Methods: We constructed tetravalent biMab harboring two single chain fragment (scFv) binding domains. The first scFv was designed to target the S-domain of HBV-envelope proteins (HBs) on the

plasma membrane of infected hepatocytes. The second binding motif engages T-cells via CD3 and co-stimulates them via CD28. The two binding moieties are connected through an IgG1-derived Fc-domain and dimerizes through disulfide bonding in the hinge region. This results in tetravalent homodimers comprising two scFv-binders for the target antigen and two for effector cell recruitment.
Results: In co-culture experiments, the engagement of HBV-positive hepatocytes and immune effector cells by the biMab induced specific elimination of target cells and activation of effector cells. Co-administration of HBs/CD3- and HBs/CD28-specific biMab constructs was synergistic and mediated up to 96% specific elimination of HBs-positive target cells in co-cultures with PBMC. Flow cytometric analysis of cytokine production showed, that retargeted effector cells were polyfunctionally activated by the biMab and secreted IFNγ, IL-2 and TNFα simultaneously. Importantly, biMab were also able to redirect T cells to HBV-infected HepaRG cell resulting in specific killing. Furthermore, soluble HBs, mimicking the high viral loads in patient serum failed to induce effector cell activation even when added to non-infected cells. Finally, first *in vivo* experiments in immunodeficient mice transplanted with HBV-positive hepatoma cells showed that transferred human PBMC mediated a marked decrease in tumor size upon biMab injection indicating a functional homing in tumors.
Conclusions: Retargeting of T cells towards HBV-positive cells using bispecific antibody constructs is a promising new immunotherapeutic approach to treat chronic hepatitis B and associated hepatocellular carcinoma.

P0633
ASSOCIATION OF HEPATITIS B VIRUS GENETIC DIVERSITY WITH TENOFOVIR DISOPROXIL FUMARATE RESPONSE RATES IN IMMUNE TOLERANT CHRONIC HEPATITIS B PATIENTS

J. Lara[1], H. Thai[1], K. Kitrinos[2], G. Xia[1], A. Gaggar[2], M. Paulson[2], L. Ganova-Raeva[1], Y. Khudyakov[1]. *[1]Division of Viral Hepatitis, Centers for Disease Control, Atlanta, [2]Gilead Sciences, Foster City, United States*
E-mail: katie.kitrinos@gilead.com

Background and Aims: Tenofovir disoproxil fumarate (TDF) is a nucleotide analogue reverse transcriptase (RT) inhibitor for the treatment of hepatitis B virus (HBV)-infected patients. TDF resistance has not been reported; however, varying viral suppression rates are observed among TDF-treated patients. We examined the association of HBV genetic diversity with response to TDF treatment in immune tolerant patients.
Methods: Study GS-US-203-0101 evaluated TDF in immune tolerant patients. 10 patients with genotypes (GT) B (n = 3), C (n = 6) and E (n = 1) were evaluated at baseline, week 4 and week 40. Five patients had a slow response (SR), never achieving HBV DNA <400 copies/mL, while 5 had a rapid response (RR), achieving HBV DNA <400 copies/mL by week 96. Patients were matched by baseline HBV DNA and ALT. Whole-genome sequences of HBV quasispecies (QS) were obtained using end-point limiting-dilution real-time PCR coupled with sequencing. Genetic diversity was evaluated using phylogenetic trees and median joining networks. Associations between amino acid (aa) or nucleotide (nt) substitutions and SR/RR to TDF treatment was examined with feature selection protocols, Bayesian Networks (BN), Artificial Neural Networks, Linear Projection techniques and multidimensional scaling.
Results: 1288 whole-genome QS were sequenced. Significant changes in the on-treatment intra-host population structure compared to baseline were observed in SR but not RR patients, suggesting differential TDF sensitivity of HBV QS. No association was found between TDF response and HBV RT substitutions. Of the 2033 substitutions evaluated, two nt substitutions in GT C RNase H (nt 1223 and 1322) were correlated among the 6 GT C patients ($R = 1.0$, $p = 0.1$) with SR/RR; this correlation was not observed for GT B or E. BN analysis revealed tight coevolution among HBV nt substitutions, with 16 nt across the Core, X, P, and S genes associated with SR/RR. Using these positions, the BN model classified HBV variants from these 10 patients into SR and RR classes with 99.7% accuracy (95% CI 99.4–100) in leave-one-out cross-validation tests.
Conclusions: We have studied a potential prediction model based on 16 nt substitutions in 10 patients across the HBV genome for response to TDF treatment. The contribution of nt substitutions to TDF response varied among HBV genotypes and was not localized to RT but involved the entire HBV genome. A larger patient set needs to be evaluated to confirm these findings.

P0634
PEGINTERFERON IS SUPERIOR TO NUCLEOS(T)IDE ANALOGS FOR PREVENTION OF HEPATOCELLULAR CARCINOMA IN CHRONIC HEPATITIS B

K.-H. Liang[1], C.-W. Hsu[1], M.-L. Chang[1], Y.-C. Chen[1], M.-W. Lai[1], C.-T. Yeh[1]. *[1]Liver Research Center, Chang Gung Memorial Hospital, Taipei, Taiwan*
E-mail: kunghao@gmail.com

Background and Aims: Clinical and virological factors associated with occurrence of hepatocellular carcinoma (HCC) in antiviral-treatment-naïve chronic hepatitis B patients have been extensively studied. However, the clinical usefulness of such data is greatly limited because of the wide availability of effective antiviral agents. We aimed to investigate clinical factors associated with HCC development in treatment-experienced patients.
Methods: 331 patients receiving pre-therapeutic liver biopsy were included for outcome assessment. Predictors for HCC occurrence were further analyzed by comparing two age-matched groups receiving different treatment methods.
Results: Cirrhosis and antiviral treatment method [peginterferon-experienced (PE) versus nucleos(t)ide analog-treatment (NAt) only] were significantly associated with subsequent HCC occurrence by initial univariate and multivariate analyses. To further examine this unexpected finding, 120 age-matched patients were retrieved from each of the PE and NAt groups for comparison. Baseline clinical variables showed no statistical difference between the two treatment groups. PE group had a significant longer time to HCC than the NAt group ($P = 0.0091$). The beneficial effect of peginterferon treatment remained when only cirrhotic patients were included ($P = 0.0437$). Additionally, patients receiving peginterferon alone had a significantly longer time to HCC than those receiving entecavir alone ($P = 0.0111$), despite the fact that serum HBV DNA levels of the entecavir-treated subjects were kept lower than those treated by peginterferon alone during the observational period ($P < 0.0001$).
Conclusions: Peginterferon treatment with or without nucleos(t)ide analog is superior to nucleos(t)ide analogs alone for the prevention of HCC occurrence in chronic hepatitis B patients.

P0635
CHRONIC HEPATITIS B TREATMENT INDIVIDUALIZATION BY MEANS OF SERUM HBsAg AND MiR-B-INDEX KINETICS

D. Cavallone[1], F. Oliveri[1], P. Colombatto[1], B. Coco[1], P. Ciccorossi[1], V. Romagnoli[1], B. Cherubini[1], F. Moriconi[1], B. Ferruccio[2], M.R. Brunetto[1]. *[1]Hepatology Unit, Reference Center of the Tuscany Region for Chronic Liver Disease and Cancer, [2]Digestive and Liver Disease, General Medicine II Unit, University Hospital Pisa, Pisa, Italy*
E-mail: brunetto@med-club.com

Background and Aims: Non-viral biomarkers of sustained control of HBV infection are an unmet need for treatment individualization in Chronic Hepatitis B (CHB). We recently reported that Inactive Carriers (IC) and patients with sustained-virologic-response (SVR) to Peg-IFN share a common serum miRNA signature (MiR-B-Index,

Table (abstract P0635).

MBI). We studied the kinetics of MBI and HBsAg during and after Peg-IFN.

Methods: 46 CHB patients (11 HBeAg pos, 29 males, median age 48.6 y, range 22.4–64.1 y; genotypes: A 5, D 39, F 2) were treated with Peg-IFN2a 180 μg/w (median 13.2 months, 8–24 mo): 20 SVR; 17 relapsers (REL) and 9 non-responders (NR). Single RT-q-PCR for miR-122-5p, miR-99a-5p, miR-192-5p, miR-126-3p, miR-335-5p and miR-320a were performed using miRCURY RNA Isolation kit, miRCURY-LNA™ Universal-RT-cDNA-Synthesis and RT-miRNA-PCR (Exiqon-A/S). HBV-DNA and HBsAg were quantified by COBAS TaqMan (Roche) and Architect (Abbott). HBsAg and MBI were tested at baseline (BL), 24–48 wks and end of therapy (EOT) and 24 wks post treatment (PTFU).

Results: Median HBsAg and MBI values at the different time points in overall patients, HBeAg pos and neg are reported in the table. MBI values >−1.7 were found: at BL in 5 HBeAg neg pts (4 SVR, 1 NR); at EOT in 14/19 (73.7%) SVR (4 HBeAg pos, 10 HBeAg neg) and at PTFU in all SVR, but in 1 NR and 1 REL only. In HBeAg neg pts at EOT MBI values ≥−3.0 and HBsAg <1000 IU/mL had 100–93.3% sens., 94.7–85.0% spec., 93.3–82.4% PPV, 100–94.4% NPV and 97.0–88.6% DA in identification of SVR (AUROC 0.988 and 0.951 respectively).

Conclusions: Both HBsAg and MBI show good performances in SVR prediction overall. In HBeAg neg CHB MBI predicts SVR since therapy beginning and identifies all SVR at EOT qualifying as the best biomarker for individual therapy monitoring.

P0636

ANTIVIRAL EFFICACY AND INDUCTION OF HOST IMMUNE RESPONSES WITH SB 9200, AN ORAL PRODRUG OF THE DINUCLEOTIDE SB 9000, IN THE WOODCHUCK MODEL OF CHRONIC HEPATITIS B VIRUS (HBV) INFECTION

K. Korolowicz[1], S. Czerwinski[1], R. Iyer[2], J. Skell[2], J. Yang[1], R. Tucker[3], S. Menne[1]. *[1]Microbiology and Immunology, Georgetown University Medical Center, Washington, DC, [2]Spring Bank Pharmaceuticals, Milford, MA, [3]3Department of Comparative Medicine, Georgetown University Medical Center, Washington, DC, United States*
E-mail: sm923@georgetown.edu

Background and Aims: Activation of the viral sensor proteins, RIG-I and NOD2, by viral nucleic acids results in the production of type I IFNs and subsequent induction of ISGs and antiviral immune cells. SB 9200, an oral prodrug of the dinucleotide SB 9000, activates RIG-I and NOD2 by binding at the nucleotide binding domain of both proteins. This interaction also inhibits the synthesis of viral nucleic acids by steric blockage of the viral polymerase. The host immune stimulating and direct antiviral activities of SB 9200 were evaluated in the woodchuck model of chronic HBV infection. SB 9200 is being developed for the treatment of chronic hepatitis B and C and has completed Phase I clinical trials in treatment-naive HCV-infected patients.

Methods: Two groups of woodchucks with chronic woodchuck hepatitis virus (WHV) infection (n = 5/group) were treated orally, daily with SB 9200 for 12 weeks at doses of 15 or 30 mg/kg. Endpoints included PK, PD, tolerability, and antiviral efficacy.

Results: Treatment with SB 9200 at two select dose levels resulted in up to 4.2 and 2.2 log_{10} reductions in serum WHV DNA or WHV surface antigen (WHsAg) loads, respectively, from pretreatment level. Treatment was also associated with reduced hepatic levels of WHV DNA (up to 41%), WHV cccDNA (up to 32%), and WHV RNA (up to 50%), lower hepatic expression of WHV antigens, and reduced liver disease progression. Following cessation of treatment, recrudescence of WHV replication was observed in all woodchucks treated with 15 mg/kg, whereas woodchucks administered 30 mg/kg had delays in the relapse of serum WHV DNA and WHsAg. The development of an anti-WHs antibody response was not observed. The antiviral effects were associated with a dose-dependent induction of IFNs (IFN-α, IFN-β) and ISGs (OAS-1, CXCL10, ISG15) in blood and liver. Prolonged SB 9200 administration at both dose levels was well tolerated with CBC, hematology and serum biochemistry parameters all appearing normal through the treatment period.

Conclusions: Oral administration of SB 9200 for 12 weeks in woodchucks with chronic WHV infection resulted in marked reductions in serum and hepatic levels of viral DNA, RNA, and antigens that were associated with (or were a result of) the induction of host immune responses. These results suggest that SB 9200 can induce an antiviral immune response during chronic active hepadnaviral infection that has the potential for a functional cure in the treatment of chronic hepatitis B, most likely in combination with approved anti-HBV drugs.

P0637

SHORT-TERM ANTIVIRAL PROPHYLAXIS IS NOT EFFECTIVE IN HBsAg-NEGATIVE, ANTI-HBc POSITIVE, AND/OR ANTI-HBs PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION

Y.J. Kim[1], M. Lee[1], Y.Y. Cho[1], J.-J. Yoo[1], Y. Cho[1], D.H. Lee[1], H. Cho[1], E.J. Cho[1], J.-H. Lee[1], S.J. Yu[1], J.-H. Yoon[1], H.-S. Lee[1]. *[1]Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, Seoul, Korea, South*
E-mail: yoonjun@snu.ac.kr

Background and Aims: Hepatitis B virus (HBV) reactivation can occur in persons who are hepatitis B surface antigen (HBsAg)-negative but hepatitis B core antibody (anti-HBc) positive, especially in patients receiving bone marrow or stem cell transplantation.

However, data are scarce regarding universal use of the prophylactic antiviral agents or optimal duration of prophylaxis to date. In this study, we compared the frequency of hepatitis B reactivation between prophylactic group and non-prophylactic group in hematopoietic stem cell transplantation patients.

Methods: From January 2008 to December 2013, a total of 315 HBsAg-negative, anti-HBc positive patients were enrolled who receive autologous or allogenic stem cell transplantation. Patients were divided into prophylactic and non-prophylactic groups. The primary endpoint was the incidence of HBV reactivation, which was defined as a increase in HBV DNA 10 times than baseline or HBsAg-reverse seroconversion.

Results: The median age of patients was 49.7 years (range, 16–71), and 181 (57.5%) were male. Among the patients, 219 (69.5%) did not take prophylaxis, and 96 (30.5%) underwent prophylaxis as follows: 90 to telbivudine; 5 to entecavir; 1 to lamivudine, respectively. Of these, 12 patients developed HBV reactivation (prophylactic group, 4; non-prophylactic group, 8). The median time to reactivation was 20.5 months (range, 10.0–39.0) after the initiation of chemotherapy. All of the patients were successfully treated with telbivudine, entecavir or tenofovir, and none of them experienced liver-related death. The risk of reactivation was not different between prophylactic and non-prophylactic group ($P = 0.061$).

Conclusions: HBV reactivation in HBsAg-negative, anti-HBc positive patients undergoing hematopoietic stem cell transplantation is not rare. However, all cases were successfully treated with on-demand antiviral agents without serious liver problems, including hepatic failure and death. Antiviral prophylaxis against HBV reactivation was not effective, especially in the short-term duration (<12 months). Therefore, careful monitoring of HBV DNA and on-demand antiviral treatment would be safe and cost-effective rather than routine prophylaxis in these patients.

P0638

GLOBAL EPIDEMIOLOGY OF HEPATITIS DELTA: FIRST DATA FROM THE HEPATITIS DELTA INTERNATIONAL NETWORK

E-mail: hardtke.svenja@mh-hannover.de

Background and Aims: Hepatitis D virus (HDV) infection is the most severe form of chronic viral hepatitis associated with accelerated fibrosis progression and an increased risk for developing liver-related clinical complications. However, the clinical and virological presentation of hepatitis delta patients varies largely between different regions and countries. The Hepatitis Delta International Network (HDIN) was established in 2011 and granted with an EASL registry award in 2014.

Methods: The primary aim of the HDIN registry is to establish a large global data base of patients chronically infected with HDV to better define the course of hepatitis delta and response to antiviral therapy in the context of different HDV and HBV genotypes and diverse host genetic and environmental backgrounds. A structured eCRF optimized for hepatitis delta was implemented and 12 centers world-wide are participating. We here report data of the first 674 patients included until November 1st 2014.

Results: 85% of patients were HDV RNA positive, 75% HBeAg-negative and 37% had liver cirrhosis with 10.9% reporting an episode of previous hepatic decompensation. Patients were divided according to the country of birth into Eastern Mediterranean (EM, n = 152), Eastern Europe and Central Asia (EE/CA, n = 158), Central and Southern Europe (CE, n = 40), South Asian (SA, mainly Pakistan; n = 242) and Africa/South America (AF/SA, n = 50). The mean patient age differed largely between regions with patients from SA being more than 10 years younger than EE/CA and EM patients (SA mean age 35.9 years vs. EE/CA 47.0 years and EM 49.7 years) while CE patients were oldest with a median age of 54.1 years ($P < 0.001$). Gender distribution of patients included in the registry differed largely with patients being male ranging from 46.8% (EE) to 82.4% (CA). Previous antiviral therapy was reported for only 37% of patients (48–70% for European patients vs. 33.5% SA vs. Brazil 5%). Patients receiving polymerase inhibitors vary from 2.48% (SA) to 13.82% (EM) and different types of IFNa from 4% (AF/SA) to 22.15% (EE/CA). Liver cirrhosis was most frequent in CE and EM patients (47.5% and 52.63% vs. 28.93% SA, 31% EE/CA and 12% AF/SA).

Conclusions: The HDIN registry confirms the severity of chronic hepatitis delta but also highlights the diversity of patient characteristics in different regions world-wide – possibly requiring different management strategies. More detailed data on virological and clinical characteristics will be presented at the ILC.

P0639

TELBIVUDINE VERSUS TENOFOVIR-BASED TREATMENT OPTIMISATION STRATEGY IN HBeAg-NEGATIVE CHRONIC HEPATITIS B PATIENTS

Z. Krastev[1], I. Kotzev[2], M.K. Celen[3], D. McNeeley[4], K. Hamed[5].

[1]Clinic of Gastroenterology, University Hospital "Sv. Ivan Rilski", Sofia, [2]Clinic of Gastroenterology, University Hospital "Sv. Marina", Varna, Bulgaria; [3]Department of Infectious Diseases, Dicle University School of Medicine, Diyarbakir, Turkey; [4]Established Medicines Dev Franchise, [5]Global Medical Affairs, Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States

E-mail: zahkrastev@gmail.com

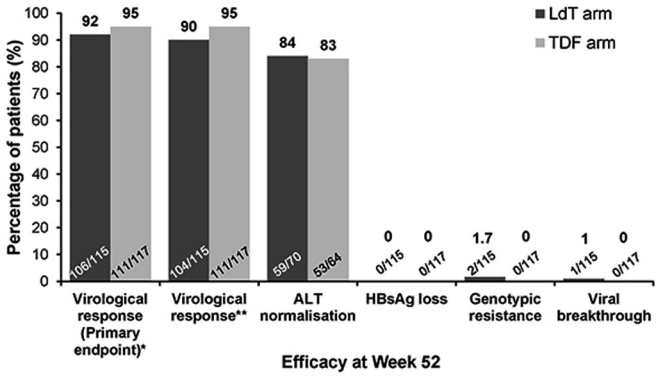
Background and Aims: Chronic hepatitis B (CHB) is a common global health problem. Early virological response with antiviral treatment with telbivudine (LdT), particularly at week 24, is associated with better long-term treatment outcomes in CHB patients. This study evaluated the treatment outcomes of conditional intensification of LdT monotherapy with tenofovir (TDF) in HBeAg-negative CHB patients.

Methods: Patients were randomised (1:1) to receive LdT 600 mg q.d. or TDF 300 mg q.d. in this prospective, open-label study. After LdT or TDF monotherapy for 24 weeks, patients with HBV DNA ≥300 copies/mL received TDF/LdT add-on therapy until week 104, whereas those with <300 copies/mL continued monotherapy. The modified intent-to-treat (mITT) population comprised patients who did not discontinue before and had not received add-on therapy at week 24.

Results: Of the 241 randomised patients (LdT, 121; TDF, 120), 232 (LdT, 115; TDF, 117) were included in the mITT population. Overall, 80% and 89.7% of patients on LdT and TDF had early virological response (HBV DNA level <300 copies/mL) at week 24. In total, 92% and 95% of patients on LdT and TDF achieved HBV DNA

levels <300 copies/mL at week 52; primary efficacy endpoint for non-inferiority (margin −10%) was met [difference in percentages (95% CI): −2.9% (−9.1, 3.4)] (figure). Among those patients who were suboptimal responders (HBV DNA ≥300 copies/mL) at week 24 and received add-on treatments, HBV DNA level decreased to <169 copies/mL at week 52 in 82% (LdT+TDF) and 91% (TDF+LdT) of patients. The percent change in estimated glomerular filtration rate (eGFR) from baseline was significantly greater in LdT monotherapy compared with TDF monotherapy at week 52 (4.21 versus −3.44; p = 0.0053) and at week 104 (6.14 versus −3.00; p < 0.0001). Compared with TDF monotherapy, twice as many patients on LdT monotherapy (60.5% LdT versus 27.5% TDF) with abnormal eGFR at baseline reverted to normal at week 104. Serious adverse events deemed unrelated to study treatment were reported in 17 patients (LdT, 8; TDF, 9). One patient in the LdT arm discontinued due to myalgia and four patients in the TDF arm discontinued due to cholestatic jaundice, hepatocellular carcinoma, hepatic cirrhosis and headache.

Conclusions: Data from this head-to-head randomised clinical trial showed that LdT was well tolerated and non-inferior to TDF for treating HBeAg-negative CHB. LdT was associated with improvement in eGFR compared with TDF.



*HBV DNA <300 copies/mL at Week 52. Difference in percentages (95% CI): -2.9% (-9.1, 3.4).
**HBV DNA <169 copies/mL at Week 52. Efficacy analysis was done for the modified intent-to-treat population.
ALT: alanine aminotransferase; HBsAg: hepatitis B surface antigen; LdT: telbivudine; TDF: tenofovir disoproxil fumarate

Figure: Efficacy outcomes of LdT versus TDF.

P0640

EFFECT OF THE COMBINATION OF THE HBV CORE INHIBITOR NVR 3-778 WITH NUCLEOSIDE ANALOGS OR OTHER HBV CORE INHIBITORS ON THE INHIBITION OF HBV DNA REPLICATION IN HepG2.2.15 CELLS

A. Lam[1], C. Espiritu[1], O. Flores[1], G. Hartman[1], K. Klumpp[1]. [1]*Novira Therapeutics Inc., Doylestown, United States*
E-mail: kklumpp@noviratherapeutics.com

Background and Aims: NVR 3-778 represents a new class of HBV core inhibitors and is in clinical development for the treatment of chronic hepatitis B. The availability of NVR 3-778 as an HBV replication inhibitor with a new mechanism of action allows the assessment of the potential for increased antiviral potency that could be achieved in combination treatment with other antiviral agents. Different classes of HBV core inhibitors may also show benefit in combination.

Methods: HepG2.2.15 cells contain stably integrated HBV DNA and generate infectious HBV particles. These cells were used to investigate the interaction between NVR 3-778 and nucleoside analogs Lamivudine (LMV), Tenofovir (TFV) and Entecavir (ETV). The combination of NVR 3-778 with another core inhibitor, NVR 3–7484 was also assessed. The reduction of HBV DNA in the cell culture supernatant was determined after cells were incubated with different concentrations of NVR 3-778 and a nucleoside analog or other core inhibitor in a checkerboard format for 6 days. Cell viability was assessed by the determination of intracellular ATP concentrations. MacSynergy II was used to evaluate the effect of compound combinations.

Results: HBV DNA replication was monitored by measuring levels of secreted, encapsidated HBV DNA in HepG2.2.15 cell supernatant. NVR 3-778, NVR 3–7484, LMV, TFV and ETV inhibited HBV DNA replication with mean EC_{50} values of 0.47 μM, 0.52 μM, 0.11 μM, 1.4 μM and 3.2 nM, respectively. Combining NVR 3-778 with each of the three nucleoside analogs resulted in additive antiviral effects. We also observed an additive antiviral effect from the combination of two HBV core inhibitors, NVR 3-778 and NVR 3–7484. Cell viability remained above 90% in all samples treated with the highest compound concentrations, either alone or in combination.

Conclusions: The combination of the HBV core inhibitor NVR 3-778 with nucleoside analogs lamivudine, tenofovir or entecavir showed additive antiviral effects against HBV replication without reductions in cell viabilty. In addition, the combination of two different HBV core inhibitors showed additive antiviral activity. These results support further exploration of the benefit of such combinations in intensifying the overall suppression of HBV replication and production of HBV from infected cells.

P0641

EXCELLENT 5-YEAR SURVIVAL IN CAUCASIAN CHRONIC HEPATITIS B (CHB) PATIENTS WITH OR WITHOUT CIRRHOSIS UNDER LONG-TERM ENTECAVIR (ETV) OR TENOFOVIR (TDF) THERAPY AND THE IMPACT OF HEPATOCELLULAR CARCINOMA (HCC)

G. Papatheodoridis[1], G. Dalekos[2], C. Yurdaydin[3], M. Buti[4], V. Sypsa[5], J. Goulis[6], J.L. Calleja[7], H. Chi[8], S. Manolakopoulos[9], G. Mangia[10], N. Gatselis[2], O. Keskın[3], S. Savvidou[6], J. De La Revilla[7], B.E. Hansen[8], I. Vlachogiannakos[1], K. Galanis[2], R. Idılman[3], M. Colombo[10], R. Esteban[4], H.L. Janssen[8,11], P. Lampertico[10]. E-mail: gepapath@med.uoa.gr

Background and Aims: Long-term ETV/TDF therapy represents the most common treatment option in CHB of any severity, but efficacy data have been mainly based on on-therapy virological remission rates. In this 9-center, large ongoing cohort study, we evaluated the survival in Caucasian CHB patients with or without cirrhosis who have been receiving ETV/TDF.

Methods: We included 1815 adult Caucasians with CHB with or without compensated cirrhosis and no HCC at baseline (mean age: 53±14 years, males: 71%, naive to antivirals: 60%, cirrhosis: 28%) who received ETV/TDF for ≥12 months. Liver transplantation free survival rates were estimated from Kaplan–Meier curves.

Results: In the total patient population, 1-, 2-, 3- and 5-year overall survival rates were 99.5%, 98.5%, 97.5% and 95% being significantly higher in non-cirrhotics (100%, 99%, 98.5% and 97%) than cirrhotics

(98%, 96.5%, 95% and 92%, P < 0.001). When only liver related deaths or LT were taken into account, 1-, 2-, 3- and 5-year survival rates were 99.7%, 99.4%, 99% and 97.5% being also significantly higher in non-cirrhotics (100%, 100%, 100% and 99%) than cirrhotics (99%, 98%, 97% and 95%, P < 0.001). After excluding patients who developed HCC, 1-, 2-, 3- and 5-year overall survival rates were 99.5%, 99%, 98% and 96.5% remaining significantly higher in non-cirrhotics (100%, 99%, 99% and 98%) than cirrhotics (98%, 97.5%, 96.5% and 94%, P = 0.001). In the 85 patients with HCC, the 1- and 3-year overall survival rates after HCC diagnosis were 76% and 56% without any difference between non-cirrhotics and cirrhotics (P = 0.997). In multivariable Cox regression analysis, better overall survival was independently associated with absence of HCC [HR: 6.446 (95% CI: 3.647–11.394), P < 0.001] and younger age [HR per year: 1.043 (1.019–1.069), P = 0.001] but not with cirrhosis (P = 0.085) or gender (P = 0.438), while better liver related survival was associated only with absence of HCC [HR: 22.451 (9.891–50.780), P < 0.001] and not with age (P = 0.823), cirrhosis (P = 0.123) or gender (P = 0.970).

Conclusions: The survival of Caucasian CHB patients treated with ETV/TDF is excellent with >95% of cases surviving at 5 years and a significant proportion of deaths coming from liver unrelated causes. HCC development is a major factor affecting the overall mortality and the only factor affecting liver related mortality in such patients.

P0642

THE EFFICACY AND SAFETY OF TELBIVUDINE OR TENOFOVIR DISOPROXIL IN PREGNANCY FOR PREVENTION OF MOTHER-TO-CHILD TRANSMISSION OF HEPATITIS B VIRUS

H. Huang[1], Y. Zhang[1], Q. Wu[1], Y. Wang[1]. [1]*Infectious diseases, Southwest hospital, Chongqing, China*
E-mail: wangyuming357@163.com

Background and Aims: This study was to evaluate the efficacy and safety of telbivudine (LdT) and tenofovir (TDF) as monotherapy or combined treatment in HBeAg-positive pregnant women with high viral load for preventing mother-to-child transmission (MTCT) in an open-labeled study.

Methods: The 355 HBeAg-positive pregnant women with HBV DNA >10^6 IU/mL enrolled were treated with antiviral therapy from 24–32 weeks of gestation (308 in LdT group, 23 in TDF group, 24 in TDF+LDT group). All infants were vaccinated with recombinant HBV vaccine and hepatitis B immune globulin (HBIG) according to standard immunoprophylaxis procedure. MTCT rate was determined by HBsAg and HBV DNA detection in 6 months after birth.

Results: Significantly lower HBV DNA levels were noted in all the enrolled mothers when delivery. The rate of HBsAg positive and HBV DNA detectable in infants at 6 months was 0% in each group. The incidence of undetectable cord blood HBV DNA levels has no significantly difference among the three groups (LdT group, 99.2%; TDF group, 100%; LdT+TDF group, 100%; P > 0.05). No severe adverse events, including blood creatine kinase (CK) and estimated glomerular filtration rate (eGFR), or complications were observed in all the mothers and infants.

Conclusions: LdT and TDF monotherapy or their combo-therapy were equally effective and well-tolerated in HBeAg positive and high viral load mothers as well as their infants on short term follow up, and they were associated with significant reduction of MTCT.

P0643

SERUM HBV RNA IS AN EARLY PREDICTOR OF HBeAg SEROCONVERSION IN PATIENTS WITH CHRONIC HEPATITIS B (CHB) TREATED WITH PEG-INTERFERON ALPHA-2A (40kD)

F. van Bömmel[1], A. van Bömmel[2], A. Krauel[3], H. He[4], C. Wat[4], V. Pavlovic[4], D. Deichsel[1], T. Berg[1], S. Böhm[1]. [1]*Hepatology Section, University Hospital Leipzig, Department of Gastroenterology and Rheumatology, Leipzig,* [2]*Max Planck Institute for Molecular Genetics, Berlin,* [3]*University Hospital Leipzig, Department of Gastroenterology and Rheumatology, Leipzig, Germany;* [4]*Roche Products Ltd., Welwyn Garden City, United Kingdom*
E-mail: florian.vanboemmel@medizin.uni-leipzig.de

Background and Aims: HBeAg seroconversion (SC) is a desired treatment outcome of current therapies in HBeAg positive CHB patients. However, this outcome is achieved only in a minority of treated patients and current biomarkers (e.g. HBsAg, HBV DNA) are limited in being able to identify patients that will ultimately respond to treatment. We explored weather serum HBV RNA levels can be used to predict HBeAg SC before or during PegIFN alfa-2a treatment.

Methods: Eighty-nine patients with HBeAg positive CHB, from two large phase III / IV PegIFN alfa-2a trials, were retrospectively studied. Patients were treated with Peg-IFN alpha-2a 180 μg/week alone (n = 58) or in combination with lamivudine 100 mg/day (n = 32) for 48 weeks. Clinical data was obtained from the completed trials and provided by Roche. After reverse transcription, polyadenylated HBV RNA was quantified based on a specific real-time PCR from serum samples collected at baseline, at weeks 12 and 24 of treatment. Response was defined as HBeAg SC occurring 24 weeks after stopping treatment. Differences in HBV RNA concentrations were assessed by Student's t-tests.

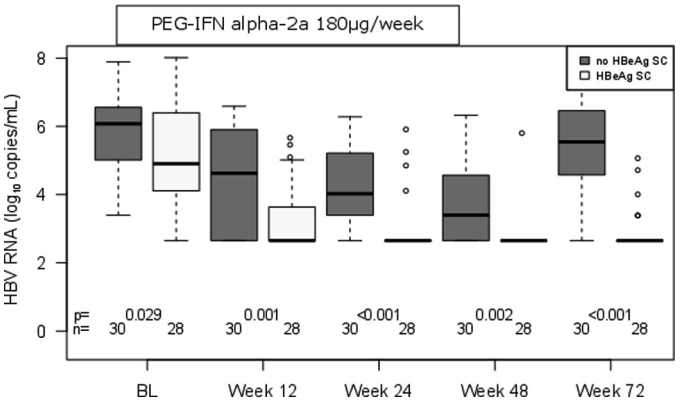

Figure 1. HBV RNA in patients treated with PegIFN alfa-2a monotherapy.

Results: In 58 patients treated with PegIFN alfa-2a alone (Figure 1), baseline HBV RNA were significantly lower in responders (n = 28) compared to non-responders (n = 30) (mean 5.2±1.4 [2.7–8.0] vs. 5.9±1.1 [3.4–7.9] $\log_{10}$ copies/mL, p = 0.029). Responders continued to show significantly lower HBV RNA levels during treatment, at weeks 12 and 24 (mean 3.2±0.9 [2.6–5.7] vs. 4.2±1.4 [2.6–6.5] $\log_{10}$ copies/mL, p = 0.001 and 2.9±0.7 [2.7–5.9] vs. 4.0±1.3 [2.7–6.3] $\log_{10}$ copies/mL, p < 0.001, respectively).

Conversely, in 32 patients treated with PegIFN alfa-2a + lamivudine, HBV RNA levels at baseline and week 12 were not significantly different between responders (n = 13) and non-responders (n = 19) (mean 5.1±1.0 [2.7–6.3] vs. 5.7±1.0 [3.4–7.4] $\log_{10}$ copies/mL, p = 0.185 and 3.1±0.5 [2.7–4.0] vs. 3.5±1.0 [2.7–5.6] $\log_{10}$ copies/mL, p = 0.185, respectively). However, at week 24 HBV RNA had become undetectable in all responders whilst it remained present in the majority of non-respodners (3.1±0.8 [2.7–4.9] $\log_{10}$ copies/mL, p = 0.018).

Conclusions: Serum HBV RNA levels is a novel baseline and on-treatment biomarker for early prediction of serological response to PegIFN alpha-2a treatment in patients with HBeAg positive CHB.

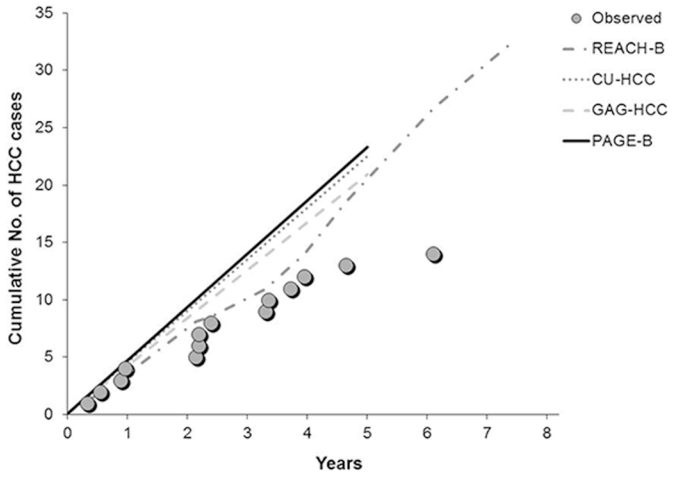
P0644

HCC RISK SCORES: APPLICATION OF THE CU-HCC, GAG-HCC AND PAGE-B SCORES TO CHRONIC HEPATITIS B (CHB) PATIENTS TREATED WITH TENOFOVIR DISOPROXIL FUMARATE (TDF)

W.R. Kim[1], R. Loomba[2], T. Berg[3], R. Aguilar Schall[4], L. Yee[4], P. Dinh[4], J.F. Flaherty[4], E.B. Martins[4], I. Jacobson[5], S. Fung[6], S. Gurel[7], M. Buti[8], P. Marcellin[9]. *[1]Division of Gastroenterology and Hepatology, Stanford University School of Medicine, Palo Alto, [2]Division of Gastroenterology, and Epidemiology, University of California at San Diego, La Jolla, United States; [3]Department of Internal Medicine, Division of Gastroenterology and Rheumatology, Section of Heptology, Universitätsklinikum Leipzig, Leipzig, Germany; [4]Gilead Sciences, Foster City, [5]Division of Gastroenterology and Hepatology, Weill Cornell Medical College, New York, United States; [6]Department of Gastroenterology, University of Toronto, Toronto, Canada; [7]Department of Gastroenterology, University of Uludag, Bursa, Turkey; [8]Department of Hepatology, Hospital General Universitari Vall d'Hebron, Barcelona, Spain; [9]Department of Hepatology, Hôpital Beaujon, University of Paris, Clichy, France*
E-mail: Leland.yee@gilead.com

Background and Aims: Hepatocellular carcinoma (HCC) remains a dreaded complication of CHB. Several nomograms have been developed to assess a CHB patient's risk of developing HCC. We have previously applied the REACH-B score to our population. Here we used additional HCC nomograms to assess the impact of therapy on HCC incidence.

Methods: We applied the CU-HCC, GAG-HCC (modified score not requiring viral mutation data), and PAGE-B risk scores to patients enrolled in pivotal trials GS-US-174-0102 (HBeAg−) and GS-US-174-0103 (HBeAg+) for tenofovir disoproxil fumarate (TDF) to assess the impact of therapy on HCC incidence. All 3 scores provide projections at 5 years, with the first two scores also providing projections at 10 years. Given that 384 weeks (7.4 years) of actual observed data are available for Studies -0102/0103, we compared the number of observed HCC cases in the study with what the prediction models estimated for the first 5 years of follow-up.



Results: Among the 641 patients who entered pivotal studies GS-US-174-0102 (HBeAg-) and GS-US-174-0103 (HBeAg+), 14 cases of HCC occurred during the first 384 weeks (7.4 years, n = 404) of the studies. At the end of year 5 (n = 472), CU-HCC predicted 22.5 cases, GAG-HCC predicted 20.9 cases and PAGE-B predicted 23.3 cases. Predicted cases HCC along with all actual observed cases through 7.4 years are provided in the figure. For comparison, our previous calculations with REACH-B predicted 20.8 cases after 5 years and 32.2 by the end of follow up and are also provided in the figure.

Conclusions: In a mixed-genotype population comprised of 75% non-Asians, all 3 risk scores predicted similar numbers of HCC cases at the end of 5 years, which was consistently higher than that observed among TDF study participants. Despite the potent viral suppression by TDF, the risk of HCC is not eliminated, necessitating continued monitoring for HCC.

P0645

NON-SYNONYMOUS SINGLE-NUCLEOTIDE POLYMORPHISMS (SNPS) IN TLR7 DO NOT IMPACT GS-9620 DEPENDENT TLR7 ACTIVATION

I. Rebbapragada[1], G. Birkus[1], J. Perry[2], S. Pflanz[1]. *[1]Biology, [2]Structural Chemistry, Gilead Sciences, Foster City, United States*
E-mail: indrani.rebbapragada@gilead.com

Background and Aims: Activation of TLR7 constitutes an important host defense mechanism against viral pathogens. GS-9620, an oral small molecule agonist of toll-like receptor 7 (TLR7), is being evaluated in phase 2 clinical trials for the treatment of chronic hepatitis B (CHB). The overall objective of the study was to gain insight into the molecular basis for GS-9620 activation of TLR7 and assess the functional impact of a number of non-synonymous single-nucleotide polymorphisms (SNPs) in TLR7. A combination of structure-based modeling, mutational analysis and cell biology was used to determine the cellular localization of GS-9620 binding to TLR7, the key binding residues of GS-9620 in TLR7, and the effect of common TLR7 SNPs on GS-9620-mediated responses.

Methods: Intracellular accumulation and sub-cellular distribution studies of radiolabelled GS-9620 were performed in the Daudi B cell line. Plasmacytoid dendritic cells (pDCs) were isolated from peripheral blood mononuclear cells and treated with Bafilomycin A to disrupt endolysosomal pH. Interferon-alpha (IFN-α) was measured by ELISA. Mapping of the GS-9620 binding site was performed by transient transfections of TLR7 harboring amino acid point mutations and measurement of NF-κB dependent luciferase reporter activity in Huh7, a human hepatoma cell line. Co-immunoprecipitation and western blotting techniques were used for receptor dimerization studies.

Results: GS-9620 rapidly and preferentially localized to, and accumulated in, lysosomes. Bafilomycin A treatment inhibited the induction of IFN-α in pDCs by GS-9620, suggesting that GS-9620 required endolysosomal acidification to activate TLR7. We also showed that TLR7 exists as preformed dimers prior to ligand binding. Consistent with structure-based modeling predictions, our data indicate that the TLR7 dimer interface provides a binding pocket for GS-9620. In particular, residues Y356, F408, D555, L557 and T586, which reside within the predicted binding pocket of TLR7, proved critical for GS-9620 activation of TLR7. Importantly, we found that the reported non-synonymous TLR7 SNPs rs179008-Q11, rs55907843-V222 and rs5743781-A448 did not affect GS-9620-dependent activation of TLR7.

Conclusions: These data indicate that GS-9620 binds to TLR7 dimers at their interface in the endo-lysosomal compartment to trigger TLR7-dependent responses. We demonstrate that prevalent SNPs in TLR7 have no detectable impact on GS-9620-dependent TLR7 activation.

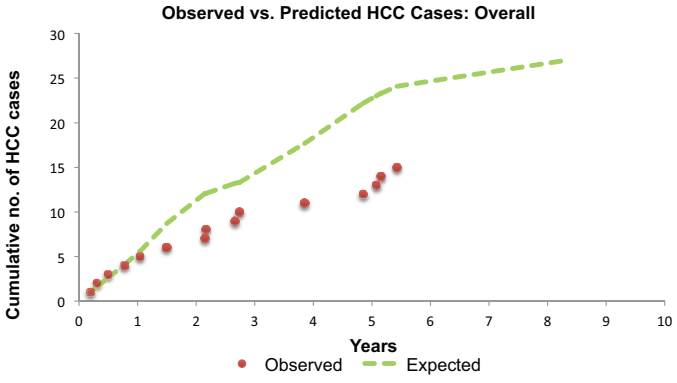
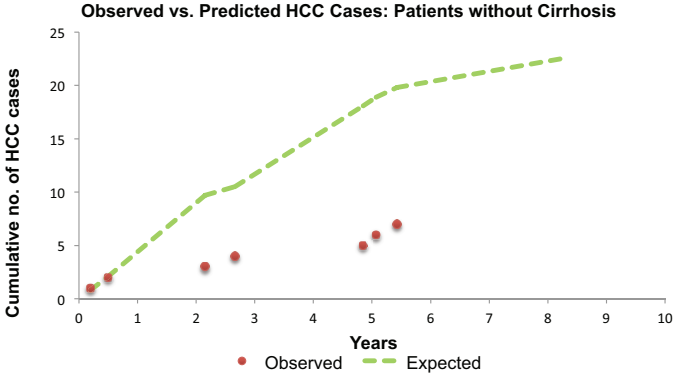
E-mail: ahnj@ohsu.edu

Background and Aims: Entecavir (ETV) has been shown to be associated with decreased hepatocellular carcinoma (HCC) incidence in patients with chronic hepatitis B (CHB). However, data from large U.S. cohorts, especially in patients without cirrhosis, is limited.
Aims: To compare the observed HCC incidence in a large multicenter U.S. cohort of CHB patients treated with ETV with the predicted incidence as estimated by the REACH-B HCC scoring system.
Methods: The ENUMERATE study was conducted in a national network of 26 academic and community liver centers in the U.S., in partnership with the AHF. The cohort included treatment-naïve CHB patients ≥18 years old who did not have a prior history of HCC and were treated with ETV for ≥12 months between 2005 and 2013. Exclusion criteria included co-infection with HIV, hepatitis C or D virus, or a history of solid organ transplantation. The primary outcomes were observed new HCC diagnosis, confirmed by AASLD criteria, and standardized incidence ratios (SIR) between the observed and predicted numbers of HCC cases. The predicted HCC incidence was calculated using the REACH-B model (Yang et al. Lancet Oncology 2011).





Results: The ENUMERATE cohort included 745 patients. Of these, 577 patients had known cirrhosis status, baseline HBV DNA, ALT, and HBeAg status and were included in the REACH-B analysis. Mean age was 45.7, 64% were men, 83% were Asians, 41% were HBeAg+, and 9.4% had cirrhosis. The overall cumulative 5-year HCC incidence was 2.0% in patients without cirrhosis and 23.2% in those with cirrhosis. During a median follow-up of 4 (1–8.3) years, 15 patients developed HCC: 8 out of 54 patients with cirrhosis and 7 out of 523 patients without cirrhosis. The estimated number of HCC cases for this cohort as predicted by the REACH-B calculation was 26.9 overall and 22.5 among those without cirrhosis. The SIR was 0.56 (95% confidence interval [CI] 0.34–0.92) overall and 0.31 (95% CI 0.15–0.65) for those without cirrhosis.
Conclusions: The observed incidence of HCC in patients treated with ETV was lower than that predicted using the REACH-B model for both the overall cohort and for patients without cirrhosis. These findings suggest that ETV can lower HCC risk even among patients without cirrhosis. However, antiviral therapy does not eliminate the risk of HCC in patients with CHB and careful surveillance for HCC remains warranted in these patients notwithstanding ETV treatment.

P0647

PROACTIVE DOSE ADJUSTMENTS ARE NECESSARY IN MANY ADV-EXPERIENCED PATIENTS TREATED WITH TDF MONOTHERAPY FOR 5 YEARS: A PROSPECTIVE COHORT STUDY IN 320 PATIENTS

P. Lampertico[1], R. Soffredini[1], M. Borghi[1], M. Viganò[2], F. Facchetti[1], E. Galmozzi[1], F. Invernizzi[1], M. Colombo[1]. *[1]Division of Gastroenterology and Hepatology, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, [2]Division of Hepatology, Ospedale San Giuseppe, Università degli Studi di Milano, Milan, Italy*
E-mail: massimo.colombo@unimi.it

Background and Aims: Tenofovir (TDF) is a popular anti-HBV strategy for NUC-experienced patients, but its safety profile in field practice patients previously exposed long-term to Adefovir (ADV) is under discussion because of recent reports of Fanconi syndrome
Methods: 320 NUC-experienced CHB patients received Tenofovir (TDF) for 69 months (range 1–106) as a switch from ADV+LAM or as a rescue therapy for LAM, ADV or ETV. Baseline features were: age 59 (24–82), 85% HBeAg-negative, 62% cirrhotics, 88% normal ALT, 74% undetectable HBV-DNA, 86% switched from ADV+LAM. Virological response was undetectable HBV DNA; safety analysis focused on glomerular (eGFR) and tubular renal function. Baseline was defined as the start of TDF.
Results: During 5 years of TDF, 89 patients (28%) had to reduce TDF dose after 31 months (2–75); 11 additional patients (3.4%) had to stop TDF because of renal side effects, and 6 (2%) withdrew for gastrointestinal side effects. TDF dose was reduced in 57 patients due to eGFR decline, in 30 patients due to phosphate decline and in 2 cases for both events. All patients who had to stop TDF had low blood phosphate levels. Overall, 106 patients (33%) either required a dose reduction or withdrew from TDF for side effects, with a 5 year estimated probability of 40%. Most of those patients who had to stop TDF were successfully rescued by switching to ETV. Of note, none of the TDF treated patients developed acute renal failure, or Fanconi syndrome and viral load did not rebound in any patient who required dose adjustment. Virological response progressively increased to 100% at year 5 with most patients achieving normal ALT. 15 patients (5%) cleared HBsAg, 26 additional patients had qHBsAg <10 and 25 reached qHBsAg between 10 and 100 IU/ml (Overall, 22% of the patients had qHBsAg <100 IU/ml). HCC attack rates were 1.3%/year in compensated cirrhotics and 0.2%/year in non cirrhotics, which were significantly lower than those described in untreated and in TDF treated naïve patients. No cases of clinical decompensation without HCC were recorded.

Overall, 7 patients (2%) were transplanted (all for HCC) and 16 (5%) died (7 for HCC, 7 for non liver causes and 2 for unknown reasons).
Conclusions: To prevent glomerular and tubular damage, proactive dose adjustments of TDF are necessary in a large proportion of ADV-experienced, TDF treated CHB patients. Current EASL guidelines on safety management and monitoring of these patients must be revised.

P0648
LONG-TERM OUTCOME OF CHEMOTHERAPY-INDUCED HBV REACTIVATION IN LYMPHOMA PATIENTS WITH RESOLVED HBV INFECTION

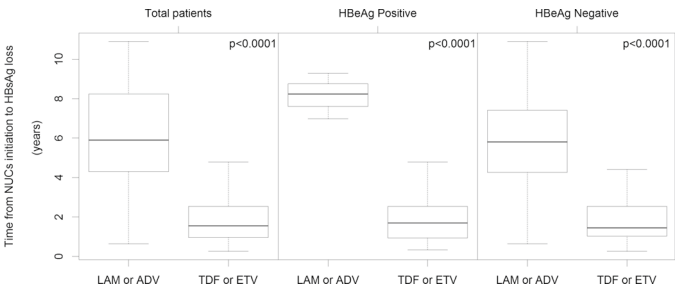
H.-C. Yang[1], H.-H. Tsou[2], M.-H. Chuang[2], C.-L. Chen[3], T.-W. Liu[4], P.-J. Chen[5], A.-L. Cheng[6], C. Hsu[6], Taiwan Cooperative Oncology Group. *[1]Internal Medicine, National Taiwan University Hospital, Taipei, [2]Biostatistics and Bioinformatics, National Health Research Institutes, Miaoli, [3]Graduate Institute of Clinical Medicine, National Taiwan University, Taipei, [4]National Institute of Cancer Research, National Health Research Institutes, Miaoli, [5]Hepatitis Research Center, [6]Oncology, National Taiwan University Hospital, Taipei, Taiwan*
E-mail: hsuchiun@gmail.com

Background and Aims: Hepatitis B virus (HBV) reactivation can occur to 10–40% of lymphoma patients with 'resolved' HBV infection (HBsAg-negative and anti-HBc-positive) who received rituximab-based chemotherapy, but its impact on survival outcome was unclear.
Methods: We prospectively followed 150 newly diagnosed lymphoma patients with resolved HBV infection who receive rituximab-CHOP (cyclophosphamide, doxorubicin, vincristine, prednisolone)-based chemotherapy by regular HBV DNA monitoring. Patients with documented HBV reactivation, defined as a greater than 10-fold increase in HBV DNA compared with previous nadir levels, were treated with entecavir. Quantification of anti-HBc and anti-HBs levels at baseline was correlated with the risk of HBV reactivation and survival.
Results: With a median follow-up of 46.0 months (range 1.1–63.9), patients who had HBV reactivation after rituximab-CHOP chemotherapy (n = 17) had worse survival than patients without (n = 133). The estimated 3-year overall survival rate was 52.3% (95% CI 50.2–54.4%) for patients with HBV reactivation and 78.2% (95% CI 72.3–84.1%) for those without (p = 0.033), and the 3-year progression-free survival rate was 46.3% (95% CI 39.9–52.7%) vs. 72.9% (95% CI 69.6–76.3%) (p = 0.062). Thirty-eight patients died during follow-up. The major causes of death were tumor progression (18 patients), infection/sepsis (17 patients) and others (3 patients) and not significantly different between patients with or without HBV reactivation. Low anti-HBs and high anti-HBc levels at baseline predicted high risk of HBV reactivation.
Conclusions: Chemotherapy-induced HBV reactivation was associated with worse survival in lymphoma patients with resolved HBV infection. Patients with low baseline anti-HBs and high anti-HBc levels may benefit most from prophylactic antiviral therapy.
(supported by grant PH-102-PP-11, PH-103-PP-11 from National Health Research Institutes, Taiwan)

P0649
CHARACTERIZATION OF HBsAg LOSS IN PATIENTS WITH CHRONIC HEPATITIS B (CHB) TREATED WITH NUCLEOS/TIDE ANALOGS (NUCS): A RETROSPECTIVE MULTICENTER STUDY (HEBESAS)

E. Suárez[1], M.A. Simón[2], M. Buti[3], M. Prieto[4], J.M. Pascasio[5], M. Rodríguez[6], T. Casanovas[7], J. Crespo[8], J. Arenas[9], R. Gómez[10], B. Figueruela[1], M. Diago[11], R. Fuentes[17]. *[1]Gastroenterology, Hospital Valme, Sevilla, [2]Hepatology, Hospital Clínico Lozano Blesa, Zaragoza, [3]Hepatology, Hospital Vall d'Hebrón-CIBERehd, Barcelona, [4]Hepatology, Hopsital La Fe-CIBERehd, Valencia, [5]Gastroenterology, Hospital Virgen del Rocío, Sevilla, [6]Hepatology, Hospital Central de Asturias, Oviedo, [7]Hepatology, Hospital Bellvitge, L'Hospitalet, [8]Gastroenterology, Hospital Valdecilla, Santander, [9]Gastroenterology, Hospital Donostia, San sebastián, [10]Gastroenterology, Hospital Virgen de la Salud, Toledo, [11]Hepatology, Clínica Quirón-Universidad Católica de Valencia, Valencia, [12]Hepatology, Hospital Germans Trías i Pujol, Badalona, [13]Gastroenterology, Hospital de Navarra, Pamplona, [14]Gastroenterology, Hospital Puerta de Hierro-CIBERehd, Madrid, [15]Gastroenterology, Hospital Torrecárdenas, Almería, [16]Hepatology, Hospital Complex, Santiago de Compostela, [17]Hepatology, Hospital Miguel Servet, Zaragoza, Spain*
E-mail: emsuar@gmail.com

Background and Aims: HBsAg loss is the optimal goal of CHB treatment but it is difficult to achieve in patients treated with NUCs, mainly in HBeAg negative patients. The aim of this study was to investigate the patient characteristics associated with HBsAg loss.
Methods: Retrospective multicenter study of CHB patients treated with NUCs that lost HBsAg after 2007. Exclusion criteria were spontaneous or occurred during IFN/PEG-IFN therapy HBsAg loss, HCV, HDV or HIV coinfection, liver transplantation or HBV reactivation due to immunosuppressive therapies.
Results: A total of 86 patients were included, 91% male and 94% Caucasian, median age of 51 years at the time of HBsAg loss. 53% (45/85) were HBeAg positive at the start of NUCs. Genotype was available in 32 patients, the majority being D (44%) and A (34%). Severe fibrosis or cirrhosis was present in 31% (15/49).
HBV DNA was persistently undetectable in 69% patients before HBsAg loss: median duration 1.19 yr in HBeAg positive and 2.97 yr in HBeAg negative patients (p = 0.014). Upon HBsAg loss, HBV DNA was detectable (52 IU/ml) only in one patient and 34% (25/73) had developed antiHBs. The time between diagnosis of CHB and HBsAg loss was significantly longer in HBeAg negative than in HBeAg positive patients: median, 10.5 vs. 3.1 yr, respectively (p < 0.0001). Although the time from NUCs initiation to HBsAg loss differed between HBeAg negative and HBeAg positive patients (median, 3.2 vs. 1.9 yr, respectively), it did not reach statistical significance (p = 0.086).
HBsAg loss occurred in 62.8% patients treated with TDF (39.5%) or ETV (23.3%), followed by LAM (15.1%) and ADV (9.3%). The mean time from NUCs initiation to HBsAg loss was 1.8 yr with ETV/TDF and 6.2 yr with ADV/LAM (difference was 4.4 yr, CI: 3.5–5.3, p < 0.0001) [Box plot].



Treatment was discontinued in 75.6% patients after HBsAg loss (median, 8.7 months). HBV DNA was undetectable in all patients

and 59% (36/61) had developed antiHBs at the time of NUCs discontinuation. No HBsAg seroreversion occurred during a median of 12 months follow-up (range, 2–55 months). No patient developed hepatic complications or hepatocellular carcinoma.
Conclusions: These data suggest the time between the diagnosis of CHB and HBsAg loss is longer in HBeAg negative than in HBeAg positive patients. In addition, HBsAg loss occurred faster with TDF/ETV than with LAM/ADV. HBsAg loss was maintained in all patients after discontinuation of NUCs.

P0650
RENAL AND BONE EVENTS IN PATIENTS WITH CHRONIC HEPATITIS B RECEIVING LONG-TERM ORAL NUCLEOS(T)IDE ANALOGUE TREATMENT – A STUDY OF 53,500 SUBJECTS

G.L. Wong[1], Y.-K. Tse[1], V.W. Wong[1], T.Y. Fung[2], H.L. Chan[1]. *[1]Medicine and Therapeutics, [2]Statistics, The Chinese University of Hong Kong, Hong Kong, Hong Kong, China*
E-mail: wonglaihung@gmail.com

Background and Aims: Oral nucleos(t)ide analogues (NAs) effectively suppress hepatitis B virus (HBV) and reduce hepatic events in patients with chronic hepatitis B (CHB). Early data suggest nucleotide analogues (adefovir and tenofovir) may cause renal and bone toxicity, but the observation was only based on small number of patients and surrogate endpoints. Long-term data on hard clinical outcomes are lacking.
Methods: We conducted a territory-wide cohort study using the database from Hospital Authority, which provides medical services at both in-patient and out-patient settings for 70–80% of the Hong Kong citizens. We identified CHB patients by International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) diagnosis codes, diagnosed between 2000 and 2012. Other relevant diagnoses, with special focus on renal failure and fracture, procedures, concomitant drugs, and laboratory parameters were retrieved and studied. The primary outcome was incident chronic renal failure and fracture. A 3-year Landmark analysis, with follow-up duration up to 7 years, was used to evaluate the relative risk of primary outcome in patients with or without NA treatment. Baseline covariates of the two groups were balanced using inverse probability of treatment weighting (IPTW) based on propensity score methods.
Results: 53,500 CHB patients (46,454 untreated and 7,046 treated) were included in the analysis. At a median follow-up of 4.9 years, chronic renal failure, renal replacement therapy, all fractures, hip fractures and spine fractures occurred in 270 (0.6%), 96 (0.2%), 318 (0.7%), 48 (0.1%) and 53 (0.1%) of untreated subjects; and 100 (1.4%), 49 (0.7%), 95 (1.3%), 17 (0.2%) and 15 (0.2%) of treated subjects. Male gender and age ≥50 years were associated with these events. After propensity score weighting, NA therapy did not increase the risk of the events (hazard ratios [HR] ranged from 0.79 to 1.31; P values ranged from 0.225 to 0.887). Exposure to nucleotide analogues, compared with nucleoside analogues, did not increase the risk of all events (HR ranged from 0.47 to 1.37; P values ranged from 0.148 to 0.893), except hip fracture (HR = 4.71, 95% confidence interval 1.67–13.3, P = 0.003). Similar findings were observed when comparing nucleotide analogues with no treatment.
Conclusions: NA treatment does not increase the risk of renal and bone events in general. Nucleotide analogues may increase the risk of hip fracture, but the overall event rate is low.

P0651
CLINICAL OUTCOME AND PREDICTOR FOR RELAPSE AFTER CESSATION OF ORAL ANTIVIRAL TREATMENT IN CHRONIC HEPATITIS B PATIENTS: A PROSPECTIVE OBSERVATIONAL COHORT STUDY

K.S. Jung[1], J.Y. Park[1], Y.E. Chon[1], H.-S. Kim[2], W. Kang[1], S.U. Kim[1], B.K. Kim[1], D.Y. Kim[1], K.-H. Han[1], S.H. Ahn[1]. *[1]Department of Internal Medicine, [2]Department of laboratory medicine, Yonsei University College of Medicine, Seoul, Korea, South*
E-mail: jks1029@yuhs.ac

Background and Aims: Little is known about stopping rules of nucleos(t)ide analog (NA) treatment for chronic hepatitis B (CHB).
Methods: A total of 164 consecutive CHB patients who met cessation criteria of NA treatment by APASL guideline were enrolled in this prospective study. Fifty-one patients were excluded by exclusion criteria, 113 patients (45 HBeAg-positive and 68 HBeAg-negative CHB), who stopped NA treatment, remained for statistical analysis. At the time of discontinuing NA, the blood parameters including biochemistry, HBV-DNA, HBsAg, IP-10, and HBcrAg level was obtained and thereafter the patients were monitored regularly with HBV-DNA and ALT. Relapse was defined as reappearance of HBV-DNA >2000 IU/mL after stopping NA treatment.
Results: Within 1 year after NA treatment, relapse occurred in 26 (57.8%) of 45 HBeAg-positive patients with median time of 219 (77–397) days and in 37 (54.4%) of 68 HBeAg-negative patients with median time of 215 (55–376) days. Among the patients with relapse, 8 (30.8%) HBeAg-positive patients had a biochemical relapse (ALT elevation>2×UNL) and 19 (51.4%) HBeAg-negative patients did. In multivariate analysis, age >40 years (OR, 10.959; 95% CI, 2.211–54.320; $P = 0.003$) and pretreatment HBV-DNA >2×10^6 IU/mL (OR, 9.285; 95% CI, 1.545–55.795; $P = 0.036$) were identified as independent risk factor for relapse in HBeAg-positive patients, and age >40 years (OR, 6.690; 95% CI, 1.314–34.057; $P = 0.022$) and HBcrAg level at end of treatment >3.7 log IU/mL (OR, 3.751; 95% CI, 1.187–11.856; $P = 0.024$) were selected in HBeAg-negative patients. In both groups, the potent of NA, duration of consolidation treatment, serum HBsAg, and IP-10 level at the time of discontinuation were not significantly related with relapse. During the study period, no liver decompensation or liver related death was reported. After relapse, HBV-DNA suppression was achieved in all patients who were re-treated by NA in both groups.
Conclusions: Our data suggested that clinical outcome of HBeAg-positive and negative CHB was similar after stopping antiviral agents, suggesting that discontinuation of NA might be considered carefully considering individual risk factors. Especially, old age and HBcrAg level at end of treatment could be useful predictor for relapse after in HBeAg negative patients.

Table (abstract P0650): Hazard ratios of events

Event(s)	NAs vs. No NAs					Nucleotide analogues vs. nucleoside analogues					Nucleotide analogues vs.no NAs		
	No. (%) of events		HR	95% CI	P-value	No. (%) of events		HR	95% CI	P-value	HR	95% CI	P-value

EFFECT OF TENOFOVIR ON KEY HEPATITIS B VIRUS MARKERS IN PREGNANT WOMEN DURING THE THIRD TRIMESTER AND POSTPARTUM

K. Jackson[1], L. Yuen[1], V. Nguyen[2], J. Bayliss[1], S. Locarnini[1], M. Levy[2].
[1]Research & Molecular Development, Victorian Infectious Diseases Reference Laboratory, Melbourne, [2]Gastroenterology, UNSW, Liverpool Hospital, Sydney, Australia
E-mail: kathy.jackson@mh.org.au

Background and Aims: The risk of hepatitis B virus (HBV) transmission from mothers to babies has been well documented, particularly when the maternal viral load (VL) is high. The use of Tenofovir Disoproxil Fumarate (TDF) during the last trimester of pregnancy has been shown to reduce HBV load and significantly decrease the risk of perinatal transmission. The aim of this study was to assess the effect of TDF on key HBV markers in pregnant women with high VL in the third trimester of pregnancy.
Methods: 38 mothers were treated with TDF in the last trimester of pregnancy until birth or 12 weeks postpartum at the Liverpool Hospital, Sydney, Australia. A total of 119 blood samples were collected (at 3 time points if possible): T1 pre-treatment, T2 at birth, T3 around 12 weeks postpartum. They were tested for VL, quantitative (q) HBeAg and HBsAg, and the HBV reverse transcriptase (RT) region was analysed for drug resistance and surface antigen changes by population-based sequencing. 19 samples were also sequenced by next generation sequencing (NGS).
Results: The mean VL for all T1 samples was 7.98 $\log_{10}$ IU/mL, and the mean VL decrease from T1 to T2 was 3.36 $\log_{10}$ IU/mL. The mean qHBeAg also decreased: T1 (2206 IU/mL), T2 (1750 IU/mL) and T3 (1503 IU/mL). Two mothers were HBeAg negative at T1 and 3 became negative during treatment. However, no decrease was observed in the mean qHBsAg at T1, T2 and T3. All isolates were found to have wildtype sequences by population-based sequencing. Although NGS analysis detected several HBV RT amino acid changes at low frequencies in the mothers' samples, none are associated with drug resistance.
One baby was diagnosed with HBV at age 9 months. The mother's VL at birth was 4.42 $\log_{10}$ IU/mL, and the viral sequences from both the mother and baby were identical by population-based sequencing. In addition, the viral population profiles between the mother and baby samples were very similar by NGS analysis.
Conclusions: TDF remains the drug of choice for preventing the transmission of HBV from mother to baby despite the transmission case documented here. The mothers' HBV loads were dramatically reduced on treatment. Even after a short duration of therapy there was a decline in HBeAg, and no emergence of drug resistance mutations as seen with Lamivudine therapy. The transmission case observed is likely to be an in-utero transmission, given treatment compliance, a dramatic drop in viral load and administration of HBIG and HBV vaccination.

P0653

PERFORMANCE EVALUATION OF THE UPDATED ELECSYS ANTI-HBs II IMMUNOASSAY

A. Mühlbacher[1], S. Böhm[2], V. Schottstedt[3], N. Hirankarn[4], S.K. Vandelaer[4], A. Woeste[5]. *[1]TILAK, Innsbruck, Austria; [2]Synlab, Munich, [3]DRK BTS West, Hagen, Germany; [4]Chulalongkorn University, Bangkok, Thailand; [5]Roche Diagnostics GmbH, Penzberg, Germany*
E-mail: andreas.woeste@roche.com

Background and Aims: Anti-HBs tests are employed worldwide to confirm a successful vaccination or to determine the stage of a Hepatitis B infection. The Elecsys Anti-HBs II test (Roche Diagnostics) has been modified to be compatible with all cobas e systems. In addition, one native antigen used in the test has been replaced by a recombinant antigen.
The aim of the study was to evaluate the specificity and sensitivity of the modified Elecsys Anti-HBs II immunoassay in blood donations, routine samples and clinically well-defined sera from individuals who have been vaccinated against Hepatitis B, or individuals who have recovered from a Hepatitis B infection. In addition, the modified assay was compared to other commercially available anti-HBs tests, and various dilutions from the 2nd WHO Standard were tested and compared between different tests.
Methods: The commercially available tests used in the study were as follows: Elecsys Anti-HBs and Anti-HBs II (Roche Diagnostics), Architect Anti-HBs (Abbott), Centaur Anti-HBs (Siemens), Liaison Anti-HBs (Diasorin). The WHO Standard dilutions were 0, 5, 10, 99, 250, 500, 750, 1000 and 1500 IU/L. 4088 samples from blood donations, 2017 samples from routine testing, 305 samples from vaccinated individuals and 270 samples from patients who recovered from Hepatitis B were investigated. External evaluation was performed at two different blood banks and two different routine laboratories. In addition, external routine samples were measured at the manufacturer (Roche Diagnostics).
Results: The specificity of the Elecsys Anti-HBs II in negative samples from blood donors at both blood banks was >99% and in negative samples from routine samples >98%. Sensitivity in vaccinated individuals and in patients who have recovered from Hepatitis B was 100%. The 10 IU/L reference sample from the WHO standards was measured by Elecsys Anti-HBs II and Architect anti-HBs to a high level of accuracy (10.1 IU/L and 9.9 IU/L, respectively). The 10 IU/L sample was overestimated by Elecsys Anti-HBs (11.0 IU/L), by Centaur Anti-HBs (12.1 IU/L) and by Liaison Anti-HBs (13.4 IU/L). Although the Liaison Anti-HBs overestimated the 10 IU/L standard, this test gave the best results over the entire range of WHO standard dilutions. The Architect Anti-HBs underestimated the concentration at the higher concentrations (>30%).
Conclusions: Finally, the Elecsys Anti-HBs II test exhibited a high agreement rate (98.5%) with Elecsys Anti-HBs and is a suitable replacement for the latter test on the cobas e system.

P0654

LONG-TERM SUSTAINED SUPPRESSION OF VIRAL REPLICATION IS ASSOCIATED WITH LOW HBsAg LEVELS IN PATIENTS WITH CHRONIC HEPATITIS B (CHB) TREATED WITH NUCLEOS(T)IDE ANALOGUES (NUCS)

E. Suárez[1], M. Prieto[2], C.A. Navascués[3], E. Hoyas[1], V. Hontagas[2], M.L. González-Gieguez[3], B. Figueruela[1], M. García-Eliz[2], M. Rodríguez[3]. *[1]Gastroenterology, Hospital Universitario Valme, Sevilla, [2]Hepatology, Hospital Universitario Politécnico La Fe, Valencia, [3]Hepatology, Hospital Central Asturias, Oviedo, Spain*
E-mail: emsuar@gmail.com

Background and Aims: The ideal endpoint of CHB treatment is loss of HBsAg but this is rarely achieved in patients treated with NUCs. The aims of the study were to assess long-term HBsAg levels in patients treated with NUCs and to identify factors associated with low HBsAg levels.
Methods: The study population consisted of 224 patients treated with NUCs for at least 1 yr. HBV-DNA levels were assessed by a TR-PCR assay and HBsAg levels by an ELISA quantitative method. Low HBsAg levels were defined as HBsAg <1000 IU/mL. Sustained virological response time (SVRT) was defined as the time elapsed between confirmed negativization of HBV-DNA and the last available HBV-DNA result.
Results: 70% of patients were male with mean age of 44.7±12 yrs; most of them had genotype D (59%) or A (30%), 28% were HBeAg+ and 22% had cirrhosis at baseline. Mean pre-treatment HBV-DNA levels were 6.08±1.47 log IU/mL and mean baseline ALT levels were 129±159 U/mL. First line of treatment consisted of first generation NUCs in 50% of the cases and second generation NUCs in the

remaining 50%. Median duration of treatment and SVRT were 6 yrs (range:1–15 yrs) and 4.6 yrs (range:0–12.6 yrs), respectively. 31% patients developed resistance to some NUC during treatment. At the last follow-up, HBV-DNA was negative in 97% of the patients and median HBsAg levels were 1606 IU/mL (range:1–21000 IU/mL). Last HBsAg levels were <1000 IU/mL and <100 IU/mL in 40.2% and 12.5% of the patients, respectively. Mean HBsAg levels were 4268±4293 IU/mL in patients treated <5 yrs, 2640±3244 IU/mL in those treated 5–10 yrs, and 1480±2217 IU/mL in those treated >10 yrs ($p = 0.007$ between <5 yrs and 5–10 yrs; $p = 0.01$ between 5–10 yrs and >10 yrs). Variables associated with low HBsAg levels in the univariate analysis: male sex ($p = 0.001$), development of NUC resistance ($p = 0.01$), baseline HBV-DNA <5.8 log IU/mL ($p = 0.01$), treatment for more than 5 yrs ($p < 0.001$), and SVRT >4 yrs ($p < 0.001$). Male sex (OR 2.06, 95% CI: 1.05–4.02, $p = 0.01$), baseline HBV-DNA <5.8 log IU/mL (OR 2.06, 95% CI: 1.05–4.02, $p = 0.01$), and SVRT >4 yrs (OR 2.91, 95% CI: 1.43–5.89, $p = 0.01$) were independently associated with low HBsAg levels in the multivariate analysis.

Conclusions: Long-term treatment with NUCs achieves suppression of viral replication in nearly all patients with CHB and low HBsAg levels in a significant proportion of them. This sustained suppression of viral replication seems to be playing a significant role in obtaining low HBsAg levels with its potential clinical implications.

P0655
LAMIVUDINE PROPHYLAXIS PREVENTS HEPATITIS B REACTIVATION IN HBsAg-NEGATIVE/ANTI-HBc-POSITIVE PATIENTS UNDERGOING RITUXIMAB-BASED CHEMOTHERAPY FOR NON-HODGKIN'S B CELL LYMPHOMA

M. Viganò[1], G. Grossi[2], E. Borsotti[2], M. Cappelletti[1], M. Goldaniga[3], L. Farina[4], M. Rumi[1], P. Corradini[4], L. Baldini[3], M. Colombo[2], P. Lampertico[2]. *[1]Division of Hepatology, Ospedale San Giuseppe, Università degli Studi di Milano, [2]Division of Gastroenterology and Hepatology, [3]Department of Oncohematology, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, [4]Division of Hematology, IRCCS Istituto Nazionale Tumori, Università degli Studi di Milano, Milan, Italy*
E-mail: massimo.colombo@unimi.it

Background and Aims: Hepatitis B surface antigen (HBsAg)-negative/anti-hepatitis B core antigen (anti-HBc)-positive patients undergoing Rituximab (RTX)-based chemotherapy (R-CT) for non-Hodgkin's B cell lymphoma (NHL) face up to 27% risk of hepatitis B virus (HBV) reactivation. Aim of the study was to assess the efficacy and safety of lamivudine (LMV) prophylaxis in these patients.

Methods: Sixty-seven consecutive HBsAg-negative/anti-HBc-positive patients (median age 70 yrs, 61% males, 13% HCV seropositive, 100% serum HBV DNA negative by sensitive PCR assay, 75% anti-HBs positive, 100% with ALT <ULN) undergoing different R-CT protocols (48% R-CHOP) in two hematological centres were retrospectively enrolled. LMV prophylaxis was started before the first R-CT dose and planned to last for 18 months after the end of R-CT. R-CT was administered for 6 cycles (range: 1–15) during 5 (range: 1–38) months, while LMV was administered for 20 (range: 3–54) months. Serum ALT, HBsAg and HBV DNA levels by PCR assay were assessed every 3–4 months.

Results: All patients remained HBV DNA and HBsAg negative during a median of 20 months (range: 2–60), including both the LMV prophylaxis and the subsequent off treatment follow-up. Anti-HBs titers declined in 18% of patients but none lost serum reactivity for anti-HBs. Overall, 2 patients had an increase of ALT (>ULN) but this event was unrelated to HBV reactivation and 7 patients died of liver unrelated causes. No safety issues related to LMV were recorded.

Conclusions: LMV monotherapy is an inexpensive, safe and effective prophylaxis regimen to prevent HBV reactivation in such a high-risk population as HBsAg-negative/anti-HBc-positive patients receiving RTX-based chemotherapy for non-Hodgkin's B cell lymphoma.

P0656
ADD ON PEGINTERFERON TO ADEFOVIR ENHANCES HBsAg LOSS IN INACTIVE HBV CARRIERS

M. Martinot Peignoux[1], F. Mouri[2], N. Boyer[3], C. Castelnau[4], M. Pouteau[5], N. Giuly[4], T. Asselah[4], P. Marcellin[4]. *[1]CRI Paris Montmartre UMR1149 inserm, Hôpital Beaujon AP-HP, [2]Service d'hépatologie, CRI paris Montmartre UMR1149 inserm, [3]Service d'hépatologie, Hôpital Beaujon, [4]Service d'hépatologie, [5]Service Hépatologie, Hôpital Beaujon AP-HP, Clichy, France*
E-mail: michelle.martinot@inserm.fr

Background and Aims: HBsAg loss, considered to be the ideal outcome of HBV infection, occurs spontaneously at low rate in inactive HBV carriers not candidates for therapy. We investigated the ability of treatment to achieve accelerate incidence of HBsAg loss in inactive carriers

Methods: 91 inactive carriers from a well phenotyped cohort (Journal of Clinical Virology 2013; 58: 401) were followed for a 2 years period. At that time point 69 remained untreated, 22 underwent 4 years adefovir therapy. At 4 years 16 patients received 48 weeks peginterferon, 6 continued adefovir monotherapy. All the patients ended therapy at 5 years, and were followed for at least 2 years after treatment cessation.

Results: At baseline; ALT were 24±7 and 23±7 (ns), HBV genotypes A, B–C, D, E observed in 33%, 15%, 33%, 19% in untreated and 37%, 20%, 37%, 6% in treated patients (ns). HBsAg levels 3.24±1.0 and 3.34±0.92 log IU/ml (ns), HBV DNA levels 2.57±0.97 and 2.90±0.84 log IU/ml (ns), in untreated and treated patients, respectively. At the end of follow up, HBV DNA was undetectable in 12/69 (17%) of untreated and 9/22 (41%) of treated patients ($p < 0.02$), an HBsAg loss was observed in 10/69 (15%) of untreated and 7/22 (32%) of treated patients, ($p = 0.06$). A baseline HBsAg level >3.3 log IU/ml shows a negative predictive value (NPV) of 92% for HBs loss. Among the treated patients a HBs loss was observed in 0/6 (0%) receiving adefovir and 7/16 (44%) receiving add-on peginterferon ($p = 0.04$). Baseline HBsAg levels were 3.50±0.99 and 2.88±1.16 log IU/ml in adefovir and add-on peginterferon therapy patients, respectively (ns). In the 16 patients receiving add-on peginterferon therapy, baseline HBsAg levels were 1.97±0.83 and 3.59±0.74 log IU/ml in patients with or without HBsAg loss, respectively ($p < 0.001$). An HBsAg titer >3.3 log IU/ml shows a NPV 100% for HBsAg loss. No patient relapsed.

Conclusions: In inactive HBV carriers treated with adefovir add-on peginterferon dramatically accelerates the HBsAg decline and rate of HBsAg loss (44%), in comparison to untreated patients (17%).

P0657
ADDING TENOFOVIR TO PEGYLATED INTERFERON ENHANCES END OF TREATMENT HBsAg LOSS IN HBeAg NEGATIVE CHRONIC HEPATITIS B PATIENTS

P. Marcellin[1], M. Martinot Peignoux[2], R. Moucari[3], M. Lapalus[2], C. Castelnau[3], F. Mouri[4], M. Pouteau[3], N. Giuliy[3], N. Boyer[3], T. Asselah[1]. *[1]Service d'hépatologie Hôpital Beaujon, [2]CRI paris Montmartre UMR1149 inserm, [3]Service d'hépatologie Hôpital Beaujon, [4]Hôpital Beaujon AP-HP, Clichy, France*
E-mail: michelle.martinot@inserm.fr

Background and Aims: It remains unclear whether adding a nucleot(s)ide analogue enhances the efficacy of pegylated interferon alfa-2a (PegIFN) by accelerating HBsAg decline and clearance. We aimed to assess efficacy of the combination of PegIFN alfa-2a + tenofovir (TDF).

Methods: 88 CHB patients [26 HBeAg(+); 62 HBeAg(−)] treated 48 weeks. HBsAg measured at baseline, weeks 12, 24, end of therapy (EOT), 24 weeks after treatment cessation.
Results: 43 patients [13 HBeAg(+); 30 HBeAg(−)] received PegIFN monotherapy and 45 patients [13 HBeAg(+); 32 HBeAg(−)] received the combination of PegIFN +TDF. SVR was 38%, 23% and 45% in the overall population, HBeAg(+) and HBeAg(−), respectively. HBe(+) positive patients were not further analysed.
Among the 62 HBe(−) patients, EOT response was 90% and 100% in PegIFN and PegIFN +TDF patients, respectively. SVR was observed in 33% and 53% of PegIFN and PegIFN +TDF patients, respectively. EOT HBsAg loss was observed in 6.6% and 12.5% of PegIFN and PegIFN +TDF patients, respectively. The negative predictive value (NPV) of baseline HBsAg >1500 IU/ml for SVR and HBs loss were 81% and 86% in PegIFN patients and 60% and 95% PegIFN +TDF patients.
The NPV of week 24 HBsAg decrease <0.5 log IU/ml were 73% and 57% of PegIFN alfa-2a and PegIFN +TDF patients, respectively. An end of follow-up HBs loss was observed in 20% and 19% of PegIFN and PegIFN +TDF patients, respectively.
Conclusions: In patients receiving PegIFN +TDF experience higher SVR rate 53% versus 33% and EOT HBsAg loss 12.5% versus 6.6% than patients receiving PegIFN monotherapy.

A NEW PROGNOSTIC MODEL FOR 1-YEAR MORTALITY IN PATIENTS WITH DECOMPENSATED HEPATITIS B VIRUS-RELATED LIVER CIRRHOSIS RECEIVING ANTIVIRAL TREATMENT

T.H. Kim[1], S.H. Um[1], D.H. Gu[1], S.B. Yoon[1], T.J. Yun[1], S.Y. Yim[1], J.Y. Jung[1], Y.S. Seo[1], H.J. Yim[1], B. Keum[1], Y.T. Jeen[1], H.S. Lee[1], H.J. Chun[1], C.D. Kim[1], H.S. Ryu[1]. [1]*Internal Medicine, Korea University College of Medicine, Seoul, Korea, South*
E-mail: lacid@korea.ac.kr

Background and Aims: Considering the remarkable survival gain achieved with the use of oral antiviral agents, we aimed to develop a more efficient prognostic model to predict 1-year mortality after initiating antiviral treatment in patients with decompensated hepatitis B virus (HBV)-related cirrhosis.
Methods: We investigated 194 treatment-naive decompensated cirrhotic patients who were administered lamivudine or entecavir for a median of 41 months. Prediction models A (pretreatment) and B (on-treatment) were created by multivariate Cox-regression analysis based on baseline and 1-month follow-up data, respectively.
Results: At baseline, 75.8% of patients had ascites, and the median Child-Turcotte-Pugh (CTP) and model for end stage liver disease (MELD) score was 9 and 13.8, respectively. Twenty-seven events (24 deaths + 3 liver transplants [LTs]) occurred within the first year of treatment, accounting for 52% of all events during follow-up. Models A and B consisted of conventional risk factors categorized differently from traditional prediction models. The area under the receiver operating characteristic curve for predicting 1-year events at baseline was significantly higher for Model A than for CTP score, MELD score, and Fontana index (0.953 vs. 0.902, 0.861, and 0.851, respectively; all $P < 0.05$). Furthermore, pretreatment Model A scores in conjunction with Model B scores within 6 months of follow-up could predict 89% (24 of 27) of 1-year events with 100% specificity; this rate was markedly higher than the 41% (11/27) for CTP score, 63% (17/27) for MELD score, and 26% (7/27) for Fontana index.
Conclusions: Our new prediction models will help to determine the need for LT in patients with decompensated HBV-related cirrhosis before and during antiviral treatment.

P0659
CYTOKINE RESPONSES IN CHRONIC HEPATITIS B PATIENTS DOSED WITH THE NUCLEIC-ACID POLYMER REP2139-Ca

F. Stelma[1,2], A. Vaillant[3], L. Jansen[1,2], M.J. Sinnige[1], E.M. van Leeuwen[1], N.A. Kootstra[1], M. Bazinet[3], M. Al-Mahtab[4], H.W. Reesink[2]. [1]*Experimental Immunology,* [2]*Gastroenterology and Hepatology, Academic Medical Center, Amstedam, Amsterdam, Netherlands;* [3]*REPLICor Inc., Montreal, Canada;* [4]*Bangabandhu Sheikh Mujib Medical University, Dhaka, Bangladesh*
E-mail: f.stelma@amc.nl

Background and Aims: Current treatment regimens for patients with chronic hepatitis B (CHB) are only successful in eradicating HBsAg (functional cure) in a minority of patients. Treatment with the HBsAg release inhibitor REP2139-Ca may be a promising new treatment option for CHB patients. The clearance of HBsAg could be the key to restoring the immune response against the hepatitis B virus. Immunologic activity in response to treatment with REP2139-Ca was analysed and patients who responded to therapy were compared to those who did not.
Methods: 12 Patients with HBeAg positive CHB (mean HBVDNA 10log7.36 IU/ml) participating in a phase 2 study were dosed with the nucleic-acid based amphipathic polymer REP2139-Ca for 20–38 weeks. Responders to REP2139 (defined as clearance of serum HBsAg) were subsequently treated with an add-on immunomodulatory agent (peginterferon alpha-2a and/or thymosin alpha-1). Serum samples were collected at baseline, during REP2139-Ca treatment (week 5, 12, 24), during add-on immunomodulatory treatment and follow-up (12–39 weeks after cessation of therapy). Cytokine and chemokine levels were measured using a Luminex 27-plex immunoassay (Affymetrix eBioscience, San Diego, USA).
Results: 9/12 patients cleared HBsAg during dosing with REP2139-Ca. From all cytokines analysed, IFNγ, TNFα, IL-1α, IP-10 and IL-18 significantly increased during treatment with REP2139-Ca. IL-7 and IL-8 serum concentration decreased. Add-on immunomodulatory treatment did not add to this effect as there were no significant differences at week 24 of REP2139-Ca treatment and during immunomodulatory treatment. IL-6, IL1RA and IL-10 did not show significant changes at any of the time points measured. Although the number of patients in this observational study was limited, no significant differences were observed in cytokine levels between responders and non-responders to REP2139-Ca.
Conclusions: In patients treated with REP2139-Ca, significant changes were observed in serum chemokine and cytokine levels during therapy compared to baseline. These results suggest that upon treatment with REP2139-Ca, immune-responses are remodeled, possibly restoring antiviral activity against hepatitis B.

P0660
A SPECIFIC KIR/HLA-C GENOTYPE IS ASSOCIATED WITH IMMUNE ACTIVITY AND RESPONSE TO PEGINTERFERON AND ADEFOVIR IN HBeAg-POSITIVE CHRONIC HEPATITIS B PATIENTS

F. Stelma[1,2], L. Jansen[1,2], M.J. Sinnige[2], E.M. van Leeuwen[2], N.A. Kootstra[2], H.W. Reesink[1,2]. [1]*Gastroenterology and Hepatology,* [2]*Experimental Immunology, Academic Medical Center, Amstedam, Amsterdam, Netherlands*
E-mail: f.stelma@amc.nl

Background and Aims: The antiviral activity of NK cells partially depends on the interaction of killer cell immunoglobulin-like receptors (KIR) and their HLA-C ligands. Genetic variations in KIR/HLA-C influence the outcome of acute hepatitis C infection and single nucleotide polymorphisms (SNPs) in HLA-C have been implicated in hepatitis B chronicity. However, the role of these variations in relation to treatment outcome in chronic hepatitis B (CHB) patients is unknown.

Methods: 86 CHB patients (41 HBeAg-positive; 45 HBeAg-negative) who completed 48 weeks of peginterferon alfa-2a and adefovir combination therapy followed by a treatment-free follow-up (week 72) were included. Patient DNA was isolated from PBMC. SNPs located within or near (±500 base pairs) the HLA-C gene were genotyped with the Illumina Human Omni1-Quad BeadChip (n = 12). Genotyping of KIR2DL1, KIR2DL2 and KIR2DL3 was performed by PCR. Combined response at week 72 (HBeAg negativity, HBV-DNA ≤2,000 IU/mL, and ALT normalization) was achieved in 14/41 HBeAg-positive and 17/45 HBeAg-negative patients.
Results: One SNP in HLA-C (rs2308557; A allele) was significantly associated with combined response in HBeAg-positive patients after correction for multiple testing (p = 0.003), but not in HBeAg-negative patients. This SNP is linked to the presence of an Asn or Lys at position 104 of HLA-C, important for binding specific KIRs (HLA-C group C1 or C2, respectively).
The distribution of C1C1, C1C2, C2C2 genotypes in HBeAg-positive patients was 7 (17%), 17 (42%), and 17 (42%), respectively. HBeAg-positive patients with the C2 allele had higher rates of combined response (13/24 vs 1/17, p = 0.001), and higher baseline ALT levels (median ALT 136 vs 50 U/L, p = 0.002) than patients with only C1 alleles. The C2 allele is specifically recognized by the KIR2DL1 receptor, which was present in all patients. Presence of HLA-C2/KIR2DL1 predicted response independent of HBV genotype A, HBV-DNA and ALT levels in multivariable analysis (p = 0.007). In contrast, the HLA-C1C1/KIR2DL3 combination was more prevalent in HBeAg-positive non-responders than combined responders (15/27 vs 1/14, p = 0.003).
Conclusions: A specific KIR/HLA-C combination was strongly associated with combined response in HBeAg-positive patients. These findings support an important role for the interaction of NK cell receptors and their HLA-C ligands in determining the host immune activity and response to interferon-based therapy in chronic hepatitis B patients.

P0661

PREDICTION OF HBeAg SEROCONVERSION IN HBeAg-POSITIVE CHRONIC HEPATITIS B PATIENTS TREATED WITH ENTECAVIR USING ALT AND PLATELET COUNT: RESULTS FROM A LARGE EUROPEAN MULTI-CENTER STUDY

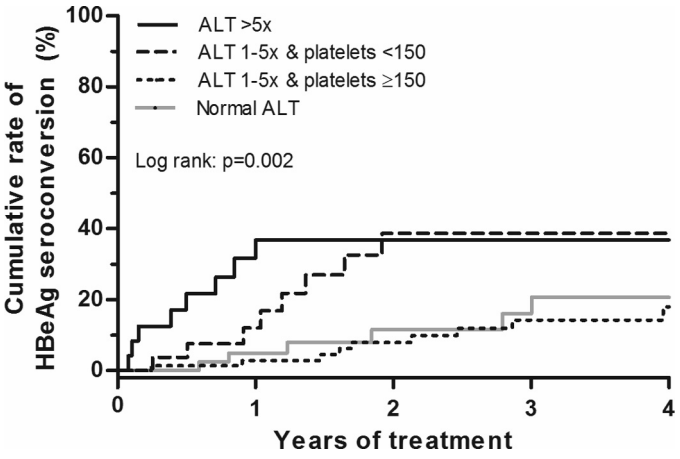
E-mail: h.chi@erasmusmc.nl

Background and Aims: For HBeAg-positive chronic hepatitis B (CHB) patients treated with nucleos(t)ide analogue (NA) therapy, HBeAg seroconversion is an important endpoint as guidelines suggest the possibility to discontinue NA therapy after HBeAg seroconversion. However, the HBeAg seroconversion rate is suboptimal with current first-line NA and there are no reliable tools to predict HBeAg seroconversion in these patients.
Methods: This is a large European multi-center cohort study (VIRGIL) enrolling all consecutive CHB mono-infected patients treated with entecavir (ETV) monotherapy for at least 3 months. Further eligibility criteria were: HBeAg positivity and HBV DNA >2,000 IU/mL at the initiation of ETV. Patients were prospectively monitored at least every 3 months. HBeAg seroconversion was defined as loss of HBeAg and the appearance of anti-HBe confirmed in a consecutive sample.
Results: In total, 218 HBeAg-positive patients were eligible for analysis. Median treatment duration was 2.9 years (IQR 1.5–4.1). Baseline characteristics were: median age 36 years, 75% male, 45% Caucasian, mean HBV DNA 7.2 log IU/mL and median ALT 1.9× upper limit of normal (ULN). ETV was effective in the suppression of viral replication resulting in virological response (HBV DNA <75 IU/mL) of 49% at 1 year, 75% at 2 years and 94% at 4 years. HBeAg seroconversion was confirmed in 41 patients resulting in cumulative HBeAg seroconversion rates of 9% at 1 year, 17% at 2 years and 24% at 4 years. Only baseline ALT levels and platelet count were associated with HBeAg seroconversion. Patients with ALT >5× were more likely to achieve HBeAg seroconversion than patients with ALT 1–5× (hazard ratio [HR] 2.7; p = 0.017), or normal ALT (HR 3.5; p = 0.021). In addition, a platelet count of <150×10^9/L was associated with an increased chance of HBeAg seroconversion, but only among patients with ALT 1–5× (HR 3.5; p = 0.01). Therefore, we combined the ALT level and platelet count to optimize the prediction of HBeAg seroconversion (Figure).
Conclusions: In this large real-life cohort of HBeAg-positive patients treated with ETV, the HBeAg seroconversion rate is low. For these patients, we present an easy to use model to predict HBeAg seroconversion using baseline ALT level and platelet count which are readily available objective parameters. Patients with a low chance to seroconvert should be consulted regarding long-term NA therapy or peginterferon addition strategy.

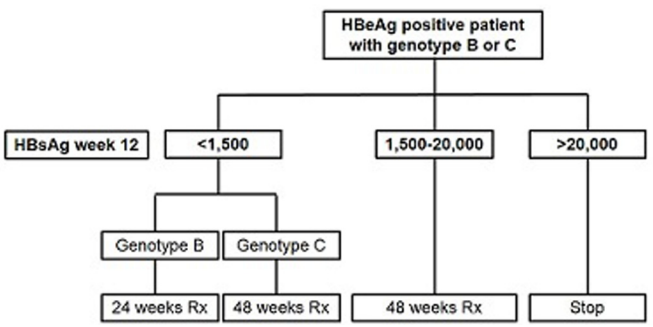


P0662

24 WEEKS OF PEGINTERFERON MAY BE AS GOOD AS 48 WEEKS IN HBeAg-POSITIVE GENOTYPE B PATIENTS WITH AN EARLY HBsAg RESPONSE: POOLED ANALYSIS OF TWO RANDOMIZED TRIALS

M.J. Sonneveld[1], H.L. Chan[2], J. Cheng[3], T. Piratvisuth[4], J.-D. Jia[5], E. Gane[6], Y.-F. Liaw[7], B.E. Hansen[1], Q. Xie[8], V.W.-S. Wong[2], J.-L. Hou[9], H.L. Janssen[10]. *[1]Gastroenterology and Hepatology, Erasmus MC University Medical Center, Rotterdam, Netherlands; [2]Medicine and Therapeutics, Prince of Wales Hospital, Hong Kong; [3]Ditan Hospital, Capital Medical University, Beijing, China; [4]NKC Institute of Gastroenterology and Hepatology, Prince of Songkla Univeristy, Hat Yai, Thailand; [5]Liver Research Center, Friendship Hospital, Beijing, China; [6]Liver Unit, Auckland Hospital, Auckland, New Zealand; [7]Liver Research Unit, Chang Gung Memorial Hospital, Taipei, Taiwan; [8]Department of Infectious Diseases, Ruijin Hospital, Shanghai, [9]Department of Infectious Diseases, Nanfang Hospital, Guangzhou, China; [10]Centre for Liver Diseases, University Health Network, Toronto, Canada*
E-mail: m.j.sonneveld@erasmusmc.nl

Background and Aims: Early HBsAg decrease during peginterferon (PEG-IFN) therapy is associated with high rates of sustained response. We hypothesized that 24 weeks (wks) may be as good as 48 wks in patients with low HBsAg levels at wk 12.
Methods: HBeAg-positive patients treated with PEG-IFN alfa-2a (180 mcg/wk) or alfa-2b (1.5 mcg/kg/wk) for 24 or 48 wks in two randomized trials (Neptune and P05170) were analysed. HBsAg at wk 12 was defined as low (<1,500 IU/mL), intermediate (1,500–20,000) or high (>20,000). Response was defined as HBeAg loss with HBV DNA <2,000 IU/mL at 24 wks off-treatment.
Results: 593 patients were analysed; 292 (49%) treated for 24 weeks, 301 (51%) for 48 weeks. HBV genotypes were A/B/C/D/other in 10/245/317/12/9. In the overall population, response was achieved more frequently with 48 weeks than with 24 weeks of therapy (21% vs 13%, p = 0.008). HBsAg levels at wk 12 were low in 148 (25%), intermediate in 298 (50%) and high in 147 (25%) with comparable rates among the treatment groups (p = 0.890). Among patients with high HBsAg levels, response rates were <5% regardless of therapy duration. Among patients with intermediate HBsAg levels, 48 wks was superior to 24 wks (23% vs 9.7%, p = 0.002). Conversely, among patients with low HBsAg levels, response rates were similar for patients treated with 24 vs 48 wks (31% vs 34%, p = 0.642). Stratification by HBV genotype (B or C only) showed that among patients with low HBsAg levels, response rates with 24 vs 48 wks of PEG-IFN were similar for genotype B [numerically higher with 24 wks, 46% (17/37) vs 31% (11/35), p = 0.207], but not for genotype C [higher with 48 wks, 14% (5/36) vs 38% (14/37), p = 0.02]. Among patients with intermediate HBsAg levels at week 12, 48 weeks of therapy was superior to 24 weeks regardless of HBV genotype. All findings were homogenous across the two separate cohorts. Based on these findings a new algorithm could be proposed for management of HBeAg-positive patients treated with PEG-IFN (figure) dependent upon further validation.



Conclusions: Genotype B patients with low HBsAg levels at wk 12 may potentially be able to shorten therapy to 24 wks, allowing a reduced therapy duration in about one-third of genotype B patients. Genotype B and C patients with intermediate HBsAg levels benefit from a full 48 wk course, as do genotype C patients with low HBsAg levels. All patients with high HBsAg levels at wk 12 have low response rates regardless of treatment duration.

P0663

FACTORS ASSOCIATED WITH NON-ADHERENCE TO ANTIVIRAL TREATMENT FOR HEPATITIS B

N. Allard[1,2,3], A. Dev[4,5], J. Dwyer[6], G. Srivatsa[7], A. Thompson[8,9], B. Cowie[2,9]. *[1]Department of Medicine, Universtiy of Melbourne, [2]Epidemiology, The Doherty Institute, [3]Joslin Clinic, Cohealth, [4]Gastroenterology, Monash Medical Centre, [5]Department of Medicine, Monash University, [6]Pharmacy, Mercy Hospital, Melbourne, [7]Gastroenterology, Western Hospital, Footscray, [8]Gastroenterology, St Vincent's Hospital, [9]Department of Medicine, University of Melbourne, Melbourne, Australia*
E-mail: Nicole.Allard@mh.org.au

Background and Aims: Anti viral therapy for chronic hepatitis B (CHB) is effective and reduces the risk of cancer and cirrhosis but is often for an indefinite duration. Adherence is important to prevent the development of resistance to current therapies and prevent complications.
Adherence can be measured by pharmacy adherence measures. The medication possession ratio (MPR) is less susceptible to social desirability bias than physician or self-report and is a measure of maximal adherence. The aim of this study was to measure adherence in public hospital patients over a 3-year period using MPR and look at factors associated with non-adherence.
Methods: A retrospective analysis of pharmacy records of patients dispensed antiviral therapy for CHB from 4 major hospitals in Melbourne between 2010–2103. De identified demographic information including age, sex, Indigenous status, country of birth, requirement for an interpreter, spoken language, postcode of residence were matched with hospital record number for 3 of the 4 sites.
The medication possession ratio (MPR) was the outcome measure. It was calculated from the amount of tablets dispensed from the hospital pharmacy over a time period and analysed as a continuous and dichotomous variable (<0.9 defined as non-adherent to therapy). Univariate analysis on factors affecting non-adherence was performed. Data were analysed in STATA 13 with two-sided tests of proportions or Chi-squared test.
Results: Records of 980 patients were included in the analysis. Median MPR for all patients was 0.99 inter quartile range 0.92–1.00. This did not vary significantly by hospital. Significant factors affecting non-adherence in univariate analysis, included patients aged <35 years (p = 0.002) or who required an interpreter (p = 0.0005). Socio-economic status as defined by postcode of residence (p = 0.38), gender (p = 0.46) and distance to hospital (p = 0.56) were not significant factors affecting adherence.
Conclusions: This is the largest study reporting on factors associated with adherence to hepatitis B treatment across multiple hospitals in Australia. While adherence was high, one in five patients were non-adherent. Extended analysis including additional demographic factors and multivariate analysis will be presented. This study will guide the development of strategies to improve adherence to treatment for people living with chronic hepatitis B.

Table 1: Adherence of hospital patients and univariate analysis of factors affecting non-adherence of patient receiving antiviral treatment for chronic hepatitis B

		Number of observations (Total)	(%)		
Adherence measure	MPR < 0.90	205 (980)	20.92

INVESTIGATION OF RESIDUALS RESPONSIBLE FOR BINDING OF TRIAZOLO-PYRIMIDINE INHIBITORS WITH HBsAg BASED ON MOLECULAR DOCKING AND PHARMACOPHORE METHODS FOR DESIGNING POTENT HBsAg INHIBITORS

E. Pourbasheer[1], M.A. Shahmohammadi[2], R. Aalizadeh[3].
[1]Department of Chemistry, Payame Noor University (PNU), P.O. Box 19395-3697, Tehran, Iran; [2]Department of Chemistry, Umea University, Umea, Sweden; [3]Laboratory of Analytical Chemistry, Department of Chemistry, University of Athens, Panepistimiopolis Zografou, 157 71 Athens, Greece
E-mail: pourbasheer@ut.ac.ir

Background and Aims: The true knowledge of binding pockets of Hepatitis B virus surface antigen can provide valuable information regarding the better designing of novel HBsAg inhibitors, however due to less information about the residuals evolved in structure of HBsAg, it is a challenging work to perform the drug design simulation. The primary purpose of this work is to compare the selected residuals of HBsAg structure with QSAR modeling analyses, and then identifying the residuals responsible for interactions with drugs; Secondly, using these results for designing some potent inhibitors by docking simulation.
Methods: The data set and biological activities (EC_{50}) of triazolo-pyrimidine inhibitors were taken from literature [J. Med. Chem. 54 (2011) 5660–5670]. The protein complexes were selected from literature [Virology 370 (2008) 362–372], and then AutoDock 4.2 program was used to understand their existing interactions. The results of docking were then analyzed with LigandScout 3.03 program. After deriving the key features for increasing the inhibition activities, new compounds were designed and their activities were predicted using a validated QSAR model (GA-OLS-MLR).
Results: From QSAR analyses, it was observed that the most responsible molecular descriptors regarding the inhibition activities are distance between Cl atoms, molecular eccentric connectivity, and three-dimensional arrangement of the atoms. This is also observed that the atomic polarizabilities cause decrease in biological activities. The results are in line with molecular docking in which it was observed that the hydrophobic characteristics play crucial role in improvements of pEC_{50}. Pharmacophore and molecular docking resulted in identification of several residuals which are shown in Figure 1. Consequently, some novel drugs were designed and their biological activities were predicted using a robust QSAR model as follows:

pEC_{50} = −1.996(±1.781) − 24.13(±3.141)RBF − 1.284(±0.3572)BEHp8 + 15.46(±1.551)MEcc − 3.573(±0.3357)PJI3 + 0.0496(±0.0071)RDF070u − 3.374(±0.6840)HATS5u + 0.300(±0.0671)B08[Cl–Cl].

Several validation methods were used to evaluate the prediction capability of the developed model, and the obtained results confirmed that the built model can be used as prediction tool for subsequent novel drugs.
Conclusions: Based on the obtained results some new inhibitors targeting HBsAg were designed and then their 50% effective concentrations were predicted using the constructed model. The newly designed potent compound i shown in Figure 1.

E-mail: julianne.bayliss@mh.org.au

Background and Aims: GS-US-174-0103 is a phase 3 study that evaluated tenofovir (TDF) in HBeAg-positive chronic hepatitis B (CHB). Approximately 25% of patients underwent HBeAg seroconversion (SC) by W48, with an additional 25% by W192 (Year 4). Additionally, 11% of patients achieved HBsAg loss by W192. The aim of this study was to quantify clinically relevant mutations within regulatory and structural regions of the HBV genome using next generation sequencing (NGS) at baseline and correlate to these with treatment response to TDF.
Methods: Illumina MiSeq full genome NGS was performed on a subset of 94 baseline samples from patients enrolled in study 103 with longitudinal clinical data to W192. A specialised platform was developed to enable quantitative determination of SNPs and

insertion/deletion events across the whole genome. The results of NGS were correlated with virological and serological data including HBV DNA, HBsAg, and HBeAg levels as well as time to viral load undetectable, HBeAg SC and HBsAg loss.

Results: Among the 94 patients, the rate of HBeAg SC was 56% and HBsAg loss was 19% by W192. Using a threshold for detection of 1%, known HBV variants were detected in patients across regulatory (NRE, BCP, PC) and structural (core, PreS1/2, HBsAg, Pol) regions (Table 1). NGS was able to detect and quantify low frequency mutations that were not detected by population sequencing.

Table 1. Key mutations identified within the 103 cohort

	n (%)	
	Pop[n]	NGS
Negative Regulatory Element (NRE) G1613A	11 (12%)	31 (33%)
Basal Core Promoter (BCP) A1762T/G1764A	32 (34%)	40 (43%)
BCP T/C1858G	9 (9%)	11 (12%)
Precore (PC) G1896A	14 (15%)	39 (41%)
Core P130T	21 (22%)	39 (41%)
PreS1 M1	0	11 (12%)
PreS2 M1	8 (9%)	27 (29%)
HBsAg P120T/G145R	6 (6%)	23 (24%)
Pol A181T/M204V/M250I	2 (2%)	28 (30%)

HBeAg SC by W192 was independently associated with older age ($p = 0.007$), higher baseline ALT, higher baseline HBeAg and genotype A (model $p < 0.0001$; $R^2 = 0.14$). Presence/absence of mutations within the NRE, BCP, PC and core regions at baseline did not independently impact on HBeAg SC.

Baseline HBeAg and HBsAg levels, genotype, fibrosis and presence of wild type variants at A1762, G1764, and P130 were independently associated with HBsAg loss by W192 (model $p < 0.0001$; $R^2 = 0.30$). Most importantly, higher HBsAg levels at baseline were predictive of HBsAg loss ($p < 0.0001$). Low levels of S and/or Pol mutations at baseline did not predict for viraemia at W24 or W48 of treatment.

Conclusions: This study has identified novel virological and serological markers of treatment response in immune clearance CHB. Patients with high baseline HBeAg and HBsAg levels and WT variants within the BCP and core are most likely to achieve HBsAg loss during TDF treatment. Our study further highlights the value of NGS for detecting clinically relevant mutations which may be overlooked by traditional sequencing.

P0666

ANALYZING THE MUTATION PATTERN OF MULTI-DRUG RESISTANT HEPATITIS B VIRUS DURING ENTECAVIR RESCUE THERAPY

B. Jin[1], Y.E. Chon[2], B.K. Kim[2], S.U. Kim[2], J.Y. Park[2], D.Y. Kim[2], K.-H. Han[1,2,3], S. Kim[2,3], S.H. Ahn[1,2]. *[1]Brain Korea 21 Plus Project for Medical Science, [2]Institute of Gastroenterology, Department of Internal Medicine, [3]Severance Biomedical Science Institute, Yonsei University College of Medicine, Seoul, Korea, South*
E-mail: deeppurple@yuhs.ac

Background and Aims: Analyzing the mutation pattern of multi-drug resistance is important in treatment of CHB. However, evolution pattern of multi-drug resistant in patients who received ETV rescue therapy has been rarely studied.

Methods: Eight CHB patients with LAM- and ADV-resistant mutations showing partial virological response to ETV and subsequent ETV plus ADV therapy were enrolled. Mutation pattern was investigated. Direct sequencing, multiplex restriction fragment mass polymorphism (RFMP), and clonal analysis were compared for the utility of affecting on clinical decision of antiviral therapy. The binding affinity of TDF was investigated by molecular modeling.

Results: Among 160 clones at baseline, wild type HBV was present in 38.8%, LAM-resistant mutations in 30.6%, and ADV-resistant mutations in 34.4%. LAM-resistant mutation increased to 67.5% at the end of ETV therapy, and increased more to 69.4% at 12 month of ETV plus ADV therapy. ETV-resistant mutations reached 46.3% at the end of ETV therapy, but slightly decreased to 38.8% at 12 month of ETV + ADV therapy. ADV-resistant mutation decreased to 3.1% at the end of ETV therapy, but slightly increased to 9.4% at 12 month of ETV + ADV therapy. Among 256 of candidate mutation sites of HBV reverse transcriptase (rt) polymerase, direct sequencing detected 14.1%, multiplex RFMP 27.7%, and clonal analysis 35.2% in mutations. All mutations detected by direct sequencing revealed identical results in the respective analyses by clonal analysis and multiplex RFMP. Among 28 mutations which revealed discordant results between clonal analysis and multiplex RFMP, clonal analysis detected 24 (85.7%) mutations which RFMP did not. However, none of the mutations exceeding 40% of total clones by clonal analysis were missed by multiplex RFMP. The binding affinities of TDF with rtM204V/I+rtA181T/V mutant or rtM204V/I+rtN236T mutant were both strong, but the latter showed minutely decreased affinity due to rtN236T.

Conclusions: The clonal evolution of multi-drug resistant HBV revealed the selection of LAM-resistant (±ETV-resistant) HBV during ETV rescue therapy, and the main reason for suboptimal response might be LAM-resistance (±ETV-resistance) which predominated over ADV resistance. Multiplex RFMP showed high sensitivity for detecting LAM-resistant (±ETV-resistant) mutation taking less time and labor than clonal analysis. The potent drug TDF showed strong binding affinity in multi-drug resistant HBV regardless of their co-location.

INTERRUPTION OF NUCLEOS(T)IDE ANALOGUE THERAPY FOR HBeAg-NEGATIVE CHRONIC HEPATITIS B – A NEW CONCEPT TO ACHIEVE HBsAg DECLINE?

C. Hoener Zu Siederdissen[1], F. Rinker[1], C. Falk[2], N. Filmann[3], B. Maasoumy[1], K. Deterding[1], K. Port[1], C. Mix[1], E. Herrmann[3], H. Wedemeyer[1], M.P. Manns[1], A. Kraft[1], M. Cornberg[1]. *[1]Department of Gastroenterology, Hepatology and Endocrinology, [2]Institute of Transplant Immunology, Hannover Medical School, Hannover, [3]Institute of Biostatistics and Mathematical Modeling, Faculty of Medicine, Goethe-University, Frankfurt am Main, Germany*
E-mail: hoenerzusiederdissen.christoph@mh-hannnover.de

Background and Aims: HBsAg loss during treatment with nucleos(t)ide analogues (NA) is a rare event. Thus, treatment duration with NA is usually not finite and stopping rules before HBsAg loss are not clearly defined, especially in HBeAg-negative patients.

Methods: In a prospective pilot trial, we stopped NA treatment in 15 patients with HBeAg-negative chronic hepatitis B. Inclusion criteria were ongoing antiviral treatment with NA and suppressed HBV DNA <20 IU/ml for at least 3 years as well as HBsAg <3500 IU/ml. Patients with co-infection, other concomitant liver disease, liver cirrhosis and immunosuppressive therapy were excluded. All patients had an indication for antiviral treatment at the time point of NA initiation according to international guidelines. At every visit, patients were assessed for virological relapse, defined by HBV DNA >2000 IU/ml. Quantitative HBsAg levels one year before and after treatment cessation were compared to assess differences in HBsAg levels. Serum IP-10 (CXCL10) levels of 13 patients were analysed using multiplex technology (BioRad Bio-Plex-System).

Results: So far, complete data are available for 13 patients with one year follow-up (FU). Virological relapse after treatment cessation was detected in 4 patients (31%) at week 4, in 7 patients (54%) at week 8 and in 1 patient at week 24. No virological relapse occurred in 1 patient. Interestingly, IP-10 levels were significantly enhanced at week 8 after stop of NA therapy ($p = 0.028$). Two patients developed an ALT flare >5 ULN during FU but no patient showed signs of liver failure or significant increase

of bilirubin. In 11/12 patients with virological relapse treatment was re-initiated with either entecavir or tenofovir and HBV-DNA was successfully suppressed at week 48 follow-up. Importantly, longitudinal monitoring before/after cessation showed a significant decline in median HBsAg levels from stop of NA therapy to 48 week FU (p = 0.0012) while there was no change during NA therapy one year before treatment cessation.

Conclusions: Treatment cessation in non-cirrhotic patients with HBeAg-negative chronic hepatitis B is safe but leads to virological relapse in >90% until week 24. Stop of NA therapy was associated with an induction of serum IP-10 that may help to explain the effect on HBsAg decline. Thus interrupting NA treatment and inducing immune responses should be further investigated as an option to facilitate HBsAg loss.

P0668

ON-TREATMENT HBsAg KINETICS TO PREDICT LONG-TERM HDV RNA RESPONSE TO PEG-IFNa TREATMENT OF HEPATITIS DELTA

M. Wöbse[1], S. Hardtke[1,2], S. Ernst[3], H. Benjamin[1,2], B. Bremer[1], O. Keskin[4], A. Koch[3], M.P. Manns[1,2], H. Wedemeyer[1,2], C. Yurdaydin[4], on behalf of HIDIT-2 Study Group. *[1]Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, [2]German Centre for Infection Research (DZIF), HepNet Study-House, [3]Institute for Biometry, Hannover Medical School, Hannover, Germany; [4]University of Ankara Medical School, Ankara, Turkey*
E-mail: woebse.michael@mh-hannover.de

Background and Aims: The only treatment option for hepatitis D (delta) is PEG-Interferon alfa (PEG-IFNa) leading to off-treatment HDV-RNA suppression in less than 25% of cases. HBsAg and HDV RNA levels correlate in untreated HDV-infected patients. In HBV monoinfection, stopping rules based on HBsAg levels or declines have been established for PEG-IFNa-based therapies. The role of on-treatment HBsAg kinetics during PEG-IFNa treatment of hepatitis D (delta) virus (HDV) infection is unknown.
Consequently the primary aim is to investigate if HBsAg kinetics during PEG-IFNa therapy can predict HDV RNA response 24 weeks after therapy.

Methods: 120 HDV-RNA-positive patients were treated for 96 weeks with PEG-IFNa-2a in combination with tenofovir or placebo in the HIDIT-2 study (Wedemeyer et al. EASL 2014). Here we selected all patients who received at least 80 weeks of therapy and for whom HDV-RNA-values 24 weeks after the end of therapy were available (n = 93). HBsAg was determined during treatment weeks 12, 24, 36 and 48.

Results: HDV RNA was undetectable at post-treatment week 24 (week 120; PTw24 response) in 31 of the 93 patients (33.3%). Mean quantitative HBsAg levels did not decline before week 24 (−0.21 log IU/ml) but gradually decreased thereafter (week 36 −0.31 log IU/ml; week 48 −0.46 log IU/ml). Mean HBsAg levels did not differ between off-treatment HDV RNA responder patients, off-treatment HDV RNA relapser and HDV RNA non-responder patients. HBsAg declines of more than 1 log IU/ml from week 24 onwards were highly predictive of long-term HDV RNA suppression with PPVs between 81% and 100%. However, only few patients achieved an HBsAg decline of >1 log IU/ml during treatment (5, 10 and 16 patients at treatment weeks 24, 36 and 48, respectively with PPVs for PTw24 response of 100%, 90% and 81%). Patients who did not show any HBsAg decline at treatment week 24 (n = 32) had a low chance for achieving a PTw24 HDV RNA response (12.5%; NPV 87.5%). However, we failed to identify distinct HBsAg cut-offs with negative-predictive values of >90%.

Conclusions: HBsAg kinetics during the first year therapy are associated with off-treatment HDV RNA response after 2 years of PEG-IFNa-based treatment of hepatitis D (delta). However, reliable stopping rules based on quantitative HBsAg levels to avoid unnecessary prolonged PEG-IFNa therapy could not be established.

P0669

CONSOLIDATION THERAPY WITH ENTECAVIR CAN PREVENT POST-TREATMENT HBsAg REBOUND IN HBeAg-POSITIVE CHRONIC HEPATITIS B PATIENTS TREATED WITH PEGINTERFERON ALPHA

W.P. Brouwer[1], M.J. Sonneveld[1], Q. Xie[2], N. Zhang[3], S. Zeuzem[4], F. Tabak[5], Q. Zhang[6], K. Simon[7], U.S. Akarca[8], A. Streinu-Cercel[9], B. Hansen[1], H.L. Janssen[10]. *[1]Gastroenterology & Hepatology, Erasmus MC Rotterdam, Rotterdam, Netherlands; [2]Gastroenterology & Hepatology, Infectious Diseases, Ruijin Hospital, Jiaotong University, [3]Gastroenterology & Hepatology, Zhong Shan Hospital, Fu Dan University, Shanghai, China; [4]Gastroenterology & Hepatology, Medizinische Klinik 1, Klinikum der Johann Wolfgang Goethe-Universität, Frankfurt am Main, Germany; [5]Gastroenterology & Hepatology, Cerrahpasa Medical Faculty, Istanbul, Turkey; [6]Gastroenterology & Hepatology, Shanghai Public Health Center, Fu Dan University, Shanghai, China; [7]Gastroenterology & Hepatology, Wroclaw Medical University, Wroclaw, Poland; [8]Gastroenterology & Hepatology, Ege Üniversitesi Tip Fakultesi, Bornova, Turkey; [9]Gastroenterology & Hepatology, National Institute of Infectious Disease, Bucharest, Romania; [10]Gastroenterology & Hepatology, Center for Liver Disease, Toronto Western and General Hospital, University Health Network, Toronto, Canada*
E-mail: w.p.brouwer@erasmusmc.nl

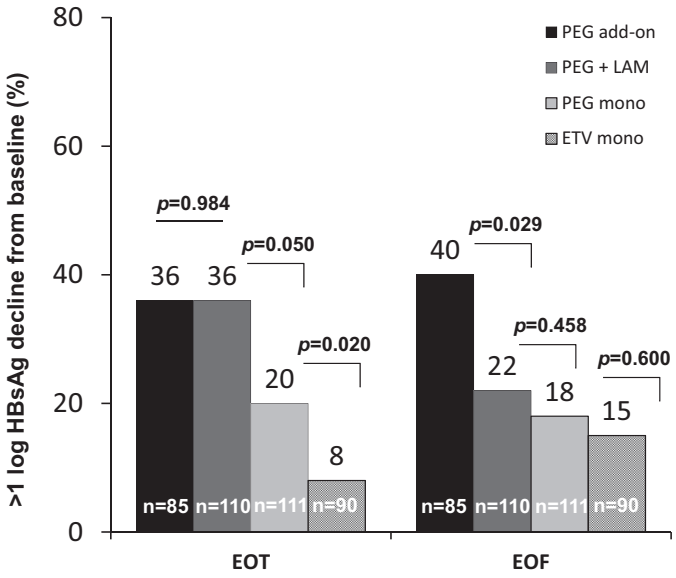
Background and Aims: It is unknown whether adding-on peginterferon (PEG-IFN) to entecavir (ETV) leads to more HBsAg decline compared to PEG-IFN monotherapy or de novo combination therapy, and whether consolidation therapy prevents HBsAg relapse after PEG-IFN cessation.

Methods: We performed a post-hoc comparison of 396 HBeAg-positive patients treated for 72 weeks with ETV + 24 weeks PEG-IFN add-on from week 24–48 (add-on, n = 85), 72 weeks with ETV monotherapy (n = 90), 52 weeks with PEG-IFN monotherapy (n = 111) and 52 weeks PEG-IFN + LAM (combination, n = 110) within 2 international randomized trials (ARES and HBV 9901 respectively). The extent of HBsAg decline was assessed on-treatment, at end-of PEG-IFN (EOT) and 6 months after PEG-IFN (EOF). Differences in baseline characteristics were accounted for using propensity scores as inversed weighting in regression analysis.

Results: Of 396 patients, 75% was male, mean age was 33 years and HBV genotype A/B/C/D was present in 22%/13%/27%/36% respectively. For add-on, combination, PEG-IFN mono and ETV the mean estimated HBsAg level decline achieved at EOT was −0.80, −1.27, −0.77 and −0.32 log IU/mL (combination vs add-on p = 0.045) and −0.84, −0.81, −0.68, and −0.33 log IU/mL, at EOF respectively (p > 0.05 for PEG-IFN arms). The estimated proportion of patients with ≥1 $\log_{10}$ HBsAg reduction from baseline at EOT and EOF was 36% and 40% for add-on, 36% and 22% for combination, 20% and 18% for PEG-IFN mono and 8% and 15% for ETV, respectively (p = 0.984 and p = 0.029 for add-on vs combination at EOT and EOF, figure). Patients treated with PEG-IFN + NUC more frequently achieved a HBsAg decline ≥1 $\log_{10}$ at one year (36% vs 20%), but this advantage was only sustained in patients who continued ETV therapy until 6 months post PEG-IFN discontinuation: the estimated proportion of patients who relapsed from >1 at EOT to <1 $\log_{10}$ HBsAg reduction at EOF was 5%, 46%, 38% and 0%, respectively. Estimated HBeAg loss rates at EOT were 22%, 40%, 27% and 11% (p = 0.039 for add-on vs combination) and 35%, 31%, 33% and 23% at EOF (p > 0.05 for PEG-IFN arms).

Conclusions: The combination of PEG-IFN with a NUC either as de novo for 52 weeks or as add-on for 24 weeks results in more on-treatment HBsAg decline than does 52 weeks of PEG-IFN alone. Continuation of ETV after PEG-IFN discontinuation may prevent

HBsAg rebound. Future randomized trials should evaluate the role of consolidation therapy.



P0670

PLASMA MICRORNA LEVELS ARE ASSOCIATED WITH THERAPY RESPONSE IN CHRONIC HEPATITIS B PATIENTS TREATED WITH PEGINTERFERON AND ADEFOVIR

M. Van Der Ree[1,2], L. Jansen[1,2], K. van Dort[2], B. Takkenberg[1], N.A. Kootstra[2], H.W. Reesink[1,2]. *[1]Department of Gastroenterology and Hepatology, [2]Department of Experimental Immunology, Academic Medical Center, Amsterdam, Netherlands*
E-mail: meike.vanderree@amc.uva.nl

Background and Aims: MicroRNAs (miRNAs) are small, non-coding RNA molecules involved in various cellular processes of post-transcriptional regulation of gene expression. Circulating miRNAs have been linked to multiple diseases, including hepatitis B virus infection. The aim of this study was to quantify miRNAs in plasma of chronic hepatitis B (CHB) patients before the start of therapy and to determine miRNA signatures associated with response to antiviral therapy.

Methods: In an investigator-initiated study, 86 CHB patients completed 48 weeks of peginterferon alfa-2a and adefovir combination therapy, followed by a treatment-free follow-up of 2 years (week 144). We selected 12 HBeAg-positive and 12 HBeAg-negative patients as an identification cohort, both consisting of 6 non-responders and 6 combined responders (HBeAg negativity, HBV-DNA ≤2,000 IU/mL, and ALT normalization) of which 3 patients had HBsAg loss. A microRNA RT-qPCR assay (Exiqon) was used to determine the expression level of 179 different miRNAs in plasma. Data were pre-processed and analyzed with GenEx software from MultiD. MiRNAs with a >2-fold change between responders and non-responders ($p < 0.05$) were identified as potential candidates.

Results: In the identification cohort ($n = 24$), 21 miRNAs were differentially expressed between HBeAg-positive and -negative patients, of which 18 miRNAs were higher in HBeAg-positive patients. Patients with combined response had higher baseline levels of miR-142 compared to non-responders, whereas levels of miR-25-3p and miR-16-5p were lower. Patients with HBsAg loss had higher levels of miR-145-5p ($p < 0.01$) and miR-143-3p at baseline compared to non-responders, irrespective of HBeAg status. In HBeAg-positive patients, levels of 3 miRNAs were higher in patients with HBsAg loss compared to non-responders (miR-652-3p, miR-18b-5p and miR-221-3p), whereas miR-92a-3p level was lower. HBeAg-negative patients with HBsAg loss had a significant higher level of miR-143-3p and lower levels of 9 miRNAs (miR-30e-3p, miR-421, miR-146-5p and miR-26a-5p, all $p < 0.01$) at baseline compared to non-responders.

Conclusions: We identified several potential miRNA candidates that are associated with HBeAg status and HBsAg loss in CHB patients. Circulating miRNAs may be used as markers to predict treatment outcome in CHB patients receiving interferon-based therapy. The results obtained in these 24 patients are presently validated in a larger group of patients.

MECHANISMS OF HCV-INDUCED DIABETES THROUGH IMPAIRED INSULIN-DRIVEN GLUCONEOGENESIS SHUT-DOWN BY HCV PROTEINS AS A RESULT OF UNCOUPLING OF FoxO1/AKT SIGNALING

H. Lerat[1], J. Polyte[1], A. Gaudin[1], M.-R. Imache[1], C. Magnan[2], F. Foufelle[3], J.-M. Pawlotsky[4]. *[1]IMRB Inserm U955, Eq 18, University Paris-Est, Creteil, [2]CNRS EAC 4413 équipe 2, University Paris Diderot, [3]Centre de Recherche des Cordeliers, UMRS 872, University Paris 6, Paris, [4]IMRB Inserm U955, Eq 18, Hôpital Henri Mondor, Creteil, France*
E-mail: herve.lerat@inserm.fr

Background and Aims: HCV infection is an independent risk factor for type 2 diabetes in humans. The underlying molecular mechanisms remain unknown. Our aims were to assess whether FL-N/35 transgenic mice expressing the full HCV-ORF develop diabetes, and to use this in vivo model to unravel the molecular mechanisms of HCV-induced diabetes.

Results: HCV transgenic mice displayed similar baseline glycemia, but significantly higher insulinemia and HOMA-IR than control littermates. Glucose tolerance tests resulted in significantly higher glycemia levels in transgenic mice, demonstrating that HCV protein expression is associated with glucose intolerance, as observed in HCV-infected patients. We measured insulin resistance and metabolic flux using hyperinsulinemic euglycemic clamps. We observed a significantly lower glucose infusion rate and higher endogenous glucose production (EGP), which were related to a drastic diminution of soleus striated muscle glucose uptake, witnessing insulin resistance in HCV mice at both muscular and hepatic levels. The insulin receptor pathway was studied in isolated HCV transgenic primary hepatocytes. We observed that the early steps of the insulin signaling pathway, from IRS1/2 to PDK1 phosphorylation, were constitutively impaired in the liver of HCV mice, potentially trough a SOCS3-dependent mechanism. Higher EGP in spite of higher fasting insulinemia in HCV mice was concomitant to lower levels of glucokinase and fructose-1,6-bisphosphatase and higher levels of phosphoenolpyruvate carboxykinase transcripts in their livers, a finding in keeping with enhanced gluconeogenesis. The lack of gluconeogenesis inhibition by insulin usually reflects abnormal AKT activation. Unexpectedly, AKT phosphorylation at serine 473 was increased in HCV mice compared to WT mice, even after insulin injection. However, phosphorylation of the forkhead transcription factor FoxO1 at serine 256, which triggers its nuclear exclusion, was lower in HCV mouse livers, demonstrating an uncoupling of the canonic AKT/FoxO1 pathway.

Conclusions: In conclusion, we showed that the sole expression of HCV proteins in the liver, in the absence of detectable inflammation, induces insulin resistance through an impairment of

insulin signaling leading to a pre-diabetic state in HCV transgenic mice, providing a valuable mechanistic explanation to HCV-induced diabetes in infected patients.

P0672

INTERACTION BETWEEN HEPATIC MEMBRANE TYPE-1 MATRIX METALLOPROTEINASE AND ACIREDUCTONE DIOXYGENASE 1 REGULATES HEPATITIS C VIRUS INFECTION

C.-T. Yeh[1], J.-C. Cheng[2], M.-L. Chang[3]. *[1]Liver Research Center, Chang Gung Memorial Hospital, Taoyuan, [2]Medical Technology, China Medical University, Taichung, [3]Liver Research Center, Chang Gung Mem Hosp, Taoyuan, Taiwan*
E-mail: chautingy@gmail.com

Background and Aims: Membrane type-1 matrix metalloproteinase (MT1-MMP or MMP14) binds to and regulates the function of tetraspanin-enriched microdomains, which comprised members of the tetraspapnin family, including CD81. MMP14 also physically interacts with two other proteins, claudin-1 and acireductone dioxygenase 1 (ADI1), which are associated with hepatitis C virus (HCV) cell entry. To gain insight into the regulatory role of MMP14 in HCV infection, we examined the liver expression levels of MMP14, ADI1, and claudin-1 in association with hepatic HCV-RNA amounts.
Methods: 104 liver biopsies obtained from chronic hepatitis C patients and 84 liver tissues derived from non-cancerous parts of surgically removed HCV-related hepatocellular carcinomas (HCC) were included. Protein expression levels were assessed by IHC and/or western blot. Physical association between MMP14 and ADI1 or claudin-1 was assessed by co-immunoprecitation.
Results: Neither the tissue ADI1, claudin-1, or the tissue MMP14 levels correlated with hepatic HCV-RNA amounts. However, in chronic hepatitis C patients, the presence of cytoplasmic localization of ADI1 in liver biopsies was associated with a higher serum HCV RNA level (P = 0.009). In HCC tissues, 45 (53.6%) samples tested positive for MMP14 – ADI1 interaction harbored a lower HCV-RNA amounts (2.22±1.61 vs. 3.10±1.40 Log IU/gram, P = 0.009). The HCV-RNA amounts in this group of patients were positively associated with the ADI1 levels in the MMP14 – ADI1 co-immunoprecipitates (P = 0.030). On the other hand, in 33 (39.3%) samples tested positive for MMP14 – claudin-1 interaction, the hepatic HCV-RNA amounts were positively correlated with the claudin-1 levels in the MMP14 – claudin-1 co-immunoprecipitates (P = 0.033). Over-expression of MMP14 in Huh7.5 cells suppressed cell entry of HCV pseudoparticles as well as HCVcc infection. The suppression effect could be reversed by co-expression of ADI1 in a dose-dependent manner.
Conclusions: MMP14 – ADI1 interaction was associated with down-regulation of HCV infection. The negative regulatory effect could be reversed by over-expression of ADI1. Our findings supported a role of tetraspanin-enriched microdomains in HCV cell entry.

P0673

PATHOPHYSIOLOGY OF HCV-RELATED HEPATOCELLULAR CARCINOMA: HCV PROTEIN EXPRESSION INDUCES THE ACTIVATION OF AKT1 IN HEPATOCYTES THROUGH AN mTORC2 DEPENDENT PATHWAY

M.-R. Imache[1], J. Polyte[1], J.-M. Pawlotsky[2], H. Lerat[1]. *[1]IMRB Inserm U955, Eq 18, University Paris-Est, [2]IMRB Inserm U955, Eq 18, Hôpital Henri Mondor, Creteil, France*
E-mail: herve.lerat@inserm.fr

Background and Aims: The Pi3K-AKT pathway is a critical intracellular node regulating cell survival and proliferation. Activation of the AKT pathway has been reported in many cancers, including hepatocellular carcinoma (HCC). We previously showed that c-MYC is overexpressed through an AKT-dependent mechanism in HCV-infected patients and transgenic mice expressing the HCV proteins (*Higgs et al., Oncogene 2013*). The present study aimed at unraveling the molecular mechanisms of AKT activation during HCV infection.
Methods: AKT activation pathway was studied in human and mouse liver samples by mean of immunoprecipitation and western blotting.
Results: We observed a significant hyperphosphorylation of AKT-ser473 in non-tumoral hepatic tissues from infected patients with HCC as compared to HBV-infected or non-infected alcoholic patients. Hyperphosphorylation of AKT-ser473 was also observed in 3 months-old HCV transgenic mouse livers as compared to wild-type mice, which persisted after EGF treatment. AKT1, but not AKT2, was the activated form. We observed an increase in the phosphorylation of mTOR-ser2448 within the mTORC2 complex and a concomitant increased kinase activity of this complex, associated with reduced phosphorylation of p70S6K-thr389 and PDK1-ser241.
Conclusions: Our results suggest that HCV protein expression modulates the negative feedback loop that controls AKT phosphorylation, thus leading to its hyperactivation, potentially playing a role in hepatic carcinogenesis. Because numerous molecules targeting the PI3K/AKT pathway have been used in other cancers than HCC, our results suggest such approaches could be valuable in the prevention or treatment of HCV-associated HCC.

CLINICALLY APPROVED T-TYPE CALCIUM CHANNEL INHIBITORS PREVENT HEPATITIS C VIRUS (HCV) MEMBRANE FUSION IN A GENOTYPE-DEPENDENT MANNER

P.M. Perin[1], S. Haid[1], R. Brown[1], K. Schulze[2], C.C. Colpitts[3], C. Zeilinger[4], M. von Schaewen[5], B. Heller[5], K. Vercauteren[6], E. Luxenburger[7], Y. Andonyadis[8], F. Vondran[9], A. Kirschning[4], L.M. Schang[3], R. Müller[7], C.A. Guzman[2], L. Kaderali[10], G. Randall[8], P. Meuleman[6], A. Ploss[5], T. Pietschmann[1]. *[1]Experimental Virology, TWINCORE, Hannover, [2]Helmholtz Centre of Infection Research, Braunschweig, Germany; [3]University of Alberta, Edmonton, Canada; [4]Leibniz University, Hannover, Germany; [5]Princeton University, Princeton, United States; [6]Ghent University, Ghent, Belgium; [7]Helmholtz Institute for Pharmaceutical Research Saarland, Saarbrücken, Germany; [8]University of Chicago, Chicago, United States; [9]Medizinische Hochschule Hannover, Hannover, [10]Technical University Dresden, Dresden, Germany*
E-mail: pietschmann.thomas@mh-hannover.de

Background and Aims: Novel directly acting antivirals have greatly improved treatment options for chronically infected HCV patients. However, due to resistance development these drugs cannot be used in monotherapy necessitating combination therapies. While several highly effective drug combinations are licensed, these regiments are costly thus limiting therapy access. The aim of this study was to identify alternative FDA-approved drugs with antiviral activity and novel mode of action against HCV.
Methods: We screened a library of licensed drugs for antiviral activity against HCV using an HCV whole life cycle assay. Antiviral activity of selected compounds was validated using wild type HCV, primary human hepatocytes and genetically humanized mice. The mode of action of compounds was assessed using cell entry, membrane fusion, RNA replication and virus assembly assays. Breadth of HCV-specific antiviral activity and viral target genes were determined using chimeric HCV constructs from genotypes 1 through 7. Drug resistance was explored by extensive cell culture passage, sequencing, reverse genetics and functional assays.
Results: Flunarizine, a T-type calcium channel inhibitor used to treat migraine specifically inhibited HCV cell entry (IC50 of 388.2 nM) in Huh-7 cells and in primary human hepatocytes. It also reduced HCV infection in a genetic mouse model for HCV cell entry. Interestingly, genotype 2a (GT2a) cell culture-derived particles (HCVcc), but not non-GT2a viruses were susceptible to

flunarizine. Shuffling structural proteins between GT1a, GT2b and GT2a chimeric viruses revealed that GT2a-derived E1-E2 genes confer susceptibility to flunarizine. Resistance mutations map to the viral envelope proteins, thus indicating that flunarizine targets glycoprotein function(s). Pretreatment of target cells, but not of virus particles inhibited HCV entry and time of addition experiments indicated that flunarizine acts at a late stage of entry. Since flunarizine interfered with HCV infection through low-pH-triggered fusion at the plasma membrane, we conclude it inhibits HCV independent of endocytosis. Finally, trans-complemented HCV particles (HCV-TCP) carrying glycoproteins from GT2a patients were inhibited by flunarizine and flunarizine-resistant viruses were more prone to neutralization by patient-derived antibodies.
Conclusions: Flunarizine may be an alternative treatment option for GT2a- and possibly other GT2-subtype infected individuals.

P0675
AN EX VIVO MODEL OF HUMAN LIVER SLICES CULTURE FOR EVALUATING LIVER FIBROGENESIS

S. Lagaye[1], J. Gaston[1], J. Guéchot[2], P.-P. Massault[3], J.-C. Vaillant[4], S. Pol[1,5]. *[1]INSERM UMS20, Institut Pasteur, [2]Pôle de Biologie Médicale et Pathologie, APHP, Hôpital Saint-Antoine, [3]Service de Chirurgie digestive, Hépato-biliaire et Endocrinienne, AP-HP, Groupe Hospitalier Cochin, [4]Service de Chirurgie digestive et Hépato bilio pancréatique, APHP, Groupe Hospitalier La Pitié Salpétrière, [5]Unité d'Hépatologie, APHP, Groupe Hospitalier Cochin, Paris, France*
E-mail: sylvie.lagaye@hotmail.fr

Background and Aims: We extended our *ex-vivo* model of human liver slices culture infected with HCV (Hepatology 2012) from 10 to 21 days and evaluated the markers of fibrosis in HCV-infected liver slices as compared to uninfected liver slices (CRTL) in presence of Ethanol or not.
Methods: Non-infected liver slices, obtained from human liver resection and cut in 350 μm-thick slices (2.7×10^6cells per slice), were cultivated for up to 21 days: either in presence or not of ethanol (EtOH) (1mM, 5mM, 25mM), or infected with HCVcc supernatant [Con1/C3 (genotype1b)] (MOI = 0.1) in presence or not of ethanol (1mM, 5mM, 25mM). Expression of liver phenotypic markers and fibrosis markers [Tumor growth factor beta (TGFβ), Heat shock protein 47 (Hsp47), Alpha smooth muscle actin (αSma) and Procollagen1 A1 (Procl1A1)] were checked by RT-qPCR. The amount of Hyaluronic acid and TGFβ were determined by ELISA assays.
Results: Hepatocyte-specific gene expression is maintained in human non infected liver slices culture for 21 days. In uninfected liver slices treated with EtOH, the gene expression of TGFβ, Hsp47, αSma and Procl1A1 increased overtime, in a dose-dependent manner up to 3, 3, 4, 4 times, respectively, at day 21, at 25mM EtOH, compared to uninfected non treated control liver slices. Human infected liver slices replicated, expressed efficiently HCVcc and produced high titers of progeny virions (HCVpc) by day 21. In HCV infected liver slices, the gene expression of TGFβ, Hsp47, αSma and Procl1A1 were increasing overtime and exhibited at day 21, a significant 3, 3.5, 3.6, 2.6 fold increase, respectively as compared to uninfected liver slices. At day 10, the amount of hyaluronic acid (HA) reached 799 μg/L, more than a 7-fold increase compared to uninfected slices. At day 21, the expression of the TGFβ protein, intracellular and in the culture supernatant, were significantly 4 and 2 times increased (up to 152 pg/mg tissue and 1100 pg/mg tissue, respectively) as compared to uninfected liver slices. In HCV infected liver slices treated with EtOH, the gene expression of TGFβ, Hsp47, αSma and Procl1A1 increased significantly in a dose-dependent manner, up to day 21, around 5, 6, 7, 5 times, respectively, at 25mM EtOH, compared to controls.
Conclusions: This *ex vivo* model, supporting hepatocyte-specific gene expression for 21 days, provides a powerful tool for studying the onset of fibrosis and for evaluating the potency of new antifibrotic therapies in the native tissue.

E-mail: laurent.mailly@unistra.fr

Background and Aims: Hepatitis C virus (HCV) infection is a leading cause of liver cirrhosis and cancer. Although direct-acting acting antivirals have revolutionized treatment, several challenges remain: these include treatment of certain genotypes, advanced liver disease, resistance and liver graft infection. Tight junction (TJ) proteins claudin-1 and occludin mediate cell entry of HCV. However, the role of TJ proteins as therapeutic target is unknown.
Methods: Using a human liver-chimeric mouse model combined with advanced *in situ* imaging and mechanistic studies we investigated the role of TJ protein claudin-1 as a therapeutic target for HCV infection.
Results: Here we report that a monoclonal antibody specific for TJ protein claudin-1 eliminates chronic HCV infection with undetectable resistance and toxicity in a human liver chimeric mouse model. In contrast to DAAs the claudin-1 specific antibody can cure infection in monotherapy. This antibody inhibits HCV entry, cell-cell transmission and virus-induced signaling events. Importantly, antibody treatment reduces the frequency of HCV-infected hepatocytes *in vivo*, highlighting the need for *de-novo* infection via host entry factors to maintain chronic infection.
Conclusions: We demonstrate that an antibody targeting a virus receptor can cure chronic HCV infection and uncover TJ proteins as targets for antiviral therapy. This host-targeting strategy provides a simple approach for prevention of liver graft infection and opens a novel perspective for treatment of drug resistance.

P0677
CIVACIR HEPATITIS C IMMUNE GLOBULIN (HCIG) POTENTLY NEUTRALIZES INFECTION OF HEPATITIS C VIRUS TRANSPLANT ESCAPE VARIANTS

R.G. Tawar[1,2], L. Heydmann[1,2], J. Schüttrumpf[3], S. Chavan[4], M.B. Zeisel[1,2], T.F. Baumert[1,2,5]. [1]*Inserm, U1110, Institut de Recherche sur les Maladies Virales et Hépatiques, Strasbourg, France;* [2]*University of Strasbourg, Strasbourg, France;* [3]*Biotest AG, Dreieich, Germany;* [4]*Clinical Research, Medical Affairs and Drug Safety, Biotest Pharmaceuticals, Boca Raton, Florida, United States;* [5]*Institut Hospitalo-Universitaire, Pôle Hépato-digestif, Strasbourg, France*
E-mail: tawar@unistra.fr

Background and Aims: Hepatitis C virus (HCV) induced end-stage liver disease is the major indication for liver transplantation in most countries. However, re-infection of the liver graft is universal. The safety and efficacy of DAAs for prevention of liver graft infection remains to be determined. Biotest Pharmaceutical's Civacir, a human hepatitis C antibody enriched immune globulin product (HCIG), has been shown to efficiently prevent liver graft infection in a phase III RCT (Terrault et al. AASLD 2014). Using well characterized patient-derived HCV transplant escape variants (Fofana et al. Gastroenterology 2012; Felmlee/Fauvelle et al. EASL 2014) we aimed to study the molecular mechanism of action of HCIG/Civacir.
Methods: Inhibition of Civacir/HCIG-mediated HCV infection was studied using 25 viral variants isolated from patients before and after liver transplantation and state-of-art HCV cell culture models. HCV pseudoparticles (HCVpp) and cell-culture-derived HCV (HCVcc) expressed patient-derived viral envelope glycoproteins from transplant escape variants.
Results: Civacir potently, broadly and dose-dependently neutralized all the patient variants in HCVpp assays including variants displaying a high entry phenotype and resistant to host neutralizing antibodies. The IC50 values (0.0016–1.50 mg/ml) for inhibition were independent of the phenoype of the viral variant indicating that virus neutralization by Civacir/HCIG is not affected by viral escape. Furthermore, at clinically relevant antibody concentrations Civacir potently neutralized HCVcc variants bearing envelopes efficiently escaping patient-derived and monoclonal anti-E2 antibodies.
Conclusions: Patient-derived HCV escape variants resistant to autologous antibodies are potently neutralized by Civacir in state-of-the-art HCV cell culture models. The potent activity of Civacir is likely because of synergy between anti-HCV antibodies derived from different patient donors. Collectively, these results uncover the mechanism of action of HCIG/Civacir and explain its clinical efficacy for prevention of HCV liver graft infection.

P0678
IL-8 PRODUCING CD4+ REGULATORY T CELLS STIMULATE ANGIOGENESIS IN CHRONIC HEPATITIS C

B. Langhans[1], H.-D. Nischalke[1], B. Krämer[1], D.J. Kaczmarek[1], P. Lutz[1], C.P. Strassburg[1], J. Nattermann[1], U. Spengler[1]. [1]*Department of Internal Medicine I, University of Bonn, Germany, Bonn, Germany*
E-mail: bettina.langhans@ukb.uni-bonn.de

Background and Aims: In chronic hepatitis C regulatory $CD4^+$ T cells (Tregs) inhibit anti-viral T cell response via soluble IL-10 and IL-35 (Langhans et al., Clin Science 2010). In addition, we demonstrated that $CD4^+$ Tregs enhance fibrosis by modulating the interaction of NK cells and hepatic stellate cells (HSC) and stimulating fibrogenesis in HSC by secreting IL-8 (Langhans et al., J Hepatol 2014 in press). Here, we analyzed in how far intrahepatic $CD4^+$ Tregs can stimulated angiogenesis.
Methods: Biopsies and explant livers from patients with chronic hepatitis C (cHCV), chronic hepatitis B (cHBV) and alcoholic liver disease (EtOH) were studied by multiple colour immunofluorescence histology on cryostat sections. Numbers of IL-8^+Foxp3^+CD127^{low}CD25^+CD4^+ Tregs were determined quantitatively using flow cytometry in freshly isolated liver infiltrating lymphocytes obtained from unfixed parts of the liver samples.
Results: Our quantitative *ex vivo* analysis revealed that HCV-specific Tregs produce marked amounts of IL-8 (MW±SEM: 650±133 pg/ml). Despite equivalent numbers of $CD4^+$ Tregs, IL-8 producing Tregs were exclusively found in the liver of patients with cHCV, but not cHBV or EtOH. *In situ* we found a close relationship between Tregs and intrahepatic blood vessels indicating that activated Tregs are focally associated with $C31^+$ endothelial cells in HCV-associated cirrhosis. Of note, Tregs attached to the vessels from outside and not the lumen. In the liver tissue of HCV-patients overall number of $CD4^+$ Tregs were significantly enhanced with advanced fibrosis and correlated with IL-8 producing Tregs ($R = 0.7501$, $p < 0.001$). Further *in vitro* experiments demonstrated that HCV-specific Tregs produce additional potent angiogenic factors such as MMP8, MMP9, TIMP-1 and activin-A and serpin-E1.
Conclusions: Our data propose that intrahepatic $CD4^+$ Tregs are associated with blood vessels in the liver of patients with chronic hepatitis C and thus have the potential to stimulate angiogenesis by producing IL-8.

P0679
DERISKING THE POTENTIAL FOR MITOCHONDRIAL TOXICITY OF NUCLEOSIDE ANALOGS

Z. Jin[1], J. Deval[1], J.A. Symons[1], H. Tan[1], K. Shaw[1], S.M. Chanda[1], Q. Zhang[1], Y. Tam[1], L.M. Blatt[1], G. Wang[1], N. Dyatkina[1], L. Beigelman[1], D.B. Smith[1]. [1]*Alios BioPharma, Inc., South San Francisco, United States*
E-mail: dsmith@aliosbiopharma.com

Background and Aims: Nucleoside analogs play an important role in the treatment of multiple viral diseases. Nucleoside analogs that fail clinically do so for multiple reasons, but primarily for lack of selectivity versus human polymerases resulting in mitochondrial toxicity. In general, nucleoside toxicity appears compound specific and does not appear to be associated with any particular base, sugar or phosphate modification. We have established a screening paradigm designed to assess the potential for mitochondrial toxicity of ribonucleoside analogs. We exemplified the strategy using nucleoside analogs previously advanced for the treatment of chronic hepatitis C (CHC), and applied the strategy to novel nucleoside analogs currently being advanced for the treatment of CHC.
Methods: The triphosphate derivative (NTP) of each nucleoside analog was prepared and evaluated for the ability to be incorporated by human mitochondrial RNA polymerase (HMRP). Nucleoside analogs were tested in HepG2 cells for 6–8 days for inhibition of the synthesis of the mitochondrial-DNA encoded protein, cytochrome c oxidase I (COX-I), relative to the nuclear DNA encoded mitochondrial protein, succinate dehydrogenase A subunit (SDH-A). Nucleoside analogs were also assessed for general cytotoxicity in 8-day assays across a panel of cell lines.
Results: The NTP's of 4′-azidocytidine, INX-08189, PSI-7851, AL-335 and AL-516 all showed potent inhibition of the HCV NS5B polymerase. 4′-azidocytidine and 2′-Me-guanosine NTP's were shown to be efficient substrates for incorporation by human mitochondrial RNA polymerase, the NTP's of 2′-Me-2′-F-uridine, AL-335 and AL-516 were not substrates for HMRP (Figure). 4′-azidocytidine and 2′-Me-guanosine prodrugs were inhibitors of human mitochondrial protein synthesis. 2′-Me-2′-F-uridine prodrug PSI-7851, AL-335 and AL-516 did not inhibit human mitochondrial protein synthesis. For most cell lines, only 2′-Me-guanosine prodrugs showed cytotoxicity.

Conclusions: Nucleoside analogs that metabolize to NTP's that are strongly incorporated by human mitochondrial RNA polymerase demonstrate potent inhibition of mitochondrial protein synthesis and have demonstrated an undesirable clinical safety profile. AL-335 and AL-516 are not substrates for the human mitochondrial RNA polymerase and do not inhibit mitochondrial protein synthesis. These compounds are being advanced in clinical and preclinical studies for the treatment of patients infected with CHC.

HEPATITIS C VIRUS ACTIVATES AUTO- AND PARACRINE CIRCUITS TO SWAY SURFACE EXPRESSION OF ErbB FAMILY MEMBERS

S. Eisnebürger[1], C. Groepper[1], B. Ralf[2,3], D. Häussinger[1], J.G. Bode[1].
[1]Department of Hepatology, Gastroenterology and Infectious Diseases, University Hospital of the Heinrich-Heine University, Düsseldorf, [2]Department for Infectious Diseases, Molecular Virology, Heidelberg University, [3]Division of Virus-Associated Carcinogenesis, German Cancer Research Center, Heidelberg, Germany
E-mail: Johannes_Bode@t-online.de

Background and Aims: Recently the EGF receptor and EGFR dependent signalling has been identified as a co-factor for HCV entry and replication. In how far HCV also interferes with expression and signal-transduction of the other three members of the EGF receptor family is unknown. The present study analyses the influence of HCV on the surface expression of the other members of the EGF receptor family and their consequences.
Methods: Huh7 cells either infected with the HCV cc strain JC1 or harbouring the HCV1 subgenomic replicon were used and analysed employing targeted gene knockdown by siRNA, rtPCR and Immunoblot-analysis.
Results: The data presented indicate that HCV, Sp1-dependently enhances the expression of Nrg1 and that this is required to down-regulate ErbB3 expression via an Nrg1-mediated autocrine circuit. This HCV-mediated reduction of ErbB3 expression in turn mediates enhanced surface expression of EGFR and ErbB2, an effect that can be mimicked by siRNA-mediated knockdown of ErbB3 expression. This seems to favour viral replication as suggested from the fact that pre-treatment with NRG1 as well as knockdown of ErbB3 expression prior to infection with the HCVcc strain JC1 results in an increased abundance of viral transcripts.
Conclusions: These data delineate a novel mechanism enabling HCV to modify the composition of the ErbB family members on the surface of its host cell by a paracrine NRG1-driven circuit. The resulting up-regulation of EGFR and ErbB2 may be in advantage for viral life cycle.

P0681

CATALASE ACTIVITY INHIBITION BY HEPATITIS C VIRUS (HCV) IN HCV-INDUCED OXIDATIVE STRESS, A TRIGGER OF HEPATIC CARCINOGENESIS

P. Chouteau[1], S. Brichler[1], P. Bruscella[1], A. Florimond[1], J.-M. Pawlotsky[1]. *[1]National Reference Center for Viral Hepatitis B, C, and Delta, Department of Virology, and INSERM U955, Henri Mondor Hospital, University of East-Paris, CRETEIL, France*
E-mail: philippe.chouteau@inserm.fr

Background and Aims: Hepatitis C virus (HCV) infection is a major risk factor for the onset and progression of hepatocellular carcinoma (HCC). Chronic HCV infection induces the accumulation of reactive oxygen species (ROS) in infected livers leading to oxidative stress. Little is known about alterations of intracellular antioxidant defense pathways involved in HCV-related oxidative stress. Cellular catalase is an enzyme that detoxifies hydrogen peroxide (H_2O_2), a ROS known to control cell proliferation, thus playing a major role in the cellular antioxidant defense mechanism.
The aim of this study was to characterize the expression and activity of cellular catalase, using different *in vitro* and *in vivo* models of HCV replication or HCV protein expression.
Results: Cirrhotic liver samples from HCV-infected patients exhibited a significant decrease of their intracellular catalase activity when compared to alcoholic and HBV-infected cirrhotic liver samples. However, the intrahepatic catalase protein levels were not different between these three groups of patients. In order to explore the impact of HCV protein expression *in vivo* in the absence of local inflammation and immune response, the transgenic (tg) mouse model expressing the full-length HCV ORF (FL-N/35 mice) was used. Tg mouse livers display high levels of oxidative stress. We observed a significantly higher oxidative nuclear DNA damage, together with an increase in the amount of advanced oxidation protein products, in tg livers compared to their wild type (wt) littermates. Like in human samples, the level of H_2O_2 detoxification in tg mice livers was weak. Primary hepatocytes isolated from tg mice displayed a dramatic, up to 80%, reduction of catalase activity when compared to wt mice. Remarkably, catalase expression (mRNA and protein levels) was similar in tg and wt liver samples and isolated primary hepatocytes. The JFH1-based cell-culture system was used to assess catalase expression and activity in a fully replicating system. Like in the other models, a dramatic increase in the intracellular oxidative stress level was observed in HCV-infected cells, concomitant to a significant decrease of catalase activity without alteration of catalase expression.
Conclusions: HCV infection is responsible for a default in intracellular catalase activity, as a result of HCV protein expression in the absence of local inflammation. This mechanism could, at least in part, contribute to the HCV-induced intracellular oxidative stress, a major trigger of HCC.

P0682

PRECLINICAL CHARACTERIZATION OF AL-335, A POTENT URIDINE BASED NUCLEOSIDE POLYMERASE INHIBITOR FOR THE TREATMENT OF CHRONIC HEPATITIS C

H. Tan[1], K. Shaw[1], A. Jekel[1], J. Deval[1], Z. Jin[1], A. Fung[1], Y. Tam[1], L.M. Blatt[1], S.M. Chanda[1], G. Wang[1], M. Prhavc[1], V. Serebryany[1], Q. Zhang[1], J.A. Symons[1], L. Beigelman[1], D.B. Smith[1]. *[1]Alios BioPharma, Inc., South San Francisco, United States*
E-mail: dsmith@aliosbiopharma.com

Background and Aims: Nucleotide analog HCV polymerase inhibitors have demonstrated a high barrier to resistance and are a key component of some interferon-free combination regimens for the treatment of chronic hepatitis C (CHC). We identified AL-335 as part of our efforts to advance potential medicines for the treatment of CHC. AL-335 is a novel, potent uridine based nucleotide analog that demonstrates a desirable preclinical profile.
Methods: The antiviral activity and selectivity of AL-335 were evaluated in vitro using the HCV replicon system encoding NS5B sequences from multiple genotypes and resistant variants.
AL-335 was also studied in replicon in combination with other compounds. The nucleoside triphosphate (AL-335 NTP) was tested for potency versus the recombinant HCV polymerase NS5B, and for selectivity against human DNA and RNA polymerases. NTP incorporation assays were conducted using HCV NS5B polymerase and the AL-335 NTP to assess the mechanism of action. Intracellular formation and half-life of the AL-335 NTP in primary human hepatocytes was assessed. AL-335 was studied in vivo following

oral dosing for the ability to form the active AL-335 NTP in dog liver.
Results: In the stable genotype (GT) 1b replicon assay, AL-335 exhibited potent antiviral activity with an EC_{50} of 75 nM. In transient chimeric GT-1b replicons with NS5B regions derived from GT 1–4, AL-335 demonstrated pan-genotypic activity with EC_{50} values between 40–60 nM. AL-335 retained activity vs. replicon mutants resistant to non-nucleoside polymerase, NS3/4A protease and NS5A inhibitors. AL-335 was additive or synergistic in all combinations studies. The AL-335 NTP was a potent inhibitor of the HCV NS5B polymerase with an IC_{50} of 120 nM and a K_i of 24 nM, and acted as a chain-terminator of RNA synthesis. The AL-335 NTP was not a substrate for human mitochondrial RNA polymerase and demonstrated no inhibition (IC_{50} >100 μM) of human DNA or RNA polymerases. In vitro, the AL-335 NTP was rapidly formed and demonstrated a long intracellular half-life of >24 hrs in primary human hepatocytes. Following oral administration to dog at 5 mg/kg parent nucleoside equivalent, the AL-335 NTP was formed at high and sustained levels in liver (AL-335 NTP levels at 24 hrs: 2.1 μM).
Conclusions: AL-335 is a potent uridine based nucleotide analog that demonstrates a desirable preclinical profile. The compound is currently advancing in preclinical studies as a potential treatment for CHC.

HEPATITIS C VIRUS NS3-4A PROTEASE TARGETS THE HOST FACTOR BNIP1 AT A NON-CANONICAL CLEAVAGE SITE
H. Thi Lan Tran[1], K. Morikawa[1], F. Penin[2], M. Quadroni[3], J. Gouttenoire[1], D. Moradpour[1]. *[1]Division of Gastroenterology and Hepatology, Centre Hospitalier Universitaire Vaudois – University of Lausanne, Lausanne, Switzerland; [2]Institut de Biologie et Chimie des Protéines, University of Lyon, Lyon, France; [3]Protein Analysis Facility, University of Lausanne, Lausanne, Switzerland*
E-mail: Jerome.Gouttenoire@chuv.ch

Background and Aims: The hepatitis C virus (HCV) NS3-4A protease plays a central role not only in the viral life cycle but also in the persistence and pathogenesis of HCV. It cleaves selected host factors, thereby modulating cellular signaling pathways. Here, we describe BNIP1 as a novel cellular substrate of the HCV NS3-4A protease.
Methods: A large-scale quantitative proteomics screen was performed to identify novel cellular substrates of the HCV NS3-4A protease. Candidates were validated in a wheat germ-based cell-free and various cellular expression systems as well as in Huh-7 human hepatocellular carcinoma cells harboring subgenomic HCV replicons or infected with cell culture-derived HCV (HCVcc).
Results: BNIP1 (BCL2/adenovirus E1B 19 kDa interacting protein 1), a BH3-only transmembrane protein, was identified as a novel cellular substrate of the NS3-4A protease. BNIP1 is localized on the outer mitochondrial membrane and has been involved in apoptosis, autophagy, and other cellular processes of potential relevance to HCV infection. Coexpression of N-terminally FLAG-tagged BNIP1 with active but not with catalytically inactive NS3-4A protease resulted in the cleavage of BNIP1 into 3 defined fragments both in a cell-free expression system and in transfected cells. Cleavage was abrogated by the protease inhibitor telaprevir, further demonstrating that it depends on the presence of active NS3-4A protease. Cleavage of endogenous BNIP1 was also observed in cells harboring subgenomic HCV replicons and in cells infected with HCVcc. Mutagenesis of Cys and Thr residues within BNIP1 did not abrogate cleavage by the NS3-4A protease, suggesting the presence of a non-canonical cleavage site. Indeed, mass spectrometry and validation by site-directed mutagenesis identified BNIP1 Ser 166 as residue targeted by the NS3-4A protease.
Conclusions: Quantitative proteomics identified BNIP1 as a novel host factor targeted by the HCV NS3-4A protease at a non-canonical cleavage site. Ongoing experiments explore the role of BNIP1 and its cleavage in the life cycle and pathogenesis of HCV.

MODULATION OF HEPATITIS C VIRUS INFECTION THROUGH KHSRP-DEPENDENT REGULATION OF MIRNA-122 MATURATION AND INTRACELLULAR RNA DEGRADATION
P. Bruscella[1], H. Danso[1], C. Baudesson[1], T. Durand[2], H. Colman[3], M. Ventura[4], M. Trabucchi[5], J.-M. Pawlotsky[1], C. Féray[1]. *[1]U955, INSERM, Créteil, [2]U913, INSERM, [3]Université de Nantes, Nantes, [4]UMR5234, CNRS, Bordeaux, [5]U1065, INSERM, Nice, France*
E-mail: patrice.bruscella@inserm.fr

Background and Aims: During infection, the hepatitis C virus (HCV) genome is exposed to degradation by the cellular RNA-decay machinery. Indeed, HCV RNA is a target for cellular RNAses due to the lack of a 5′ methylated cap and of a 3′ polyA tail and to the presence of a destabilizing RNA element (the 3′ polyU region). miR-122 has been shown to play a role in protecting the HCV genome from 5′-end degradation. The goal of this work was to unravel the role of KHSRP, an AU-Rich Element mRNA-binding protein capable to recruit 5′- and 3′-RNAses such as XRN1 and DIS3 respectively, and participating in miRNA maturation, during HCV infection.
Methods: Transient gene knockdown was performed by means of siRNA transfection. Translation efficiency was measured by means of luciferase non-replicative constructs containing viral UTRs. RNA stability was evaluated by Northern-Blot analysis. Viral replication was measured using a modified JFH1 strain expressing Gaussia luciferase. Gene and miRNA expression was quantified by qRT-PCR. The post-translational modifications and subcellular localization of KHSRP were studied by means of *in situ* Proximity Ligation Assay (PLA).
Results: XRN1 and DIS3 silencing increased JFH1 replication in Huh7 cells and the stability of nonreplicative viral RNA, whereas KHSRP silencing inhibited both viral replication and degradation of nonreplicative HCV RNA. Because KHSRP is involved in miRNA maturation, we studied miR-122 expression in the context of KHSRP silencing and expression. KHSRP expression dramatically increased miR-122 maturation. Using nonreplicative JFH1 variants and the con1 SubGenomic Replicon (SGR), we showed that the expression of structural HCV proteins decreased the amount of KHSRP mRNA. In HCV-SGR cell line, the AKT-dependant phosphorylation of KHSRP at position Ser193 led to the nuclear relocalization of phospho-KHSRP (Figure 1) concomitantly to the maturation of nuclear pri-miR-122. PLA showed the co-localization of KHSRP, the HCV NS5A protein and HCV RNA in the cytosol.

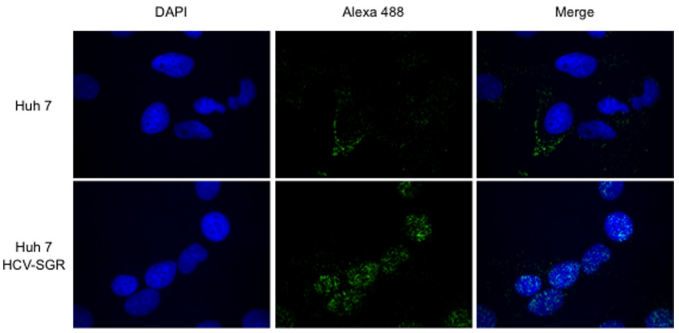

Figure 1. Nuclear relocalization of Phospho Ser^{193}-KHSRP in Huh7 cells containing the HCV Con1 Sub Genomic Replicon (HCV-SGR) by *in situ* Proximity Ligation Assay.

Conclusions: Our results show that HCV down-regulates KHSRP gene expression in hepatocytes, thus protecting HCV RNA from intracellular degradation by XRN1 and DIS3 RNAses. HCV infection also leads to the phosphorylation and relocalization of phospho-KHSRP to the nucleus, where it induces miR-122 maturation,

thereby increasing HCV RNA stability and favoring replication. This thus far unknown regulatory mechanism at the same time promotes viral replication through miR-122 maturation and limits viral RNA degradation.

THE ROLE OF CAVEOLIN-1 IN THE PHENOTYPE OF HUMAN T LYMPHOCYTES AFTER UPTAKE OF HCV NON-ENVELOPED PARTICLES

P.P. Doumba[1], E. Serti[2], M. Boutsikou[1], M.M. Konstandoulakis[3], U. Georgopoulou[2], J. Koskinas[1]. *[1]Second Academic Department of Internal Medicine, Medical School of Athens, Hippokration Hospital Athens, [2]Molecular Virology Laboratory, Hellenic Pasteur Institute, [3]Laboratory of Surgical Research, 1st Department of Propaedeutic Surgery, Medical School of Athens, Hippokration Hospital Athens, Athens, Greece*
E-mail: koskinasj@yahoo.gr

Background and Aims: The existence of Hepatitis C (HCV) non-enveloped particles (HCVne) circulate in the serum of HCV infected patients has been correlated with viral persistence. Previous study from our group demonstrated that recombinant HCVne particles can efficiently enter PBMCs with concomitant secretion of cytokines leading them to partial T cell exhaustion and rise of Tregs. Caveolin-1 is a protein that plays important role in the signaling events of the cells. Caveolin-1 role in T lymphocytes is still under investigation. The aim of this study was to investigate the role of caveolin-1 in the above mechanisms/response.
Methods: PBMCs were isolated from the peripheral blood of healthy donors. Using the baculovirus expression system we have generated recombinant HCVne in the absence of other viral proteins. PBMCs were incubated either with HCV non-enveloped particles (HCVne) or the control fraction for 12 h, 24 h, 48 h and 66 h. Expression of caveolin-1, CD107a (cytotoxicity) and T regulatory cells (CD4+CD127-CD25+) were estimated by flow cytometry in all samples.
Results: Caveolin-1 expression was increased in PBMCs after 48 h incubation with HCVne compared to the control fraction group (12.59% vs 10.7%). There was no change in the caveolin-1 expression at all time points in the control group. The percentage of CD4+ T cells expressing caveolin-1 (CD4+cav1+) was significantly increased at 48 h compared to the respective percentage at 24 h in the HCVne group (2.53% vs 1.65%, $p = 0.025$). After 66 h incubation with HCVne, %CD4+cav1+ were positively correlated with %Tregs ($r = 0.957$, $p = 0.040$) and %CD4+CD25+ T cells ($r = 0.941$, $p = 0.017$) and negatively correlated with %CD107 expression after 48 h ($r = -0.893$, $p = 0.042$). Moreover, the percentage of %CD8+cav1+ after 12 h, 48 h and 66 h were negatively correlated with %CD107a expression ($r = -0.996$, $p = 0.001$, $r = -0.884$, $p = 0.046$ and $r = -0.953$, $p = 0.012$, respectively).
Conclusions: Caveolin-1 seems to play a crucial role in the establishment of the partial exhausted phenotype of T lymphocytes after HCVne incubation.

RECIPROCAL ANTAGONISM BETWEEN THE UNCOORDINATED PHENOTYPE-5A (UNC5A) DEPENDENCE RECEPTOR AND THE HEPATITIS C VIRUS

M.-L. Plissonnier[1], T. Lahlali[1], M. Michelet[2], P. Mehlen[3], F. Zoulim[4], R. Parent[2]. *[1]Pathogenesis of Hepatitis B and C – Equipe labellisée LabEx DEVweCAN, INSERM U1052, Centre de Recherche en Cancérologie de Lyon, CRCL, INSERM, [2]Pathogenesis of Hepatitis B and C – Equipe labellisée LabEx DEVweCAN, INSERM U1052, Centre de Recherche en Cancérologie de Lyon, INSERM, [3]Apoptosis, Cancer and Development Laboratory – Equipe labellisée 'La Ligue', LabEx DEVweCAN, CNRS UMR5286, Centre de Recherche en Cancérologie de Lyon, CNRS, [4]Pathogenesis of Hepatitis B and C – Equipe labellisée LabEx DEVweCAN, INSERM U1052, Centre de Recherche en Cancérologie de Lyon, Hospices Civils de Lyon, INSERM, Lyon cedex 03, France*
E-mail: marie-laure.plissonnier@inserm.fr

Background and Aims: Hepatitis C virus (HCV) infection is a leading cause of hepatocellular carcinoma (HCC), mainly through cirrhosis induction. Cirrhosis may be detrimental for SVR rates upon usage of recently developed direct acting antivirals (DAAs), spurring research for a deeper understanding of HCV infection in cirrhosis. This study investigated the interplay between HCV and UNCA, a dependence receptor that is inactivated in cancer.
Methods: The impact of HCV on UNC5A expression was evaluated on liver resections from three cohorts of chronically HCV-infected, HBV-infected and uninfected patients ($n = 503$) and on in vitro JFH1, H77 and N strain-infected Huh7.5 cells and primary human hepatocytes (PHH). Conversely, the impact of UNC5A expression on HCV replication parameters was evaluated in UNC5A RNAi and forced expression approaches.
Results: UNC5A expression is significantly decreased in HCV(+) but not HBV(+), liver biopsies as compared to uninfected samples. UNC5A is downregulated in F2 (3-fold; $p = 0.003$) and more dramatically in F4/cirrhosis (44-fold; $p < 0.0001$) histological stages in HCV(+) hepatic lesions compared to histologically-matched HCV(−) tissues. This down-regulation is not reversible upon SVR. UNC5A expression is significantly decreased by HCV genotypes *in vitro*, through decreased mRNA transcription and translation in vitro and in patients. The NS3/4A protease is involved in UNC5A downregulation. Knockdown and forced-expression experiments identified UNC5A as capable of HCV restriction through impeded morphogenesis, release, and specific infectivity of HCV virions, in a DAPK-dependent and cell-death independent manner. Finally, UNC5A was found strongly downregulated in HCC and UNC5A modulation conditioned cell survival of apoptosis-sensitized Huh7.5 and PHH cells, suggesting its implication in hepatocytic turn-over.
Conclusions: UNC5A-depleted hepatocytes by HCV may acquire selective advantage for ongoing viral replication and at the same time resistance to cell death, especially at the cirrhosis stage, a condition strongly exposed to HCC development.

P0687

REGULATION OF HEPCIDIN (HAMP) AS DRIVING FORCE FOR MACROPHAGE-MEDIATED HEPATITIS C (HCV) PERSISTENCY

P. Foka[1], A. Dimitriadis[2], E. Karamichali[3], E. Kyratzopoulou[2], D. Giannimaras[2], J. Koskinas[4], A. Mamalaki[2], U. Georgopoulou[3]. *[1]Molecular Virology Laboratory and Molecular Biology and Immunobiotechnology Laboratory, [2]Molecular Biology and Immunobiotechnology Laboratory, [3]Molecular Virology Laboratory, Hellenic Pasteur Institute, [4]2nd Department of Internal Medicine, Hippokration Hospital, Medical School of Athens, Athens, Greece*
E-mail: uraniag@pasteur.gr

Background and Aims: What favours viral persistence over clearance during the acute phase of HCV infection remains unclear, but deregulated cellular and humoral immune responses are involved. Chronic HCV infection is associated with hepatic iron

overload and hyperferraemia that also correlate to poor antiviral responses. Hepcidin controls iron homeostasis and is increased by inflammation and iron excess. Chronic HCV patients possess low hepcidin levels, but HAMP knock-down has been linked to altered HCV replication.
We aimed to: (a) assess the interplay between HCV and hepcidin during acute and chronic infection, (b) investigate whether any putative hepcidin modulation alters iron homeostasis in macrophages, key players both in iron regulation and inflammation initiation, thereby favouring viral persistence.
Methods: Indirect co-cultures of liver (Huh7.5)–macrophage (THP-1) cells and patients' sera were employed to investigate the effect of HCV infection on hepcidin *in vitro* and *in vivo*. Hepcidin-expressing hepatoma cells transfected with HCV replicons were used to assess HCV translation and replication.
Results: HAMP expression was up-regulated early in HCV infection, dropping at later times. Ferritin and ferroportin levels changed accordingly. Hepcidin overexpression enhanced both viral translation and replication. In HCV-infected co-cultures, increased HAMP expression was observed. Ferritin was diminished in Huh7.5 cells with time, while a concurrent increase was observed in THP-1. This change in iron content was accompanied by 2–3 HCV replication rounds in Huh7.5 cells and one round in THP-1. Iron-loading of THP-1 reversed the observed ferritin "flow" and resulted in enhancement of hepatic HCV replication. Moreover, both macrophage populations managed to infect naïve Huh7.5 cells, but infection occurred faster in the presence of iron. Hepcidin changes were independent of IL-6 expression. Finally, hepcidin serum levels were significantly increased in acutely infected patients, but correlated with viral load levels in chronic patients.
Conclusions: HCV differentially modulates HAMP expression in both acute and persistent chronic infection *in vivo* and *in vitro*, thereby supporting its own life cycle. Hepcidin regulation may promote viral persistence, since iron level changes in both macrophages and hepatocytes render the former "viral reservoirs", able to support low levels of replication of infectious transmittable virus.
P. Foka and A. Dimitriadis contributed equally.

PRECLINICAL CHARACTERISATION OF MIV-802, A NOVEL URIDINE NUCLEOTIDE HCV NS5B POLYMERASE INHIBITOR, FOR TREATMENT OF HEPATITIS C VIRUS INFECTION

A. Lindqvist[1], H. Kylefjord[2], H. Wähling[2], S. Juric[2], S. Torssell[2], G. Kalayanov[2], L. Vrang[2], E. Hoberg[3], C. Gustafsson[3], A. Eneroth[2], E. Lindström[2], K. Wikström[2], P. Targett-Adams[2], P. Pinho[2], R. Bethell[2], Å. Rosenquist[2]. *[1]Medivir, Huddinge, Sweden; [2]Medivir, Medivir, Huddinge, [3]Dept of biochem and cell biology, University of Gothenburg, Gothenburg, Sweden*
E-mail: asa.rosenquist@medivir.se

Background and Aims: HCV NS5B polymerase nucleotide inhibitors have pan-genotype activity and high barriers to resistance and are therefore considered to be central to future DAA combination therapies for HCV. MIV-802 is the protide of a novel uridine analogue that is being developed for HCV therapy.
Methods: Antiviral activity was evaluated using chimeric HCV replicons expressing NS5B sequences from HCV genotypes 1–6, including resistance mutations conferring to resistance to nucleotides and other classes of HCV antivirals, and using clinical isolates (genotypes 1–4). The cellular and mitochondrial toxicity and the genotoxicity of MIV-802 and its parent nucleoside were characterized using a panel of cell lines and human primary cells. The uridine nucleoside triphosphate (MIV-802-UTP) was tested against recombinant HCV NS5B polymerase and against human RNA and DNA polymerases. MIV-802-UTP levels were determined in primary human hepatocytes *in vitro* and in dog liver after oral dosing.
Results: MIV-802-UTP is a potent and selective chain-terminating inhibitor of HCV NS5B polymerase with a Ki of 0.71 μM, but has IC_{50} >200μM against human DNA polymerases α, β and γ. MIV-802 displays pan-genotypic potency in replicon assays with an EC_{50} range of 22–74 nM, and against clinical isolates with an EC_{50} range of 17–108 nM. MIV-802 retains potency against mutant replicon variants resistant to the other HCV drug classes. The CC_{50} values for MIV-802 and its parent nucleoside are >50 μM when tested against a broad panel of human cell lines including fresh human hepatocytes, bone marrow progenitor cells and cardiomyocytes in assays of 6–14 days. MIV-802 and its parent nucleoside are negative in micro-Ames up to 250 μg/plate and were negative in genotoxicity assays using mammalian cells. MIV-802 does not significantly affect mitochondrial DNA and RNA levels in cells. High levels of MIV-802-UTP (100-fold above its Ki against HCV NS5B polymerase) are rapidly formed in human hepatocytes, and decayed with a $t_{1/2}$ of 14 h. Hepatic MIV-802-UTP levels in dog 4 hours after MIV-802 dosing (50 mg/kg, p.o.) are 40-fold above the HCV NS5B polymerase Ki.
Conclusions: MIV-802 is a potent nucleotide analogue with excellent safety margins *in vitro* and delivers pharmacologically relevant amounts of UTP to human hepatocytes and dog liver. Its attractive preclinical profile supports progression of MIV-802 into clinical development for the future treatment of HCV infection in combination with other DAAs.

THE HEPATITIS C VIRUS CONTRIBUTES TO THE AGGRAVATION OF THE IMMUNOSUPPRESSIVE ENVIRONMENT BY INCREASING THE SUPPRESSIVE ACTIVITY OF NATURAL REGULATORY T CELLS

L. Ouaguia[1], O. Morales[2], C. Wychowski[3], A. Carpentier[4], L. Aoudjehane[5], J. Dubuisson[3], Y. Calmus[5], Y. deLaunoit[1], F. Conti[5], N. Delhem[1]. *[1]CNRS UMR 8161 Biology Institute of Lille, Lille, France; [2]Nord, CNRS UMR 8161 Biology Institute of Lille, [3]InsermU1019-CNRS UMR8204 – Centre d'Infection et d'immunité de Lille, Lille, France; [4]National Institutes of Health (NIH), Bethesda, United States; [5]UPMC Université Paris 06 & INSERM, UMR_S 938, CdR Saint-Antoine, F-75012, Paris, France*
E-mail: laurissa.ouaguia@ibl.cnrs.fr

Background and Aims: HCV infection is characterized by a high risk of chronicity. We have shown in a previous work that natural and induced human regulatory T cells play an important role in the progression of hepatitis C and are associated with the severity of viral recurrence after liver transplantation. However, nothing is known concerning the specific impact of HCV on these two regulatory T cell sub-populations. Our hypothesis is that HCV may promote the recruitment of regulatory T cells in the infected liver, and alter their phenotype and suppressive activity for the progression of liver pathogenesis.
Methods: Treg were isolated from the blood of healthy donors and infected *in vitro* with HCVcc/JFH-1. Internalization of viral proteins was highlighted by immunofluorescence and western blot (WB). Moreover, the expression of markers associated with phenotype and suppressive function of Treg cells was analyzed by Q-PCR, flow cytometry and WB. Proliferation and suppressive activity of infected Treg cells was analyzed by Thymidine of ^3H incorporation technique. In addition, the chemokines produced by hepatic cells and known to attract Treg were analysed by RT-QPCR.
Results: We showed that Treg infection with HCV significantly increases the expression of viral receptors and that the viral proteins are internalized into Treg. Interestingly, we also showed that viral infection raises the Treg anergy and promotes the recruitment of infected Treg cells by HCV-infected hepatic cells. In addition, HCV infection induced a significant increase in the expression of markers associated with Treg cells thus potentiating their "suppressive

phenotype". These results are correlated with the functional analysis of infected Treg cells, showing (i) a significant increase in the expression of markers associated with their suppressive activity (ii) a significant increase in the secretion of immunosuppressive cytokines and (iii) an increase in immunosuppressive function. Finally, we have shown that HCV promotes conversion of conventional T lymphocytes into induced T regulatory type 1 cells.
Conclusions: This study shows for the first time that HCV can be able to be internalized into human Treg cells and could promote Treg recruitment into the infected liver. Moreover, the fact that HCV can potentiate the suppressive function of nTreg and favor the induction of Tr1 may contribute to explain the mechanisms by which HCV escapes the immune system and promotes the progression of hepatitis C to cirrhosis and HCC

P0690
IFN-FREE THERAPY FOR CHRONIC HCV: TRANSCRIPTOMICS AND NK CELL ANALYSES

M. Spaan[1], G. van Oord[1], K. Kreefft[1], J. Hou[1], B. Hansen[1], H. Janssen[1,2], R. de Knegt[1], A. Boonstra[1]. *[1]Department of Gastroenterology and Hepatology, Erasmus MC Rotterdam, Rotterdam, Netherlands; [2]Liver Clinic University Health Network, University of Toronto, Toronto, Canada*
E-mail: m.spaan@erasmusmc.nl

Background and Aims: Chronic hepatitis C is a global health problem, resulting in liver failure, hepatocellular carcinoma and liver-related death. NK cells are players of the innate immune system and known to correlate to viral treatment response of HCV. In this study we investigate the effect of viral load decline with IFN-free direct acting antivirals (DAA) on T cells, natural killer (NK) cells and at the gene expression level in blood.
Methods: 12 patients with chronic HCV were treated with asunaprevir and daclatasvir and peripheral blood was analyzed at baseline, day 3, week 1, 2, 4, 8 and 12 during therapy. Virus-specific $CD8^+$ T cell frequency, blood transcriptomics and serum cytokines were analyzed. NK cell frequency, phenotype and ability to produce interferon-gamma (IFN-γ), perforin and granzyme were analyzed by flowcytometry. Sorted NK cells were cultured with K562 to analyze specific killing by 7-AAD. Inhibition of viral replication was determined by using $HuH7_{A2}$HCV replicon cell system.
Results: Our results show restoration of HCV-specific T cell frequency and fast down-regulation of interferon stimulating genes (ISGs) during IFN-free therapy. Serum IP-10, IFN-γ, IL-12p40 and IL-18 levels decreased early upon viral load decline. Surface expression of activation receptors NKp30, NKp46 and inhibitory receptor NKG2A on blood NK cells reduced during therapy. No effect of IFN-free therapy was observed on NK cell function, except for the expression of TRAIL on NK cells, which declined during therapy.
Conclusions: We demonstrate enhanced HCV-specific T cells during IFN-free DAA therapy and reduced ISG mRNA and protein. IFN-free therapy causes a reduction in NK cell stimulating cytokines in serum. In line, viral clearance corrects the NK cell phenotype by lowering the expression of activation and inhibitory signals and TRAIL.

P0691
KNOCKDOWN OF LYSOPHOSPHATIDYLCHOLINE ACYLTRANSFERASE 1 (LPCAT1) INCREASES BOTH THE SECRETION OF VERY-LOW-DENSITY LIPOPROTEINS (VLDL) AND THE INFECTIVITY OF HEPATITIS C VIRUS (HCV)

M. Lemasson[1], F. Beilstein[2,3], V. Pène[1], A.R. Rosenberg[1,4], S. Demignot[2,3]. *[1]EA 4474 "Hepatitis C Virology", Université Paris Descartes, [2]UMR-S 1138 (CRC), Inserm; Université Pierre et Marie Curie; Université Paris Descartes, [3]Laboratoire de Pharmacologie Cellulaire et Moléculaire, EPHE, [4]GH Cochin, Service de Virologie, AP-HP, Paris, France*
E-mail: arielle.rosenberg@parisdescartes.fr

Background and Aims: The hepatocyte is both the cell specialised in the secretion of VLDL, which are apolipoprotein (Apo) B-containing triacylglycerol (TG)-rich lipoproteins, and the primary replication site of HCV. Unique to this virus is its intimate link with the host lipid metabolism. The most infectious HCV particles are those of lowest density due to their association with TG-rich lipoproteins. Moreover, HCV-infected patients frequently have hepatic steatosis, i.e., accumulation of TG in cytosolic lipid droplets (LD), which store neutral lipids within a monolayer of phospholipids, mainly phosphatidylcholine. We recently showed that HCV downregulates LPCAT1, about which little is known except that it can synthesize phosphatidylcholine on the LD surface. Here we investigated the role of LPCAT1 in the lipid metabolism of hepatocytes and in HCV infectious cycle.
Methods: Huh-7.5.1 cells and primary human hepatocytes (PHH) were infected with JFH1. Knockdown of LPCAT1 was achieved by RNA interference technology. Cells were monitored for LD size (immunofluorescence) and TG level (enzymatic assay). Culture supernatants were probed for the secretion of ApoB (ELISA) and lipids (metabolic labelling using C^{14}-oleic acid), and for HCV production (viral load test) and infectivity (titration). The density of viral particles was assessed by isopycnic ultracentrifugation.
Results: LPCAT1 knockdown in either naïve or infected Huh-7.5.1 cells increased the mean size of LD and the intracellular level of TG in the steady state, thus causing steatosis. It also increased the secretion of both ApoB and newly synthesized TG, consistent with an impact on VLDL biosynthesis. In infected Huh-7.5.1 cells or PHH, LPCAT1 knockdown increased production of the viral particles with highest infectivity and lowest density, consistent with their enrichment in TG. Finally, the excess of ApoB secreted from infected PHH was found at the density of the viral particles, compatible with the formation of hybrid structures between HCV and VLDL.
Conclusions: LPCAT1, a LD-associated protein thought to be a phospholipid membrane remodelling enzyme, has a role in the metabolism of TG. Its downregulation by HCV appears as a viral strategy to hijack the VLDL biosynthesis pathway for the production of highly infectious hybrid particles. Targeting the LPCAT1-regulated lipid metabolism pathway may thus represent an attractive therapeutic approach able to reduce both the viral titre and hepatic steatosis.
FB and ML, or ARR and SD: equal contribution.

PKC/AP-1 SIGNALING DRIVES TRANSCRIPTION OF INTERFERON-STIMULATED GENES AND EXERTS POTENT ANTIVIRAL ACTIVITY AGAINST HEPATITIS C AND E VIRUSES

W. Wang[1], Y. Wang[1], X. Zhou[1], Y. Yin[1], L. Xu[1], D. Sprengers[1], H.J. Metselaar[1], Y. Debing[2], J. Neyts[2], M.P. Peppelenbosch[1], Q. Pan[1]. *[1]Department of Gastroenterology and Hepatology, Erasmus MC, Rotterdam, Netherlands; [2]Department of Microbiology and Immunology, Rega Institute for Medical Research, Leuven, Belgium*
E-mail: w.wang.2@erasmusmc.nl

Background and Aims: Protein kinases are enzymes that modifies proteins by chemically adding phosphate groups (phosphorylation)

and are considered pivotal regulators of almost all cellular processes. Strikingly, however, their involvement in viral infection is less well defined. This study aimed to identify kinase-mediated signaling pathways modulating hepatitis C (HCV) and E (HEV) virus infections and to explore the feasibility of modulators of kinase activity as antiviral targets.
Methods: Huh7 cell line harboring subgenomic HEV luciferase reporter, full-length HEV infectious genome or subgenomic HCV were used.
Results: Screening of a library containing 132 kinase inhibitors identified a Protein Kinase C (PKC) inhibitor that significantly promotes HEV infection. Consistently, RNAi mediated knockdown of PKCα, a key member of the PKC family, results in a significant 7-fold increase in HEV RNA levels. Conversely, overexpression of an active form of PKCα inhibited HEV RNA production by 77.5%. Phorbol-12-myristate-13-acetate (PMA) is a well-established PKC activator. As expected, treatment with PMA significantly inhibits both HCV (by 50%) and HEV (by 68%) replication. Combining PMA with ribavirin, but not interferon-alpha exerted additive antiviral activity, suggesting a possible convergence of PKC and interferon signaling. Indeed, in our experimental system PMA potently transactivates Interferon stimulated response elements (ISRE) and induces expression of Interferon stimulated genes (ISGs) independent of the canonical elements of the interferon signaling, including IRF9 and JAK1. Knockdown of c-fos, a key component of the AP1 complex that is downstream of PKC, completely abolishes the capacity of PMA to activate the ISRE and to induce ISGs. Bioinformatical analysis reveals a consensus nucleotide sequence within the ISRE and AP1 DNA binding motifs. Mutagenesis of this homologous region within the ISRE motif removes the capacity of PMA to transactivate the ISRE, confirming that the AP1 complex directly driving the transcription of ISRE to induce ISG expression.
Conclusions: Together with canonical interferon signaling, the PKC/AP1 signaling converges on ISRE-containing promotors to induce the expression of antiviral ISGs. Thus PKC/AP1 signaling a novel indispensable branch of cell-autonomous antiviral signaling constraining HCV and HEV infection.

THE TUMOR SUPPRESSOR PML MEDIATES EVEROLIMUS-INDUCED CHANGES OF THE HCV REPLICATION ACTIVITY
A. Frey[1], E.-M. Ecker[1], K. Piras-Straub[1,2], A. Walker[3], T. Hofmann[4], G. Gerken[1], K. Herzer[1,2]. *[1]Dept of Gastroenterology and Hepatology, [2]Dept of General, Viszeral and Transplantation Surgery, University Hospital Essen, Essen, [3]Dept of Virology, University Hospital Düsseldorf, Düsseldorf, [4]German Cancer Research Center, Heidelberg, Germany*
E-mail: alexandra.frey@uk-essen.de

Background and Aims: Successful liver transplantation (LT) due to hepatitis C virus infection is often followed by a deleterious course of HCV reinfection of the liver graft. New antiviral treatment options give hope for improvement the course of disease and prognosis. Nevertheless, the influence of immunosuppression on HCV replication and reinfection, particularly of mTor inhibitors, is not clarified yet. A previously described interaction of the tumor suppressor PML with the mTor signaling cascade as well as findings that the HCV interacts with PML suggest some relevance of the tumor suppressor in that context. The aim of our study is to analyze the influence of everolimus (EVR) on HCV replication activity *in vitro* in the context of the underlying molecular mechanisms with focus on the role of PML.
Methods: Subgenomic HCV replicons for genotype (GT) 1a and 2b were treated with different immunosuppressive substances. For detection of cell viability FACS-based CFSE analyses as well as MTT assays were performed. PML expression was silenced employing shRNA constructs. Protein and mRNA expression was quantified by qrt-PCR and western blot analysis. Gene array analysis was employed to reveal underlying molecular mechanisms.
Results: mTor-Inhibitors and calcineurin inhibitors (CNIs) have different effects on HCV replication activity. Therapeutic doses of EVR impair HCV replication activity of GT2a up to 50% (P≤0.001). In contrast, replication activity of HCV GT1b is increased by more than 50% (P≤0.001) under the influence of EVR. Interestingly, in absence of PML the effect of EVR on HCV replication activity is nearly abrogated. Even without EVR treatment, HCV replication activity is impaired in the absence of PML while transfection of PML-deficient replicon-containing cells with different PML isoforms results in a recovery of HCV replication activity. Gene array analyses of Huh7.5 replicon cells reveal a divergent expression pattern upon treatment with CNIs or mTor-Inhibitors and, thus, interesting candidate genes as further key components in EVR-induced regulation of HCV replication activity.
Conclusions: We demonstrate a genotype-dependent influence of EVR on HCV replication activity *in vitro*. Our results demonstrate an interplay between the expression of PML and the EVR-induced reduction of HCV replication activity. The results of this study suggest that the choice of immunosuppressive therapy after LT may significantly influence the progress of HCV reinfection.

17BETA-ESTRADIOL INHIBITS HCV INFECTION VIA BINDING TO ITS RECEPTOR
A. Magri[1], C.Z. Foglia[1], E. Boccato[1], M.E. Burlone[1], R. Minisini[1], E. Grossini[1], M. Pirisi[1]. *[1]Translational Medicine, Università del Piemonte Orientale, NOVARA, Italy*
E-mail: minisini@med.unipmn.it

Background and Aims: Hormonal factors may play a role in controlling hepatitis C virus (HCV) infection. In fact, spontaneous HCV clearance is more common among premenopausal women than in men and, when infection persists, histologic progression of chronic hepatitis is slower in pre-menopausal women in comparison to postmenopausal women and men. Based on these premises, we aimed to evaluate sex hormones as inhibitors of HCV replication.
Methods: Huh-7.5 cells infected with the JFH-1 virus (genotype 2a) were exposed to one each among the following hormones: dehydroepiandrosterone (DHEA), testosterone, progesterone and 17β-estradiol (the latter in the presence/absence of the estradiol receptor antagonist fulvestrant). Based on the inhibition of viral replication, dose-response curves covering the physiological range were established allowing calculation of IC50 values. In model A, hormones were added 3 hours post-infection. In model B, Huh-7.5 cells were incubated with hormones for 1 h before being infected; 3 h later, the inoculum was replaced with fresh medium. In model C, a 16 h pre-incubation 17β-estradiol preceded replacement with fresh medium, followed by infection.

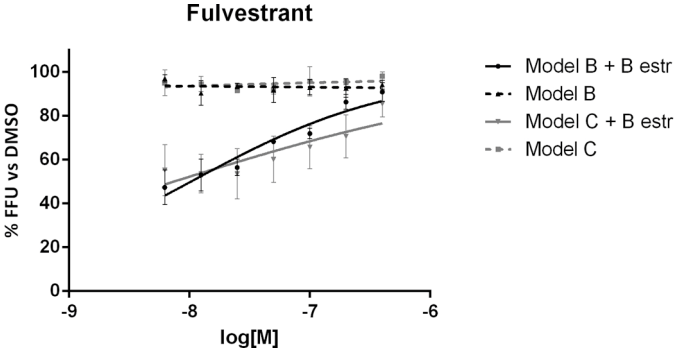

Figure: %FFU indicates the percentage of focus forming unit reduction (FFU); the horizontal line represents the IC50 values.

Results: Progesterone and testosterone did not show any inhibitory effect on viral replication at the concentrations tested for both model A or B. DHEA exhibited only a partial antiviral effect in both model A and B (39%). In contrast, in model A 17β-estradiol inhibited viral replication up to 45%, allowing to estimate IC50 = 490 nM. Moreover, the inhibitory effect of 17β-estradiol reached 67% in model B and 64% in model C, with IC50 values of 140 and 160 nM, respectively. Although fulvestrant did not exhibit any appreciable effect on viral replication, in its presence the inhibition exerted by 17β-estradiol was reverted in a dose-dependent manner (Figure).
Conclusions: In vitro, 17β-estradiol is able to block HCV infection, likely by modulation of intracellular pathways following binding to the estradiol receptor, whose activation leads to an antiviral state.

P0695
TRIPLE THERAPY FOR CHRONIC HCV PATIENTS INDUCES EARLY ACTIVATION OF INTRAHEPATIC NK CELLS
M. Spaan[1], G. van Oord[1], R. de Groen[1], H. Janssen[1,2], R. de Knegt[1], A. Boonstra[1]. *[1]Department of Gastroenterology and Hepatology, Erasmus MC, Rotterdam, Netherlands; [2]Liver Clinic University Health Network, University of Toronto, Toronto, Canada*
E-mail: m.spaan@erasmusmc.nl

Background and Aims: Previous studies have correlated therapy outcome in HCV to the expression of various markers on NK cells, including inhibitory killer immunoglobulin-like receptors CD158a and CD158b as well as natural cytotoxicity receptor NKp46 and activating receptor CD69. This study is the first to investigate intrahepatic NK cells in HCV patients during triple therapy with telaprevir. By collecting multiple liver fine-needle aspirate biopsies (FNABs) we have the unique opportunity to investigate liver NK cells during therapy-induced viral load reduction.
Methods: 10 chronic HCV patients were treated with peg-interferon/ ribavirin and telaprevir according to prescription protocol and all responded well to therapy. Intrahepatic leukocytes were obtained via aspirate biopsy at baseline, 6-hours, 1-week, and 12-weeks of treatment. Peripheral blood was collected at various time-points and peripheral blood mononuclear cells (PBMC) were obtained via ficoll separation. Expression levels of CD158a, CD158b, NKG2A, NKG2D, NKp46, and CD69 were analysed on $CD56^+$ $CD3^-$ NK cells by flowcytometry.
Results: At baseline, liver NK cells displayed a more activated phenotype compared to blood based on the expression of CD69 and NKG2D ($p = 0.001$ and $p = 0.05$ respectively). Expression of NK cells receptors in liver of individual patients highly correlated with frequencies in blood (all $p < 0.05$). Sampling of the liver 6 hours after start of therapy showed no evidence for an immediate effect of triple therapy on liver NK cells, since no modulation of NK cell phenotype was observed. After 1 week therapy, paired sampling of the liver showed a significant increase in activating receptors NKp46 and NKG2D ($p = 0.02$ and $p = 0.05$ respectively) and a decrease in inhibitory receptor NKG2A ($p = 0.03$) on total NK cells, indicating a more activated phenotype. Interestingly, after 12 weeks of therapy, expression of NKG2D and NKp46 on liver NK cells returned to baseline levels, while expression of NKG2A significantly increased compared to all time-points ($p = 0.03$).
Conclusions: Our results demonstrate that liver NK cells are more activated compared to blood. Our data suggest an active role for liver NK cells during triple therapy with dynamic alterations of NKG2A, NKG2D and NKp46 levels on liver NK cells of chronic HCV patients during the early phase of triple therapy.

PROTEASOME SUBUNIT ALPHA TYPE-6 REGULATES THE EXPRESSION OF PROVIRAL HOST GENES IN HEPATITIS C VIRUS INFECTION
R. Broering[1], M. Trippler[1], M. Lutterbeck[1], C.I. Real[1], D.A. Megger[2], T. Bracht[2], V. Schweinsberg[2], B. Sitek[2], M. Eisenacher[2], H.E. Meyer[2,3], H.A. Baba[4], F. Weber[5], A.-C. Hoffmann[6], G. Gerken[1], J.F. Schlaak[1,7]. *[1]Dept. of Gastroenterology and Hepatology, University Hospital Essen, Essen, [2]Medizinisches Proteom-Center, Ruhr-Universität Bochum, Bochum, [3]Leibniz Institute, ISAS, Dortmund, [4]Department of Pathology and Neuropathology, [5]Department of General, Visceral and Transplantation Surgery, [6]Department of Medicine (Cancer Research), University Hospital Essen, Essen, [7]Evangelisches Klinikum Niederrhein, Duisburg, Germany*
E-mail: ruth.broering@uni-due.de

Background and Aims: The interferon stimulated gene 15 (ISG15) plays an important role in the pathogenesis of hepatitis C virus (HCV) infection. ISG15-regulated proteins have previously been identified that putatively affect this proviral interaction. The present observational study aimed to elucidate the relation between ISG15 and these host factors during HCV infection.
Methods: Proteomic and transcriptomic analyses were performed using liver samples of HCV-infected ($n = 54$), HBV-infected patients ($n = 23$) and uninfected controls ($n = 10$). Primary human hepatocytes (PHH) were treated with toll-like receptor ligands, interferons and kinase inhibitors. Expression of *ISG15* and proteasome subunit alpha type-6 (*PSMA6*) was suppressed in subgenomic HCV replicon cell lines using specific siRNAs.
Results: Comparison of hepatic expression patterns revealed significantly increased signals for ISG15, IFIT1 (interferon-induced protein with tetratricopeptide repeats 1), HNRNPK (Heterogeneous nuclear ribonucleoprotein K) and PSMA6 on the protein level as well as *ISGs* and *PSMA6* on the mRNA level in HCV-infected patients. In contrast to *ISGs*, *PSMA6* expression occurred independent of HCV load and genotype. Expression of *ISG15* and *PSMA6* was induced by poly(I:C), depending on interferon regulatory factor 3 activation and phosphoinositide 3-kinase/AKT signalling, respectively. Interestingly, suppression of *PSMA6* led to significant induction of *ISG15* expression, thus combined knockdown of both genes abrogated the antiviral effect induced by the separate suppression of *ISG15*.
Conclusions: PSMA6 is up-regulated during viral hepatitis and functions as a negative regulator for ISG15, a proviral factor in the pathogenesis of HCV infection. These findings suggest that the proteasome might affect the enigmatic interaction between ISG15 and HCV.

INTERPLAY BETWEEN VIRUS-SPECIFIC AND APOPTOTIC EPITOPE-SPECIFIC CD8+ T CELLS IN CHRONIC HEPATITIS C VIRUS
H. Martini[1,2], A. Citro[1,2], C. Martire[1,2], D. Accapezzato[1,2], G. Labbadia[1], E.N. Cavallari[3], G. D'Ettorre[3], L. Calvo[1], F. Rizzo[4], M. Severa[4], E.M. Coccia[4], V. Barnaba[1,2]. *[1]Medicina Interna e Specialità Mediche, Sapienza University of Rome, [2]Istituto Pasteaur-Fondazione Cenci Bolognetti, [3]Public Health and Infectious Diseases, Sapienza University of Rome, [4]Infectious, Parasitic and Immune-mediated Diseases, Istituto Superiore di Sanità, Rome, Italy*
E-mail: alessandra.citro@uniroma1.it

Background and Aims: $CD8^+$ T cells specific to caspase-cleaved antigens derived from apoptotic T cells (apoptotic epitopes [AE]) represent a principal player of chronic immune activation (CIA), known to amplify immunopathology in various inflammatory conditions. The purpose of this study was to investigate the interplay among HCV-specific $CD8^+$T cells, AE-specific $CD8^+$T cells, and disease activity in chronic hepatitis C virus (cHCV) infection.
Methods: We enumerate both HCV- and AE-specific $CD8^+$T cells from PBMCs of patients and donors by MHC-I

dextramers complexed to the relevant peptides. We analyzed cytokine production in dextramer$^+$CD8$^+$ T cells in response to peptide stimulation by intracellular staining. We characterized dextramer$^+$CD8$^+$ T cell phenotype with surface and nuclear markers. mRNA levels of IFN stimulated gene (MxA, PKR, ISG15) were analysed done by Quantitative PCR assays (SYBR Green technology). The genotyping for the *IL28B* rsl2979860 SNP was performed with LightMix® *in-vitro* diagnostics Kit IL28B.

Results: Both HCV- and AE-specific CD8$^+$ T cells exhibited parallel frequencies and correlated with transaminase levels and liver fibrosis score, respectively, supporting a possible disparity in sustaining liver damage (direct hepatocyte killing *vs.* by-stander inflammation). Regardless, both AE- and HCV-specific CD8$^+$ T cells displayed unusual functional properties, on the basis of both the expression of a functional phenotype (T-bet^{high}/Eomes$^+$/PD-1^{low}) and the capacity to produce IFN-g by a high percentage of them, particularly when they migrated into the inflamed liver. Importantly, AE-specific (but not the HCV-specific) CD8$^+$ T cells correlated with the level of some IFN type I-stimulated gene transcripts in PBMCs.

Conclusions: Our data strongly indicate that these cells are not terminally dysfunctional and may contribute to maintain chronic active disease. Accordingly, the evidence that only a minority of them expressed a "dysfunctional phenotype" (i.e., PD-1$^+$, PD-1$^+$/T-bet$^-$/Eomes$^+$, or Tbet^{low}/Eomes$^+$ cells), and that the immunoregulatory PD-1/PD-L1 pathway was operative *in vitro*, suggests that the latter likely contributes to limit immunopathology, rather than to induce severe T cell dysfunction. The finding that AE-specific (but not the HCV-specific) CD8$^+$ T cells correlated with the level of IFN type I-stimulated gene transcripts in PBMCs suggest that the chronic IFN-I signaling contributes in establishing CIA and disease progression by modulating AE-specific CD8$^+$ T cell responses in cHCV infection.

QUERCETIN MODIFIES LIPID DROPLET MORPHOLOGY AND IMPAIRS HEPATITIS C VIRAL LIFE-CYCLE STEPS FROM ASSEMBLY TO REPLICATION STEPS

Á. Rojas[1], S. Clement[2], J.A. Del Campo[1], M. Lemasson[3], M. García-Valdecasas[1], L. Rojas[1], A. Gil-Gómez[1], I. Ranchal[1], J. Bautista[4], A.R. Rosenberg[3], F. Negro[5], M. Romero-Gómez[1]. *[1]Unit for Clinical Management of Digestive Diseases and CIBERehd, Valme University Hospital, Seville, Spain; [2]Division of Clinical Pathology, University Hospital, Geneva, Switzerland; [3]Hepatitis C virology, University Paris Descartes, Paris, France; [4]Biochemistry and Molecular Biology, Faculty of Pharmacy, University of Seville, Seville, Spain; [5]Division of Clinical Pathology and Gastroenterology and Hepatology, University Hospital, Geneva, Switzerland*
E-mail: angela_rojas16@hotmail.com

Background and Aims: Hepatitis C virus (HCV) life cycle can be divided into several steps: (i) entry of viral particles, (ii) translation of the viral proteins, (iii) replication of the viral genome, a step which requires the activity of HCV non structural proteins including the protease NS3, and (iv) assembly of new viral particles, a step which requires the localization of HCV core and NS5A protein to lipid droplets mediated by the host diacylglycerol acyltransferase type 1 (DGAT1). Quercetin, a bioflavonoid, seems to prevent the localization of HCV core protein to lipid droplets and to inhibit HCV replication (Rojas et al., AASLD 2013). Here we aimed at evaluating the potential of quercetin as antiviral drug and further defining its mechanism(s) of action on the different steps of HCV life cycle.

Methods: To reproduce the complete HCV life cycle, Huh7.5 cells and primary hepatocyte were infected with JFH1and subsequently treated with doses of quercetin. (i) Replication of HCV genome was assessed by measuring the intracellular levels of negative-strand HCV RNA by qRT-PCR. (ii) Production of infectious virus was assessed by measuring the infectivity titers in filtered culture supernatants with focus-formation assay and by COBAS® TaqMan® HCV Test v2.0. (iii) NS3 protease activity *in vitro* was measured using a comercial Kit SensoLyte® 520 HCV Protease Assay. (iv) DGAT activity was analyzed using the protocol previously described by McFie and coll. (2011) in Huh7.5 cells infected by JFH1.

Results: Infectivity assay in Huh7.5.1 and primary hepatocytes were IC50: 37.83 and 23.63 μM respectively. At 50μM HCV-RNA levels decreased (Huh7.5.1: 39% and PHH: 24%). The amount of HCV-RNA (evaluated by the quantity of viral RNA produced in the supernatant) was decreased as well by 60%±26.7 ($p < 0.05$) compared to the supernatant from Huh7.5 infected by JFH.1 (1MOI). *In vitro* NS3 activity was inhibited by quercetin by 45.40%±1.15 RFU ($p < 0.001$) compared to the vehicle, DMSO (no inhibition). DGAT enzyme activity in infected cells was increased relative to non-infected cells (*fold induction* 2.29±0.23 $p < 0.01$). However, this increase was significantly inhibited by treatment with quercetin [63.5±2.9% ($p < 0.01$)]

Conclusions: In the current study, quercetin was observed to inhibit DGAT activity, to decrease NS3 activity, as such, resulting in impairment of viral infectivity and replication. Thus, the antiviral activity of this flavonoid is promising and mediated through several viral and host mechanisms.

P0699
EPIGENETIC HARNESSING OF HCV VIA MODULATING THE LIPID DROPLET-PROTEINS, ADRP AND TIP47, IN HCV CELL MODELS

N. El-Ekiaby[1], R.Y. Mekky[1], M. El-Sayed[2], G. Esmat[2], A.I. Abdelaziz[1]. *[1]Pharmacology and Toxicology, German University in Cairo, [2]Endemic Medicine and Hepatology, Cairo University, Cairo, Egypt*
E-mail: nada.magdy@guc.edu.eg

Background and Aims: Host cell lipid droplets (LDs), along with their associated perilipin protein family (PAT), were reported to promote hepatitis C virus (HCV) life cycle. The regulation of PAT proteins expression and subsequently cellular LDs by microRNAs (miRNAs) has never been investigated in HCV cell models. Therefore, this study aimed at identifying miRNAs that target and modulate the hepatic PAT proteins, adipose differentiation related protein (ADRP) and Tail interacting protein of 47 kDa (TIP47), and subsequently regulate LDs and HCV infection.

Methods: Bioinformatics analysis was performed to predict miRNAs that target ADRP and TIP47. Expression profile of identified miRNAs and their targets was examined in 21 HCV-infected liver biopsies and 9 healthy donor liver tissues obtained during liver transplantation as well as in JFH-I infected compared to naïve Huh7 cells using qRT-PCR. JFH-1 infected cells were transfected with identified miRNA mimics or antagomirs or siRNAs against ADRP or TIP47 followed by oleic acid treatment to induce LD formation to study their effect on ADRP and TIP47 expression as well as on intracellular LD and HCV RNA levels. LDs were stained with oil-red-O and visualized using immunofluorescence microscopy. HCV RNA was quantified using qRT-PCR.

Results: Bioinformatics revealed that ADRP is a potential target of miR-148a and TIP47 potentially targeted by miR-148a and miR-30a. Expression profiling showed that miR-148a, miR-30a and ADRP were downregulated ($p = 0.0216$, $p = 0.0041$ and $p = 0.0261$), while TIP47 was upregulated ($p = 0.0489$) in patients compared to controls. Infection of Huh7 cells with JFH-I suppressed ADRP and induced TIP47 expression ($p = 0.0167$, $p = 0.0167$), suggesting that the alteration in PAT protein expression is due to the viral infection. Mimicking of both miRNAs significantly induced ADRP ($p = 0.0103$, $p = 0.02$), while they suppressed TIP47 expression ($p = 0.0488$, $p = 0.0262$). Cellular LD content was reduced in miR-148a, miR-30a mimicked and TIP47 knockdown cells. HCV RNA was markedly decreased upon mimicking with miR-148a and miR-30a

by a mean of 36% and 42.65%, respectively, and in TIP47 knockdown cells by 42.9% but was not affected by ADRP knockdown.
Conclusions: In conclusion this study shows for the first time that HCV infection deregulates hepatic ADRP and TIP47 expression in HCV infected patients and cell lines. Forcing the expression of miR-148a and miR-30a, induces the expression of ADRP and suppresses TIP47, decreases cellular LDs and subsequently suppresses HCV infection.

P0700
IMMUNOLOGICAL RATHER THAN VIROLOGICAL RESPONSE TO HAART IS ASSOCIATED WITH IMPROVED ANTI-HCV NK CELL ACTIVITY IN HIV PATIENTS

A. Glässner[1,2], B. Krämer[1,2], F. Wolter[1,2], P. Kokordelis[1,2], F. Goeser[1,2], D. Kaczmarek[1,2], C. Boesecke[1,2], C. Schwarze-Zander[1,2], C.P. Strassburg[1,2], U. Spengler[1,2], J.K. Rockstroh[1,2], J. Nattermann[1,2].
[1]Internal Medicine I, [2]German Center for Infection Research (DZIF), Universitiy of Bonn, Bonn, Germany
E-mail: andreas.glaessner@ukb.uni-bonn.de

Background and Aims: Co-infection with the hepatitis C virus (HCV) is a major cause of morbidity and mortality in HIV(+) patients.
Natural killer (NK) cells are considered to play an important role in the immunobiology of HCV-infection, as they have been shown to exert anti-viral functions. Interestingly, in HIV/HCV co-infected individuals anti-HCV activity of NK cells is impaired. However, it is unclear, how HIV-infection affects NK cell activity. Thus, we analyzed the anti-HCV activity of NK cells in HIV mono-infected patients.
Methods: 40 HIV-infected patients, including 21 individuals who were HIV RNA(−) under HAART and 19 treatment-naïve HIV RNA(+) patients, as well as 20 healthy HIV(−)/HCV(−) controls were enrolled into this study. Anti-viral activity of total PBMCs was studied using the HUH7-HCV-replicon system. IFN-γ secretion of NK cells was analyzed in the presence/absence of CD3/CD28 stimulated $CD4^+$ T cells
Results: Compared to healthy individuals we found PBMCs from HIV-RNA(+) patients to display significantly impaired anti-HCV activity. Of note, HIV-RNA(−) patients under effective HAART displayed a similar dys-regulation of anti-viral activity. Accordingly, we found IFN-γ production following co-incubation with replicon cells to be significantly impaired in HIV patients, irrespective of HAART. However, when patients were stratified according to $CD4^+$ T cell counts we found high $CD4^+$ T cell numbers (>400/μl) to be associated with strong anti-HCV activity. In line with this finding we observed IFN-γ production of NK cells to be significantly correlated with frequency of $CD4^+$ T cells. In co-culture experiments we found that $CD4^+$ T cells effectively stimulate IFN-γ production of NK cells.
Conclusions: Here, we show that HIV-infection caused an impaired anti-HCV activity and IFN-γ secretion of NK cells in HIV-RNA(+) and HIV-RNA(−) patients. However, in contrast to viral loads we found $CD4^+$ T cell frequency to be correlated with anti-HCV activity. Therefore, our findings indicate that immunological rather than virological response to HAART might be associated with an improved anti-HCV NK cell activity in HIV(+) patients.

NEXT GENERATION SEQUENCING REVEALS DIFFERENTIAL EXPRESSION PROFILES OF HEPATIC MICRORNAS IN CHRONIC HEPATITIS C PATIENTS

A.M. Butt[1,2], L. Castellano[2], M. Idrees[1], Y. Tong[3]. *[1]Centre of Excellence in Molecular Biology (CEMB), University of the Punjab, Lahore, Pakistan; [2]Imperial Centre for Translational and Experimental Medicine (ICTEM), Department of Surgery and Cancer, Imperial College London, London, United Kingdom; [3]State Key Laboratory of Pathogen and Biosecurity, Beijing Institute of Microbiology and Epidemiology, Beijing, China*
E-mail: azeem@cemb.edu.pk

Background and Aims: Hepatitis C virus (HCV) is a major cause of chronic liver disease worldwide. MicroRNAs (miRNAs) are small, non-coding RNA molecules of 20–22 nucleotides that that act post-transcriptionally to regulate gene expression. Previous studies have demonstrated association of several miRNAs to the HCV disease progression and implicated as potential new therapeutic targets and biomarkers. However, the data from such studies is restricted to analysis of limited miRNAs. Recently, we have reported next generation sequencing (NGS) based profiling of differentially expressed miRNAs (DE-miRNAs) between chronic hepatitis C (CHC) and healthy subjects. In the present study, we report deep sequencing analysis of DE-miRNAs between different groups of CHC patients grouped according to the response to interferon therapy.
Methods: A total of eight pre-treatment percutaneous liver biopsy specimens from the CHC patients (genotype 3) [sustained virological responders (SVR; n = 4) and non-responders (NR; n = 4)] were selected according to the end treatment response (ETR) to interferon plus ribavirin therapy. The libraries were sequenced on HiSeq2000. DE-miRNAs were identified by edgeR package. Selected DE-miRNAs were also validated by using real time PCR in an independent cohort of CHC patients (n = 120).
Results: We identified 29, 14, and 12 DE-miRNAs between SVR: NR, SVR: R and NR: R patients groups (-1.5 < fold change >1.5; $P < 0.05$) respectively (Figure 1). DE-miRNAs from each group was then profiled in cohort group and found to be in agreement with NGS findings. The diagnostic and prognostic potential of DE-miRNAs in different groups was assessed by ROC curves and regression analyses. Furthermore, in order to assess the effect of DE-miRNAs on the host's genes expression and biological functions, expression profiles of liver-specific genes in CHC patients were obtained and an integrated miRNA-mRNA interaction, ontology and pathway analysis was performed. This showed that DE-miRNAs in SVR and NR groups target several genes associated with interferon-α, TNF, JAK-STAT, immune response and lipid metabolism pathways.

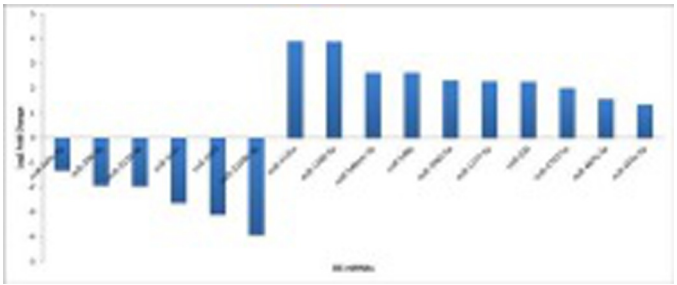

Figure 1.

Conclusions: In summary, we show that liver-expressing miRNAs show significantly different expression patterns among CHC patients when classified on the basis of ETR. The findings highlight that DE-miRNAs have the potential to serve as novel biomarkers in CHC patients. Moreover, the miRNA-mRNA interactions and pathway analysis show that DE-miRNAs can also serve as attractive therapeutic targets in CHC patients.

P0702

CC IL28B GENOTYPE IS ASSOCIATED WITH HIGH LIVER NECROINFLAMMATION AND INCREASED EXPRESSION OF TH1 CYTOKINES (CYK) AND CHEMOKINES (CHK), BUT ALSO HIGHER TH2 CYK WHICH MAY DRIVE LOW ISG EXPRESSION

J.A. Holmes[1,2], N. Skinner[2], M. Congiu[1], R. Millen[2], S.J. Bell[1], T. Nguyen[3], D.M. Iser[3], W. Sievert[4], P.V. Desmond[1], K. Visvanathan[2], A.J. Thompson[1]. *[1]Gastroenterology, [2]Immunology Research Centre, St Vincent's Hospital, University of Melbourne, [3]Gastroenterology, St Vincent's Hospital, Fitzroy, [4]Gastroenterology, Monash Health, Monash University, Clayton, Australia*
E-mail: jacinta_holmes@hotmail.com

Background and Aims: IL28B genotype (gt) and ISG expression predict IFN response, but the mechanisms are poorly understood. We hypothesized that ChK and Th1 CyK that mediate inflammatory responses higher in C/C *IL28B* genotype which leads to upregulation of Th2 CyK resulting in lower intrahepatic ISG expression. We also hypothesize that there is an early and more potent induction of ChK/CyK in C/C *IL28B* genotype patients which predicts for HCV clearance. We performed a detailed study of the relationship between *IL28B* genotype and expression in of a panel of ChK and relevant Th1/Th2 CyK in HCV patients (pts) with paired plasma and liver. We also compared on-treatment changes in plasma ChK/CyK during the first 4 weeks of pegIFN+RBV dual therapy (PR) in a subset of HCV pts.

Methods: HCV-1 pts with paired plasma and liver tissue were included. IL28B gt (rs12979860) was determined. Liver necroinflammatory activity was scored using METAVIR activity score. Liver expression of ChK (CCL2/CXCL9/CXCL10) and CyK (IL1b/IL6/IL8/IL10/IL12/TNFa) were measured (rtPCR). Plasma CyK/ChK were measured by cytometric bead array (BD). Plasma was collected at days 0, 1, 7, 14, 28 for detailed analysis of IFN-induced ChK/CyKs in a subset of pts treated with PEG+RBV. ChK/CyK expression were correlated with liver necroinflammation, IL28B gt and treatment outcome.

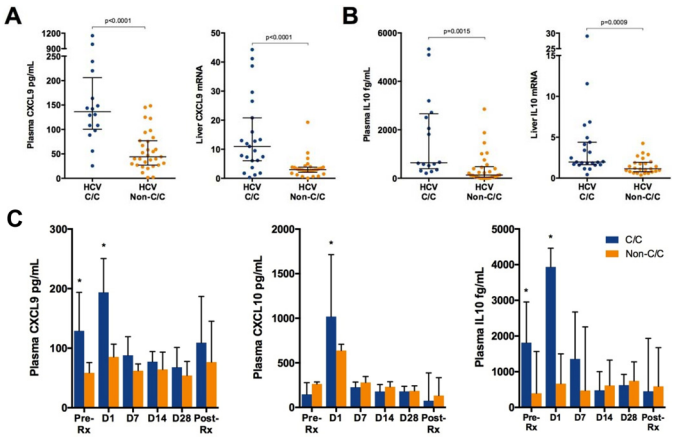

Figure 1. (A) Plasma and liver CXCL9 levels according to *IL28B* genotype. (B) Plasma and liver IL10 levels according to *IL28B* genotype. (C) On-treatment CXCL9, CXCL10 and IL10 according to *IL28B* genotype. *Significant p-value.

Results: 47 pts with paired liver/plasma samples were included: 34% CC IL28B gt. Necroinflammation was significantly higher in CC IL28B with 81% having A2–3 METAVIR activity (vs 32% for non-CC pts, p = 0.001). ALT was also significant higher (109 vs 57 in CC vs non-CC, p = 0.036). Plasma and liver Th1 CyK and CXCL9 levels were significantly higher in CC IL28B gt patients (Figure 1a). Plasma and liver IL10 (Th2 CyK) were also significantly higher in CC pts (Figure 1b). In treated patients (n = 19), an early and rapid increase in plasma CXCL9, CXCL10, and IL10 levels were observed in CC pts and those with subsequent SVR, compared to non-CC pts and pts who did not achieve an SVR (Figure 1c). Peak CyK and ChK levels peaked at day 1 of PR therapy.

Conclusions: The data identify an important role for the chemokine CXCL9 in mediating inflammation in the HCV liver, which is strongly associated with IL28B gt. IL10 upregulation was also observed in CC pts which may represent a secondary response to Th1 upregulation which then lowers liver ISG expression. Interferon treatment induces a potent and early ChK and IL10 response, which is associated with IL28B gt and predicts for HCV clearance.

P0703

PRE-TREATMENT RIBAVIRIN SENSITIVITY CORRELATES WITH TREATMENT OUTCOME IN GENOTYPE 3 HCV

M.E. Cunningham[1], P. Wing[1], S. DeSilva[1], J. Davidson-Wright[1], M. Jones[1], G.R. Foster[1]. *[1]Queen Mary, University of London, London, United Kingdom*
E-mail: m.e.cunningham@qmul.ac.uk

Background and Aims: New therapies for chronic HCV infection have substantially increased rates of sustained virological response (SVR). However relapse after therapy remains a problem, especially in patients with cirrhosis. We have developed a novel capture-fusion assay to study patient-derived HCV (1). Here we demonstrate that this assay can identify pre-treatment sofosbuvir (SOF), interferon (IFN) and ribavirin (RBV) sensitivity in patients with G3 HCV, and RBV sensitivity correlates with treatment outcome.

Methods: Archived pre-treatment sera were obtained from 10 G3 patients treated with pegIFN/RBV, 4 with SVR and 6 who relapsed, and from 4 G3 patients treated with SOF/RBV, 3 with SVR and 1 who relapsed. THP-1 cells were exposed to donor serum, fused with Huh7.5 cells and treated with SOF, IFN or RBV before qPCR assessment of HCV replication. Results are given as mean ± sem and p values were calculated using Mann Whitney U test.

Results: No difference in pre-treatment IFN sensitivity was seen between patients with SVR and those who relapsed after pegIFN/RBV (IFN IC_{50} 0.61±0.11 IU/mL for patients with SVR versus 0.55±0.09 IU/mL for relapse, p = 0.61). However pre-treatment isolates from patients with SVR were significantly more sensitive to RBV than those from patients who relapsed (ribavirin IC_{50} 0.62±0.05 μM for patients with SVR versus 1.25±0.13 μM for relapse, p = 0.01). Amongst patients treated with SOF/RBV, pre-treatment SOF sensitivity was similar between patients with SVR and relapse (SOF IC_{50} 0.036±0.016 μM for SVR versus 0.023 μM for the patient who relapsed). However pre-treatment RBV sensitivity appeared greater in patients with SVR than relapse (RBV IC_{50} 0.377±0.037 μM for SVR versus 1.049 μM for the patient who relapsed).

Conclusions: These data confirm the value of the capture-fusion assay in predicting response to treatment of chronic HCV infection. We found a reduced response to RBV in patients with G3 HCV who relapsed compared to patients who achieved SVR following both IFN- and SOF-based therapy, suggesting that RBV sensitivity may be an important determinant of treatment response in this genotype. Further studies to confirm this observation, including viral sequencing and phenotyping in chimeric replicons, are underway.

DEEP-SEQUENCING ANALYSIS DEMONSTRATES THE PERSISTENCE OF THE PRE-TRANSPLANT HCV DOMINANT VARIANT WITHIN A MORE HOMOGENEOUS QUASISPECIES AFTER LIVER TRANSPLANTATION IN CHOLESTATIC HEPATITIS C PATIENTS

M. Gambato[1], J. Gregori[2,3], J. Quer[2], N. Caro-Pérez[1], P. González[1], D. García-Cehic[2], J.I. Esteban[2], G. Crespo[1], M. Navasa[1], X. Forns[1], S. Pérez-del-Pulgar[1]. *[1]Liver Unit, Hospital Clinic, IDIBAPS, CIBERehd, [2]Liver Unit, Vall d'Hebron Institut de Recerca-Hospital Universitari Vall d'Hebron, [3]Roche Diagnostics SL., Barcelona, Spain*
E-mail: martina.gambato@gmail.com

Background and Aims: Little is known about the pathogenic mechanisms implicated in cholestatic hepatitis C (CH), a severe form of hepatitis C (HCV) recurrence leading to high graft loss rates early after liver transplantation (LT). Classically, host failure to mount specific T-cell responses against HCV (leading to uncontrolled HCV replication and hepatocyte damage) has been implicated in the pathogenesis of CH. However, a direct role of HCV is not well established. The aim of this study was to analyze, for the first time, the pattern of HCV quasispecies evolution in patients with CH (compared to a control group) by ultra-deep pyrosequencing (UDPS).
Methods: 13 HCV-infected liver transplant recipients with CH (Wiesner et al., Liver Transpl 2003) and 10 patients with mild HCV recurrence (control group) have been analyzed so far. A serum sample obtained at the time of LT and a second sample obtained 1–3 months after transplantation (acute hepatitis phase) were analyzed for each patient. UDPS of a NS5B fragment (339 nucleotides) was performed using the 454 GS Junior platform (Roche).
Results: All 23 patients were infected with genotype 1 (87% G1b). Donor age ($p = 0.007$), recipient age ($p = 0.022$) and viral load after LT ($p < 0.001$) were significantly higher in patients with CH compared to controls. The mean number of reads per sample was 6146 (range 2491–25820). NS5B quasispecies complexity before LT was similar in CH and control group ($p = 0.396$). On the contrary, genetic diversity and mutation frequency of NS5B quasispecies decreased significantly after LT in patients with CH ($p = 0.013$ and $p = 0.013$), but not in the control group ($p = 0.069$ and $p = 0.327$). Interestingly, phylogenetic analysis showed that the major HCV variant pre-LT successfully propagated and remained as the major variant after LT in 64% of patients with CH, but only in 12% of controls ($p = 0.026$).
Conclusions: Using UDPS, a marked homogenization of HCV quasispecies was demonstrated in HCV-infected patients who developed CH after LT. In addition, in most CH patients, the major HCV strain before LT remained as dominant after LT. The latter suggests that, in the context of immunosuppresion, the propagation of more fitted viral strains could play a role in the pathogenesis of CH.

P0705

ANTIVIRAL ACTIVITY OF HUMAN NON-PARENCHYMAL LIVER CELLS IS RESTRICTED TO TOLL-LIKE RECEPTOR 3 AND INVOLVES TYPE I INTERFERONS

M. Lutterbeck[1], S. Driftmann[1], K. Kleinehr[1], A. Paul[2], G. Gerken[1], J.F. Schlaak[1], R. Broering[1]. *[1]Gastroenterology and Hepatology, [2]General-, Visceral- and Transplantation Surgery, University Hosphital of Essen, Essen, Germany*
E-mail: melanie.lutterbeck@uni-due.de

Background and Aims: Chronic hepatitis C infection is associated with increased expression of interferon-sensitive genes (ISGs) in the liver. However, the role of non-parenchymal liver cells (NPC) in the defence against hepatitis C virus (HCV) infection is not well understood. Aim of the study was to characterize primary human Kupffer cells (KC), liver sinusoidal endothelial cells (LSEC) and hepatic stellate cells (HSC), isolated from a single liver tissue, to analyse the toll-like receptor (TLR) signalling and antiviral capacities against HCV.
Methods: NPC were isolated after two step collagenase perfusion of liver resections ($n = 25$), using low speed centrifugation, density centrifugation and MACS. Cell purities were controlled by immunofluorescence staining of cell type-specific markers: CD68, CD146 and α-smooth muscle actin (α-SMA). The functional activity of NPC was determined by cell type-specific assays. Cultured cells were stimulated with TLR ligands for 6–24 h, RNA was extracted and analysed by qRT-PCR and supernatants were collected to analyse the antiviral activity by co-culturing supernatants with HCV replicon system con1 and neutralizing antibodies against type I and III interferon (IFN) receptors. In addition, cells were stimulated with TLR ligands for 90min and cell lysates were examined for the activation of the interferon regulatory factor 3 (IRF3).
Results: Immunofluorescence analysis indicated high purities of KC (94.4±2.0%), LSEC (98.1±0.3%) and HSC (96.6±0.9%) with retained physiological activity *in vitro*. NPC secreted inflammatory cytokines (e. g. IL-6), in response to TLR1–9 stimulation in a cell type-specific manner. However, only supernatants of TLR3-activated NPC mediated an antiviral activity against HCV. Poly I:C treatment led to the activation of IRF3, an important transcription factor for IFNs. Neutralization experiments revealed that the antiviral effect was mediated by type I IFNs.
Conclusions: NPC were isolated in high cell yield and purity. Cell populations retained specific morphologies and physiological activity *in vitro*. The presented cell isolation technique is a valuable tool with high potential to investigate liver function and disease. Here, NPC responded to TLR ligands by producing inflammatory cytokines. An antiviral effect was restricted to TLR3-activated NPC and seemed to be mediated by type I IFNs. These findings shed new light on the impact of NPC in the pathogenesis of HCV.

P0706

INTRAHEPATIC EXPRESSION OF ABCA1 IN PATIENTS WITH CHRONIC HEPATITIS C

P. Giarda[1], M.E. Burlone[2], R. Minisini[2], M. Pirisi[1]. *[1]Translational Medicine, University of Piemonte Orientale "A. Avogadro", [2]Translational Medicine, University of Piemonte Orientale "A. Avogadro", Novara, Italy*
E-mail: paola.giarda@gmail.com

Background and Aims: ATP binding cassette-A1 (ABCA1) is an integral transmembrane protein, essential for cholesterol and phospholipid homeostasis, with anti-atherogenic and anti-tumoral properties. It has been recently shown that the up-regulation of ABCA1 gene expression impairs hepatitis C virus HCV infection "in vitro", acting on virus protein mediated-host cell fusion (PLoS One 2014; 9(3): e9214). We wished to confirm these results "in vivo", hypothesizing that differences in ABCA1 expression may affect viral load and/or affect the progression of liver disease.
Methods: We studied 48 naïve patients with chronic hepatitis C (25 males; median age 54 years; 19/48 with fibrosis absent/mild, S0–1, and 12/48 with advanced fibrosis, S4–6), who underwent a liver biopsy before starting standard antiviral therapy with pegylated interferon-α (PEG-IFNα) plus ribavirin. A fragment was stored for mRNA quantification by realtime-PCR; mRNA expression of ABCA1 in the liver biopsy was related to that measured in pooled normal liver tissue and presented as relative ratio (RR). ABCA1mRNA-RR was studied in relationship to HCV viral load, liver and metabolic tests, Ishak staging, IL28B rs12979860 and rs8099917 genotypes, response to treatment.
Results: There was no linear association between ABCA1 expression and viral load. Moreover, an inverse correlation existed between ABCA1-RR and the serum levels of aspartate aminotransferase (AST) (correlation coefficient −0.3, $p = 0.02$) and γ-glutamyl transferase (GGT) (correlation coefficient −0.3, $p = 0.01$): the higher were the AST and GGT levels, the lower was the expression of ABCA1. ABCA1 expression was significantly reduced in patients with

advanced fibrosis versus fibrosis absent/mild ($p < 0.05$), although plasma albumin levels had no relationship with ABCA1 expression. Moreover, the more advanced Ishak stages were, the higher were serum GGT levels ($p = 0.009$). ABCA1 expression was not related to gender, viral genotype, IL28B polymorphisms and rapid or sustained virological response to PEG-IFN plus ribavirin.

Conclusions: In chronic hepatitis C, ABCA1 expression in the liver does not have a linear relationship with viral load, but is reduced in association with hepatic inflammation, necrosis and advanced fibrosis. Since its alleged anti-tumoral properties, ABCA1 reduced expression in advanced stages of hepatitis C-related liver disease may be worth exploring as a contributor to progression towards hepatocellular carcinoma.

P0707

DIFFERENCES IN THE INTESTINAL MICROBIOTA IN PATIENTS WITH CHRONIC HEPATITIS C

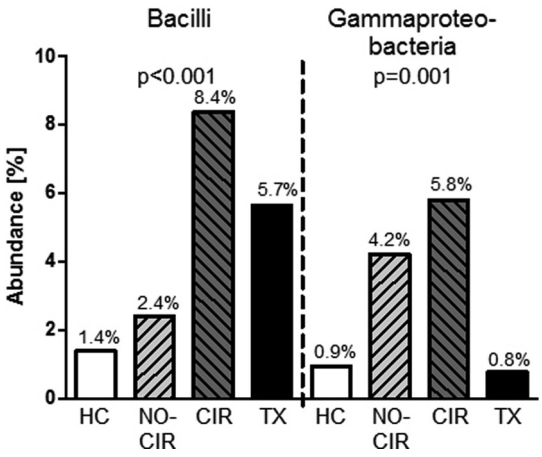
B. Heidrich[1,2,3], I. Plumeier[2], S. Kahl[2], R. Jauregui[2], W.I. Barrantes-Bustinza[2], J. Kirschner[1], L. Sollik[1], S. Ziegert[1], M.P. Manns[1,3], H. Wedemeyer[1,3], D.H. Pieper[2,3]. *[1]Department of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, [2]Microbial Interactions and Processes Research Group, Centre for Infection Research, Braunschweig, [3]German Center for Infection Research (DZIF), partner site Hannover-Braunschweig, Germany*
E-mail: heidrich.benjamin@mh-hannover.de

Background and Aims: The importance of the intestinal microbiota in the onset and clinical course of many diseases, including liver diseases like AFLD or NAFLD and liver cirrhosis, is becoming obvious. However, the role of the intestinal microbiota in chronic HCV infections remains unclear

Methods: We performed a cross sectional study comprising 51 patients infected with HCV [n = 18 w/o cirrhosis (NO-CIR); n = 28 with cirrhosis (CIR); n = 5 after solid organ transplantation (TX)] and 26 healthy controls (HC). Stool samples were prospectively collected, mixed with RNAlater and stored at −20°C. DNA was extracted using TRIzol reagent. The V1–2 region of the 16S rRNA gene was amplified followed by sequencing on the Illumina MiSeq platform. Sequences were quality filtered, trimmed collapsed and clustered and the annotation was performed using the RDP classifier. Statistical analysis was performed using SPSS 22 and Primer 6.

Results: A total of 4,328,784 reads were obtained out of which 3,060,948 (71%) reads passed the quality control giving a median of 35,132±16,611 per sample. The mean Shannon diversity index (H′) was significantly lower in individuals infected with HCV compared to HC (4.22±0.38 vs. 3.97±0.51; $p = 0.025$). In addition, H′ was significantly decreasing in HC, NO-CIR and CIR (4.22±0.38 vs. 4.10±0.51 vs. 3.86±0.53; $p = 0.037$). H′ showed a negative correlation with disease status (HC vs. NO-CIR vs. CIR) and the Child–Pugh score (CPS) ($r = -0.322$; $p = 0.006$ and $r = -0.478$; $p < 0.001$). Significant different community structures could be observed for the different stages of disease (HC vs. CO-CIR vs. CIR vs. TX). Bacilli and Gammaproteobacteria became more abundant during the course of HCV infection and descreased after organ transplantation ($p < 0.001$ and $p = 0.001$; Figure). Concomitantly, Alphaproteobacteria declined during the course of HCV infection and increased after TX ($p = 0.008$). Bacilli and Gammaproteobacteria showed a negative correlation with H′ ($r = -0.490$; $p < 0.001$ and $r = -0.412$; $p < 0.001$). In contrast, the frequency of Bacilli showed a positive correlation with CPS ($r = 0.505$; $p < 0.001$).

Conclusions: Our cross sectional study reveals significant differences between the microbial communities in patients during different stages of chronic HCV infection. The diversity is decreasing and the frequency of Bacilli and Gammaproteobacteria is increasing. These factors could be used to identify patients at risk of disease progression. However, these results need to be confirmed in long term studies



P0708

S-ADENOSYLMETHIONINE (SAM) ENHANCES ANTIOXIDANT ENZYME SYSTEMS, GLUTATHIONE BIOSYNTHESIS AND SWITCHES MAT2/MAT1 TURNOVER IN HEPATITIS C VIRUS EXPRESSING CELLS

S.A. Lozano Sepúlveda[1], E. Bautista Osorio[1], P. Cordero Pérez[2], L.E. Muñoz Espinosa[2], M.C. Gutiérrez Ruiz[3], A.M. Rivas Estilla[1]. *[1]Biochemistry and Molecular Medicine, [2]Liver Unit, "Dr. José Eleuterio González" University Hospital, UANL, Monterrey, [3]Departamento de Ciencias de la Salud, CBS, Universidad Autónoma Metropolitana, Distrito Federal, Mexico*
E-mail: soniachan_@hotmail.com

Background and Aims: SAM decreases HCV viral expression by unknown mechanisms. SAM is the main precursor of glutathione synthesis. Methionine adenosyltransferase 1A (MAT1A) enzyme is responsible of its biosynthesis in normal liver, but is replaced by MAT2 in liver regeneration and HCC. Our aim was to elucidate the mechanism(s) by which SAM decreases HCV expression, using a hepatoma cell line expressing HCV non-structural proteins.

Methods: Huh7 HCV-replicon and parental cells were treated with 1mM SAM. Total glutathione level was evaluated at different times by Ellman's recycling method (0–24 h). ROS level was determined by diclorofluorescein method (0–48 h), PDTC treatment was used as an antioxidant agent and hydrogen peroxide as a positive damage agent. Total RNA and protein were extracted (24–72 h). cDNA was synthesized and real time-PCR was performed to quantify HCV-RNA, SOD1, SOD2, catalase, thioredoxin 1, MAT1A and MAT2A expression and RPS18 as endogenous gene. Cellular and viral protein expression was evaluated by western blot using antibodies vs. HCV-NS3, HCV-NS5A, SOD1, SOD2, catalase, thioredoxin-1, MAT1A, MAT2A and actin.

Results: SAM treatment decreased HCV-RNA levels 50–70% compared to untreated control (24–72 h). Total glutathione levels increased upon 6 and 12 h post-treatment in replicon cells, but it was earlier in parental cells (2 h post-treatment). Transcriptional antioxidant protein expression (SOD1, SOD2 and thioredoxin1) was increased at different times but this effect was not observed for catalase. Interestingly, there was no significant change in ROS levels in both cells types upon SAM treatment, contrary to what was observed with PDTC, where an average of 30% reduction was detected. Finally, MATIA expression was increased (2.5 fold-times at 48 h) and MATII was decreased (from 24 h) upon SAM exposition at both transcriptional and translational level in both cell lines.

Conclusions: A posible mechanism(s) by which SAM decreases HCV expression could involve modulating antioxidant enzymes systems,

biosynthesis of glutathione and switching MAT2/MAT1 turnover in Hepatitis C virus expressing cells.

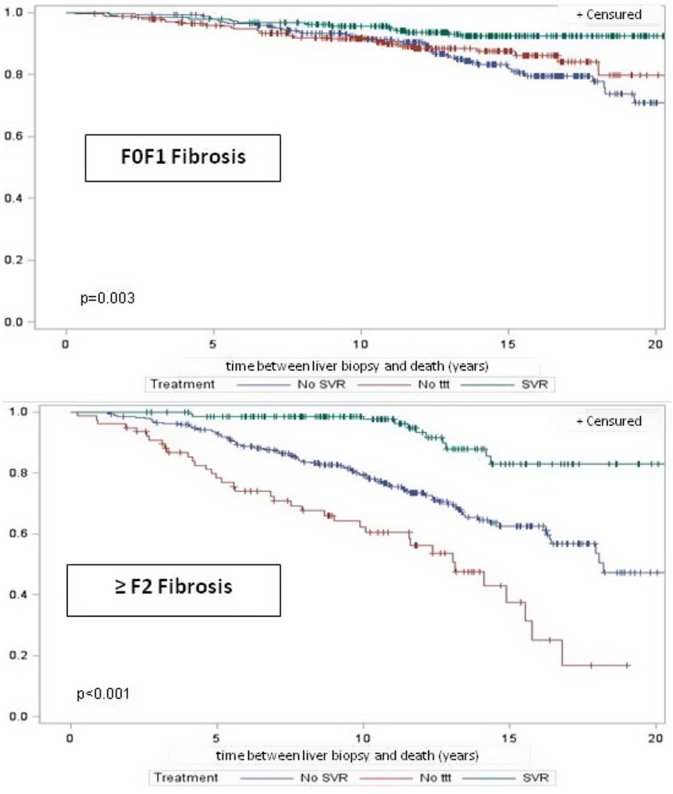
Viral hepatitis: Hepatitis C – b. Clinical (except therapy)

P0709

SURVIVAL OF PATIENTS INFECTED BY CHRONIC HEPATITIS C AND F0F1 FIBROSIS AT BASELINE AFTER A 15 YEARS FOLLOW-UP

C. Jézéquel[1,2], E. Bardou-Jacquet[1,2], Y. Desille[1], I. Renard[1], F. Lainé[1], C. Lelan[1], M. Latournerie[1], A. Guillygomarch[1], P. Houssel-Debry[1], R. Moirand[1,2], Y. Deugnier[1,2], D. Guyader[1,2]. [1]*Liver Unit, CHU Pontchaillou,* [2]*University of Rennes 1, Rennes, France*
E-mail: caroline.jezequel@chu-rennes.fr

Background and Aims: The cost of direct antivirals for the treatment of chronic viral hepatitis C (CHC) is currently very high. In France, antiviral agents are restricted to patients with significant fibrosis (≥F2), and patients with F0F1 fibrosis are excluded. However long-term follow-up and survival of these patients without significant fibrosis is not well described.
Methods: Patients were selected from a single-center cohort of 4293 consecutive CHC patients included since 1992. Inclusion criteria were HCV-RNA positivity and liver fibrosis evaluated by biopsy at baseline. Survival was obtained from death certificate. Two groups were compared according to baseline fibrosis: F0F1 versus ≥F2.



Results: 1381 patients were included (60% male, 52.4% G1 and 19.4% G3, 38.8% drug users). At baseline median age was 43 years [36–53], stage of fibrosis: F0F1 59.4%, F2 18.5%, F3 9.5% and F4 12.6%. Compared to F2, F0F1 patients were younger (42±12 vs 50±13 years, $p < 10^{-3}$), had lower prevalence of male (57% vs 64.5%, $p = 0.005$) and antiviral treatment (68.8% vs 86.1%, $p < 10^{-3}$) and a higher prevalence of sustained virological response (SVR: 48% vs 34.9%, $p < 10^{-3}$). After a median follow-up of 4.6 [2.9–7.7] years, a 2nd liver biopsy was performed in 157 F0F1 patients (19.1%), 50 F2 patients (19.5%) and 28 F3 patients (21.4%). An increased fibrosis stage to F3 or F4 was observed in 15.3% of F0F1 patients, 48% of F2 patients and 46.7% in F3 patients (to F4). After a median follow-up of 11.9 years [8.7–15.5], 248 patients died (16.7%), more frequently in ≥F2 patients (24.4%) than in F0F1 patients (11.5%), $p < 10^{-3}$. Median survival at 5, 10 and 15 years after the first liver biopsy was 97.4%, 93.1% and 87% in F0F1 patients and 93.2%, 83.4% and 65.4% in ≥F2 patients. Survival was better in treated patient with SVR than in untreated patient or treated without SVR regardless fibrosis stage, as shown in the figure.
Conclusions: Antiviral treatment for F0F1 patients at baseline should be considered due to (i) an evolution to severe fibrosis in at least 15%, (ii) a better response to treatment (SVR achieved in 48%), (iii) an improved survival in patients with SVR compared to those without SVR demonstrated in both F0F1 and F≥2 groups.

P0710

ROLE OF HEPATITIS C VIRUS (HCV) IN THE EARLY ARTERIOSCLEROTIC PROCESS AND AUTONOMIC DISFUNCTION

L. Cavalletto[1], F. Bilora[1], L. Sarolo[1], M.T. Sartori[1], P. Prandoni[1], A. Gatta[1], L. Chemello[1]. [1]*Dept. of Medicine, Hospital-University od Padua, Padova, Italy*
E-mail: liliana.chemello@unipd.it

Background and Aims: HCV infection may not only affects the hepatocytes, provoking chronic hepatitis, cirrhosis and HCC, but it also involves nerves, lymphocytes and endothelial cells determing an *extrahepatic disease*. Therefore we investigated the role of HCV in the atherosclerosis, autonomic dysfunction and endothelial injury.
Methods: From January 2011–2012, we recruited 101 subjects (48M/53F; aged 50±10 yrs) with chronic hepatitis C, who were matched for age, sex, BMI and cardiovascular risk factors to a control group without HCV. Eighty-four cases (83%) were treated with Peg-IFN+RBV, and 48 cases (56%) achieved the sustained viral eradication long-lasting, while 53 cases remained HCV-RNA positive. All cases underwent measuring of: (a) intima-media thickness (IMT) with US-Doppler of carotid arteries (CC, common carotid; B, bulb carotid, ICA, internal carotid), (b) flow-mediated dilation (FMD) of brachial artery to evaluate endothelial function, (c) Tilt, Valsalva, Hand-grip and Deep tests, to analyze peripheral autonomic nervous system and (d) PAI-1 plasma levels to define the involvement in trombotic and artheriosclerotic risk.
Results: The IMT for *CC, B* and *ICA* was significantly higher in patients with HCV compared to controls (1.1±0.3; 1.3±0.5; 1.1±0.4 vs 0.9±0.2; 0.9±0.3; 0.9±0.2, respectively; all $p < 0.01$), while FMD was significantly lower (12.8±6.4 vs 21.8±9.7; $p < 0.01$). Using Pearson correlation, the relationship between IMT and FMD in cases with and without HCV showed a significant difference only in controls (*CC,* $r = -0.48$; *B,* $r = -0.5$; *ICA,* $r = -0.53$; all $p < 0.01$), but not in cases with HCV (p = ns). Results obtained by autonomic tests significantly differed between subjects with and without HCV (Tilt, 1.1±0.2 vs 1.3±0.1; Valsalva, 1.3±0.2 vs 1.5±0.2; Hand, 2.0±1.7 vs 6.5±3.7; Deep, 1.2±0.2 vs 1.4±0.1; all $p < 0.01$), but between subgroups of cases with or without HCV-RNA, there were no statistical differences. Also PAI-1 levels did not result statistically different either between subjects with and without HCV (6.6±4.7 vs 6.0±4.8; p = ns) or cases with and without HCV-RNA (5.9±4.8 vs 7.4±4.4, p = ns).
Conclusions: HCV appears to play a pathogenetic role in early atherosclerotic process and autonomic dysfunction, thus, it might be likely that during the course of chronic hepatitis C irreversible damages are induced especially into the endothelium and the nerv us autonomic system. This events might recommend a

cardiovascular and neurologic follow-up in patients with present and past HCV infection.

GENOME-WIDE ASSOCIATION STUDY OF RESPONSE TO SOFOSBUVIR–RIBAVIRIN TREATMENT IN GT2/3 HCV PATIENTS

S.E. Kleinstein[1], T.J. Urban[1,2], N. Long[1,2], A. Thompson[3], E.J. Gane[4], S. Zeuzem[5], Z. Jiang[6], D. Ge[6], M.S. Paulson[6], R.H. Hyland[6], D.M. Brainard[6], A. Gaggar[6], G. Mani Subramanian[6], J.G. McHutchison[6], A. Muir[7], M. Sulkowski[8], E. Lawitz[9], D.B. Goldstein[1]. *[1]Duke Center for Human Genome Variation, Duke University, Durham, [2]Institute for Pharmacogenomics and Individualized Therapy, University of North Carolina, Chapel Hill, United States; [3]St. Vincent's Hospital and the University of Melbourne, Melbourne, Australia; [4]University of Auckland, Auckland, New Zealand; [5]Johann Wolfgang Goethe University, Frankfurt, Germany; [6]Gilead Sciences, Inc., Foster City, [7]Duke Clinical Research Institute, Durham, [8]Johns Hopkins University, Lutherville, [9]The Texas Liver Institute, University of Texas Health Science Center, San Antonio, United States*
E-mail: kellie.chu@gilead.com

Background and Aims: We examined the association of host genetic variants with treatment outcome in patients participating in studies of Sofosbuvir (Sovaldi™, SOF)+RBV.
Methods: 572 patients infected with HCV genotype 2 or 3 who received 12 or 16 weeks of SOF+RBV therapy in Phase 2 and 3 studies (ELECTRON, FISION, POSITRON, FUSION) were genotyped on the Omni5Exome chips. 431 samples from Caucasian patients infected with HCV (GT2=167; GT3=264) passed quality control and were retained as the final discovery dataset, containing 130 cases (relapse) and 301 controls (SVR). A logistic regression model was fitted to the data, adjusting for principal components and clinical characteristics. The candidate SNPs identified in the initial discovery set were genotyped in patients from 3 independent clinical trials (VALENCE, n = 280 patients infected with GT2 or GT3 HCV; PHOTON-1, n = 109 patients co-infected with HIV and HCV GT1, 2 or 3; NEUTRINO, n = 130 patients infected with GT1, 4, 5 or 6 HCV) for validation.

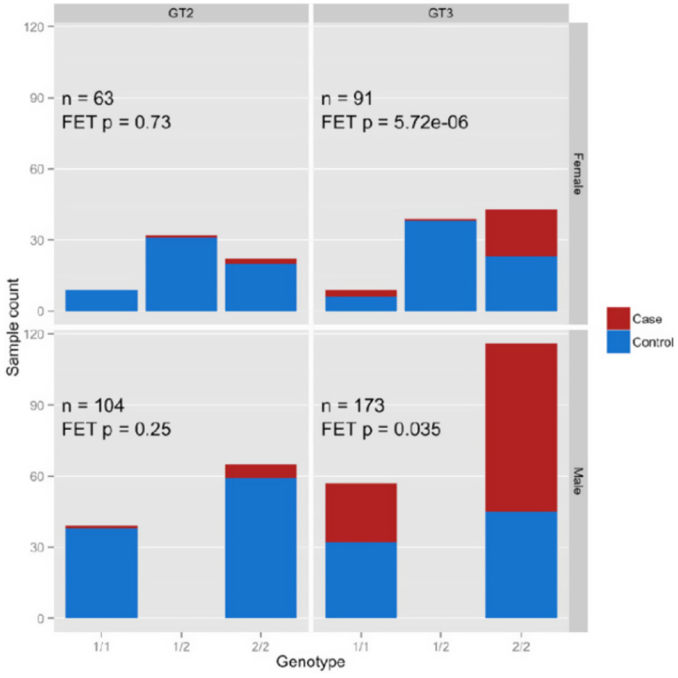

Figure 1. Gender and HCV genotype stratified effect of rs787078 on SVR and relapse.

Results: The top SNP identified in the discovery set (rs787078, $p = 7.28 \times 10^{-8}$) mapped to the downstream region of the gene *DDX3X*, located on the X chromosome with a MAF=0.35. *DDX3X* may be involved in regulation of viral replication, including HCV assembly. After Bonferroni multiple testing corrections, this SNP did not reach genome-wide significance ($p = 1.52 \times 10^{-8}$) but it did deviate from neutrality. When patients were stratified by HCV genotype and gender, the rs787078 association was primarily driven by female patients infected by genotype 3 HCV (Figure 1). Within the GT3 subset, SVR rates were 56% in males and 92% in females with the protective allele, and patients homozygous for the major allele had a greater relapse risk regardless of gender. However, data from the three independent, separate HCV studies failed to replicate the observed association.
Conclusions: The current study is the first comprehensive genome-wide investigation of the role of human genetic variants associated with SVR following HCV treatment with SOF-based all-oral regimens. No significant genetic associations were observed linking SVR among Caucasians. The *DDX3X* gene region was identified as a candidate with biological relevance. However, this association was not confirmed by data from independent cohorts. This study emphasizes the need for rigorous validation of hypothesis-generating genetic findings. It remains unclear whether this variant or *DDX3X* has a functional role in SVR outcome in HCV patients.

P0712

THE PHARMACOKINETICS OF GS-5816, A PANGENOTYPIC HCV-SPECIFIC NS5A INHIBITOR, IN HCV-UNINFECTED SUBJECTS WITH SEVERE RENAL IMPAIRMENT

E. Mogalian[1], A. Mathias[1], D. Brainard[2], G. Shen[3], J. McNally[2], K. Sajwani[4], R. Robson[5], D. Ries[6], K. Lasseter[7], T. Marbury[8]. *[1]Clinical Pharmacology, [2]Clinical Research, [3]Biostatistics, [4]Clinical Operations, Gilead Sciences, Inc., Foster City, United States; [5]Christchurch Clinical Studies Trust, Ltd, Christchurch, New Zealand; [6]Prism Research, Inc., St. Paul, [7]Clinical Pharmacology of Miami, Inc., Miami, [8]Orlando Clinical Research Center, Orlando, United States*
E-mail: erik.mogalian@gilead.com

Background and Aims: GS-5816, a potent pangenotypic HCV NS5A inhibitor, is in clinical development for the treatment of genotype 1–6 chronic HCV infection in combination with sofosbuvir (SOF). GS-5816 is primarily eliminated in the feces as parent drug and metabolites with <1% of the dose excreted in the urine. This study evaluated the short-term safety and pharmacokinetics (PK) of GS-5816 in subjects with severe renal impairment (RI) versus matched control subjects with normal renal function (NF). Results from this study will inform dosing recommendations for GS-5816 and, in part, SOF/GS-5816 in this population.
Methods: Ten subjects with stable severe RI (CL_{cr} <30 mL/min), and corresponding healthy subjects with NF (CL_{cr} ≥90 mL/min), matched for age (±10 yrs), sex, and BMI (±15%), received a single dose of GS-5816 100 mg after a light meal (~400 kcal, 30% fat) followed by intensive PK sampling over 120 hours. Safety assessments were performed throughout the study. Comparative statistics for GS-5816 AUC and C_{max} were calculated with an exposure increase >100% being considered clinically relevant.
Results: GS-5816 was generally safe and well tolerated in all study subjects. All treatment-emergent AEs were Grade 1 (mild) in severity. No AEs occurred in greater than 1 subject. An approximately 50% increase in GS-5816 AUC was observed in subjects with severe RI compared to subjects with NF. Maximum GS-5816 concentrations (C_{max}) were similar in both groups. Plasma protein binding was similar in both groups. The modest increase in GS-5816 exposure is consistent with changes in drug transport and/or (hepatic) metabolism associated with renal impairment.
Conclusions: GS-5816 exposure (AUC and C_{max}) was not substantially altered, and no change in protein binding was

observed in subjects with severe RI relative to those with NF. GS-5816 may be administered without dose adjustment to patients with mild, moderate, or severe renal impairment.

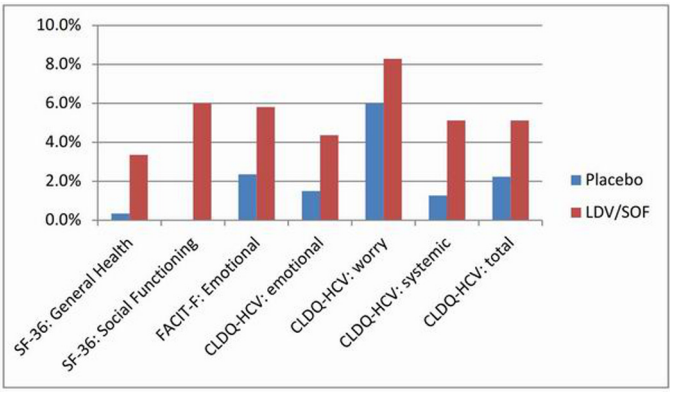
GS-5816	Mean (%CV)		GMR% (90% CI)
PK Parameter	Severe RI (N = 10)	Normal function (N = 9)	Severe RI:NF
AUC_{inf} (ng·h/mL)	8110 (32.4)	5650 (31.2)	150 (117, 192)
AUC_{last} (ng·h/mL)	7970 (31.8)	5600 (31.2)	149 (117, 190)
C_{max} (ng/mL)	732 (24.1)	703 (28.1)	111 (90.8, 135)

P0713

THE IMPACT OF LEDIPASVIR (LDV)/SOFOSBUVIR (SOF) COMBINATION ON HEALTH-RELATED QUALITY OF LIFE (HRQL) AND PATIENT-REPORTED OUTCOMES (PROS) IN CIRRHOTIC PATIENTS WITH CHRONIC HEPATITIS C (CH-C): THE SIRIUS STUDY

Z. Younossi[1,2], M. Stepanova[1,2], S. Pol[3], J.-P. Bronowicki[4], P. Carrieri[5], M. Bourlière[6]. *[1]Center for Liver Diseases, Department of Medicine, Inova Fairfax Hospital, [2]Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church, VA, United States; [3]Department of Hepatology, Hôpital Cochin et Université Paris-René Descartes, Paris, [4]CHU de Nancy-Hôpital Brabois Adulte, Vandoeuvre-lès-Nancy, [5]INSERM U912 (SESSTIM), [6]Hôpital Saint Joseph, Marseille, France*
E-mail: zobair.younossi@inova.org

Background and Aims: Interferon (IFN) and ribavirin (RBV) can negatively impact PROs. In contrast, IFN-RBV-free regimens may improve PROs during treatment. The aim is to compare PROs during treatment with LDV/SOF to placebo and to LDV/SOF+RBV.
Methods: Treatment-experienced CH-C genotype 1 patients with compensated cirrhosis (N = 154) were randomized to be treated with 24 weeks of LDV/SOF or with 12 weeks of placebo followed by 12 weeks of LDV/SOF+RBV (SIRIUS clinical trial). While blinded to their HCV RNA results, patients completed 4 validated PRO questionnaires [Short Form-36 (SF-36), Chronic Liver Disease Questionnaire-HCV (CLDQ-HCV), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), and Work Productivity and Activity Index: Specific Health Problem (WPAI:SHP)] which were administered at baseline, during and post-treatment.
Results: The study cohort was 74% male, age 56.5±9.2 years, and 96.75% achieved SVR. Baseline PRO scores were similar between the study arms. As early as 4 weeks after treatment, patients receiving LDV/SOF showed improvement of mental component summary score (MCS) of SF-36, overall CLDQ-HCV score, emotional well-being score of FACIT-F and activity score of WPAI:SHP (all p-values <0.05), while no significant changes in these scores were noted in the placebo group. After 12 weeks of treatment with LDV/SOF, improvements in social functioning and general health of SF-36 were also noted ($p < 0.05$) (Figure 1). In the second 12 weeks of the study, patients receiving LDV/SOF continued to show gains in PROs (up to +9.2% on a 0–100% scale from baseline, $p < 0.05$), while patients receiving LDV/SOF+RBV had less PRO gains or no improvement. Nevertheless, regardless of the regimen, achieving SVR-12 was associated with significant improvement in all aspects of PROs (up to +12.2% in both regimens). Multivariate analyses showed that, in addition to previously reported factors (pretreatment depression, anxiety, insomnia, older age, diabetes, all p-values <0.05), receiving RBV was independently associated with PRO impairment (beta up to −10.5%, $p < 0.05$).
Conclusions: Treatment-experienced cirrhotic patients experience a notable improvement of their PROs with LDV/SOF. Achieving SVR-12 is associated with improvement in most of the PROs in this difficult to treat group of patients with CH-C.



P0714

IMPACT OF PRIORITIZING TREATMENT IN A HIGH RESOURCE SETTING – MINIMIZING THE BURDEN OF HCV RELATED DISEASE IN 15 YEARS

A.L.H. Øvrehus[1], S. Blach[2], P.B. Christensen[3], J. Gerstoft[4], N. Weis[5], H. Krarup[6], M.R. Clausen[7], H. Razavi[2]. *[1]Department of Infectious Diseases, Odense University Hospital, Denmark, Odense, Denmark; [2]Center for Disease Analysis, Louisville, Colorado, United States; [3]Department of Infectious Diseases, Odense University Hospital, Denmark, Odense C, [4]Department of Infectious Diseases, Rigshospitalet, [5]Department of Infectious Diseases, Hvidovre Hospital, Copenhagen, [6]Department of Medical Gastroenterology and Section of Molecular Diagnostics, Department of Clinical Biochemistry, Aalborg University Hospital, Aalborg, [7]Department of Medical Gastroenterology, Rigshospitalet, Copenhagen, Denmark*
E-mail: aholm@health.sdu.dk

Background and Aims: Even in a high resource setting, prioritizing direct acting antiviral (DAA) treatment for Chronic Hepatitis C (CHC) is an issue. The effect of DAA treatment on the burden of disease can be measured on many parameters including preventing progression to advanced liver disease and halting transmission to reduce prevalence. In Denmark, the majority of CHC patients have been infected through needle sharing and intravenous drug use. Prevalence is comparatively low, approximately 0.4% in the +15 year old population (21,000 patients), and most patients are between 45–55 years of age. This relatively young infected population is beginning to progress to advanced disease, with cirrhosis identified in ~20% of patients followed for CHC. Treatment with interferon free DAA regimens is now available for patients with biopsy or FibroScan proven severe fibrosis (F3) or cirrhosis, however little is known about the impact of these new criteria.
The aim of this study is to evaluate
1. The impact of current treatment strategies on the number of viremic patients, liver related mortality, decompensated cirrhosis and HCC
2. The numbers needed to treat to halve prevalence by 2030

Methods: The model for CHC disease progression developed by Razavi et al was applied and fitted to the Danish setting. **Base case scenario (pre 2014):** interferon based therapy and annual treatment of 100 ≥F2 patients. **DAA era (2014):** increased treatment efficacy, eligibility and numbers (n = 200); restricted to patients with fibrosis ≥F3. **After 2015:** Scenarios examining the effect of expanding treatment (less restriction on degree of fibrosis) and increased treatment were added.
Results: Treating 400 or 600 patients with ≥F3 fibrosis from 2014 onward would reduce liver related mortality by 50% or 75%, respectively, HCC by 50% and 75%, and decompensated cirrhosis by 55% and 85% by 2030. Total viremics would be reduced by 30%. To

reduce prevalence by half by 2030, 880 patients have to be treated annually if treatment is restricted to fibrosis ≥F2 starting in 2016. Due to the undiagnosed population, annual treatment numbers of ≥F3 patients cannot be increased beyond about 700 after 4–5 year of treatment

Conclusions: If the aim is to reduce liver related mortality, HCC and decompensated cirrhosis, the strategy of prioritizing treatment for patients with ≥F3 is effective but does little by way of reducing prevalence. Finding undiagnosed patients with severe fibrosis and cirrhosis is essential to further reduce liver related morbidity and mortality.

P0715

STEADY-STATE PHARMACOKINETICS AND SAFETY OF COADMINISTRATION OF PAN-GENOTYPIC, DIRECT ACTING PROTEASE INHIBITOR, ABT-493 WITH PAN-GENOTYPIC NS5A INHIBITOR, ABT-530, IN HEALTHY ADULT SUBJECTS

C.-W. Lin[1], W. Liu[1], A. Asatryan[1], A. Campbell[1], W. Zhao[1], H. Wang[1], D. Sidhu[1], J. Clifton II[1], J. Kort[1], S. Dutta[1]. [1]*AbbVie, North Chicago, United States*
E-mail: chih-wei.lin@abbvie.com

Background and Aims: A next generation direct acting antiviral (DAA) combination of ABT-493 (NS3/4A protease inhibitor discovered by AbbVie and Enanta) + ABT-530 (NS5A inhibitor) is being developed for the treatment of chronic hepatitis C (HCV) genotype 1–6 infection. Each compound demonstrated potent antiviral activity following 3-day monotherapy (AASLD 2014). The purpose of this study was to evaluate pharmacokinetics (PK) and safety of several different dose levels of ABT-493 and ABT-530 when given in combination.

Methods: Open-label 5-arm, cohort study in 72 healthy subjects with assessment of steady-state PK and safety of ABT-493 (100, 400, 700 or 1200 mg QD) combined with ABT-530 (40, 120, 160 or 200 mg QD). Intensive blood sampling for determination of ABT-493 and ABT-530 concentrations was performed. Safety and tolerability were assessed throughout the study.

ABT-530 dose	ABT-493 dose	Results
40 mg	100 mg	ABT-530 had minimal impact on ABT-493 ABT-493 increased ABT-530 to 1.5×
40 mg	400 mg	ABT-530 had minimal impact on ABT-493 ABT-493 increased ABT-530 to 6×
120 mg	400 mg	ABT-530 slightly increased ABT-493 exposures ABT-493 increased ABT-530 to 3–4×
160 mg	700 mg	ABT-530 slightly increased ABT-493 exposures ABT-493 increased ABT-530 to 5–7×
200 mg	1200 mg	Arm was prematurely discontinued, no steady state data were available

Results: ABT-493 exposures increased in a greater than dose proportional manner across the 100 mg to 1200 mg dose range. In the presence of ABT-530 (120 and 160 mg), geometric mean ABT-493 exposures were higher (41% to 83%) compared with ABT-493 administered alone. ABT-530 exposures increased in a greater than dose-proportional manner across the 40 mg to 120 mg dose range and approximately dose-proportionally from 120 mg to 200 mg. Co-administration with 400 mg ABT-493 increased ABT-530 120 mg exposures to 3- to 4-fold and 40 mg ABT-530 exposures to 6-fold compared with ABT-530 administered alone (Table). In contrast, 100 mg ABT-493 increased 40 mg ABT-530 exposures to 1.5-fold (Table). The ABT-493 1200 mg + ABT-530 200 mg arm was prematurely discontinued due to ABT-493 exposures exceeding the pre-specified upper exposure limit by the protocol. Two subjects discontinued prematurely, one was due to a Grade 2 adverse event of allergic dermatitis after a single dose of ABT-493, and the other was due to an asymptomatic Grade 3 ALT elevation after 7 days of 1200 mg ABT-493. One subject developed asymptomatic, isolated, Grade 3 total bilirubin elevation. Described laboratory abnormalities were observed with 1200 mg or 700 mg ABT-493, and improved/normalized after conclusion of dosing.

Conclusions: ABT-530 at doses of 120 or 160 mg QD, but not 40 mg QD, slightly increased ABT-493 exposures (≤83%). ABT-493 dose-dependently increased the exposures of ABT-530. Both ABT-530 and ABT-493 were well tolerated and not associated with clinically significant/relevant laboratory abnormalities when the ABT-493 dose was less than 700 mg QD.

P0716

THE SIGNIFICANCE OF PLATELET MICROPARTICLES IN PATIENTS WITH CHRONIC HEPATITIS C AND THEIR ASSOCIATION WITH ANTIVIRAL TREATMENT AND SMOKING

T. Kanellopoulou[1], A. Alexopoulou[2], F.N. Kontopidou[2], P. Konstantinidis[2], G.V. Papatheodoridis[3]. [1]*Blood Bank and Hemophilia Unit, [2]2nd Department of Internal Medicine, Athens Medical School, Hippokration General Hospital, [3]Department of Gastroenterology, Athens University Medical School, General Hospital of Athens Laiko, Athens, Greece*
E-mail: alexopou@ath.forthnet.gr

Background and Aims: Platelet-microparticles (PMPs) are platelet-derived membrane vesicles generated by cell activation and apoptosis which have been involved in cardiovascular diseases and atherosclerosis. Chronic hepatitis C (CHC) is associated with increased atherosclerosis, but the effect of antiviral treatment on the atherogenic potential of CHC has not been adequately studied so far. The aim of this study was to evaluate PMPs levels before and after antiviral treatment in CHC patients.

Methods: 28 CHC patients (13 G1/G4, 15 G3) were included, whereas 20 healthy volunteers (HV) and 20 patients with non-alcoholic fatty liver disease (NAFLD) were used as controls. Patients with cardiovascular diseases, diabetes, anticoagulant and antiplatelet treatment were excluded. All CHC patients were treated with pegylated-interferon/ribavirin. Twenty-four (86%) achieved sustained virological response (SVR). PMPs levels were determined by flow-cytometry (CD61-Annexin V) at baseline in all CHC patients and controls as well as at end of treatment (EOT) and 24 weeks post-treatment (SVR24) in all CHC patients.

Results: PMPs levels at baseline were higher in CHC compared to NAFLD patients ($P < 0.001$) and HV ($P = 0.007$). Higher PMPs levels at baseline were observed in smokers ($n = 18$) compared to non smokers ($n = 10$) with CHC ($P = 0.006$). Among smokers from all groups, CHC patients had higher PMPs at baseline compared to NAFLD ($P = 0.001$) and HV ($P = 0.024$). During antiviral treatment in all CHC patients, PMPs levels declined from baseline to both EOT ($P = 0.035$) and SVR24 ($P = 0.006$). PMPs levels decline during treatment was mainly observed in smokers [PMPs declined significantly from baseline to EOT ($P = 0.004$) and SVR24 ($P = 0.009$)]. Only patients achieving SVR had a significant decline in PMPs from baseline to SVR24 ($P = 0.018$), while those without SVR did not experience any significant change. Patients with G1/G4 experienced a higher decline in PMPs compared to G3 patients. PMPs levels at EOT and SVR24 in all CHC patients as well as in smokers became similar to those in control groups.

Conclusions: The higher PMPs levels in CHC patients and particularly in smokers further support the atherosclerotic potential of CHC and suggest a potentially synergistic effect of smoking and CHC on the atherosclerotic process. Since PMPs levels in CHC patients with SVR do not differ from those in controls, the atherosclerotic potential of CHC seems to be abolished by effective antiviral treatment.

P0717

THE PRESENCE OF A PNPLA3 (RS738409) SINGLE NUCLEOTIDE POLYMORPHISM (SNP) IS NOT ASSOCIATED WITH INCREASED RISK FOR FIBROSIS, PORTAL HYPERTENSION, AND HEPATIC STEATOSIS IN HIV/HCV-COINFECTED PATIENTS

B. Scheiner[1,2], M. Mandorfer[1,2], P. Schwabl[1,2], B.A. Payer[1,2], M.C. Aichelburg[2,3], K. Grabmeier-Pfistershammer[2,3], A. Stättermayer[1], P. Ferenci[1], M. Trauner[1], M. Peck-Radosavljevic[1,2], T. Reiberger[1,2]. *[1]Department of Internal Medicine III, Division of Gastroenterology and Hepatology, [2]Vienna HIV & Liver Study Group, [3]Department of Dermatology, Division of Immunology, Allergy and Infectious Diseases, Vienna, Austria*
E-mail: n0942122@students.meduniwien.ac.at

Background and Aims: HIV/HCV-coinfected patients often show hepatic steatosis, faster fibrosis progression, and a higher risk of developing end-stage liver disease. While several risk factors for faster fibrosis progression have been established, the role of a genetic variation of the patatin-like phospholipase domain-containing protein 3 (PNPLA3) remains unclear. Thus, we examined the impact of the PNPLA3 single nucleotide polymorphism (SNP rs738409) on liver steatosis and fibrosis in a cohort of HIV/HCV-coinfected patients.
Methods: 177 HIV/HCV-coinfected patients with available data on PNPLA3 (SNP rs738409) and IL28B (SNP rs12979860) were enrolled. Liver fibrosis and steatosis was staged either by liver biopsy or by transient elastography [FibroScan® using the Controlled Attenuation Parameter (CAP™) module]. Parameters associated with advanced liver fibrosis (≥F3) and portal hypertension (hepatic venous pressure gradient, HVPG) were examined. Fibrosis progression rate (FPR in METAVIR F stages/year) was calculated using the estimated year of HCV infection. Sustained virological response (SVR) rates were assessed across PNPLA3 genotypes.
Results: Patients tested positive for a PNPLA3 minor (G/C, n = 66) or major (G/G n = 9) risk allele (42.4%) showed comparable fibrosis stages (both median F2; p = 0.106) and a similar amount of hepatic steatosis (CAP: 200.3±44.7 vs. 217.7±56.2; p = 0.484). Advanced liver fibrosis was neither associated with PNPLA3 (p = 0.418) nor with IL28B-genotype (p = 0.637) but was associated with HCV-GT 3 (p < 0.001), lower CD4 count (p = 0.024), lower CD4 nadir (p = 0.011) and higher AST values (p = 0.016). Fibrosis progression rate (0.21±0.27 vs. 0.46±0.74 units/year; p = 0.313) and HVPG-values (3.7±2.5 vs. 4.6±3.1 mmHg; p = 0.172) were comparable in patients with and without PNPLA3 risk alleles.
SVR rates to PEGIFN/RBV therapy were 68.5% in PNPLA3-C/C, 51.6% for G/C, and 100% for G/G. However, the proportion of IL28B-C/C genotype in the PNPLA3 risk allele subgroup was surprisingly high with 54.7%.
Conclusions: The presence of a PNPLA3 risk allele had no influence on liver fibrosis progression, portal hypertension, or hepatic steatosis in HIV/HCV-coinfected patients. The small number of patients with a major PNPLA3 risk allele may represent a potential limitation. However, our data indicated that the presence of a PNPLA3 risk-allele does not comprise virological response rates to IFN-based therapies in IL28B-C/C HIV/HCV-coinfected patients.

P0718

COST-EFFECTIVENESS OF INTERFERON-FREE THERAPY FOR HEPATITIS C IN GERMANY – AN APPLICATION OF THE EFFICIENCY FRONTIER APPROACH

C. Gissel[1,2], G. Götz[1], J. Mahlich[3], H. Repp[2]. *[1]Economics I – Industrial Organization, Regulation and Antitrust, [2]General Medicine, Justus Liebig University, Giessen, [3]Janssen-Cilag GmbH, Neuss, Germany*
E-mail: repp@phec.de

Background and Aims: The approval of direct-acting antivirals for Interferon-free treatment revolutionized the therapy of chronic Hepatitis C infection. As of August 2014, two treatment regimens for genotype 1 infection received approval in the European Union: Sofosbuvir and Ribavirin for 24 weeks and Sofosbuvir and Simeprevir with or without Ribavirin for 12 weeks. We aim to analyze the cost-effectiveness of both regimens in Germany.
Methods: We set up a Markov model with a lifetime horizon to simulate immediate treatment success and long-term disease progression for treatment-naive patients. The model analyzes both shortterm and longterm costs and benefits from the perspective of the German Statutory Health Insurance. We apply the efficiency frontier method, which was suggested by German Institute for Quality and Efficiency in Health Care for cost-effectiveness analysis in Germany.
Results: The efficiency frontier is defined by dual therapy and first generation direct-acting antiviral Boceprevir, yielding a maximum of € 1,447.69 per additional percentage point of sustained virologic response gained. Even without rebates, Sofosbuvir/Simeprevir is very close with € 1,560.13 per additional percentage point. It is both more effective and less expensive than Sofosbuvir/Ribavirin.
Conclusions: In addition to higher sustained virologic response rates, new direct-acting antivirals save long-term costs by preventing complications such as liver cirrhosis, hepatocellular carcinoma and ultimately liver transplants, thereby offsetting part of higher drug costs. Our findings are in line with the guidance published by German Society for Gastroenterology, Digestive and Metabolic Diseases, which recommends Sofosbuvir/Simeprevir for Interferon ineligible or intolerant patients.

P0719

HEALTHCARE COSTS BY STAGE OF LIVER DISEASE IN CHRONIC HEPATITIS C PATIENTS IN THE UNITED STATES

D.R. Walker[1], S.R. Manthena[1], T.R. Juday[1]. *[1]Health Economics and Outcomes Research, Abbvie, North Chicago, United States*
E-mail: david.r.walker@abbvie.com

Background and Aims: Hepatitis C virus (HCV) is a leading cause of chronic liver disease worldwide and can lead to significant increases in healthcare resources. The aim of this study was to examine all-cause direct medical and pharmacy costs in US HCV patients in various stages of liver disease compared to patients without HCV.
Methods: This US-based cohort study was conducted comparing all-cause healthcare (medical and pharmacy) costs of adult patients with or without HCV using MarketScan's Commercial insurance claims database for the period 5/2000 through 9/2013. HCV patient cohorts were defined by their most severe liver disease stage based on ICD-9 diagnosis codes, least to most severe stage: HCV non-cirrhotic (NCHCV), compensated cirrhotic (CCHCV), decompensated cirrhotic (DCCHCV), hepatocellular carcinoma (HCCHCV), and liver transplant (LTHCV). The HCV patient index date was defined by their most severe liver disease diagnosis date. Five non-HCV patients were randomly selected for each HCV patient. Non-HCV patient index date was randomly chosen during the study period. Patients were required to have at least one-year of continuous enrollment pre and post index date. Patients were excluded if <18 years old, or had a diagnosis for HIV or Hepatitis B. Propensity score-adjusted bin bootstrapping (PSB) method was used to estimate the difference in total per patient per month (PPPM) healthcare costs between each severity stage cohort and the non-HCV cohort. The PSB model accounts for the skewed nature of cost data. Age, gender, Charlson comorbidity score and previous HCV treatment experience were covariates in the PSB model. Costs are in 2013 US dollars.
Results: All HCV liver disease severity cohorts were statistically significantly (p < 0.05) older and male with higher mean Charlson Comorbidity Index scores than the non-HCV cohort. The total PPPM unadjusted all-cause mean costs were statistically significantly higher for all HCV cohorts compared to the non-HCV cohort (Table). The PPPM adjusted all-cause mean cost (95% CI) difference between

Table (abstract P0719): Cost by Liver disease stage

Parameter	Non-cirrhotic HCV	Compensated cirrhosis HCV	Decompensated cirrhosis HCV	Hepatocellular carcinoma HCV	Liver transplant HCV	No chronic HCV
Number of patients	20,873	5216	11,135	1802	1434	199,824
PPPM Unadjusted all-cause costs (95% CI)	$2139 ($2077–$2201)	$2491 ($2361–$2622)	$5038 ($4799–$5277)	$10,798 ($10,145–$11,451)	$30,100 ($27,308–$32,893)	$434 ($426–$443)
PPPM Adjusted all-cause cost difference between disease severity stage and no chronic HCV (95% CI)	$1633 ($1572–$1697)	$1885 ($1778–$1999)	$3360 ($3172–$3561)	$7904 ($7250–$8581)	$21,589 ($18,894–$23,457)	–

each severity stage and the non-HCV cohort were statistically significant ranging from a difference of $1633 PPPM in the NCHCV cohort up to a difference of $21,589 PPPM in the LTHCV cohort (Table).

Conclusions: Mean healthcare costs increased as liver disease severity stage worsened. These costs were significantly higher in all the HCV liver disease stage cohorts compared to a cohort without HCV.

P0720

IMPROVEMENT OF ADVANCED LIVER FIBROSIS AND REGRESSION OF LIVER CIRRHOSIS IN PATIENTS WITH HEPATITIS C GENOTYPE 1 AFTER HCV PROTEASE INHIBITOR-BASED TRIPLE THERAPY

F. Sáez-Royuela[1], P. Linares[2], L.A. Cervera[1], C. Almohalla[3], F. Jorquera[2], I. García[4], A. Moncada[1], G. Karpman[5], E. Badia[1], M.A.A. Vallecillo[3], S. Lorenzo[6], J.L. Olcoz[2], Asociación Castellano y Leonesa de Hepatología (ACyLHE). *[1]Gastroenterology and Hepatology, Hospital Universitario de Burgos, Burgos, [2]Gastroenterology and Hepatology, Complejo Asistencial Universitario León, León, [3]Hepatology, Hospital Universitario Rio Hortega, Valladolid, [4]Gastroenterology and Hepatology, Complejo Asistencial Palencia, Palencia, [5]Gastroenterology and Hepatology, Hospital El Bierzo, Ponferrada, [6]Gastroenterology and Hepatology, ospital Clínico Universitario, Valladolid, Spain*
E-mail: fsroyuela@ya.com

Background and Aims: Triple therapy with pegylated interferon alpha, ribavirin and a HCV protease inhibitor (PI) is currently the standard of care for chronic hepatitis C genotype 1 (GT1) in many European countries. Data on the course of liver fibrosis and cirrhosis regression after treatment with PI are scarce. The same applies to the influence of sustained virologic response (SVR) or other factors in the evolution of liver fibrosis. We aim to evaluate the impact of PI-based therapy on liver fibrosis measured by transient elastography in clinical practice.

Methods: A multicenter observational and prospective study was conducted. Patients with GT1, treated with PI-based therapy (telaprevir or boceprevir), with advanced liver fibrosis (>9.5 kPa) at baseline were included. Liver stiffness measurements were performed with the FibroScan®502 device and M probe at the baseline and 24 weeks after the end of treatment. Patients with baseline liver stiffness values above 12.5 kPa were considered to have cirrhosis. By now, 72 patients have completed treatment, following them for 24 weeks (age/male/RNA/subtype/ IL28B/ previous treatment/type of PI/fibrosis/SVR 12).

Results: Baseline patient characteristics: 58 male, median 52±8.9 years, prior treatment: 75%, subtype: 1a: 34.7%, 1b: 56.9%, IL28B CC: 18%, median baseline liver stiffness: 13.2±10.2 kPa (F4: 48.6%, no F4: 51.4%), 65.3% were treated with telaprevir and 34.7% with boceprevir. 49 of 72 (68.05%) patients achieved SVR. In patients who achieved SVR the median intra-patient decrease relative to baseline at the end of follow-up was −3.8 kPa, vs +1.1 kPa in the patients who did not achieve an SVR ($p = 0.001$). Liver stiffness decreased more than 30% in 52% of patients with SVR and in 21% of patients who did not achieve SVR ($p = 0.01$). Three patients in the non-SVR group and one in the SVR group progressed to cirrhosis. 14 out of 23 (60.87%) SVR patients with cirrhosis at baseline demonstrated a regression to values below 12.5 kPa after therapy.

Conclusions: In patients with advanced liver fibrosis at the beginning of PI-based therapy, liver stiffness is significantly reduced after treatment, but only if they achieved SVR, in a short term follow up of 24 weeks after the end of treatment. These findings even suggest the possibility of regression of liver cirrhosis after SVR in a significant proportion of patients.

P0721

VIRAL AND HOST PARAMETERS IN ASSOCIATION WITH OUTCOME OF ACUTE HEPATITIS C IN HIV-COINFECTED PATIENTS

J. Dietz[1], T. Lutz[2], G. Knecht[3], P. Gute[2], C. Berkowski[1], C.M. Lange[1], P. Khaykin[4], C. Stephan[4], H.-R. Brodt[4], S. Zeuzem[1], C. Sarrazin[1]. *[1]Department of Internal Medicine 1, Goethe University Hospital, [2]Infektiologikum Frankfurt-City, [3]Infektiologikum Frankfurt-Sachsenhausen, [4]Department of Internal Medicine 2, Goethe University Hospital, Frankfurt, Germany*
E-mail: julia.dietz@em.uni-frankfurt.de

Background and Aims: The HCV (hepatitis C virus) NS3 protease is essential for HCV replication, is a target for direct acting antivirals and cleaves the host protein CARDIF, which is involved in innate immune signaling. In this study, we investigated the NS3 protease evolution and function as well as other viral and host parameters in correlation with the outcome of acute hepatitis C.

Methods: Blood was collected prospectively from 82 consecutive patients with HIV (human immunodeficiency virus) coinfection at diagnosis of acute hepatitis C and every 4 weeks thereafter. Liver enzymes, HCV viral load (VL) and genotype, IP10 levels (interferon-gamma inducible protein) and IL28B genotype (rs129797860, rs8099917) were investigated in correlation with outcome. Longitudinal clonal NS3 protease sequencing was performed for a quasispecies characterization (Hamming distance/Shannon entropy) and major patient NS3/4A variants were expressed in U2OS cells to analyse CARDIF cleavage.

Results: We observed a spontaneous clearance rate of 13% (n = 11). Treatment was initiated during the acute phase in 43 (52%) individuals, 24 (30%) patients developed a chronic HCV infection (positive HCV-RNA 6 months after diagnosis) and the outcome is unclear for 4 (5%) persons. In comparison to a control group with a long-term chronic hepatitis C, acutely infected individuals displayed a significantly higher NS3 quasispecies diversity and complexity (both $P < 0.001$). However, the mean Hamming distance/Shannon entropy at diagnosis was comparable in patients with spontaneous clearance versus treatment-induced SVR (sustained virologic response) (both 0.010/0.031) or development of chronic hepatitis C (0.008/0.025). Longitudinal NS3 quasispecies kinetics showed a significant trend to a decreasing quasispecies diversity and complexity (both $P < 0.05$) within 4 weeks after diagnosis in patients with spontaneous clearance compared to SVR or progression to chronic hepatitis C. Furthermore, spontaneous clearance is predictable by a significantly higher HCV VL decline compared to development of a chronic hepatitis C (3.5 versus 1.7 log10 IU/mL,

P = 0.003). CARDIF was cleaved similarly by individual patient NS3/4A proteases independent of the outcome.
Conclusions: We detected a rapid NS3 quasispecies evolution during acute hepatitis C. Together with a high viral load decline, an early decreasing NS3 quasispecies evolution is indicative for a spontaneous clearance while the natural course of acute hepatitis C correlated not with NS3 CARDIF cleavage activity.

P0722

NON-INVASIVE DETECTION, STRATIFICATION AND TREATMENT OF CHRONIC HEPATIC C RELATED LIVER DISEASE AMONGST SUBSTANCE USERS IN THE COMMUNITY: A PROSPECTIVE STUDY

M. O'Sullivan[1], H. Williams[2], A.-M. Jones[3], S. Verma[1,4].
[1]Gastroenterology and Hepatology, Brighton and Sussex University Hospital, [2]Psychiatry, [3]Sussex Partnership Trust, [4]Medicine, Brighton And Sussex Medical School, Brighton, United Kingdom
E-mail: S.Verma@bsms.ac.uk

Background and Aims: Despite discovery of direct acting antiviral agents (DAA), a two–three fold increase in hepatitis C virus (HCV) detection and treatment is necessary to reduce the national HCV disease burden. Ninety percent of HCV positive individuals in England are people who inject drugs (PWID) with poor engagement with health services
Methods: Two-year prospective study (December 2013 to November 2015) conducted at a large substance misuse service in SE England. Individuals offered dry blood spot testing (DBST), mobile transient elastography (TE), and HCV treatment (pegylated interferon/ribavirin/telaprevir). Clinically significant hepatic fibrosis defined as liver stiffness measurement (LSM) ≥7.5 kPa.
Results: To date, 165 individuals have been recruited, mean age 39.8±8.9 yrs, 84.8% male. One hundred and forty-one (85.5%) had history of injecting drug use (IDU) with 59 (35.8%) currently injecting, 143 (86.7%) reported past alcohol use with 62 (37.6%) currently drinking. Eighty-three (50.3%) had had a psychiatric diagnosis. Uptake of DBST was 75 (45.5%), the main reason for declining being recent prior testing. Overall prevalence of positive serological markers/PCR were: HBcAb 28.8% (n = 42), HCV antibody 62.2% (n = 97) and HCV PCR 75.2% (73/97) (genotype 3a 42.8%, 1a 34.3%). Of those with a positive HCV PCR (n = 73), 62 (84.9%) underwent TE, mean LSM being 7.7±6.6 kPa, 21 (33.9%) having LSM ≥7.5 kPa including13 (21%) with cirrhosis (LSM ≥12 kPa), one of whom had decompensated disease. One of the 73 with a positive HCV PCR none had had prior treatment. Fifteen (20.5%) were not treatment candidates (chaotic life style), interferon was inappropriate and or contraindicated in 35 (47.9%) and only 23 (31.5%) eligible were for interferon based treatment. Thirteen have commenced therapy (nine genotype 3a, three 1a and one 2b), of whom 4 have successfully completed with 8 achieving rapid virological response
Conclusions: Both DBST and mobile TE have good uptake amongst PWID though prevalence of a positive HCV antibody remains high (62.2%). Despite a mean age of <40 yrs about a third of PWID have clinically significant HCV related hepatic fibrosis with 1:5 having established cirrhosis. Though community based interferon therapy is feasible in PWID despite ongoing drug and alcohol use, it is contraindicated in approximately 50% emphasizing the urgent need for interferon-free regimens in this vulnerable population

P0723

HCV REINFECTION INCIDENCE DECLINE AMONG HIV-POSITIVE MEN WHO HAVE SEX WITH MEN IN THE UK

T.C. Martin[1], N. Martin[2], A. Tang[3], M. Nelson[1]. *[1]HIV Department, Chelsea and Westminster NHS Foundation Trust, London, [2]School of Social and Community Medicine, University of Bristol, Bristol, [3]Imperial Medical School, Imperial College London, London, United Kingdom*
E-mail: thomas.martin@cantab.net

Background and Aims: Hepatitis C virus (HCV) infection is a leading cause of morbidity and mortality among HIV-positive men who have sex with men (MSM). Since 2000, there have been increasing reports of an epidemic of sexually transmitted HCV among HIV-positive MSM. Published incidence rates range from 0.5–4 infections per 100 person-years (py) among HIV-positive MSM, but work has indicated that since 2008 the incidence has stabilized or may now be falling. Previous studies in Amsterdam and London have also reported high HCV reinfection rates following treatment or spontaneous clearance (9–12/100py), however it is currently unknown whether HCV reinfection incidence has also fallen over this period.
Methods: We retrospectively identified all patients with a positive HIV and HCV antibody result from 2002–2012 at Chelsea and Westminster Hospital in London, UK. Primary HCV infections that were either successfully treated or spontaneously cleared were included in the analysis. HCV PCR results were followed through time calculating reinfection incidence for the time periods 2002–2008 and 2008–2014 using survival-time analyses.
Results: 191 HIV/HCV coinfected MSM were included in the analysis with a total of 589 years of follow-up. In total, 52 reinfections occurred between 2002–2014. From 2002–2008, 22 reinfections occurred at a rate of 13.2/100py (95% CI 8.7–20.1) compared to the period 2008–2014 where 30 reinfections occurred at a rate of 5.3/100py (95% CI 3.7–7.6) (Figure 1).
Conclusions: Among HIV/HCV coinfected MSM in London, there has been a statistically significant fall in HCV reinfection incidence over the past decade. This may be due to increased awareness of HCV transmission among patients and a concomitant reduction in risk behaviour. Reductions may also be due to increased uptake of screening and early treatment in this population preventing onward transmission. Future work should include analysis of reinfection over time in other cohorts, modelling of the epidemic to elucidate effective interventions and an analysis of risk-behaviour changes over time.

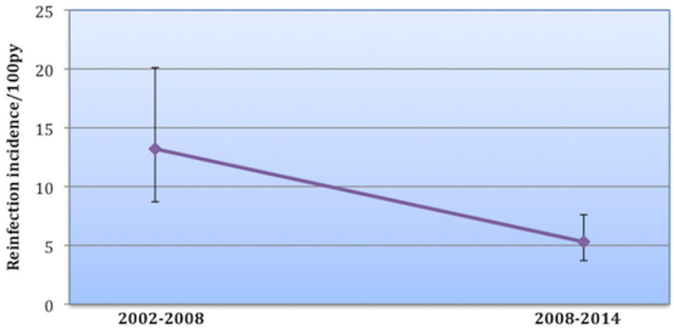


Figure 1.

P0724

DIRECT MEDICAL COSTS ASSOCIATED WITH THE EXTRAHEPATIC MANIFESTATIONS OF HEPATITIS C INFECTION IN THE UNITED STATES

Z. Younossi[1,2], M. Stepanova[1,2], L. Henry[1,2], H. Park[3], A. Racila[2], Z. Younoszai[2], S. Hunt[1,2]. [1]*Center for Liver Diseases, Department of Medicine, Inova Fairfax Hospital,* [2]*Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church, VA,* [3]*College of Pharmacy, University of Florida, Gainesville, FL, United States*
E-mail: zobair.younossi@inova.org

Background and Aims: Hepatitis C virus (HCV) infection is a systemic disease which is associated with both hepatic and extrahepatic manifestations. Although disease burden associated with the hepatic manifestation of HCV is well documented, the economic impact of the extrahepatic manifestation (EHM) of HCV [mixed cryoglobulinemia vasculitis (MCV), porphyria cutanea tarda (PCT), lichen planus (LP), type 2 diabetes (DM), depression (DD), chronic renal disease (CRD), and end-stage renal disease (ESRD)] remains unknown. The aim is to estimate the direct medical costs associated with the EHM of HCV in the United States.
Methods: We estimated the annual direct medical cost associated with EHM of HCV. The prevalence of each EHM in HCV was determined from an exhaustive review of recent literature (2005–2014). For the manifestations with definitive casual association, the actual HCV rates were used while for conditions without definitive causal association with HCV, the general population rates were subtracted. Outpatient resource utilization for HCV patients with different EHM were obtained from literature and the expert opinion. Inpatient utilization and per-patient-per-year (PPPY) inpatient and outpatient costs were estimated from Medicare billing data (adjusted to the 2014 U.S. dollars). Prescription drug costs were taken from literature or from the Red Book Drug Reference.
Results: In 2014, 2.68 million Americans were infected with HCV. The prevalence rates for the extrahepatic conditions in HCV-infected patients were as follows: MCV 7.5%, PCT 3.0%, LP 4.3%, CRD 4.8% (general population 1.3%), ESRD 0.4% (general population 0.3%), DM 14.8% (general population 9.3%), and depression 23.9% (general population 14.4%). The total PPPY costs associated with inpatient, outpatient and drugs ranged between $127 for LP to $29,000 for ESRD. To estimate the total annual economic burden for each extrahepatic manifestation, the respective prevalence rates were multiplied by PPPY costs. Thus, the total annual direct medical cost associated with the care of patients with extrahepatic manifestation of HCV in the U.S. was estimated to be $1,447 million per year. The sensitivity analyses (±25% to prevalence rates or ranges taken from the literature) suggested a range of $533 million to $2,618 million in total cost associated with extrahepatic manifestation of HCV.
Conclusions: Extrahepatic manifestations of HCV are quite costly and substantially add to the overall economic burden of HCV infection.

P0725

LIPIDOMICS ANALYSIS OF FASTING SERUM IDENTIFIES NOVEL LIPID BIOMARKERS SPECIFIC FOR HCV GENOTYPE 3 AND GENOTYPE 1 CHRONIC HEPATITIS C VIRUS INFECTION

D.A. Sheridan[1], M. Gomez Romero[2], S. Bridge[3], M. Crossey[2], I.T. Shawa[1], D. Neely[4], D. Felmlee[1], E. Holmes[2], M. Bassendine[2,5], S. Taylor-Robinson[2]. [1]*Institute of Translational & Stratified Medicine, Plymouth University Peninsula Schools of Medicine & Dentistry, Plymouth,* [2]*Imperial College London, London,* [3]*Northumbria University,* [4]*Clinical Biochemistry, Newcastle upon Tyne Hospitals NHS Foundation Trust,* [5]*Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom*
E-mail: david.sheridan@plymouth.ac.uk

Background and Aims: HCV genotype 3 (G3) is now considered the most difficult to treat genotype in the era of new oral direct acting antiviral (DAAs) drugs, particularly in those with advanced liver disease. HCV-G3 is also associated with more rapid progression to cirrhosis. Evidence suggests that HCV-G3 has different effects on lipid metabolism compared to HCV-G1, associated with hepatic steatosis, low LDL cholesterol and distinct interactions in the formation of lipoviral particles. A lipidomic analysis was performed to identify lipid species differentially regulated in HCV-G3 compared to HCV-G1, to gain further insight into genotype-specific metabolic pathways.
Methods: Lipidomic analysis was performed on fasting sera [N = 112 (73 G1, 39 G3); 25% cirrhosis] using a UPLC system coupled to a QToF mass spectrometer. Profiles were acquired in positive and negative ion modes. System suitability and stability was confirmed by injection of a quality control (QC) sample at regular intervals throughout the analytical run, prepared by combining equal aliquots of all the study samples. Data was pre-processed (alignment, noise filtering, normalisation) using XCMS and in-house developed scripts, and subjected to multivariate statistical analysis using Simca-P. Principal component analysis (PCA) and orthogonal projection on latent structures-discriminant analysis (OPLS-DA) were performed on all data after pareto scaling.
Results: Spectra were explored by PCA for initial visualisation to detect inherent trends and outliers. Samples clustered based on the differences between the HCV-G1 and HCV-G3. Pairwise analysis using OPLS-DA allowed establishing the lipids with the strongest contribution to the genotype separation in positive ion mode. Preliminary assignment based on mass, fragmentation pattern and retention time of lipid species upregulated in HCV-G3 included *Cholesteryl linoleate* [M+NH4] 666.621 m/z @ 15.47 min. Other lipid species were specifically increased in HCV genotype 1 [M+H] 784.588 *m/z* @ 6.29 min *PC (36:30)*. In negative ion mode, additional novel lipid species were found to be differentially unregulated in HCV-G1. The novel lipid species are currently being identified and evaluated in an independent validation cohort.
Conclusions: UPLC MS lipidomics methods identify novel lipid species differentially regulated in HCV-G3 compared to HCV-G1. Understanding of the lipidome in HCV-G3 may help identify factors associated with DAA relapse.

P0726

DISCREPANCIES OF DATA ON THE EXISTENCE OF COMPLEX NATIONAL APPROACH TO HEPATITIS C TREATMENT DERIVED FROM GOVERNMENTAL, PROFESSIONAL/CIVIL SOCIETY AND PATIENT INSTITUTIONS IN 33 EUROPEAN COUNTRIES

J. Videčnik Zorman[1], S. Gregorčič[1], M. Matičič[1]. [1]*Department for infectious diseases, University clinical center Ljubljana, ljubljana, Slovenia*
E-mail: jerneja.videcnik@gmail.com

Background and Aims: In the era of safe and highly effective hepatitis C virus (HCV) infection treatment the management of HCV infected patients including national strategies and HCV treatment guidelines should become a healthcare priority in all European countries. The aim of the study was to search for potential discrepancies between governmental, civil society/professional and patient institution replies regarding the existence of complex national approach to HCV treatment.
Methods: For individual European countries governmental data on existence of HCV national strategies, clinical treatment guidelines and availability of publicly founded HCV treatment were extracted from the 2012 WHO Global Policy Report. They were compared to data given by highly motivated civil society and professionals (22 non-governmental, 7 public health and 4 university institutions) derived from the 2013 survey of 33 European countries (33 ECS). Data on governmental funding of hepatitis strategy and adherence to the European Association for the Study of the Liver (EASL) clinical treatment guidelines were derived from the 2012 Euro Hepatitis

Index Report performed by the European Liver Patient Association (ELPA) and compared to data of the two previous sources.
Results: Comparing WHO Report and 33 ECS, replies on existence of national strategy on viral hepatitis were almost identical, except for 1 country where the government reported on having national strategy which was in discordance to the civil society report, and for 2 countries with the government reports on no strategy whereas the professionals confirmed its existence. WHO Report on existence of national HCV treatment guidelines showed some discrepancies to 33 ECS in which in the opposite to governmental institutions the civil societies of 5 countries denied and of 3 countries confirmed their existence. 6 out of 8 countries that by ELPA reported high extent of adherence to EASL clinical guidelines, reported by 33 ECS to have national HCV treatment guidelines. According to WHO HCV treatment was publicly funded in all countries but 1 whereas patients institutions in only 11 countries reported access to publicly founded treatment as completely satisfactory.
Conclusions: Discrepancies in replies between governmental institutions and highly motivated civil society/professional and patient institutions, found in the study, may help creating future management of HCV infection in European countries.

P0727
CLINICAL UTILITY OF THE ARTUS HCV QS-RGQ ASSAY FOR HCV RNA QUANTIFICATION

J. Vermehren[1], D. Perner[1], D. Clark[2], S. Susser[1], J. Hubb[2], S. Zeuzem[1], G. Foster[3], C. Sarrazin[1]. *[1]University Hospital Frankfurt, Frankfurt, Germany; [2]Department of Virology, Barts and The London NHS Trust, [3]The Liver Unit, The Blizard Institute, Barts & The London School of Medicine, London, United Kingdom*
E-mail: johannes.vermehren@kgu.de

Background and Aims: Sensitive detection and accurate quantification of HCV RNA is essential for monitoring and determination of response to antiviral therapy. In this study we evaluated the clinical performance of the recently developed artus HCV QS-RGQ assay (artus HCV; Qiagen, Hilden, Germany).
Methods: A set of clinical samples representing HCV genotypes 1–4 (n = 108) was tested by artus HCV in comparison to COBAS AmpliPrep/COBAS TaqMan (CAP/CTM; Roche, Pleasanton, CA, USA) and Abbott RealTime HCV (ART; Abbott, Des Plaines, IL, USA). In addition, baseline and on-treatment (week 4, 8, 12) samples (n = 88) from patients with HCV genotype 1 infection treated with telaprevir-based triple therapy were also tested by all three assays.
Results: Overall, artus HCV showed good agreement with CAP/CTM and ART across all genotypes tested (mean difference 0.47 and 0.56 log10 IU/ml HCV RNA). The mean difference between artus and CAP/CTM in samples harbouring genotypes 1, 2, 3 and 4 was 0.37, 0.50, 0.40, and 0.60 log10 IU/ml HCV RNA, respectively. The mean difference between artus and ART for genotypes 1, 2, 3 and 4 was 0.50, 0.45, 0.58, and 0.67 log10 IU/ml HCV RNA, respectively. Analyses of on-treatment samples showed that overall concordance between artus HCV and CAP/CTM to classify samples as HCV RNA undetectable or below 25 IU/ml vs. detectable was 99%. Only one week 4 sample was HCV RNA positive by CAP/CTM but negative by artus HCV. Concordance between artus HCV and ART was 95% and only 3 samples collected at week 4 were positive by ART and negative according to artus HCV.
Conclusions: Artus HCV showed good agreement with CAP/CTM and ART for the quantification of HCV-RNA across genotypes 1–4. Overall, HCV RNA levels were approx. 0.5 log10 IU/ml higher according to artus HCV when compared to CAP/CTM and ART. Concordance of on-treatment samples obtained at major decision time-points (week 4, 12) was high between artus HCV and both comparator assays.

P0728
INVESTIGATION OF GENETIC RECOMBINATION OF HEPATITIS C VIRUS IN PATIENTS INFECTED WITH GENOTYPES 1, 2 AND 4

J. Dietz[1], N. Hamdi[2], K.-H. Peiffer[1], S. Susser[1], C. Berkowski[1], D. Perner[1], S. Zeuzem[1], C. Sarrazin[1]. *[1]Department of Internal Medicine 1, Goethe University Hospital, Frankfurt, Germany; [2]Department of Pharmacology and Toxicology, German University in Cairo, Cairo, Egypt*
E-mail: julia.dietz@em.uni-frankfurt.de

Background and Aims: Genetic recombination is important for the evolution of RNA viruses. Different from other viruses for hepatitis C virus (HCV), only very few natural inter- and intragenotypic recombinant strains were reported. Recently, a putative recombination point was found within the NS2/NS3 junction and the identified inter-genotypic recombinants identified at a frequency of 0.8–1.4% in U.S. patients consisted of genotype (GT) 2 in the 5′ and GT1 in the 3′ part which led to determination of GT2 by standard Lipa genotyping assay and exhibited a reduced response to sofosbuvir + ribavirin treatment. Frequencies of recombinant HCV strains in European HCV genotype 1 and 2 isolates as well as HCV genotype 4 isolates from Egypt with evolution to a large number of subtypes is unknown.
Methods: Serum of patients chronically infected with HCV genotype GT1 from a German multicenter study (n = 162) and of consecutive patients infected with HCV genotype 2 (n = 58) and 4 (n = 121) who presented at University Hospitals in Frankfurt, Homburg and Cairo were investigated. To differentiate geno- and subtype recombinants according to the previously described NS2-NS3 breaking point, we amplified part of the core and NS5A or NS5B genes in GT1/4- and GT2-infected individuals with genotype-specific primers. Obtained PCR products were population-based sequenced and geno- and subtypes were determined using BLAST (HCV sequence database).
Results: Using sequence-based analyses, intragenotypic recombinants were investigated in patients with GT1 and 4 infection. In GT1, 47% (n = 76) of patients were infected with subtype 1a and 53% (n = 86) with 1b and no discordant subtypes or genotypes were observed between core and NS5A genes. In GT4-infected individuals, subtype 4a was most prevalent (87%, n = 106), followed by 4n (9%, n = 11) and the minor subtypes 4l and 4o (each 2%, n = 2) and all sub and genotypes were consistent between core and NS5A. Patients with GT2 were infected with subtype 2b (48%), 2a (26%), 2c (24%) and 2i (2%) and geno- as well as subtypes were in accordance between core and NS5B genes.
Conclusions: No inter- or intragenotypic HCV recombinants were detected in a cohort of >200 patients with chronic HCV genotype 1 or 2 infection in Europe which makes wrong selection of DAA-based antiviral therapy unlikely. Despite the large number of existing genotype 4 subtypes also no recombinants have been detected in genotype 4 infected patients by means of population based sequencing in the present study.

P0729
RENAL DISEASE PREVALENCE AND ASSOCIATION WITH HEPATIC FIBROSIS MEASURED BY FIB4 SCORE AMONG US PATIENTS WITH CHRONIC HEPATITIS C VIRUS (HCV) INFECTION IN THE CHRONIC HEPATITIS COHORT STUDY (CHECS)

S.D. Holmberg[1], A.C. Moorman[1], X. Tong[1], P.R. Spradling[1], E.H. Teshale[1], S.C. Gordon[2], J.A. Boscarino[3], V. Vijayadeva[4], M.A. Schmidt[5], L.B. Rupp[2], M. Lu[2], F. Xu[1], for the CHeCS Investigators. *[1]Division of Viral Hepatitis, Centers for Disease Control and Prevention, Atlanta, [2]Henry Ford Health System, Detroit, [3]Geisinger Health System, Danville, [4]Kaiser Permanente – Hawaii, Honolulu, [5]Kaiser Permanente – Northwest, Portland, United States*
E-mail: sdh1@cdc.gov

Background and Aims: Chronic HCV infection has been associated with several types of renal disease as both a causative and a

complicating factor; patients with severe renal manifestations of chronic HCV are at high priority for HCV treatment. We sought to describe the extent of renal disease and its relationship with other comorbidities and hepatic fibrosis among patients participating in the Chronic Hepatitis Cohort Study (CHeCS), a population-based prospective, observational cohort study at four large US health systems.

Methods: We observed HCV-monoinfected patients with renal and hepatic laboratory data, beginning from patient's HCV diagnosis in the health system through the end of 2012, with censoring at one year before any of the following events: death, loss to follow-up, sustained viral response to HCV therapy, or liver transplant. Hypertension (HTN), diabetes mellitus (DM), and chronic renal disease were defined by the presence of two ICD9 codes for the conditions at least 30 days apart. Generalized estimating equations were used to measure the correlation of impaired renal function (defined as estimated glomerular filtration rate [eGFR] <60) with level of hepatic fibrosis (assessed by FIB4 score) estimated from laboratory testing that occurred on the same day.

Results: Among 8,179 persons with mean follow-up of 7.5 years, the diagnosis of vasculitis, nephrotic syndrome and cryoglobulinemia was low: 0.3%, 0.6% and 0.8%, respectively. About one-half (53%) of patients were diagnosed with either DM or HTN; these patients were more likely to have the following renal disease conditions compared to those without HTN or DM ($p < 0.001$ for all, chi-square test): chronic kidney disease (16% vs 1%), eGFR <60 (19% vs 6%), and dialysis (4% vs 1%). Among patients with DM or HTN, the percent with eGFR <60 did not differ by FIB4 score categories. However, among patients without DM or HTN, the percent having eGFR <60 increased from 4% in those with FIB4 <1.6 to 10% in those with FIB4 ≥2.5 (Table). In a multivariate analysis, FIB4 ≥2.5 was associated with the risk of having eGFR <60 (adjusted OR = 1.5; 95% CI, 1.2, 1.8), after adjusting for age and other factors.

Table: eGFR levels by FIB4 score categories, CHeCS patients (N = 8,179)

eGFR levels	FIB4 score, n (%)		
	<1.6	1.6–2.5	≥2.5
Persons with HTN or DM			
≥90	589 (40)	418 (43)	863 (40)
60–89	602 (41)	378 (39)	865 (41)
45–59	90 (6)	86 (9)	201 (9)
30–44	57 (4)	36 (4)	119 (6)
<30	137 (9)	62 (6)	86 (4)
Persons without HTN or DM			
≥90	1075 (54)	350 (46)	667 (49)
60–89	842 (42)	359 (47)	569 (41)
45–59	56 (3)	38 (5)	101 (7)
30–44	12 (1)	7 (1)	22 (2)
<30	12 (1)	6 (1)	14 (1)

Conclusions: The prevalence of renal conditions associated with HCV infection such as cryoglobulinemia was low. In those without HTN or DM, advanced liver fibrosis measured by FIB4 score was significantly associated with high prevalence of impaired renal function (decreasing eGFR).

P0730

PREVALENCE AND CHARACTERISTICS OF HEPATITIS C GENOTYPES IN THE CHRONIC HEPATITIS COHORT STUDY (CHECS)

S. Gordon[1], J. Li[1], L.B. Rupp[1], J.A. Boscarino[2], V. Vijayadeva[3], M.A. Schmidt[4], L.E. Lamerato[1], M. Lu[1]. *[1]Henry Ford Health System, Detroit, [2]Geisinger Health System, Danville, [3]Kaiser-Permanente Hawaii, Honolulu, [4]Kaiser-Permanente Northwest, Portland, United States*

E-mail: strudea1@hfhs.org

Background and Aims: We sought to determine the prevalence of hepatitis C (HCV) genotypes (GT) /subtypes (ST), including demographics, disease characteristics, and death rates in the Chronic Hepatitis Cohort Study (CHeCS), an ongoing, observational cohort study which draws patients from four large and diverse US health systems.

Methods: Demographics, HCV GT/ST, viral load, aminotransferases, platelet count, FIB4, HBV/HIV coinfection, history of antiviral therapy, attainment of sustained viral response (SVR), development of hepatic decompensation and liver transplant were collected at last follow-up (date of last encounter or last antiviral therapy). We studied the prevalence of HCV GT/ST and compared patient and disease characteristics among non-deceased patients using the chi-square test. GTs 4–6 were grouped together due to small numbers. Death rates per 1000 person-years (p-y) were calculated and compared by Poisson regression.

Treatment experienced	43.3	50.3	53.0	51.6		
SVR attained	22.5	53.1	46.6	36.5		

Results: 11,111 patients were included, of whom 9106 (82%) were alive; median follow-up was 6.7 years. Genotype data were available for 6265 (69%) patients. The table shows GT/ST prevalence and characteristics among non-deceased patients. The chi-square test showed significant differences among the GTs in all demographic and disease variables ($p < 0.001$) except HBV/HIV coinfection ($p = 0.10$ and 0.06). In general, GT2 patients have lower ALT, FIB-4, and rates of liver transplant and decompensation than GTs 1 and 3. Viral loads are higher in GT 1 than in GTs 2, 3 and 4–6. Fewer GT1 patients received antiviral therapy than others. SVR responses were 2-fold or higher in patients with GT 2 or 3

compared to those with GT 1. Blacks were dominantly GT 1 (30%), compared to other GTs (3%>8%). Death rates were 31.6, 25.7, 28.8 and 18.7 per 1000 p-y for GTs 1, 2, 3 and 4–6 respectively (p = 0.0214).

Conclusions: Our current real-world US data (up to January 1, 2013) showed 75% patients were infected with G1, among those 57% and 31% were subtype 1a and 1b respectively. Significant differences were observed among GT1, 2 and 3 in patients' race, fibrosis biomarkers, treatment allocation and response to treatment. Patients with GT2 and 3 had lower HCV RNA levels, higher likelihood of receiving therapy and higher SVR compared to GT1.

P0731

LEDIPASVIR (LDV)/SOFOSBUVIR (SOF) TREATMENT OF HEPATITIS C VIRUS (HCV) IS ASSOCIATED WITH REDUCTION OF SERUM APOLIPOPROTEIN LEVELS

Z. Younossi[1,2], E. Elsheikh[1,2], M. Stepanova[2], L. Gerber[2], F. Nader[1,2], D. Brainard[3], J.G. McHutchinson[3]. [1]*Center for Liver Diseases, Inova Fairfax Hospital,* [2]*Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church,* [3]*Gilead Sciences, Foster City, United States*
E-mail: zobair.younossi@inova.org

Background and Aims: The interaction of lipoproteins with HCV has been of pathogenic and therapeutic interest. It is postulated that HCV circulates in the blood, bound to lipoproteins such as very-low-density lipoprotein, which potentially plays a role in its ability to escape immune clearance. HCV also potentially uses lipoproteins receptors to gain access into hepatocytes. Our aim is to evaluate changes in the apolipoprotein profile of patients with chronic hepatitis C (CH-C) during and after successful cure with LDV/SOF±ribavirin (RBV).

Methods: CH-C genotype 1 patients who had achieved SVR-12 after treatment with 12 weeks of LDV/SOF±RBV were selected from the ION-1 clinical trial. Frozen serum samples from baseline, end of treatment and 4 week follow-up were used to assay apolipoproteins (Apo A1, Apo AII, Apo B, Apo CII, Apo CIII, Apo E) using the Multiplex platform. Changes in serum apolipoprotein level (mcg/mL) from baseline levels were assessed at the end of treatment and after 4 weeks of follow-up.

Results: 100 CH-C patients were included (mean age 53 years, 57% male, 17% cirrhosis, 73% genotype 1a). At the end of treatment, a significant reduction in Apo AII levels (−14.97±63.44 mcg/mL, p = 0.0067) and Apo E levels (−4.38±12.19 mcg/mL, p < 0.001) was noted. These declines in Apo AII (−16.59±66.15 mcg/mL, p = 0.0075) and Apo E (−2.66±12.64 mcg/mL, p = 0.01) persisted after 4 weeks of follow-up. On the other hand, Apo CII level increased from baseline to end of treatment (2.74±11.76 mcg/mL, p = 0.03) and persisted after 4 weeks of follow-up (4.46±12.81 mcg/mL, p = 0.0005). However, this increase in Apo CII during treatment was observed in patients receiving RBV-free SOF/LDV only (5.52±11.92 mcg/mL, p = 0.0007), while no similar increase was noted in SOF/LDV+RBV (p = 0.64). In the multivariate analysis, treatment with LDV/SOF+RBV was independently associated with lower levels of all lipoproteins at the end of treatment. In particular, the reduction in Apo E associated with RBV-containing treatment (compared to RBV-free SOF/LDV) was −5.31 mcg/mL (p < 0.05).

Conclusions: Treatment with LDV/SOF±RBV is associated with a persistent reduction in the apolipoprotein AII and E, as well as with an increase in Apo CII after achieving cure. Adding RBV is independently associated with reduction in Apo E, and essentially eliminates the increase in Apo CII. These data suggest that LDV/SOF±RBV may overcome this mechanism of escape for HCV.

P0732

IMPACT OF OLD SCHISTOSOMIASIS INFECTION ON THE USE OF FIBROSCAN FOR STAGING OF FIBROSIS IN CHRONIC HCV PATIENTS

I. Ramzy[1], R. Fouad[1], M. ElRaziky[1], A. Elsharkawy[1], W. ElAkel[1], H. Abdelhafez[1], M. Elsayed[1], H. Khattab[2], M. Shehata[3], A. Radwan[4], G. Esmat[1]. [1]*Endemic Medicine Department, Faculty of Medicine, Cairo University,* [2]*Pathology Department, Faculty of Medicine, Cairo University,* [3]*Clinical Pathology, Faculty of Medicine, Cairo University,* [4]*Academy of Scientific Research and Technology, Cairo, Egypt*
E-mail: a_m_sharkawy@yahoo.com

Background and Aims: *Background:* Diagnosis of the stage of liver fibrosis is essential for deciding an antiviral therapy. Multiple non invasive methods for assessment of liver fibrosis as fibroscan have been studied. HCV-Schistosomiasis coinfection is more common among Egyptian patients.

Aim: Assess the impact of Schistosomiasis on the use of fibroscan for staging of fibrosis in chronic HCV patients.

Methods: This study was conducted on 326 chronic HCV patients. Routine laboratory workup was done and serum Antischistosomal antibody using ELISA technique was performed. Reference needle liver biopsy was histopathologically assessed based on Metavir scoring for staging of fibrosis (F0–F4) and Liver stiffness measurement by FibroScan® was done for all the patients.

Results: Antischistosomal antibody was positive in 59.3% of the studied population. The disagreement between the results of liver biopsy and fibroscan was more obvious in those with positive schistosomal serology with p value 0.08 (approaching significant). Although Periportal tract thickening was found in 24% of the studied population, it showed no impact on the agreement between liver biopsy results and fibroscan (p value 0.22). Multivariate logistic regression analysis showed that high BMI (≥30) and positive anti schistosomal antibody were the most important factors associated with disagreement between the results of fibroscan and liver biopsy especially in F3 group with p values (0.023 and 0.029 respectively)

Conclusions: Performance of fibroscan for staging of fibrosis may be impaired by the presence of schistosomiasis coinfection.

P0733

DIABETES MELLITUS INCREASES THE RISK OF LIVER CIRRHOSIS AND HCC IN SAUDI HCV PATIENTS

A. AlBenmousa[1], M. Qadri[1], A. Mdani[1], K. Bzeizi[1]. [1]*Gastroenterology & Hepatology, Prince Sultan Military Medical City, Riyadh, Saudi Arabia*
E-mail: alibenmousa@gmail.com

Background and Aims: *Background:* Several epidemiological studies have suggested an association between type II DM and HCV infection. Some other studies have shown a lower viral response to treatment in diabetic patients and higher incidence of HCC. Few reports from Saudi Arabia demonstrated a higher prevalence of DM in HCV infected patients but the association with liver cirrhosis, response to treatment and development of HCC is not known.

Aims: To assess the impact of the prevalence of Diabetes mellitus in HCV infected patients on the risk of development of liver cirrhosis and hepatocellular carcinoma.

Methods: Retrospective chart review of patients diagnosed with HCV infection between 2002 and 2012. patients were identified from an institutional database for hepatology patients. Demographic, clinical, histological, biochemical and serological data were collected. Variables were analyzed descriptively and inferentially using SPSS.

Results: Retrospectively we evaluated 392 patients infected with HCV. The mean age of this cohort was 51.6±13.6 years and 51% were males. Genotype was available for 50% of the patients. Genotype 4 was the commonest (56%) and genotype 1 was found in 32.3% while the rest (11.7%) had genotype 2, 3, 6 or mixed genotype. The

prevalence of diabetes was 47.8%. There was no difference in BMI between diabetic and non diabetic patients (p 0.139). Histology data were available for 232 patients (59%). At presentation, 31.3% of the patients had early (stage 0–2) fibrosis and 27.2% had advanced (stage 3–4) fibrosis. Diabetic patients were more likely to have advanced fibrosis (53.3% vs 42.3%) but difference was not statistically significant, p 0.096. Cirrhosis occurred more frequently in diabetic patients (OR 1.98, p 0.001). Similarly, HCC was more prevalent in HCV infected patients with diabetes (OR 1.89, p 0.056) and the mortality rate was higher (p 0.033). Treated patients with diabetes had less SVR (OR 0.63) however the difference was statistically insignificant (p 0.106).
Conclusions: Diabetes mellitus is highly prevalent in HCV infected patients. This was independent of obesity in this population. HCV infected patients with diabetes tend to have less response to antiviral therapy, higher incidence of cirrhosis and HCC and higher mortality rate compared to those without DM.

P0734
HEALTHCARE UTILISATION FOLLOWING TREATMENT OF HIV/HCV PATIENTS WITH MILD LIVER DISEASE

P. Padam[1], S. Clark[1], E. Thomson[2], J. Main[1], G. Cooke[1]. *[1]Imperial College London, London, [2]University of Glasgow, Glasgow, United Kingdom*
E-mail: pritpalpadam20@gmail.com

Background and Aims: New directly acting antiviral (DAA) therapy for hepatitis C (HCV) offers the potential for high cure rates in many patient groups previously considered difficult-to-treat, including those HIV/HCV co-infected. However, the high price of these medications is likely to limit access to treatment in all healthcare settings, at least in the short term. Early treatment priority is likely to be given to those with advanced disease but there are potential benefits in treating those with mild disease including the reduction of transmission and reduction HCV-related healthcare utilisation. Benefits in healthcare utilisation are likely to differ between mono- and HIV co-infection as HIV patients remain within healthcare services. We hypothesised that successful HCV treatment within a HIV/HCV co-infected population with mild liver disease would lead to a reduction in the HCV-related use and costs of healthcare services in the 5 years following treatment completion.
Methods: In a retrospective analysis, HIV/HCV co-infected patients that completed a course of therapy between January 2004 and March 2014 at St. Mary's Hospital were evaluated, excluding those with a fibroscan ≥9.6 kPa and/or a biopsy with ISHAK score ≥2/6 in the 2 years prior to treatment. Detailed analysis of healthcare utilisation up to 5 years following treatment for each patient was conducted using electronic records and subsequent costs were calculated.
Results: 63 patients with mild disease completed a course of HCV therapy between January 2004 and March 2014, of which 48/63 (76%) attained SVR12. Both SVR and non-SVR groups were predominantly white males with a mean age of 46 and 41, respectively. Genotype 1 was the most prevalent, present in 33/48 (69%) SVR and 11/15 (73%) non-SVR patients. Individuals that failed treatment were more likely to spend at least one night in hospital in the 5 years following therapy with a RR of 4.00 (p = 0.0213, 95% CI, 1.23–13.02). Overall, patients achieving SVR12 incurred lower health utilisation costs (£3,712.20 per patient) compared to (£9,299.70 per patient) non-SVR patients.
Conclusions: Healthcare utilisation rates and costs in the immediate 5 years following treatment were significantly higher in co-infected patients with mild disease that failed to achieve SVR12 compared to those who successfully cleared the virus. This data suggests additional value to achieving cure beyond the prevention of complications of disease.

P0735
ASSESSMENT OF BASELINE VIRAL LOAD CUT-OFF FOR SHORTENED LEDIPASVIR/SOFOSBUVIR THERAPY BY WIDELY USED HCV RNA ASSAYS

J. Vermehren[1], B. Maasoumy[2], S. Chevaliez[3], J.J. Feld[4], G. Cloherty[5], J.-M. Pawlotsky[3], C. Sarrazin[1], H. Wedemeyer[2]. *[1]University Hospital Frankfurt, Frankfurt, [2]Hannover Medical School, Hannover, Germany; [3]Department of Virology, Hôpital Henri Mondor, Paris, France; [4]Toronto Centre for Liver Disease, University of Toronto, Toronto, Canada; [5]Abbott Molecular, Des Plaines, United States*
E-mail: johannes.vermehren@kgu.de

Background and Aims: The recent approval of ledipasvir/sofosbuvir combination therapy for the treatment of HCV genotype 1 infection includes the possibility to shorten treatment duration from 12 to 8 weeks in non-cirrhotic treatment-naïve patients who have a baseline viral load (VL) <6 million IU/ml (i.e. 6.8 $\log_{10}$ IU/ml). In this multicentre study we assessed the reliability of this new cut-off with three commercially available HCV RNA assays.
Methods: Baseline samples from patients enrolled in the m11-206 phase 2 study (n = 73) as well as patients referred to our outpatient clinics (n = 148) were tested for HCV RNA with the Roche HighPureSystem Cobas TaqMan (HPS/CTM) or Cobas Ampliprep/Cobas TaqMan (CAP/CTM) and Abbott RealTime HCV (ART) assays. All patients were non-cirrhotic and naïve to antiviral therapy, thus in principle eligible for an 8-week regimen. In a subset of patients (n = 48 with CAP/CTM; n = 12 with ART) with baseline VL >1 million (6.0 log) IU/ml, samples from 1–2 additional screening time-points were available for repeated HCV RNA testing.
Results: Of the m11-206 study baseline samples tested, 44/73 (60%) and 7/73 (10%) had >6 million (6.8 log) IU/ml according to HPS/CTM and ART, respectively. Among patients referred to our clinics, 20/148 (14%) had >6 million IU/ml by CAP/CTM. Of the 75/148 outpatient samples tested with both CAP/CTM and ART, 6 (8%) and 2 (3%) had >6 million IU/ml. In patients with repeated pre-baseline measurements clinical decisions could be impacted in 29% of cases for CAP/CTM due to variability in the measured HCV RNA level (above and below 6 million IU/mL). Eight patients could have shortened and 5 extended treatment depending on the time point considered for treatment decision. In contrast, only one patient with a baseline VL <6 million IU/ml according to ART would have received extended therapy based on a VL >6 million IU/ml at a preceding visit.
Conclusions: A baseline viral load below 6 million (6.8 log) IU/ml was present in 59% of patients in the ION-3 registration trial and 40% in the present study based on HPS/CTM. However, measurements with CAP/CTM and ART, two assays widely used in the real-world setting, revealed that 86% and 90% of patients tested were, in principle, eligible to receive an 8-week treatment regimen. A substantial proportion of patients had fluctuating VL levels below and above 6 million IU/ml at different screening time points according to CAP/CTM that could potentially impact treatment decisions.

P0736
IMPACT OF PHYSICAL ACTIVITY ON OXIDATIVE STRESS IN PATIENTS WITH HEPATITIS C

J.A. Del Campo[1], M. Rivas[2], M. García-Valdecasas[1], R. Gallego-Durán[1], C. Rodríguez-Ramos[2], M. Romero-Gómez[1]. *[1]Digestive Diseases, Valme University Hospital & CIBERehd, Sevilla, [2]Digestive Diseases, Hospital Universitario Puerta del Mar, Cádiz, Spain*
E-mail: joseantonio.delcampo@gmail.com

Background and Aims: The beneficial effects of increased physical activity (PA) on non-alcoholic fatty liver disease (NAFLD) in obese subjects have been reported recently. The goal of this study was to evaluate the effect on oxidative stress of moderate PA in patients with hepatitis C.

Methods: Patients with Hepatitis C (n = 13) were exposed to moderate PA for 12 weeks. An individualized program of aerobic exercise lasting 16 weeks in 3 sessions of 60 minutes/week was designed. Different clinical parameters were recorded during that period, including samples from whole blood. Serum and plasma sample were obtained and PBMC cells were isolated for further RNA extraction and gene expression analysis. Catalase activity was monitored at t = 0 (T0; baseline), t = 6 weeks (T6) and t = 12 (T12) weeks using the Catalase Assay kit (Cayman Chemicals, Michigan USA). PBMC were isolated for t = 0 and t = 6 weeks. Superoxide dismutase 1 (SOD1), SOD2 and Nitric oxide synthase 2 (NOS2) gene expressions were analyzed. Statistical analysis was performed using SPSS v22.
Results: PBMCs are considered a good model to reflect important metabolic changes in the liver. Gene expression was analyzed in t = 0 and t = 6 weeks samples from HCV patients. 30% of patients showed reduced expression of NOS2 and SOD2 after 6 weeks of PA (fold inhibition 31±4.3; $p < 0.05$). SREBP1c, which plays a pivotal role in lipid metabolism, was also found down-regulated in the T6 group compared to T0 (27±3.3 fold inhibition). Mean values of catalase activity was analyzed in T0, T6 and T12 groups. Difference in enzyme activity was not significant when T0 and T6 groups were compared (t test) (20.37±1.32 vs. 22.44±1.84; p = ns). However, significant differences were found between T0 and T12 groups (20.37±1.32 vs. 27.33±1.94; $p = 0.005$) and between T6 and T12 groups (22.44±1.84 vs. 27.33±1.94; $p = 0.003$).
Conclusions: A common pathogenic feature present in HCV infection is oxidative stress. We have demonstrated that physical exercise improves antioxidant state in patients with HCV through regulation of catalase activity and the expression of oxidative stress-related genes (SOD2 and NOS2). Hence, moderate PA is recommended for patients with HCV.

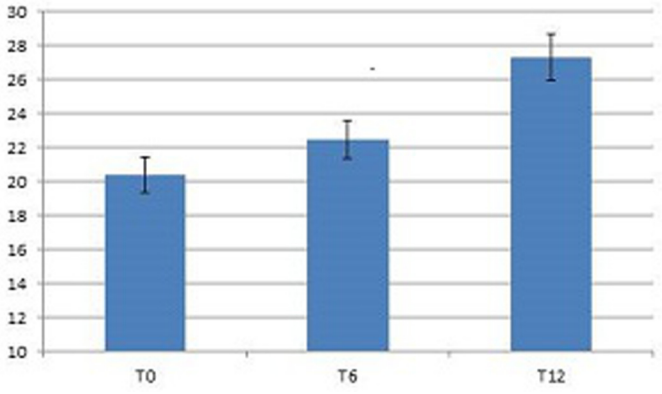

Figure 1. Catalase activity (in relative units) in HCV patients at baseline (T0), 6 weeks (T6) and 12 weeks (T12) of physical activity.

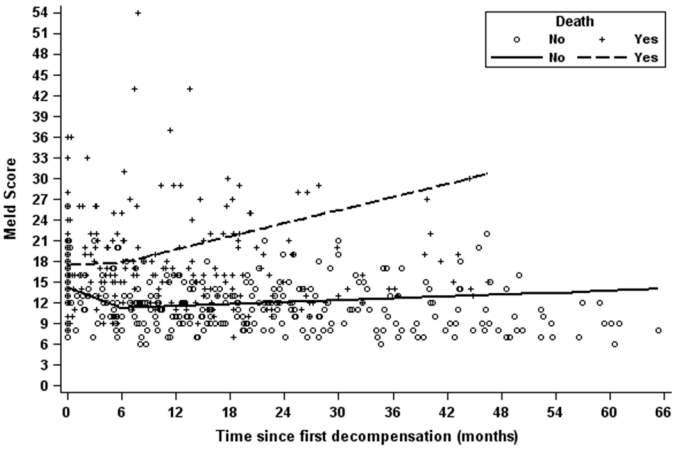
P0737
MELD SCORE KINETICS AND SURVIVAL IN HIV/HCV PATIENTS: THE ANRS EP 25 PRETHEVIC COHORT

M. Gelu-Simeon[1,2,3,4], T. Bayan[5], M. Ostos[1], F. Boufassa[5], J.-M. Steyaert[6], I. Bertucci[7], E. Teicher[2,3,4,8], R. Anty[9], G.-P. Pageaux[10], L. Meyer[5], J.-C. Duclos-Vallee[1,2,3,4]. *[1]Centre Hepato-Biliaire, AP-HP Hôpital Paul-Brousse, [2]Unite 785, INSERM, [3]UMR-S 785, Univ Paris-Sud, [4]DHU Hepatinov, Villejuif, [5]Unite 1018, INSERM, Le Kremlin-Bicetre, [6]Laboratoire d'Informatique LIX, Ecole Polytechnique, Palaiseau, [7]ANRS, Paris, [8]Service Medecine Interne et Immunologie clinique, AP-HP Hôpital de Bicetre, Le Kremlin Bicetre, [9]CHU de Nice – Hôpital de l'Archet, Nice, [10]CHU de Montpellier – Hôpital Saint Eloi, Montpellier, France*
E-mail: jean-charles.duclos-vallee@pbr.aphp.fr

Background and Aims: HIV infection fastens liver disease progression in patients with hepatitis C virus infection. HIV/HCV coinfected patients have higher rates of hepatic decompensation and more severe liver events than HCV mono-infected patients. There are conflicting data concerning the predictive factors of mortality of patients with end stage liver disorder, particularly after the first episode of decompensation. It has been demonstrated that MELD score was an independent predictor of the pre-transplant mortality. The aim of this study was to assess prognostic factors of survival and describe longitudinal MELD dynamics in HIV/HCV co-infected patients who further died (D) or not (ND) after a first episode of liver decompensation (DC).
Methods: 67 HIV/HCV co-infected pts without hepatocellular carcinoma and with a first episode of DC within 1 year (yr) before enrollment were prospectively followed. Clinical and biological data were collected at 1st DC and then every 3 months. Survival rate and risk factors of death were studied by using Kaplan–Meier curves and Cox models. A two-slope mixed linear model with a node at 6 months (mths) was used to estimate change of MELD in D and ND from 1st DC.
Results: Patients were included in 32 centers in 2009–2013 (72% male, median age: 48 yrs [IQR 44–51], median follow-up: 23.4 mths [13.9–44.8]). The median number of recurrent episodes of DC was 2 [1–3] after 1st episode. Overall survival rate was 87%, 77% and 60% at 6, 12 and 24 mths after 1st DC, respectively. In multivariate analysis, MELD score at 1st DC was predictive of mortality, adjusted for age, sex, severity of 1st DC and time between HIV/HCV diagnosis and 1st DC: aRR was 1.32 [95% CI: [1.10–1.57], $p < 0.003$ for an increase of 3 units of MELD. The kinetics MELD scores (Figure) from 1st DC significantly differed between D and ND pts. In ND patients, mean MELD significantly decreased during the first 6 mths (−0.49/mth; $p = 0.02$), while it remained flat in D patients (+0.06/mth, $p = 0.75$). After 6 mths, mean MELD increased significantly by +0.32/mth ($p < 0.0001$) in D patients while it was only +0.05/mth ($p = 0.17$) in ND pts. Before and after 6 mths, the slopes significantly differed in D and ND subjects.
Conclusions: MELD is an effective tool to predict mortality in HIV/HCV co-infected patients with liver decompensation. An increase in MELD, 6 months after the 1st decompensation, should alert for a pre-transplant assessment. This is especially important in this poor prognosis population.



P0738
HEPATITIS C VIRUS INFECTION IN SUB-SAHARAN AFRICA: PREVALENCE META-ANALYSIS AND RISK FACTOR REVIEW

N. Mora[1], W. Adams[2], S. Kliethermes[1], J. Layden[3], S. Scaglione[1,2], C. Small[1], H. Nde[1], L. Dugas[1]. *[1]Public Health Sciences, [2]Department of Medicine, [3]Division of Infectious Disease, Department of Medicine, Loyola University Chicago, Maywood, United States*
E-mail: namora@luc.edu

Background and Aims: The Global Burden of hepatitis C working group estimates that the prevalence of Hepatitis C virus (HCV) infection is approximately 2.2% worldwide, with Sub-Saharan

Africa (SSA) region having among the highest prevalences. In Western countries the modes of transmissions are widely established. However, in developing countries, especially in SSA, the transmission pathways and risk factors are not well known.
The primary aim of the study was to conduct a meta-analysis on the HCV sero-prevalence in SSA, and examine the impact of region, cohort and year of study on the estimates. The second aim was to perform a literature review of risks factors for HCV infection in SSA.
Methods: Articles published from January of 2000 to December of 2013 on HCV prevalence and risks factors were assessed. Studies were excluded if they were missing information on prevalence, year of study, serologic assay used, or were not from sub-Saharan countries.
Study populations were grouped by cohorts based on different risk factors (i.e. general population, HIV positive, chronic illness, high risk, and blood donors).
Results: Data from 265 studies representing the SSA region were. A total of 146 articles meeting the inclusion criteria. Studies came from 26 countries across 4 sub-regions in SSA.
Overall, the prevalence estimate was 4.9% (95% CI: 1.9–12.0). The prevalence varied by region. There was a higher prevalence in studies from current years (4.4%), as opposed to earlier years (2.9%). Prevalence also varied by population cohort. Table 1 depicts the prevalence estimates by population cohort, region, and year of study. A paucity of data limited the possibility to conduct a meta-analysis on risk factors for HCV infection. However, risk factors consistently associated with HCV infection amongst others include: gender, traditional circumcision, ethnic group, history of past injections, HIV and HBV co-infection, education level, and occupation (farming).

Table: Prevalence of HCV infection in Sub-Saharan Region. Meta-analysis results [a]

Group	Prevalence, %	95% CI
Overall	4.9	0.2–12.0
Cohort		
General population	4.2	3.1–5.7
Blood donors	1.5	0.8–3.1
HIV positive	3.0	0.9–10.0
High risk population	11.8	1.7–79.0
Chronic illness	7.5	0.2–236.0
African Region		
Central	7.0	4.6–10.0
Eastern	3.0	1.5–5.7
Western	3.9	2.0–7.5
Southern	0.3	0.06–17.0
Year		
2000 to 2005	2.9	1.8–4.6
2006 to 2013	4.4	2.9–6.6

[a] Random effect model.

Conclusions: There is limited primary data on HCV prevalence. This meta-analysis, however, suggests that HCV prevalence has increased and is higher than previously reported estimates. There is even less data on HCV risk factors, limiting our understanding of present day transmission pathways. Such knowledge gaps limit the ability to create screening and treatment guidelines relevant to this region.

P0739
IMPACT OF SERUM APOLIPOPROTEIN PROFILES IN CHRONIC HCV INFECTION: DIFFERENCE BETWEEN HCV GENOTYPES 1B AND 2

N. Seki[1], T. Nagano[1], T. Sugita[1], Y. Aida[1], H. Abe[1], Y. Aizawa[1].
[1]Division of Gastroenterology and Hepatology, Jikei University Katsushika Medical Center, Tokyo, Japan
E-mail: novseki@jikei.ac.jp

Background and Aims: The life cycle of hepatitis C virus (HCV) is tightly associated with host lipoprotein metabolic pathways. Many articles have demonstrated prominent lipid metabolism disturbances with HCV genotype 3a (G3a). Although HCV G3a infection is extremely rare in Japan, abnormalities of lipids/lipoproteins are recognized in Japanese HCV G1b/G2 patients. In order to clarify abnormality of lipoprotein in chronic HCV infection, we examined serum apolipoprotein profiles, because apolipoprotein is present on the outer surface of lipoprotein particles and plays a crucial role in lipoprotein metabolism.
Methods: Fasting serum apolipoprotein profiles of 358 subjects with active or cleared HCV infection were examined. Basic laboratory data including lipids were examined at the same time. Concentrations of apo A-I, A-II, B, C-II, C-III, and E were measured by immunoturbidimetric assay using a commercially available kit according to the manufacturer's instructions (Sekisui Medical Co., LTD, Tokyo, Japan). Subsequently, the association between chronic HCV infection and serum apolipoprotein levels was determined using multiple regression analysis.
To clarify the significance of the genotype (G1b or G2) of actively infected HCV patients on the serum level of apolipoproteins/lipids, similar multiple regression analysis using indicator variables was performed.
Results: Active HCV infection was associated with high serum levels of apo A-II ($p < 0.001$) and low serum levels of apo C-II ($p = 0.04$) and C-III ($p < 0.001$). In contrast, active HCV infection was not found to be a significant factor affecting any alteration of serum lipid levels. HCV infection with both G1b and G2 was associated with low serum levels of apo C-III ($p < 0.001$), whereas only HCV G1b infections caused high levels of apo A-II ($p < 0.001$) and low levels of apo B ($p = 0.047$) and C-II ($p = 0.04$). Additionally, IFNL3 rs8099917 non-major genotype (TG/GG) was associated with high levels of apoA-II and low levels of serum apo B in chronic HCV G1b infection.
Conclusions: Our results demonstrate that active HCV infection is distinctively associated with characteristic serum apolipoprotein profiles. The influence on apolipoprotein profiles varies with different HCV genotypes. Moreover, genotype of IFNL3 affected serum apolipoproteins in HCV G1b infection.

P0740
USEFULNESS OF INTERFERON LAMBDA4-, HLA CLASS II-POLYMORPHISM AND KILLER-IMMUNGLOBULIN-LIKE RECEPTOR-2DL3:C1/C1 TO PREDICT SPONTANEOUS CLEARANCE OF ACUTE HEPATITIS C VIRUS INFECTION

Hofer[2]. *[1]Department of Internal Medicine III, Division of Gastroenterology and Hepatology, [2]Department of Internal Medicine III, Department of Gastroenterology and Hepatology, Medical University of Vienna, Vienna, [3]Hospital Oberndorf, Hospital Oberndorf, Oberndorf, [4]Hospital Elisabethinen, Hospital Elisabethinen, Linz, [5]Otto Wagner Spital, Otto Wagner Spital, [6]Department of Internal Medicine IV, Wilhelminen Spital, Vienna, [7]Department of Gastroenterology and Hepatology, Medical University of Graz, Graz, [8]Department of Blood Group Serology and Transfusion Medicine, [9]Department of Internal Medicine III, Division ofGastroenterology and Hepatology, Medical University of Vienna, Vienna, Austria*
E-mail: sandra.beinhardt@meduniwien.ac.at

Background and Aims: Spontaneous resolution of acute hepatitis C virus infection (AHC) largely depends on the patient's immunogenetic background. Besides IL-28B (rs12979860), Interferon-Λ4/rs469415590- and HLA-class-II/rs4273729 polymorphisms (PMs) as well as the detectability of killer-cell-immunoglobulin-like-receptor with its ligands (KIR)2DL3:HLA-C1/C1 might influence spontaneous clearance (SC) of AHC. We aimed to investigate if these genetic factors predict SC in patients with acute HCV-infection.
Patients and Methods: IL-28B/rs12979860-, IFNΛ4/rs469415590- and HLA-class-II/rs4273729 polymorphisms were determined in

163 patients [m/f: 97/66; age: 34.7±14.9 years (mean±SD); SC: N = 73]. Presence of KIR2DL3:C1/C1 was evaluated in 100 AHC-patients [m/f: 55/45; age: 35±15 years (mean±SD); SC: N = 61]. In addition 96 healthy individuals (healthy control [HCo]) were examined. IL28B-, interferon-Λ4- and HLA-class-II-PMs were analyzed by StepOnePlus-Real-Time-PCR. Presence of KIR2DL3:C1/C1 was determined by use of a commercial kit [HistoSpot, BAG, Lich, Germany].

Results: Since IFNΛ4-TT/TT and IL-28B C/C (rs12979860) genotypes were overlapping, both were equally predictive for spontaneous resolution of acute hepatitis C virus infection [IFNΛ4-TT/TT&IL28B-C/C: SC: N = 50/73 (68.5%) vs. non-SC: N = 45/90 (50%); P = 0.025]. Both SNP's were more frequent in patients with SC compared to the healthy controls [SC: 50/73 (68.5%) vs. HCo: 38/96 (39.6%); P < 0.001]. Neither the favorable HLA-II/rs4273729-genotype G/G [SC: N = 31/73 (42.5%) vs. non-SC: 29/90 (32.2%); P = 0.19] nor the detectability of KIR2DL3:HLA-C1/C1 [SC: N = 20/61 (32.8%) vs. non-SC: N = 10/39 (25.6%); P = 0.5] were found to be associated with SC.

Conclusions: Polymorphisms within IFNΛ4 or HLA-class-II as well as the detectability of KIR2DL3:C1/C1 could not improve predictability of SC in AHC-patients compared to the determination of IL28B/rs12979860 alone. Thus, their determination does not provide additional benefit to identify patients who will clear HCV spontaneously.

P0741

IMPACT OF PILL COUNT ON MEDICATION ADHERENCE DURING THE FIRST 12 WEEKS OF HIV ANTIVIRAL TREATMENT: IMPLICATIONS FOR HCV TREATMENT

T.R. Juday[1], R.W. Baran[1], S.R. Manthena[1], D.R. Walker[1]. *[1]Health Economics and Outcomes Research, Abbvie, North Chicago, United States*
E-mail: david.r.walker@abbvie.com

Background and Aims: The impact of pill count on adherence to the new all-oral antiviral hepatitis C (HCV) treatments has not been studied. In another therapeutic area where treatment consists of a combination of antiviral drugs – HIV – research has shown that pill count can negatively affect long-term adherence. However, unlike HCV where all-oral regimens generally involve only 12 weeks of treatment, ongoing treatment is required in HIV. To better understand the possible impact of pill count on adherence to a short-term HCV regimen, we examined the impact of pill count on adherence to the first 12 weeks of HIV treatment.

Methods: This retrospective study assessed real world adherence as proportion of days covered (PDC) over the first 12-weeks of treatment for HIV patients initiating first-line therapy. Three once-daily treatment regimens containing the same medications but in different formulations were examined:

- Cohort 1: Atripla (Efavirenz + Tenofovir + Emtricitabine); 1 pill per day,
- Cohort 2: Efavirenz + Truvada (Tenofovir + Emtricitabine); 2 pills per day,
- Cohort 3: Efavirenz + Tenofovir + Emtricitabine; 3 pills per day.

Analyses were conducted using MarketScan US commercial pharmacy claims and enrollment data (January 2003 through September 2013). Index date was first fill date for each drug combination. Inclusion criteria: continuous enrollment 6-month pre-index date and 3-month post-index date. Exclusion criteria: patients with a 90 day drug supply on initial fill, <18 years of age, and use of any HIV drug in the pre-index period or use of any other HIV drug besides cohort drugs in the post-index period. Generalized linear modeling was used to adjust adherence by age and gender. Statistical significance was defined as $p < 0.05$.

Results: Patients totaled 7411 for cohort 1, 562 for cohort 2, and 80 for cohort 3. Median age was 40, 41 and 40 years and percent male was 86%, 83% and 88% for cohorts 1, 2 and 3, respectively. The 12-week adjusted adherence rates were 83%, 81% and 81% in cohorts 1, 2, and 3, respectively. There was no statistically significant difference in adjusted adherence rates between any cohort. Male gender and older age were associated with better adherence.

Conclusions: These findings suggest that pill count does not appear to be a factor in antiviral medication adherence over the initial 12-weeks of treatment. As more all-oral HCV treatments become available, this research should be replicated in the HCV population.

P0742

HEPATITIS C TESTING IN PEOPLE ATTENDING AN INNER CITY DRUG MISUSE CENTRE – ARE SCREENING GUIDELINES ADHERED TO?

V. Appleby[1], E. Darnbrough[1], K. Forrester[1], C. Clarke[1], R. Simpson[1], S. Moreea[1]. *[1]Digestive Diseases Centre, Bradford Royal Infirmary, Bradford, United Kingdom*
E-mail: toryappleby@hotmail.co.uk

Background and Aims: Worldwide 130–170 million people have chronic hepatitis C (HCV); annually 350,000 deaths occur secondary to HCV cirrhosis and hepatocellular carcinoma [1]. The advent of direct acting antivirals has revolutionised HCV treatment but identifying those infected remains a barrier to treatment and virus eradication. Guidance states that annual screening for HCV should be performed in people accessing drug services; however testing in this group remains haphazard. We aim to review HCV screening in a large inner city substance misuse centre to establish whether guidelines are adhered to.

Methods: We reviewed the electronic medical records of every service user (SU) still registered at the unit as of October 2014 to establish the timing and result of their last screening test. When screening had not been performed in the preceding twelve months, we looked for reasons in the records.

Results: 550 SU attended the unit; 455 males (M) (83%) [age range (AR) 21–64, median age (MA) 41], 95 females (F) (17%) (AR 23–61, MA 39). 520 (95%) SU had been screened at least once since 2006, 30 (5%) SU had never been screened. 335/520 (64%) SU (277M, 58F) were HCV antibody (Ab) negative, 133 (26%) SU (117M, 16F) were HCV Ab positive PCR positive, 51 (9.9%) SU (37M, 14F) were HCV Ab positive PCR negative and 1 (0.1%) SU was Ab positive PCR unknown. In the HCV Ab negative cases, 113/335 (34%) had undergone screening in the last 12 months; 107 (32%) were screened between months 13–24, 48 (14%) between 25–36 months and 67 (20%) had not been screened for more than 3 years. Review of the records revealed that in 140/222 (63%) cases no reason was documented for not having annual screening. In 81 (36%) cases screening was declined by the SU and in 12% the reason stated was 'SU considers themselves not at risk'. Failed venepuncture was documented in 1 case (0.4%).

In the HCV Ab positive patients, 21/52 (41%) had been tested within the last 12 months, 10 (19%) tested between months 13–24, 12 (23%) between months 25–36, 9 (17%) had not been tested for more than 3 years.

Conclusions: Despite clear guidelines on HCV testing, this study highlights that annual testing in SU is not performed. Re-education of staff, access to less invasive testing methods including dry blood spot and additional staff to support screening requirements may all help to adhere to guidelines

INTERLEUKIN-6 IS ASSOCIATED WITH LIVER FIBROSIS IN HCV-INFECTED PATIENTS WITH ALCOHOL ABUSE

L.D. Silva[1,2], Y.G.G. Giampietro[2], B.D.M. Theobaldo[2], L.R. da Cunha[2], R. Teixeira[1,2], G.A. Rocha[3], D.M.D.M. Queiroz[3], O.A. Martins Filho[4], F.S. Neves[5]. *[1]Department of Internal Medicine, Faculdade de Medicina da Universidade Federal de Minas Gerais (UFMG), [2]Ambulatório de HepatitesVirais, Instituto Alfa de Gastroenterologia, Hospital das Clínicas, IAG-HC-UFMG, [3]Laboratory of Research in Bacteriology, Faculdade de Medicina da Universidade Federal de Minas Gerais (UFMG), [4]Diagnoses and Monitoring Biomarkers Laboratory, Instituto René Rachou, Fundação Oswaldo Cruz, [5]Department of Mental Health, Faculdade de Medicina da Universidade Federal de Minas Gerais (UFMG), Belo Horizonte, Minas Gerais, Brazil*
E-mail: lucianadinizsilva@gmail.com

Background and Aims: Both hepatitis C virus (HCV) and alcohol abuse cause chronic hepatic inflammation and alterations in serum inflammatory cytokines. The mechanisms by which alcohol worsens hepatitis C virus-related liver disease have not been fully clarified; however, impairment of host's immune response should be highlighted. In this context, the influence of cytokines on liver fibrosis needs to be well characterized. In this study, we investigated the association between interleukin (IL-6), IL-10, IL-17A and tumour necrosis factor (TNF-α) and liver fibrosis in HCV-infected patients with current or past alcohol abuse.

Methods: A total of 130 consecutive patients (73 females; mean age, 52.6±11.6 years) with chronic hepatitis C (CHC) were enrolled in the study. All patients completed several surveys including semi-structured interview, Mini-International Neuropsychiatry Interview (MINI-Plus 5.0) and CAGE screen (defined as two or more affirmative answers). The amount, frequency, and duration of use of alcohol were evaluated in CHC patients (alcohol abuse was defined as >20 g/day for females and >40 g/day for males). The diagnosis and staging of the underlying liver disease was based on standard clinical, biochemical, serological, radiological and histological parameters. The serum levels of IL-6, IL-10, IL-17A and TNF-α were determined by Cytometric Bead Array Assay. The protocol was approved by Ethical Board of UFMG. Data were analyzed with SPSS 17.0. Linear and logistic regression models were used to assess the association between cytokines and cirrhosis, adjusting for age, sex, body mass index and alcohol use.

Results: Baseline characteristics were: 102 (78.5%) with CHC and 28 (21.5%) with compensated cirrhosis; 43 (33.1%) with alcohol abuse. Higher levels of IL-6 was associated with alcohol abuse ($\beta = 0.43$; $t = 3.14$; $p = 0.003$) and hepatic necroinflammatory activity ($\beta = 0.41$; $t = 3.42$; $p = 0.001$). In multivariate analysis, cirrhosis was associated with higher levels of IL-6 (OR = 15.27; 95% CI 1.28–182.50; $p = 0.03$), but not with IL-10, IL-17A and/or TNF-α ($p > 0.05$). Cirrhosis was also associated with alcohol abuse/dependence (OR = 3.11; 95% CI 1.10–9.67; $p = 0.04$).

Conclusions: In the current study, alcohol abuse was associated with an imbalance in IL-6 production in CHC patients. Moreover, the highest levels of IL-6 were found in patients with hepatic necroinflammatory activity graded as moderate/severe. PROEX, PRPq, CAPEs, CNPq.

PREVALENCE OF CO-MORBIDITIES BY HEPATITIS C VIRUS STATUS IN THE U.S. POPULATION

M. Lazo[1], N. Daya[2], C. Nwankwo[3], K. Willis[4], M. Grams[5], E. Selvin[2]. *[1]Medicine, Johns Hopkins University, [2]Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, [3]Merck & Co., Inc, Whitehouse Station, [4]National Kidney Foundation, Lutherville, [5]Johns Hopkins University, Baltimore, United States*
E-mail: mlazo@jhu.edu

Background and Aims: An estimated 2.2–3.0% people worldwide are affected by hepatitis C virus (HCV) infection. Some people infected with HCV may also have other chronic common co-morbid conditions such as chronic kidney disease (CKD), obesity and type 2 diabetes mellitus, which may affect how they respond to treatment for HCV. The prevalence of these chronic co-morbid conditions amongst people infected with HCV has not been well characterized and may vary by country. Therefore, the purpose of this study was to provide estimates of the prevalence of common co-morbid conditions among people infected with HCV in the U.S.

Methods: A cross-sectional analysis was done using data from a representative sample of the non institutionalized U.S. adult population which was collected as part of the 1999–2012 National Health and Nutrition Examination Surveys (NHANES). Data from survey participants aged ≥20 years who received a physical examination at the Mobile Examination Center were included in the study. As part of NHANES, serum samples were analyzed for the presence of anti-HCV using Ortho HCV enzyme-linked immunosorbent assay (ELISA), and confirmed using a recombinant immunoblot assay (RIBA) (RIBA HCV 3.0 Strip Immunoblot Assay). Age, sex, and race adjusted prevalence estimates of common co-morbid conditions were calculated amongst persons with or without antibodies to HCV.

Results: Overall the prevalence of anti-HCV in the U.S. was 1.8%. Higher anti-HCV prevalence was observed among those aged 40–50 years of age (3.6%), non-Hispanic blacks (3.3%), men (2.4%), and those living in poverty (3.7%). Age, sex and race adjusted estimates of the prevalence of co-morbidities by anti-HCV status are shown in the Table. Compared to those anti-HCV negative, adults with anti-HCV positive results had significantly higher prevalence of hypertension, history of heart failure, stroke, albuminuria, and low cholesterol levels.

Table: Age, sex and race adjusted prevalence (95% CI) of selected co-morbid conditions in the U.S. adult population (NHANES 1999–2012) by anti-hepatitis C virus status

	Anti-HCV positive	Anti-HCV negative	P value
Diabetes, %	10.9 (7.8–14.11)	10.2 (9.7–10.6)	0.62
Uncontrolled diabetes (HbA1c >7%)	46.7 (30.9–62.5)	48.5 (45.8–51.1)	0.830
Hypertension, %	36.5 (32.6–40.5)	32.3 (31.3–33.3)	0.03
Congestive heart failure, %	4.9 (2.6–7.2)	2.3 (2.1–2.5)	0.002
Stroke, %	5.5 (3.6–7.5)	2.7 (2.4–2.9)	<0.001
Dyslipidemias [a], %			
Low total cholesterol	41.6 (36.6–46.7)	31.5 (30.8–32.2)	<0.001
Low LDL-cholesterol	42.7 (34.1–51.4)	29.5 (28.4–30.5)	0.002
Low HDL-cholesterol	24.7 (17.2–32.2)	27.8 (25.8–29.7)	0.46
Low triglycerides	27.9 (21.4–34.3)	28.6 (27.4–29.9)	0.82
Albuminuria [b], %	14.5 (10.9–18.1)	10.9 (10.4–11.4)	0.034
eGFR <60 mL/min/1.73m^2, %	18.5 (14.5–22.5)	16.5 (15.7–17.4)	0.302
Obesity, %	23.1 (19.0–27.2)	33.3 (32.3–34.3)	<0.001
Metabolic syndrome, %	19.3 (15.2–23.5)	15.4 (14.5–16.3)	0.06
Anemia, %	5.8 (3.8–7.8)	7.4 (6.8–8.0)	0.17

[a] Lowest sex-specific quartile of each lipid parameter: Total cholesterol <177 mg/dL for men and <180 mg/dL for women; LDL-cholesterol: <100 mg/dL for men and <96 mg/dL for women; HDL-cholesterol: <38 mg/dL for men and <46 mg/dL for women ; triglycerides: <90 mg/dL for men and <79 mg/dL for women.
[b] Albuminuria >30 mg/g.

Conclusions: The study suggests that there may be a substantial burden of co-morbid conditions among individuals who previously or currently are infected with HCV (anti-HCV positive). Additional analysis will have to be done to look at the prevalence of these co-morbid conditions in people with chronic HCV since these are the patients that will be the target for the new treatment regimens that are being developed.

Methods: We conducted a cross-sectional study in three referral hepatology centers in Northern and Southern regions of France and in Paris. Patients aged 18–70 with CHC mono-infection were prospectively enrolled and interviewed before treatment initiation. The structured questionnaire included the EQ-5D-3L instrument. Patients perceptions on CHC infection and new antivirals was also assessed. In particular, patients were asked if they found that the CHC disease progression over the past was: very comforting, rather comforting, rather worrying, very worrying. Determinants of the EQ-5D utility index, and the overall health, as measured by a visual analogue scale (VAS), were analyzed in mixed models taking into account the clustering effect of hepatology centers.

Results: By Nov. 2014, 357 patients were enrolled. Patients' main characteristics were: 51% male; mean (SD) age of 54.0 (9.6) years old; 55% had completed high school; 42% were overweight (BMI >25); 39% had severe comorbidities other than liver disease stage; 67% had CHC genotype 1; 33% had severe liver fibrosis (F3–F4); 49% were treatment-naïve, and patient had never been treated with new direct-acting antivirals (DAA). Overall, 12%, 56%, 25%, and 7% patients perceived that CHC disease progression was very comforting, rather comforting, rather worrying, very worrying, respectively.

In the univariate analysis, low EQ-5D utility index was associated with female gender, older age, lower education attainment, severe liver fibrosis, having severe comorbidities, being overweight, having psychiatric diseases, and a bad perception of CHC progression (Table). In the multivariate analysis, when individual perceptions on CHC disease progression were introduced in the model, in contrast to patients' characteristics and comorbidities, liver fibrosis stage was no more associated with EQ-5D utility index. Similar results were found with use of the VAS.

Conclusions: This study suggests that comorbidities and perceptions of CHC disease progression highly impact patient's quality of life. It would be important to evaluate the impact of highly efficacious new direct acting agents on these variables that may not be associated with the underlying liver disease.

LOW VIRAEMIA IN HCV-INFECTED HAEMODIALYSED PATIENTS DEPENDS ON IL28B GENOTYPE

S. Frankova[1], M. Jirsa[2], R. Senkerikova[3], M. Neroldova[2], M. Volfova[4], V. Hejda[5], D. Merta[6], O. Viklicky[7], J. Spicak[3], J. Sperl[1]. *[1]Institute for Clinical and Experimental Medicine, Prague, Czech Republic; [2]Laboratory of Experimental Hepatology, [3]Department of Hepatogastroenterology, Institute for Clinical and Experimental Medicine, Prague, [4]Hepato-gastro, Hradec Kralove, [5]Department of Internal Medicine, University Hospital, Plzen, [6]Department of Anesthesiology and Intensive Care, [7]Department of Nephrology, Institute for Clinical and Experimental Medicine, Prague, Czech Republic*
E-mail: sona.frankova@ikem.cz

Background and Aims: Low viraemia in HCV-infected haemodialysed patients have repeatedly been reported in the past. Two different hypotheses were postulated to explain this fact. The one hypothesis is a simple adsorption of the HCV virus on the haemodialysis membrane, the other hypothesis is based on an immune mediated decrease owing to higher levels of interferon alpha during haemodialysis session. The aim of or study was to support one of the mentioned hypotheses explaining low HCV RNA levels in haemodialysed patients.

Methods: The study compared pretreatment variables of 39 haemodialysed patients with 109 control patients with normal renal function. All patients in both groups were infected with HCV genotype 1b and were treated with pegylated interferon alpha and ribavirin. Viraemia below 600,000 IU/ml was considered as low.

Results: Pretreatment viraemia was significantly lower in haemodialysed patients than in controls (median HCV RNA 193,000 IU/ml, IQR 16,000–810,000 IU/ml; median 540,500 IU/ml, IQR 163,250–1,852,500 IU/ml, respectively, $p = 0.003$). IL28B CC

genotype carriers among haemodialysed patients had significantly lower viraemia, such a difference was not found in controls (see Figure). No other factors associated with low pretreatment viraemia in haemodialysed patients were found (age, sex, BMI, duration of haemodialysis). Haemodialysed patients with low pretreatment vireamia (10/11 CC genotype carriers and 14/28 non-CC genotype carriers) achieved significantly higher SVR rate ($p < 0.001$) than patients with high viraemia (1/11 and 0/10, respectively).

Conclusions: Low HCV vireamia in haemodialysed patients may be caused by a so far unknown immune mediated mechanism which is more pronounced in IL28B CC genotype carriers and facilitates interferon alpha induced clearance of the virus.

	Haemodialysed patients		Controls	
IL28B genotype	CC	Non-CC	CC	Non-CC

HEALTH RELATED QUALITY OF LIFE AND UTILITY VALUES IN CHRONIC HEPATITIS C PATIENTS: A CROSS-SECTIONAL STUDY IN FRANCE, THE UK AND GERMANY

S. Pol[1], J. Chevalier[2], S. Branchoux[3], R. Perry[4], G. Milligan[4], A.-F. Gaudin[3]. *[1]Hepatology, Cochin Hospital, Paris, [2]Chaire ESSEC, Cergy-Pontoise, [3]Health Economics & Public Health, Bristol-Myers Squibb, Rueil-Malmaison, France; [4]Adelphi Real World, Bollington, United Kingdom*
E-mail: sebastien.branchoux@bms.com

Background and Aims: Accurate measuring of Health Related Quality of Life (HRQoL) is a major issue, especially in chronic disease as Chronic Hepatitis C (CHC). HRQoL could be derived as weights within quality-adjusted life year measurement (utility values), one of the frequently used outcomes in cost-effectiveness analysis. No utility values stratified by CHC health state have been retrieved in France. Recent data on HRQoL are also scarce. Two objectives of this study were to estimate HRQoL and utility values of CHC patients in 3 European countries.

Methods: This study is a cross-sectional one using data from the Adelphi Hepatitis C Disease Specific Programme implemented in France, the UK and Germany. In each country, 60 physicians recruited 10 consecutive CHC out-patients. They were asked to collect patients' demographic and clinical characteristics. Patients were invited to complete the EQ-5D questionnaire. This questionnaire is composed of two sections: (1) a description of the health state on 5 dimensions converted to a single value (called utility); (2) a Visual Analogue Scale (VAS) ranging from 0 to 100 (worst to best imaginable health state), known as a proxy of HRQoL. In order to improve accuracy of the utility values, clinically similar health states were merged. The French value set was used to derive utilities. For HRQoL, influence of patients' characteristics has been studied using univariate analyses and generalized least squares random effects model. Both utility values and VAS scores were presented by health state.

Results: 831 patients filled out the EQ-5D questionnaire. The mean age was 47.1±14.1 years old; 58.8% of them were male. French patients were slightly older; a higher proportion of patients infected by drug injection was found in the UK. As expected, as liver disease progressed, utility values decreased (Table). Increase in utility values was higher in patients with a Sustained Virologic Response (SVR) from F2–F3–F4 fibrosis stage (+27%). For HRQoL, results from multivariate analysis showed that 4 variables had significant negative impact: liver disease stage, number of concomitant conditions, being an intravenous drug user and being unemployed. Positive response to treatment and having some knowledge about the disease had a positive impact on HRQoL.

Table. VAS and utility mean scores stratified by health state

Health state (N = 831)	VAS, Mean (SE)	Utility, Mean (SE)
F0–F1 (N = 239)	72.0 (1.08)	0.82 (0.02)
F2 (N = 246)	65.2 (1.10)	0.78 (0.02)
F3–F4 (N = 101)	55.9 (1.98)	0.67 (0.03)
Decompensated cirrhosis / Hepatocellular carcinoma (N = 25)	55.4 (3.73)	0.51 (0.07)
Liver transplant		
initial year (N = 5)	52.0 (3.74)	0.46 (0.10)
subsequent years (N = 10)	73.0 (6.48)	0.80 (0.08)
Unclassified (N = 205)	67.5 (1.40)	0.79 (0.02)
SVR		
from F0–F1 (N = 35)	80.2 (2.46)	0.95 (0.01)
from F2–F3–F4 (N = 36)	66.1 (2.68)	0.85 (0.02)

Conclusions: This utility value set might be helpful to populate cost-effectiveness analysis. Consideration of EQ-5D and CHC-specific HRQoL questionnaires in large national studies will be useful for confirming these findings.

P0748

COURSE OF HCV RNA AND HCV CORE ANTIGEN TESTING ARE PREDICTORS FOR REACHING SVR IN TRANSPLANT RECIPIENTS

S. Pischke[1], M. Lang[1], S. Polywka[2], S. Jordan[1], S. Stauga[1], S. Meisner[1], B. Nashan[3], A.W. Lohse[1], M. Sterneck[1]. *[1]Gastroenterology, [2]Medical Microbiology, [3]Transplant surgery, University Hospital Hamburg Eppendorf, Hamburg, Germany*
E-mail: s.pischke@uke.de

Background and Aims: Hepatitis C in liver transplant recipients (LTR) is associated with reduced graft survival. The former standard therapy consisting of peg interferon and ribavirin was associated with the risk of rejection and with relevant side effects. The new direct acting antivirals (DAAs) seem to be a safe and efficient therapeutic option, but the knowledge on the use of these cost intensive drugs in LTR is limited. Thus a predictor of sustained virological response (SVR) is needed to identify LTR who benefit from this expensive therapy. The HCV antigen assay (HCV Ag) has shown to be a cheap and efficient method to detect HCV but the value of this technique to predict SVR in LTR still needs to be determined.

Methods: All LTR who have been treated with Sofosbuvir at our center between 03/2014 and 08/2014 were analysed (n = 20). HCV Ag and HCV RNA (PCR) were determined each visit (week 1, 2, 4, 8, 12 and 24 of treatment). Primary endpoints of this study were SVR 4 and SVR 12.

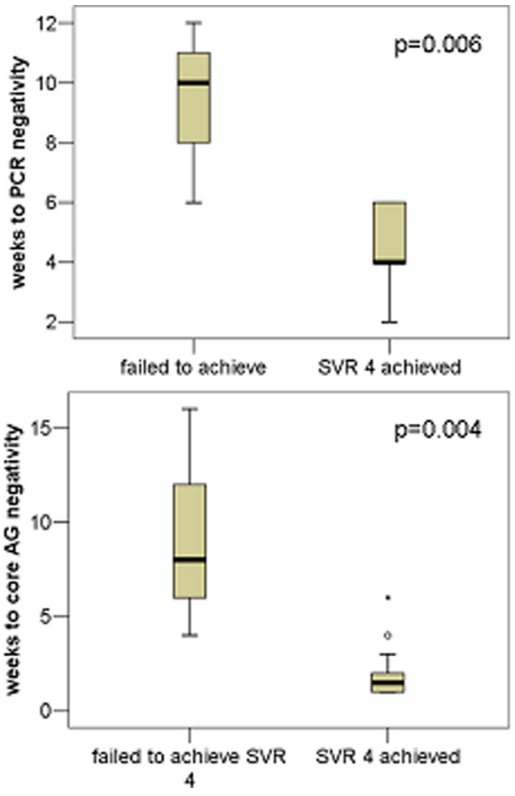
Results: To date 20 patients have been treated. The majority was male (n = 14, 70%). The age ranged from 31–68 years (mean 56). Mean baseline HCV RNA was 3506500 IU/mL [range 5000–10,000,000 IU/mL]. Patients were infected with HCV genotype (GT) 1 (n = 12), GT 2 (n = 3), GT 3 (n = 1), GT 1 and 3 (n = 1) and GT 4 (n = 3). Patient's immunosuppresion contained CSA (n = 3), CSA and MMF (n = 6), CSA and Pred (n = 1), Tac (n = 3), Tac and EVR (n = 3), Tac and MMF (n = 1) and Tac and Pred (n = 1). DAA medication consisted of sofosbuvir plus ribavirin (n = 14), sofosbuvir, simeprevir and ribavirin (n = 5) and sofosbuvir, peg interferon and ribavirin (n = 1).

HCV core antigen tested negative after a mean of 3 weeks (range 1–16) and PCR tested negative after a mean of 5 weeks (range 2–12).

Currently 18 patients have reached week 4 after end of treatment and 15/18 (83%) achieved SVR 4. A short interval between treatment start and HCV PCR negativity ($p = 0.006$) or HCV Ag negativity ($p = 0.004$) was associated with reaching SVR 4 (figure). No severe side effects were observed.

Conclusions: DAA treatment is safe and well tolerated in LTR. The time point of HCV Ag loss and PCR negativity was a predictor of SVR 4. In this pilot study the HCV Ag seems to be superior to predict

SVR in comparison to PCR (p = 0.004 vs p = 0.006). However we can currently not draw further valid conclusions as SVR 12 results are pending.



P0749

IMPLICATION OF TYPE 2 DIABETES SUSCEPTIBILITY LOCI IN HEPATITIS C VIRUS INFECTION

W. Zhang[1], H. Rao[1], L. Wei[1]. [1]*Peking University People's Hospital, Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Diseases, Beijing, China*
E-mail: jiesuifanny@163.com

Background and Aims: There is a significant association between hepatitis C virus (HCV) infection and the risk of type 2 diabetes (T2D). However, the implications of genetic susceptibility loci for T2D in populations with HCV infection are unclear. We therefore conducted a study to detect susceptibility loci for T2D in Chinese infected with HCV.

Methods: A total of 100 representative single-nucleotide polymorphisms (SNPs) in susceptibility loci for T2D that were previously reported in GWAS were genotyped in 762 Han Chinese with HCV infection by using illumina infinium iSelect HD Custom Genotyping BeadChips.

Table 1. Baseline of patients infected with HCV.

	Spontaneous clearers (N = 155)	HCV persisters (N = 607)
Age (years), mean±SD	51.88±7.44	48.84±10.16
Gender (male/female)	76/72	334/231
HCV genotype (1b/others)	NR	217/107
HCV RNA levels (high/low)	NR	494/107

Data are presented as mean± standard deviation.
HCV RNA levels: high, ≥5 log IU/mL; low, <5 log IU/mL.

Results: 607 patients infected with HCV (persisters) and 155 spontaneous resolvers were enrolled in this study. Baseline characteristics of the patients are shown in Table 1. Table 2 summarizes the results of these SNPs. Sixteen genetic variants (rs340874, rs243021, rs6712932, rs780094, rs4689388, rs12518099, rs864745, rs3802177, rs896854, rs564398, rs649891, rs1111875, rs1552224, rs5219a, rs1359790, and rs7119) were not identified, and 14 SNPs with minor allele frequency (MAF) < 0.05 (rs10923931, rs7578597, rs11708067, rs10010131, rs1801214, rs7636, rs12255372, rs4506565, rs7901695, rs7903146, rs1153188, rs7957197, rs8042680, and rs11642841) were excluded in the following analyses. In comparison with data of Han Chinese from HapMap (Table 3), the higher risk allele frequencies of 21 SNPs (rs11677370, rs7593730, rs4607103, rs10440833, rs4712523, rs6931514, rs7756992, rs9465871, rs4607517, rs972283, rs13266634, rs10741243, rs12779790, rs2237892, rs5215, rs1495377, rs730570, rs11634397, rs7172432, rs472265, and rs2833610) were reported in HCV persistence and spontaneous resolvers. There were no significant differences between HCV persistence and spontaneous resolvers (P < 0.05). Among them, the risk allele frequency of rs1495377 mapped in *TSPAN8-LGR5* was three times higher than that in general population in China. The risk allele frequency of rs7020996 in HCV persistence was higher than that in spontaneous resolvers (P < 0.05). On the contrary, the risk allele frequencies of rs2063640, rs5015480 and rs6583826 in spontaneous resolvers were higher (P < 0.05).

Conclusions: This is the first study performed to examine the prevalence of risk allele in susceptibility loci for T2D in Chinese with HCV infection. Our results suggest that 21 SNPs with higher risk allele frequencies should be explored.

P0750

ENHANCED LIVER FIBROSIS (ELF) TEST DOES NOT PREDICT RESIDUAL CIRRHOSIS AFTER A SUSTAINED VIROLOGICAL RESPONSE TO HEPATITIS C TREATMENT

R. D'Ambrosio[1], E. Degasperi[1], M. Fraquelli[2], P. Riccardo[1], A. Aghemo[1], P. Lampertico[1], P. Bedossa[3], W. Rosenberg[4], M. Colombo[1]. *[1]Division of Gastroenterology and Hepatology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, [2]Division of Gastroenterology and Endoscopy, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [3]Pathology Department, Beaujon Hospital, Assistance Publique-Hôpitaux de Paris, Clichy, France; [4]Institute for Liver and Digestive Health, Division of Medicine, University College London, London, United Kingdom*
E-mail: massimo.colombo@unimi.it

Background and Aims: Regression of cirrhosis is a potential clinical benefit of successful interferon alfa (IFN) therapy of hepatitis C virus (HCV) infection. Non invasive serum assays and transient elastography (TE) have suboptimal accuracy for diagnosis of cirrhosis in patients who achieved a cure of infection (SVR), yet the diagnostic accuracy of serum assays based upon direct markers of liver fibrosis is unknown. The aim is to investigate the accuracy of Enhanced Liver Fibrosis (ELF) test in identifying residual cirrhosis in SVR patients.
Methods: HCV patients with histologically diagnosed cirrhosis and a post-SVR liver biopsy (LB) were investigated with ELF test at baseline and after an SVR. Four cut-offs were used for the diagnosis of cirrhosis i.e. 9.5, 9.8, 10.3 and 11.3 and compared to histological staging of fibrosis by METAVIR. ELF performance was calculated using receiver operating characteristic (ROC) curves analysis.
Results: 19/29 patients (66%) had cirrhosis regression after a median of 61 (48–104) months from an SVR. Overall, median ELF values decreased from 10.7 to 8.6 at the time of SVR ($p < 0.0001$), independently from cirrhosis regression ($p < 0.0001$ in regressed and $p = 0.001$ in non-regressed patients). None of the four cut-offs showed an acceptable diagnostic accuracy for the identification of residual cirrhosis, as 4%, 3%, 0% and 0% of the patients showed the 9.5, 9.8, 10.3 and 11.3 cut-offs. By ROC analysis, the derived 8.1 cut-off was the most accurate however with a suboptimal performance (Sn 50%, Sp 68%, LR+ 1.58, LR− 0.73, AUROC 0.54). In SVR patients, ELF test did not show any correlation with fibrosis stage ($r = 0.34$), area of fibrosis ($r = 0.29$), or histological grading ($r = 0.35$) which did correlate with ELF test at baseline ($p = 0.02$).
Conclusions: ELF test, a direct marker of liver fibrosis, does not accurately identify residual cirrhosis in HCV patients who achieved an SVR, thus LB remains the reference standard for this endpoint.

P0751

POLYMORPHISMS IN THE FAS PROMOTER REGION ARE NOT ASSOCIATED WITH FIBROSIS PROGRESSION IN HCV-1 AND -4 PATIENTS

S. De Nicola[1], E. Galmozzi[1], R. D'Ambrosio[1], A. Aghemo[1], R. Perbellini[1], E. Grassi[1], M. Colombo[1]. *[1]Division of Gastroenterology and Hepatology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy*
E-mail: massimo.colombo@unimi.it

Background and Aims: Identification of patients with chronic hepatitis C virus (HCV) infection and rapid fibrosis progression has significant prognostic and therapeutic implications. The rs1800682 A>G genetic polymorphism in the promoter region of the FAS gene, which is involved in liver cells apoptosis, has been associated with histological activity and lesser stages of fibrosis in HCV-4 Egyptian patients carrying the A allele. Its impact in HCV-1 patients as well as in HCV-4 patients of European descent is unknown.

Methods: We analyzed data from 2 published patients cohorts of HCV-1 and 4 patients with at least one pre-treatment liver biopsy. Liver staging and grading were evaluated using the Ishak Score. In patients with known date of infection, the fibrosis progression rate (FPR) was calculated as the ratio between biopsy staging score and years of disease. Genotype was assessed by using TaqMan SNP Genotyping Assay.
Results: Overall, 203 HCV infected patients (121 HCV-1, 82 HCV-4 of them 61% Egyptians) were analyzed. The date of infection could be estimated in 131 of them. No differences in rs1800682 distribution was observed between Italian and Egyptian patients: AA/AG 106/152 (69%), GG 46/152 (31%) *vs* AA/AG 34/50 (68%), GG 16/50 (32%). No differences in median FPR values were observed in subjects carrying the AA/AG or the GG genotypes (0.12 *vs* 0.13). In genotype 4 patients the different rs1800682 genotypes were equally distributed in patients with mild (S0–S1) fibrosis (AA/AG vs. GG: 72% vs 28%) and advanced (S3–S6) fibrosis (AA/AG vs. GG: 74% vs. 26%), p = 1.0. In HCV-1 patients we observed a protective role of A allele (AA/AG) in genotype 1 patients with mild fibrosis vs. advanced fibrosis: 52/70 (72%) vs. 28/51 (54%), p = 0.033. No impact of the rs1800682 polymorphism was seen on histological activity both overall and stratified by HCV genotype: Grading ≥7: AA/AG 54/83 (65%), GG 29/83 (35%); Grading <7: AA/AG 86/120 (71%), GG 34/120 (29%), p = 0.3.
Conclusions: The rs1800682 polymorphism is not a useful genetic predictor of liver fibrosis progression when assessed through FPR, fibrosis stage or inflammation grade in HCV genotype 1 and 4 patients.

P0752
NOTCH4 AND MHC CLASS II POLYMORPHISMS CONTIBUTE TO HCV-RELATED BENIGN AND MALIGNANT LYMPHOPROLIFERATIVE DISEASES

A. Piluso[1], L. Gragnani[1], A. Genovesi[1], V. De Re[2], M. Libra[3], A.L. Zignego[1]. *[1]Department of Experimental and Clinical Medicine, University of Florence, Florence, [2]Bio-Proteomics Facility, Department of Translational Research, CRO, National Cancer Institute, Aviano, [3]Department of Biomedical Sciences, Section of Pathology and Oncology, Laboratory of Translational Oncology and Functional Genomics, University of Catania, Catania, Italy*
E-mail: alepilu80@libero.it

Background and Aims: Hepatitis C virus (HCV) leads to chronic liver disease, but more rarely it causes lymphoproliferative disorders (LPDs). The most frequent HCV-related LPD is mixed cryoglobulinemia (MC). MC is clinically benign, but it evolves in about 10% of cases into a non Hodgkin's lymphoma (NHL). The exact pathogenesis of HCV-related LPDs is still unknown and few and conflicting data exists about the host genetic contribution. Recently, a GWAS study allowed the discovery of an association of two particular SNPs on chromosome 6 and HCV-related MC vasculitis; the first one is a SNP (rs2071286) located in an intronic region of the NOTCH4 gene, the second one is a SNP (rs9461776) located between HLA-DRB1 and HLA-DQA1 gene segments.
Aim: To define the contribution of rs2071286 and rs9461776 in the predisposition to develop HCV-related LPDs (MC and NHL).
Methods: rs2071286 and rs9461776 SNP were determined using TaqMan SNP Genotyping Assay in 438 patients: 85 HCV patients without LPDs (HCV), 73 HCV patients with circulating cryoglobulins (MC-HCV), 108 with HCV-associated MC syndrome (MCS-HCV), 62 with HCV-related NHL (NHL-HCV) and 110 HCV negative patients with NHL (NHL).
Results: Concerning rs2071286, significantly higher minor allele frequency (maf) was observed in all the case groups respect to controls (MC-HCV, $p = 0.035$; MCS-HCV, $p < 0.001$; NHL-HCV, $p = 0.001$ and NHL, $p = 0.019$). Comparing to HCV group, the odds-ratio associated with rs2071286 maf were: MC-HCV, OR 1.79; MCS-HCV, OR 2.59; NHL-HCV, OR 2.6; NHL, OR 1.81.
Regarding rs9461776, the higher maf was observed in NHL-HCV and in NHL groups ($p = 0.011$ and $p = 0.0283$ respect to HCV, respectively). Furthermore, we described an increasing trend, although not significant, following the evolution of the LPDs. The presence of minor allele of rs9461776 conferred an OR of 2.42 to NHL-HCV and an OR of 1.7 to NHL group, in respect to controls.
Conclusions: We confirm the previously demonstrated association between the two SNPs and HCV-related MC vasculitis (Zignego et al, 2014), and showed a similar associations for HCV-related NHLs and, regarding NOTCH4 SNP, also for patients with CGs but without symptoms. Furthermore, HCV negative NHLs showed higher frequencies of the two minor alleles respect to controls, but lower compared to HCV positive lymphomas. This suggests that HCV acts on a permissive genetic substrate and confirms the virus contribution to the pathogenesis of lymphoma.

P0753
GENETIC POLYMORPHISMS OF IL28B AND PNPLA3 ARE CLOSELY ASSOCIATED WITH FIBROSIS PROGRESSION IN CHRONIC HEPATITIS C

N. Tamaki[1], M. Kurosaki[1], Y. Yasui[1], S. Suzuki[1], T. Hosokawa[1], K. Tsuchiya[1], H. Nakanishi[1], J. Itakura[1], N. Izumi[1]. *[1]Department of Gastroenterology and Hepatology, Musashino Red Cross Hospital, Tokyo, Japan*
E-mail: tamaki@musashino.jrc.or.jp

Background and Aims: The assessment of individual risk of fibrosis progression in patients with chronic hepatitis C who failed interferon based antiviral therapy is an unmet clinical need.
Methods: Genetic risk factors associated with fibrosis progression were analyzed in 176 viremic patients who did not achieve sustained virological response by interferon-based therapy and linked to the fibrosis progression rate (FPR). FPR was determined in all patients by paired liver biopsy performed before and after therapy (mean interval: 6.2 years).
Results: Mean FPR in patients with IL28B (rs8099917) TG/GG and PNPLA3 (rs738409) CG/GG were significantly higher than in those with IL28B TT (FPR: 0.144 vs. 0.034, p < 0.001) and PNPLA3 CC (FPR: 0.10 vs. 0.018, p = 0.005), respectively. IL28B TG/GG [hazard ratio (HR): 2.1, p = 0.003] and PNPLA3 CG/GG (HR: 2.5, p = 0.004) remained independent predictors of fibrosis progression upon multivariate analysis together with age ≥60 years (HR: 2.2, $p = 0.003$), and average alanine aminotransferase after interferon therapy ≥40 IU/l (HR: 2.2, $P = 0.005$). Based on these data, we developed a new clinical score predicting the risk of fibrosis progression. This score identified subgroups of patients with a low (FPR: 0.00, HR: 1), intermediate (FPR: 0.06, HR: 3.0, $p = 0.007$), and high (FPR: 0.17, HR: 7.5, $p < 0.001$) risk of fibrosis progression. Further, cumulative incidence of hepatocellular carcinoma development was significantly higher in high risk patients than other patients ($P = 0.006$).
Conclusions: *IL28B/PNPLA3* genotypes are associated with rapid fibrosis progression.

P0754
CLINICAL SIGNIFICANCE OF DRUG–DRUG INTERACTIONS DURING THERAPY WITH NOVEL DAAS AGAINST HCV

C. Hoener Zu Siederdissen[1], B. Maasoumy[1], F. Marra[2], K. Deterding[1], K. Port[1], M.P. Manns[1], M. Cornberg[1], D. Back[2], H. Wedemeyer[1].
[1]Department of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany; [2]Department of Molecular and Clinical Pharmacology, University of Liverpool, Liverpool, United Kingdom
E-mail: hoenerzusiederdissen.christoph@mh-hannnover.de

Background and Aims: Up to 50% of hepatitis C virus (HCV) infected patients (pts) are at risk for clinically significant drug–drug interactions (DDI) between first wave protease inhibitors (boceprevir/telaprevir) and their regular outpatient medication. This risk is considered to be lower with the second wave direct-acting antiviral agents (DAA) sofosbuvir (SOF), simeprevir (SMV), daclatasvir (DCV) and ledipasvir/sofosbuvir (LDV/SOF). We here aimed to evaluate the risk for DDI between the regular outpatient medication and recently approved DAAs.
Methods: Concomitant outpatient medication including over-the-counter medicine and herbals was assessed in 261 unselected HCV-monoinfected pts that were evaluated for antiviral treatment at Hannover Medical School between 2011–2014.
DDI between the regular outpatient medication and the DAAs SOF, SMV, DCV and LDV/SOF were evaluated using the website www.hep-druginteractions.org and the prescribing information of all analyzed drugs. DDIs were classified in four different categories (0=Classification not possible due to lack of information, 1=no significant interactions, 2=moderate interaction, may need dose adjustment/monitoring, 3=co-administration not recommended).
Results: The 261 pts took 188 different drugs with a median of 2 drugs per patient (range 0–15). Importantly, only one drug (eslicarbazepine) (0.5%) taken by one patient (0.4%) was a category 3 drug for all four DAAs. Monitoring/dose adjustment (category 2) was recommended in the case of LDV/SOF for 18 drugs (10%) affecting 127 pts (49%). For SOF this was 5 drugs (3%) affecting 25 pts (10%), for SMV 30 drugs (16%) in 101 pts (39%) and DCV 20 drugs (11%) in 116 pts (44%).
Drugs taken for cardiovascular diseases (ATC C) were frequently affected by DDI with 16 of 41 drugs (39%) showing a potentially significant interaction with at least 1 of the four DAAs. Drugs taken for diseases of the nervous system (ATC N) showed DDIs in 11 of 36 drugs (31%).
DDI could not be assessed due to lack of information for 32 drugs (17%) in 72 pts (28%). Eighteen of these drugs (56%) were herbals or nutritional supplementations.
Conclusions: Treatment with recently approved DAA is associated with a low potential for serious DDI (category 3). However, moderate DDI are frequent and have to be considered in order to prevent adverse effects or a lack of antiviral efficacy.

P0755
HEPATITIS C INFECTION IS ASSOCIATED WITH AN INCREASE IN CARDIOVASCULAR DISEASES

F. Wubiee[1], C. Howell[2]. *[1]Medicine, Howard University, [2]Medicine, Howard Unviversity, Washington, DC, United States*
E-mail: firewmw@yahoo.com

Background and Aims: Chronic Hepatitis C virus (HCV) infection is associated with insulin resistance, diabetes mellitus and systemic inflammation, which predisposes to atherosclerosis that may increase cardiovascular events.
The aim of this study is to explore the association of HCV infection and cardiovascular events in and analyze the impact of HCV on cost and length of stay in patients with cardiovascular disorders.
Methods: We used the weighed 2011 Nationwide Inpatient Sample (NIS) data to characterize patients with HCV infections. We identified all patients who had a cardiovascular event [Acute myocardial infarction (AMI) n = 201,950, coronary artery disease (CAD) n = 1,454,012, congestive heart failure (CHF) n = 944,870 and cerebrovascular accident (CVA) n = 53,623] in their primary discharge diagnosis for the 2011 data. Patients were compared based on their exposure (HCV) status in relation to cardiovascular outcomes.
Results: The inpatient prevalence of diagnosed HCV infection was 1.9%. Patients with HCV infection tended to be younger, poorer, male, smokers, alcohol consumers diabetic, minorities and more likely to die in the hospital compared to those without diagnosed HCV.
For patients with HCV infection, the adjusted odds ratio was for AMI (OR: 2.29, CI: 2.22–2.36), CAD: (OR: 1.88, CI: 1.83–1.93), CVA (OR: 1.98, CI: 1.93–2.04) and congestive heart failure: OR 1.08 (1.06–1.10).
The inpatient treatment cost and length of hospital stay of HCV patients with cardiovascular morbidity were consistently and significantly higher than non-HCV patients.
Conclusions: HCV is associated with a higher risk of developing a cardiovascular outcome, increased cost of care and length of hospital stay. HCV need to be considered a cardiovascular risk factor.

P0756
HEPATITIS C REINFECTION RATES FOLLOWING TREATMENT INDUCED SVR IN PATIENTS WHO ACTIVELY INJECT DRUGS AT THE TIME OF TREATMENT

J.M. Baxter[1], A. Verma[2], F.J. Vilar[1]. *[1]Infectious Diseases, North Manchester Hospital, [2]Manchester University, Manchester, United Kingdom*
E-mail: joanne.baxter@pat.nhs.uk

Background and Aims: Data on reinfection rates following treatment induced SVR in actively injecting drug users warrants further clarification1. This was the main aim of our study. Actively injecting drug users are often excluded from treatment or participation in clinical trials. One main barrier is the perception that they will be reinfected with hepatitis C2.
Methods: This is a prospective study looking at reinfection rates in a cohort of intravenous drug users that have been treated and achieved SVR with pegylated interferon and ribavirin. Potential participants were identified from our hepatitis C database. A group was identified who were actively injecting in the six months prior to treatment. This group included those who continued to inject during treatment. These are the 'current' drug using group. A second group that stopped injecting at least six months prior to treatment were identified. These are the 'past' drug using group. Information was collected on different outcomes including reinfection rates using annual HCV RNA (with subsequent genotyping if positive) and liver disease progression using liver function blood tests and fibroscan.
Results: Sixty patients were recruited, 36 classified as 'current' IDUs at the time of treatment and 24 'past' IDUs. There were two cases of reinfection in the 'current' group and no cases in the 'past' group. Both cases of reinfection were with a new genotype. The time between SVR and reinfection was 61 months in case one and 30 months in case two. The total duration of patient follow up was 245.9 years. The rate of reinfection was 0.81 cases per 100 patient years. If we examine only the 'current' IDU group, the rate of reinfection was 1.57 cases per 100 patient years.
Conclusions: This low rate of reinfection in current IDUs provides confidence as we move into the era of treatment with DAAs. Inclusion of current drug users in DAA programs is important to provide real life data on reinfection following SVR with these newer agents, in this group with the highest potential for onward transmission.

P0757
EXPRESSION OF INHIBITORY CD158B AND CD158E NK CELL RECEPTORS IS ASSOCIATED WITH SIGNIFICANT LIVER INJURY IN THE COURSE OF CHRONIC HEPATITIS C IN CHILDREN

A. Mania[1], M. Kaczmarek[2], P. Kemnitz[1], I. Mozer-Lisewska[3], M. Figlerowicz[1], J. Sikora[2], W. Sluzewski[1], J. Żeromski[2]. *[1]Department of Infectious Diseases and Child Neurology, [2]Chair of Clinical Immunology, [3]Department of Infectious Diseases, University of Medical Sciences Poznań, Poznań, Poland*
E-mail: maniaanna@hotmail.com

Background and Aims: Although chronic hepatitis C (CHC) has relatively mild clinical course in children, some patients may develop significant liver lesions including liver cirrhosis still in childhood. Determination of such patients is extremely important for proper clinical management. NK cells play an important role in innate immune response and their high proportion is situated in the liver.
The aim of this study was to analyse possible relation between NK cells and the expression of their receptors and varied intensity of liver lesions in the course of CHC in children.
Methods: Study included 106 children with CHC – 54 boys and 52 girls, age 13.62±3.48 years. Blood for biochemical, virological and cytometric testing was taken prior to the liver biopsy. Histological evaluation was preformed according to METAVIR scoring system. NK cells was evaluated by flow cytometry.
Results: In 58 children with CHC (55.2%) significant liver fibrosis was observed assessed at least F2 in METAVIR scoring system. In 18 children (17.2%) advanced liver fibrosis was found. Number of NK cells was comparable in the subgroups of children with varied ALT activity, presence of significant and advanced fibrosis and liver steatosis. Higher proportion of cells expressing CD158e inhibitory receptors was observed in the group of children with ALT >2UNL (21.11±14.60 vs 12.22±8.99%; $p = 0.037$). While higher proportion of cells expressing inhibitory CD158b receptor was observed in children with advanced fibrosis ($F \geq 2$) compared to minimal fibrosis ($F < 2$) – 34.14±12.44 vs. 27.48±8.71%; $p = 0.049$. Similar findings regarded MFI of CD158b in children with advanced fibrosis ($F \geq 3$) compared to fibrosis <3 – 5344.20±3407.49 vs 2979.67±1190.64; $p = 0.049$. Number of NK cells with the expression of CD158b was found a predictor of significant fibrosis in univariate analysis – OR 1.065; 95% CI 1.07–1.15; $p = 0.046$.
Conclusions: Higher proportion of NK cells with the expression of inhibitory CD158b and CD158e receptors is associated with liver injury expressed as higher aminotransferase activity, more advanced liver fibrosis and the presence of steatosis.

P0758
THE RELATIONSHIP BETWEEN HEPATITIS C RELATED LIVER DISEASE WITH DIABETES MELLITUS AND VITAMIN D

V. Gupta[1], A. Kumar[1], P. Sharma[1], A. Arora[1]. *[1]Department of Gastroenterology and Hepatology, Sir Ganga Ram Hospital, New Delhi, India*
E-mail: varun_doc@yahoo.co.in

Background and Aims: The high prevalence of Diabetes mellitus and vitamin D deficiency among HCV patients is a cause for concern. The effect of diabetes mellitus and levels of 25-Hydroxy Vitamin D on cirrhosis, decompensation and HCC remains unclear in HCV patients. This study iis aimed to assess the influence of diabetes mellitus and levels of 25-Hydroxy Vitamin D on hepatitis C related liver disease patients
Methods: In this retrospective study, all patients who tested positive for Anti-HCV from December 2010 to August 2014 and presented to department of Gastroenterolgy and Hepatology at our center were included and were reviewed for gender, age, diabetes, genotype, level of 25-Hydroxy Vitamin D, status of liver disease including HCC at inclusion. The association of diabetes mellitus and low 25-Hydroxy Vitamin D levels (<30 ng/mL) with liver status and child pugh class (CTP) was analyzed
Results: A total of 777 patients were included in the study. At presentation 439 (56%) patients had cirrhosis; including 51 (7%) with HCC and 287 (37%) had chronic hepatitis. 25-Hydroxy Vitamin D level was available in 206 patients at baseline. Low 25-Hydroxy Vitamin D level was present in [126/206 (61%)] of the patients. Diabetes mellitus was present in [165/777 (21%)] of the patients. Diabetes was associated more commonly with genotype 1 and 4 [25% (35/139)] in comparison to genotype 2 and 3 [18% (59/325)] ($p = 0.056$). Patients who had associated diabetes presented more commonly with cirrhosis 122/439 (28%) and HCC 122/439 (29%) in comparison to chronic hepatitis 28/287 (10%) ($p < 0.01$). Lower 25-Hydroxy Vitamin D level (<30 ng/mL) was seen in 67% (98/147) of patients with cirrhosis, 78% (11/14) with HCC and 47% (28/59) with chronic hepatitis ($p = 0.012$). In cirrhotic patients vitamin D deficiency was significant in child B 72% (52/72) and Child C 75% (12/16) patients in comparison to child A patients 52% (62/118) ($p = 0.013$). No significant relation of diabetes with child class was seen.
Conclusions: 25-Hydroxy Vitamin D deficiency was present in 61% and diabetes mellitus co-existed in 21% of HCV patients at presentation. Diabetes and low levels of 25-OH vitamin D at presentation was associated with higher incidence of cirrhosis and HCC. Lower 25-Hydroxy Vitamin D levels also leads to a higher incidence of decompensation. Improving diabetes control and correcting vitamin D deficiency can improve outcomes in hepatitis C related liver disease.

P0759
HEPATITIS C VIRUS INFECTION SELECTIVELY AFFECTS "EXECUTIVE FUNCTIONS" IN PATIENTS WITH CHRONIC NON ADVANCED LIVER DISEASE

A. Rocco[1], D. Angrisani[1], M. Sanduzzi Zamparelli[1], V. Occhipinti[1], D. Compare[1], D. Galletta[2], G. Nardone[1]. *[1]Department of Clinical Medicine and Surgery, Gastroenterology Unit, [2]Department of Neurosciences Section of Psychiatry, Federico II University, Naples, Italy*
E-mail: alba.rocco@unina.it

Background and Aims: Growing evidence suggests that patients with chronic Hepatitis C virus (HCV) infection develop neurocognitive deficits unrelated to staging of liver disease, indices of liver dysfunction, viral load, or genotype. Early symptoms of mental impairment have been described as "brain fog" or problems with attending to and recalling everyday information. However, until now, no study performed a comprehensive evaluation of the HCV infected patient's cognitive status by anlysing all specific neurologic domains, *i.e.*, memory, attention, problem solving, language, visuospatial, processing speed motor, and emotion.
We aimed to analyze the neuropsychological and cognitive functions in patients with chronic HCV genotype 1 infection without cirrhosis by using standardized neuropsychological tests validated in clinical practice.
Methods: Thirty patients with histologically proved HCV genotype 1b chronic hepatitis, naive to antiviral therapy were enrolled. Exclusion criteria were: causes of concomitant liver disease (such as HBV infection, autoimmunity or alcohol abuse), clinical, laboratory or histological signs of liver cirrhosis, <4 years of education, major depression or other psychiatric disorders, vitamin B12 and/or folate deficiency, hypothyroidism.

All patients were evaluated biochemically and underwent standardized neuropsychological tests: Wechsler Adult Intelligence Scale (WAIS-R) for the assessment of intelligence quotient (IQ), Corsi test to explore the visual-spatial memory, *attentional matrices for the assessment of attentional capacity* and trail-making test A and B (TMT-A and TMT-B) for the evaluation of psychomotor speed, attention and concentration.
Results: WAIS-R, which synthesizes the intellectual functioning, was in the average range expected in the general population (100±20). Corsi test and attentional matrices also showed no different scores from the expected average. TMT-A and TMT-B significantly deviated from the average values in 25% and 38% of the patient, respectively. While in the first case the results were independent of educational level, clinical, laboratory, virological and histological variables, in the latter there was a significant linear correlation with age.
Conclusions: Chronic HCV infection was associated with altered visual scanning, psychomotor speed, mental flexibility, and executive functions even if overall neurocognitive functions were preserved

P0760
PNPLA3 rs738409 I748M IS ASSOCIATED WITH STEATOHEPATITIS IN NON OBESE SUBJECTS WITH HEPATITIS C

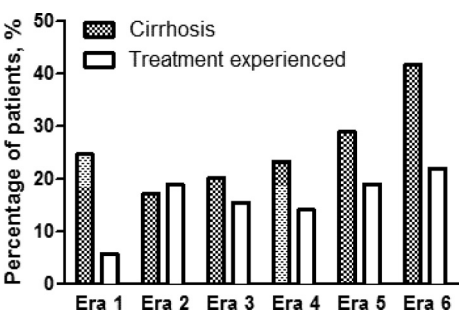
S. Petta[1], E. Vanni[2], E. Bugianesi[2], C. Rosso[2], D. Cabibi[3], C. Cammà[1], V. Di Marco[1], M. Eslam[4], S. Grimaudo[1], F.S. Macaluso[1], D. McLeod[5], R.M. Pipitone[1], M.L. Abate[2], A. Smedile[2], J. George[4], A. Craxì[1].
[1]Di.Bi.M.I.S., Section of Gastroenterology, University of Palermo, Palermo, [2]Division of Gastro-Hepatology, Department of Medical Sciences, San Giovanni Battista Hospital, University of Torino, Torino, [3]Cattedra di Anatomia Patologica, University of Palermo, Palermo, Italy; [4]Storr Liver Unit, Westmead Millennium Institute and Westmead Hospital, [5]Institute of Clinical Pathology and Medical Research, Westmead Millennium Institute and Westmead Hospital, University of Sidney, Sidney, Australia
E-mail: fsmacaluso@gmail.com

Background and Aims: The PNPLA3/Adiponutrin rs738409 C/G single nucleotide polymorphism is associated with the severity of steatosis, steatohepatitis and fibrosis in patients with non-alcoholic fatty liver disease, as well as with the severity of steatosis and fibrosis in patients with chronic hepatitis C (CHC). We tested in genotype 1 (G1)-CHC patients the putative association between the *PNPLA3* variant and histological features of steatohepatitis, as well as their impact on the severity of fibrosis.
Methods: 434 consecutively biopsied Caucasian G1-CHC patients were genotyped for *PNPLA3* rs738409. Histological features of steatohepatitis in CHC were assessed using the Bedossa classification. Hepatic expression of PNPLA3 mRNA was evaluated in 63 patients.
Results: The prevalence of steatohepatitis increased from 16.5% in patients with PNPLA3 CC, to 23.2% in CG and 29.2% in GG genotype ($p = 0.02$). By multiple logistic regression, PNPLA3 genotype (OR 1.54, 95% CI 1.03–2.30, $p = 0.03$) together with age (OR 1.03, 95% CI 1.00–1.05, $p = 0.02$), BMI ≥30 kg/m^2 (OR 2.06, 95% CI 1.04–4.10, $p = 0.03$) and HOMA (OR 1.18, 95% CI 1.04–1.32, $p = 0.006$) were independently linked to steatohepatitis. When stratifying for obesity, PNPLA3 was associated with NASH in non obese patients only (12.0% in CC vs 18.3% in CG vs 27.3% in GG, $p = 0.01$), including after correction for metabolic confounders (OR 2.06, 95% CI 1.26–3.36, $p = 0.004$). We confirmed the independent association of rs738409 with the severity of steatosis (OR 1.71, 95% CI 1.20–2.45, $p = 0.003$), and, indirectly by steatohepatitis promotion (OR 2.05, 95% CI 1.05–4.02, $p = 0.003$), with severe fibrosis. Higher liver PNPLA3 mRNA was associated both with the severity of steatosis (adjusted $p = 0.03$) and steatohepatitis after adjusting for gender, age, BMI and HOMA ($p = 0.002$).
Conclusions: In G1-CHC patients, the *PNPLA3* G variant is associated with a higher risk of steatosis severity and steatohepatitis in chronic hepatitis C, particularly among non obese subjects.

P0761
EPIDEMIOLOGICAL TRENDS AMONG PATIENTS WITH CHRONIC HCV INFECTION IN A TERTIARY CENTRE IN THE NETHERLANDS

E. Zoutendijk[1], R. Maan[1], A.J. van der Meer[1], B.J. Veldt[1], N. Haddo[1], B.E. Hansen[1], R.J. de Knegt[1]. *[1]Gastroenterology and Hepatology, Erasmus MC University Medical Center Rotterdam, Rotterdam, Netherlands*
E-mail: r.maan@erasmusmc.nl

Background and Aims: The field of antiviral therapy for chronic HCV infection is rapidly evolving, with the introduction of very promising regimens. As these treatment regimens are genotype-specific, this study aimed to assess the epidemiological changes in patient and disease characteristics among patients with chronic HCV infection in a Dutch population.
Methods: All consecutive patients with chronic HCV mono-infection who were referred to the Erasmus MC University Medical Centre Rotterdam (EMC), a large tertiary centre in the Netherlands between 1990 and 2013 were included. To assess the trends in patient characteristics, the study population was divided in six eras based on date of first visit to the outpatient clinic (1990–1993, 1994–1997, 1998–2001, 2002–2005, 2006–2009 and 2010–2013).
Results: A total of 1779 patients were diagnosed with chronic HCV infection by positive HCV RNA. At time of referral mean age was 47 years (SD 12), 1210 (68%) were male and 459 (26%) had cirrhosis and 915 (51%) had genotype 1. From the total cohort, 1687 (79.1%) were born between 1940–1970. Age at referral increased over time with a mean age of 43.6 (SD 13.8) in era 1 and a mean age of 51.7 (SD11.2) in era 6 ($p < 0.001$). The number of patients who were referred with cirrhosis increased over the era's ($p < 0.001$), with respectively 31 (25%) patients in era 1 and 118 (42%) patients in era 6. In the first era, 7 (6%) treatment experienced patients were referred compared to 63 (22%) patients in era 6 ($p < 0.001$). Among patients with HCV genotype 1, 27 (48%) patients with subtype 1a and 29 (52%) patients with subtype 1b were referred in era 1 compared to 58 (54%) and 49 (46%) patients with respectively 1a and 1b in era 6 ($p = 0.001$). In the population of 454 patients who are currently visiting the outpatient clinic, 309 (68%) patients are male, 298 (66%) patients have genotype 1 [with 114 (38%) patients having subtype 1a and 94 (32%) patients subtype 1b] and 140 (31%) have cirrhosis.
Conclusions: Over the last 25 years, the HCV-infected population being referred to a tertiary center is aging, more often treatment experienced and more often affected by severe liver disease. Patients with HCV genotype 1 infection have formed a stable majority, with an increasing referral of patients with HCV subtype 1a. These results implicate increasing need for treatment in patients with genotype 1a, higher age and more severe liver disease and optimisation of treatment among these patients is warranted.



P0762

NON-RNA TESTING AMONG HEPATITIS C VIRUS ANTIBODY-POSITIVE PATIENTS IN A NATIONAL PUBLIC HEALTH INSURANCE CARE SYSTEM: PREVALENCE, CHARACTERISTICS AND PREDICTIVE FACTORS

D.E. Morales Arraez[1], A. Alonso[2], F. Diaz-Flores[2], J.A. Garcia Dopico[2], A. de Vera[2], E. Quintero[1], M. Hernandez Guerra[1]. [1]*Servicio de Aparato Digestivo,* [2]*Laboratorio Central, Hospital Universitario de Canarias, la laguna, Spain*
E-mail: Dalia_648@hotmail.com

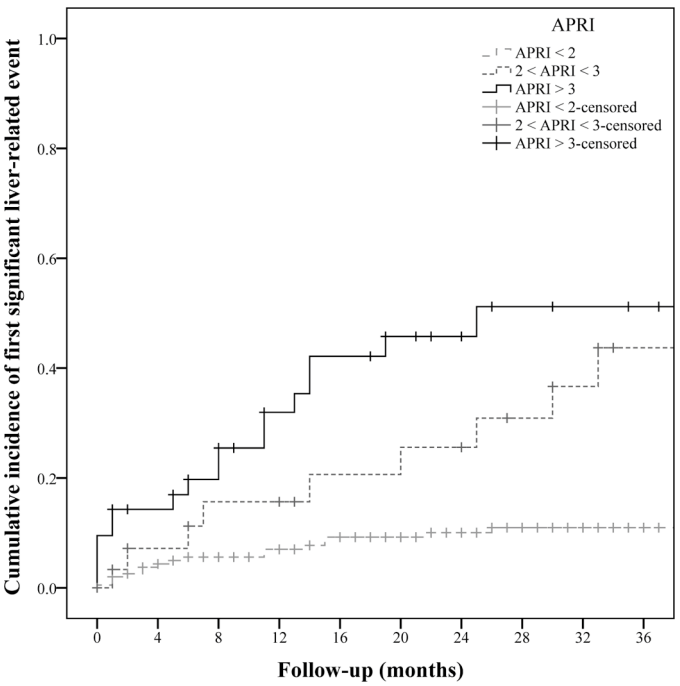
Background and Aims: Current treatment for hepatitis C virus (HCV) infection achieves high rates of sustained virological response. However, only a minority of infected patients receive treatment. A low adherence to diagnostic clinical guidelines which recommends HCV RNA testing after a positive HCV antibody test to define HCV active or past infection, impacts in appropriate evaluation. Our aim was to evaluate the prevalence, characteristics and predictive factors for non-RNA testing.
Methods: Laboratory records were retrospectively reviewed to identify consecutive tests for HCV antibodies between 1 January 2011 and 31 December 2012 for an area of 380,000 inhabitants. Positive tests were identified and patients' medical records reviewed until 1 August 2014 to determine HCV RNA testing and to assess demographic and clinical factors associated with non-RNA testing (patient demographics, comorbidities, physician specialty, health behaviours, HVB and HIV co-infection, low social support, and blood tests). Multivariate analysis was performed to predict non-RNA testing.
Results: Of the 37,700 tests for HCV-antibodies (29,169 subjects), 995 patients (3.4%) tested positive and of these, 347 (34.8%) patients (77.5% male, 47 years, range 11–88) did not receive RNA testing. Excluding 26 deaths that occurred during follow-up, in 71.3% of patients RNA was not determined by physician decision (48% primary care, 24% drug-abuse detoxification unit, 9% penitentiary center, 19% academic center). In the multiple logistic regression analysis presence of normal alanine aminotransferase (OR 2.40, 95% CI 1.10–5.26, p = 0.028) and comorbidities (OR 2.03, 95% CI 1.03–4.03, p = 0.041) were independent predictors for non-RNA testing. Only half of the patients (n = 157) had limitations for peg-interferon based treatment (7% severe comorbidity; 56% psychiatric disease, 6% epilepsy, 6% thrombocytopenia, 1% decompensated cirrhosis, 16% lack of social support and 8% over 65 years).
Conclusions: In our cohort one third of HCV antibody-positive patients did not receive RNA testing and appropriate evaluation of HCV infection status. Presence of normal alanine aminotransferase and comorbidities are associated with non-RNA testing. However, half of the patients were eligible to peg-interferon-based therapies. Multidisciplinary educational interventions are needed to reduce current barriers concerning appropriate evaluation of HCV to optimize treatment of chronic HCV infection.

P0763

HIGHER APRI PREDICTS EARLY SIGNIFICANT LIVER-RELATED EVENTS IN HEPATITIS C GENOTYPE 1 CHRONIC LIVER DISEASE

E. Rodrigues-Pinto[1], H. Cardoso[1], R. Coelho[1], P. Andrade[1], G. Macedo[1]. [1]*Gastroenterology, Centro Hospitalar São João, Porto, Portugal*
E-mail: edu.gil.pinto@gmail.com

Background and Aims: Aspartate aminotransferase platelet ratio index (APRI) is highly sensitive and specific for predicting the presence of hepatic fibrosis, cirrhosis and portal hypertension in chronic hepatitis C (CHC). Nevertheless, the use of APRI in clinical practice remains under debate. Evaluate the prognostic accuracy of APRI in the prediction of liver-related events in a large cohort of CHC patients.
Methods: Retrospective observational study based on medical records from patients with a new diagnose of CHC genotype 1, followed at a tertiary center between January 2006 and December 2013.
Results: A total of 274 patients (65% males) were analyzed. Patients were followed for a mean time of 28 months (±24). At diagnosis, 36% of the patients had cirrhosis, of which 70% were Child–Pugh A. Twenty-five percent of the latter had decompensation. The median APRI was 0.987 [P_{25-75}: 0.568–2.124] and there was a positive correlation between APRI and METAVIR score ($p < 0.001$). The APRI was higher in patients with hepatocellular carcinoma (HCC) (2.060 [P_{25-75}: 1.017–3.636] *vs* 0.886 [P_{25-75}: 0.510–1.656], $p < 0.001$), ascites (2.299 [P_{25-75}: 1.584–4.487] *vs* 0.867 [P_{25-75}: 0.508–1.570], $p < 0.001$), encephalopathy (2.463 [P_{25-75}: 1.329–4.088] *vs* 0.907 [P_{25-75}: 0.511–1.756], $p = 0.009$), varices (2.675 [P_{25-75}: 1.633–4.269] *vs* 0.860 [P_{25-75}: 0.499–1.449], $p < 0.001$) and gastrointestinal bleeding (3.174 [P_{25-75}: 1.849–6.615] *vs* 0.906 [P_{25-75}: 0.512–1.750], $p < 0.001$). APRI higher than 1.250 predicted HCC with 67% sensitivity and 64% specificity; higher than 1.336 predicted cirrhosis with 73% sensitivity and 80% specificity; higher than 1.722 predicted varices with 73% sensitivity and 80% specificity; higher than 1.839 predicted ascites with 70% sensitivity and 80% specificity and encephalopathy with 70% sensitivity and 76% specificity; higher than 1.994 predicted gastrointestinal bleeding with 73% sensitivity and 79% specificity. The higher the APRI, the earlier the onset of complications in the disease follow-up, with the first significant liver-related event presenting later in patients with APRI lower than 2 than in patients with APRI between 2 and 3 and patients with APRI higher than 3 ($p_{Log\ Rank}$ <0.001; $p_{Breslow}$ <0.001).
Conclusions: APRI could be used as a rapid screening tool to allocate cirrhotic patients to specific risk categories, as well as a marker for a tighter surveillance interval in patients with higher APRI.



P0764

HEPATITIS C VIRUS INFECTION INDUCES AN "EARLY" SUBCLINICAL LEFT VENTRICULAR DISFUNCTION

A. Rocco[1], M. Sanduzzi Zamparelli[1], D. Angrisani[1], D. Compare[1], C. Santoro[2], M. Galderisi[2], G. Nardone[1]. [1]*Department of Clinical Medicine and Surgery, Gastroenterology Unit,* [2]*Department of Advanced Biomedical Science, Federico II University, Naples, Italy*
E-mail: alba.rocco@unina.it

Background and Aims: Hepatitis C virus (HCV) infection has been associated with several extrahepatic manifestations in a variety of tissues and organs, including the myocardium. Reduced myocardial perfusion or increased pro-B-type natriuretic peptide (NT-proBNP) have been described in HCV-infected individuals but, until now, no study clearly demonstrated the occurrence of myocardial dysfunction in the early stages of HCV-related liver diseases.
Based on these premises, aim of this study was to evaluate the impact of HCV infection on left ventricular (LV) geometry and function by a standard 2D and 3D echocardiography.
Methods: Thirty consecutive patients with histologically proved HCV-related chronic hepatitis and twenty normal controls (NCs), comparable for age and gender prevalence were enrolled in the study. Exclusion criteria were: other causes of liver diseases, coronary artery and/or valvular heart disease, heart failure, cardiomyopathies, atrial fibrillation or alcohol abuse. The echocardiography protocol consisted of: standard echo Doppler plus LV volumetric and systolic function analysis through 3D echocardiography. Left ventricular systolic function thorough 3D echo was evaluated by STE derived global longitudinal strain (GLS), global circumferential strain (GCS), global area strain (GAS) and global radial strain (GRS).
Results: Overall we enrolled 16 males and 14 females with HCV (genotype 1) related chronic liver disease. Mean age was 60.9±6.5 yrs. NCs were comparable for age, gender distribution, body mass index, heart rate and blood pressure. In HCV infected subjects standard 2D echocardiography point out a transmitral E/A ratio marginally lower (0.84±0.2) compared to NC (1.01±0.3) (p = 0.04). Moreover, more detail 3D STE showed a subclinical alteration of LV function documented by lower GCS (HCV=-15.3±2.2%, NC=-17.6±3.9%, p = 0.02), GAS (−25.2±2.6%, NC −29.9±5.2%, p = 0.03), and GRS (37.6±4.6% vs 44.9±12%, p = 0.04) whereas HCV-releated changes of GLS were not significant.
Conclusions: HCV chronic infection is associated a subclinical myocarditis-like damage documented by the alteration of the circumferential fibers of the ventricular mid wall.

P0765

CONTINUUM OF CARE OF HEPATITIS C FROM DETECTION TO CURE: IMPACT OF PEER-TO-PEER SESSIONS IN PRIMARY CARE

R. Llorca Fernandez[1], M.A. Otero Fernández[2], J. Ampuero[3], M.C. Rico[3], B. Fombuena[3], M. Romero-Gómez[3]. [1]*1UCM Digestive Diseases & CIBERehd Valme University Hospital,* [2]*UCM Primary Care "El Greco",* [3]*UCM Digestive Diseases & CIBERehd Valme University Hospital, Seville, Spain*
E-mail: llorca_@hotmail.com

Background and Aims: To analyze the continuum of care in hepatitis C from primary care to academic hospital including the impact of peer-to-peer sessions in detection rate, referral rate and diagnostic and therapeutic management.
Methods: Peer-to-peer sessions were conducted in 13 of 26 Primary Care Centers (PCC) of our Area for Health Management. The sessions consisted in 1-hour of discussing epidemiological and clinical aspects of hepatitis C focusing on barriers to screening and referral of anti-HCV positive patients. The anti-HCV serology requested from PCC was analyzed (comparing trained centers versus non-trained centers) between 2008 and 2013 (n = 37846). The detection rate per 100000 attended population per year; the referral rate, the number of patients evaluated at the hospital and the number of patients treated were calculated. Statistical analysis was done by Chi2 test and t-student test using SPSS 20.0 (Chicago, IL).
Results: Detection rate of anti-HCV in trained centers was 52.7 per 100,000 population per year and 30.4 per 100,000 population per year in non-trained centers; p = 0.001 (OR 2.63; 95% CI: 1.47–4.7). The number of HCV positive patients was 3 times higher in trained centers (737 vs. 211) due to 3 times more requests. In multivariate analysis, age (OR 1.012; 95% CI: 1.01–1.015), male gender (OR 6.06; 95% CI: 5.20–7.04), number of peer-to-peer sessions (OR 1.58; 95% CI: 1.36–1.83) and trained (OR 2.307; 95% CI: 1.757–3.029) were independently associated with the possibility of detecting antiHCV positive cases. The highest prevalence of anti-HCV positive was in the group of men between 40–50 years (14.3%; 393/2350). The referral rate was 81.2% (770/948), with difference in absolute numbers in trained centers (598 vs. 172). Patients followed in the outpatient office in the Hospital were 733/948 (77%). Risk factors were: 197 drug users (27%), 176 transfused (24%), 42 tattoos (6%), 13 sexual (1.7%), 15 no disposable injections (2%), 11 vertical transmission (1.5%) and in 279 unknown (38%). Received antiviral therapy 203 patients (30%), 156 from trained centers (77%) and 47 from non-trained centers (23%).
Conclusions: Peer-to-peer sessions in primary care increased hepatitis C detection rate, which affected the number of referred and treated patients. The epidemiological profile of hepatitis C in our environment shows a concentration of cases in men between 30 and 60 years. These data support the need to implement peer-to-peer sessions in primary care to improve the continuum of care of hepatitis C.

EPIDEMIOLOGY OF VIRAL RESISTANCE IN GENOTYPE 1 INFECTED PATIENTS AT APPROVAL OF IFN-FREE DAA COMBINATION THERAPY OF CHRONIC HEPATITIS C IN GERMANY

H. Farnik[1], J. Vermehren[1], S. Susser[1], J. Dietz[1], D. Perner[1], C. Berkowski[1], S. Zeuzem[1], C. Sarrazin[1]. [1]*Medizinsche Klinik 1, Johann Wolfgang Goethe Universität, Frankfurt am Main, Germany*
E-mail: harald.farnik@kgu.de

Background and Aims: IFN-free direct antiviral agents (DAA)-based antiviral therapies including either a NS5A and/or a NS3 protease inhibitor are currently available for patients with chronic hepatitis C. In patients with pre-existence of resistance associated variants (RAVs) lower SVR rates have been observed especially in combination with other negative response predictors like liver cirrhosis, failure to PEG/R and failure to BOC/TVR-based previous antiviral therapy. A large number of patients with urgent need of antiviral

therapy have been treated with first generation protease inhibitors before. The rate of patients with RAVs to NS3 protease-, and NS5A-inhibitors at approval of DAA combination therapies is unknown.
Methods: Population based sequencing of NS3 and / or NS5A genes for identification of RAVs have been performed in a large number (n = 978) of treatment naïve and experienced HCV genotype 1 infected patients in Germany.
Results: Patients were either treatment-naïve (n = 97; GT1a n = 63, GT1b n = 34) or treatment experienced with PEG/R (n = 169; GT1a n = 104, GT1b n = 65), TVR+PEG/R (n = 463; GT1a n = 270, GT1b n = 193), or BOC+PEG/R (n = 249; GT1a n = 132, GT1b n = 117). For the NS3 protease the most frequent RAV observed in treatment naïve and PEG/R experienced patients was Q80K with 19.5–21% for GT1a and 1.1–1.2% for GT1b. In first generation protease inhibitor pre-treated patients RAVs at positions V36, R155, T54, A156 and V170 were most common. Here for TVR 19% V36 and 20% R155, 17% T54, 12% A156 and 12% V170 variants in GT1a and 8.8% V36, 9% A156 and 8% V170 variants in GT1b patients were observed while for BOC RAVs were less common with 2% V36, 12% R155, 7% A156 and 3% V170 in GT1a and 13% T54, 9% V170 and 10% V36 in GT1b. Frequencies of NS5A RAVs (L31, Y93, M28, Q30, L31, H58%, P58% and A92) did not differ between treatment-naïve and -experienced patients with 1.9% L31, 3.1% Y93, 3% M28, 2.7% Q30, 3.6% L31, 1.2% H58, 0.7% P58 and 0.6% A92.
Conclusions: A large number of patients with chronic hepatitis C and urgent need for antiviral therapy received first generation triple therapies. With the availability of all oral IFN-free therapies up to 36% and 7% of patients harbor RAVs within NS3 and NS5A genes which may affect treatment efficacy of protease- and NS5A-inhibitors.

P0767

CLINICAL UTILITY OF HEPATITIS C VIRUS CORE ANTIGEN TESTING IN THE MONITORING OF TREATMENT NAÏVE NON-CIRRHOTIC PATIENTS RECEIVING AN ALL-ORAL, INTERFERON-FREE REGIMIEN

G. Cloherty[1], K. Cheng[2], S. Chevaliez[3], H. Wedemeyer[4], C. Sarrazin[5], J. Feld[6], B. Maasoumy[7], C. Herman[1], J. Hackett Jr.[8], G. Dawson[9], J.M. Pawlotsky[10]. *[1]Abbott Molecular, Des Plaines, [2]Abbott Diagnostics, Abbott Park, United States; [3]Henri, Mondor, France; [4]Department of Gastroenterology, Hepatology and Endocrinology, Hannopver Medical School, Hannover, [5]Department of Medicine, JW Goethe-University Hospital, Frankfurt, Germany; [6]Toronto Western Hospital, Toronto, Canada; [7]Department of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany; [8]Abbott Laboratories, Abbott Park, [9]Abbott Laboratories, Abbott Parrk, United States; [10]Henri Mondor Hospital, Paris, France*
E-mail: Gavin.cloherty@abbott.com

Background and Aims: Advances in the treatment of Hepatitis C virus (HCV) have demonstrated >90% Sustained Virologic Responses (SVR) after 12 weeks interferon-free, direct-acting combination therapy regardless of viral genotype, degree of liver fibrosis or previous treatment history. Simplification of treatment monitoring is required to ensure broad access to these new therapies. Introduction of these highly potent therapies have negated the role of response-guided therapy and reduced the role of treatment monitoring with highly sensitive HCV RNA tests. This study aims to demonstrate the utility of the HCV Core Ag (HCV Ag) test to accurately identify patients with active viremia and discriminate those who achieve SVR from those who fail therapy.
Methods: Samples from treatment naïve non-cirrhotic subjects with HCV genotype 1 infection enrolled in AbbVie Sapphire I clinical trial (ritonavir-boosted paritaprevir, ombitasvir and dasabuvir w/o ribavirin 12 weeks) were tested in a blinded fashion with Abbott HCV Ag test and results were later compared to the manual Roche High-Pure-System/COBAS® TaqMan (HPS) HCV RNA. The 451 samples tested in this study represented Baseline or Screening samples (N = 246), Day 1 samples (prior to first dose: N = 5), SVR 12 samples (N = 195), and 5 samples with last available time points (1 at SVR, 1 at SVR8, 1 each on treatment week 2, 8, and 10).
Results: Using 10 fMol/mL cutoff for HCV Ag detection, the HCV RNA and HCV Ag tests were in 100% agreement for truly negative samples and 99.6% agreement for truly positive samples. One discordant (screening) sample was identified. This sample was Target Not Detected by HCV RNA method but highly positive by HCV Ag (7912 fMol/mL). The mean (range) HCV Ag value was 7751 (25 to 66469) fMol/mL and 1.47 (0.5 to 8.4) fMol/mL for true positives and negative samples, respectively.
Conclusions: In this study HCV Ag, with a 10 fMol/mL cutoff, accurately identified 99.6% of patients with active viremia and discriminated all subjects who achieved SVR from those who failed therapy. In this context the HCV Core Antigen test (HCV Ag) is a useful tool in the identification and management of treatment naïve, non-cirrhotic patients with chronic HCV receiving all-oral, interferon-free therapy. 10 fMol/mL appears an appropriate clinical cutoff to determine active HCV viremia and discriminate SVR from non-SVR. HCV Core Antigen test can be used as an alternative to HCV RNA testing to improve global access to new HCV therapies.

E-mail: jp.bronowicki@chu-nancy.fr

Background and Aims: Sustained virological response (SVR) rate has increased with the use of triple therapy including

boceprevir (BOC) or telaprevir (TVR) in genotype (GT) 1 cirrhotic patients. However, the prognosis of these patients is not clearly established. The aim of this analysis was to determine the rate and the predictors of late mortality in patients included in the CUPIC cohort.

Methods: Between January 2011 and April 2013, 629 treatment-experienced GT 1 patients with compensated cirrhosis received triple therapy including BOC or TVR. We analysed rates and causes of death occurring before (early death) or after (late death) 12 weeks post-treatment of follow-up (FU). Baseline predictors of late death were determined.

Results: The median follow-up from the start of treatment was 30 months. Overall, 7% (44/629) of patients died, among them 29 (66%) died lately. The median interval time between FU12 and death was 15.7 months. Late deaths were related to hepatic events (10) and/or infections (4) in 48% (14/29). The SVR rate in the late death group was 34% (10/29) vs 48% in the survivor group (p = 0.5664 Log-rank). Baseline liver stiffness was available in 17/29 patients who died lately and in 334/585 survivors. The mean baseline liver stiffness was significantly higher in the dead group compared to the survivor group (31.5 vs 22 kPa, p = 0.03, Wilcoxon test). The baseline predictors of late death (uni and multivariate analysis adjusted on age and gender) are presented in the table. SVR12 status was not a predictor of death.

Conclusions: The 30 months mortality in GT 1 cirrhotic patients treated with triple therapy is high (7%). Two third of deaths occurred lately. In near of 50% of cases, late deaths were due to hepatic events or infection and were mostly associated with the severity of cirrhosis. SVR 12 was not an independent predictor of survival at 20 months but follow up is still limited.

P0769

EFFICACY OF AN EIGHT-WEEK REGIMEN OF GRAZOPREVIR PLUS ELBASVIR WITH AND WITHOUT RIBAVIRIN IN TREATMENT-NAIVE, NONCIRRHOTIC HCV GENOTYPE 1B INFECTION

J.M. Vierling[1], M. Kugelmas[2], E. Lawitz[3], P. Hwang[4], M. Robertson[4], J. Wahl[4], E. Barr[4], B. Haber[4]. *[1]Baylor College of Medicine, Houston, [2]South Denver Gastroenterlogy, Englewood, [3]The Texas Liver Institute, University of Texas Health Science Center, San Antonio, [4]Merck & Co., Inc., Whitehouse Station, United States*
E-mail: vierling@bcm.edu

Background and Aims: The combination of grazoprevir (GZR; 100 mg) a highly potent NS3/4 inhibitor and elbasvir (EBR; 50 mg) an NS5A replication complex inhibitor exhibits a high barrier to resistance. In C-WORTHY parts A and B, GZR + EBR with or without ribavirin (RBV) demonstrated robust efficacy with >95% SVR_{12} in genotype (GT)1 HCV-infected patients (modified intent to treat) treated for 12 weeks. Since shorter treatment durations can improve adherence, reduce drug exposure and decrease cost, we assessed the safety and efficacy of an 8-week regimen of GZR + EBR ± RBV in treatment-naive, noncirrhotic patients with HCV GT1b infection.

Methods: 61 patients with HCV GT1b infection were randomized to GZR plus EBR with or without RBV for 8 weeks. Absence of cirrhosis was confirmed by either liver biopsy or noninvasive tests. The primary end point was the proportion of patients with HCV RNA <25 IU/mL 12 weeks after treatment (SVR12) assessed by COBAS TaqMan v2.0 (lower limit of quantitation <25 IU/mL).

	HCV GT1B infection	
	GZR + EBR + RBV (8 weeks) n = 30	GZR + EBR (8 weeks) n = 31
TW4 [a], n/N (%)	30/30 (100%)	30/31 (97%)
TW8 [a] (EOT), n/N (%)	30/30 (100%)	31/31 (100%)
SVR 4 [a], n/N (%)	29/30 (97%)	30/31 (97%)
SVR 12 [a], n/N (%)	27/29 [b] (93%)	29/31 (94%)
Breakthrough, n	0	0
Relapse, n	2	2

[a] Proportion of patients with HCV RNA <25 IU/mL (mITT, excluding 8 of 471 patients lost to follow-up or who discontinued early unrelated to adverse event or virologic failure).
[b] Excludes 1 patient who discontinued unrelated to adverse event or virologic failure.

Results: At baseline, the mean viral load was 6.4 $\log_{10}$ (4.4, 7.7), mean age was 53 years (range 28–71), 48% were male, 82% were white and 77% had *IL28B* non-CC. HCV RNA was undetectable after 4 weeks in 100% of patients treated with RBV and 97% without RBV (table). By end of treatment (EOT) at 8 weeks, 100% of patients had HCV RNA <25 IU/mL. Twelve weeks after EOT, 2 patients in each arm had relapsed. The most common adverse events (AEs) were fatigue, headache and nausea, occurring in 23%, 18% and 13%, respectively. No drug-related serious AEs or discontinuations due to AEs were reported.

Conclusions: Therapy for 8 weeks with GZR (100 mg) plus EBR (50 mg) ± RBV in treatment-naive, noncirrhotic HCV GT1b-infected patients was highly efficacious, safe and well tolerated.

P0770

EFFECT OF HEPATITIS C ANTIVIRAL THERAPY ON ALL-CAUSE MORTALITY AND DEVELOPMENT OF CANCER IN THE CHRONIC HEPATITIS COHORT STUDY (CHECS)

M. Lu[1], J. Li[1], L.B. Rupp[1], S.D. Holmberg[2], A.C. Moorman[2], P.R. Spradling[2], E. Teshale[2], F. Xu[2], J.A. Boscarino[3], V. Vijayadeva[4], M.A. Schmidt[5], L.E. Lamerato[1], S. Gordon[1]. *[1]Henry Ford Health System, Detroit, [2]Centers for Disease Control, Atlanta, [3]Geisinger Health System, Danville, [4]Kaiser-Premanente Hawaii, Honolulu, [5]Kaiser-Permanente Northwest, Portland, United States*
E-mail: strudea1@hfhs.org

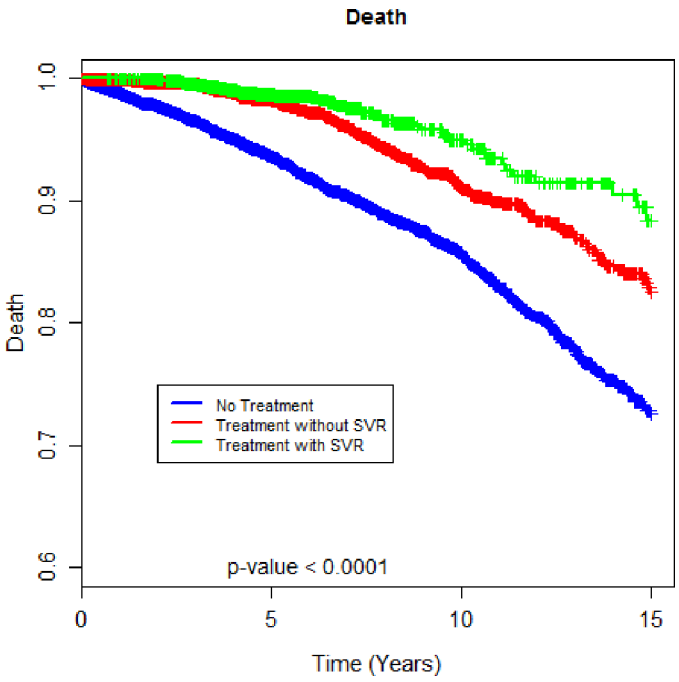
Background and Aims: We sought to study the effect of hepatitis C (HCV) antiviral therapy, with and without sustained viral response (SVR, HCV RNA negative 12 weeks after completion of therapy), on the incidence of (a) hepatocellular carcinoma (HCC), (b) non-liver cancer, and (c) all-cause mortality.

Methods: Data were drawn from the Chronic Hepatitis Cohort Study (CHeCS), an observational study from 4 large US health systems. Demographics, HCV genotype, FIB4, decompensated status, and comorbidities including diabetes and history of alcohol abuse were collected at the index date (defined as date of first HCV diagnosis or antiviral therapy). HCV treatment detail and virologic response were captured until end of follow-up or HCC, non-liver cancer, or death. Cox regression, univariate followed by multivariate, and propensity score were used to control for possible imbalances at index between treated and untreated groups. Sensitivity analyses were performed.

Results: A total of 9,143 patients were included with a median follow-up of 6.4 years; 2,855 (31%) were treated, of whom 39% achieved an SVR. Treatment reduced mortality (aHR = 0.40, 95% CI 0.28–0.56 for treated patients who achieved SVR; aHR = 0.69, 95% CI 0.56–0.85 for treated patients without SVR; see figure). Moderate-to-advanced fibrosis (FIB4 >1.21) was an independent risk factor both for HCC (aHR = 3.9, 95% CI 1.86–8.59) and death (aHR = 2.04, 95% CI 1.45–2.86). Patients with genotype 3 had a higher risk of HCC compared to genotype 1 (aHR = 1.8, 95% CI 1.15–2.84). Males had higher risk of both HCC (aHR = 2.94, 95% CI 2.12–4.16) and

death (aHR = 1.51, 95% CI 1.23–1.85). HCC screening was lower in the treated than the untreated group (0.20 vs. 0.28 screenings/person-year). Nevertheless, patients with SVR had a lower risk of HCC (aHR = 0.54, 95% CI 0.34–0.84) compared to treated patients without SVR, while treated patients without SVR had a higher risk of HCC than untreated patients (aHR = 1.97, 95% CI 1.48–2.63). Blacks had a higher risk of non-liver cancer compared to whites (aHR = 2.09, 95% CI 1.44–3.02), while treatment, with or without SVR, had no effect. Older age was a risk factor for all outcomes.

Conclusions: In a large, real world US multicenter cohort following both treated and untreated HCV patients, presence of moderate-to-advanced fibrosis and genotype 3 independently increased risk of HCC, while SVR reduced development of HCC by 46%. Treatment, regardless of whether SVR was attained, reduced all-cause mortality.



P0771

C-SCAPE: EFFICACY AND SAFETY OF 12 WEEKS OF GRAZOPREVIR +/− ELBASVIR +/− RIBAVIRIN IN PATIENTS WITH HCV GT2, 4, 5 OR 6 INFECTION

A. Brown[1], C. Hezode[2], E. Zuckerman[3], G. Foster[4], A. Zekry[5], S. Roberts[6], A. Howe[7], C. Durkan[7], C. Badshah[7], B. Zhang[7], M. Robertson[7], J. Wahl[7], E. Barr[7], B. Haber[7]. *[1]Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Henri Mondor Hospital, University of Paris-Est, Creteil, France; [3]Liver Unit, Carmel Medical Center Technion Faculty of Medicine, Haifa, Israel; [4]Liver Unit, Queen Marys University of London, London, United Kingdom; [5]St George Hospital Clinical School, Inflammation and Infection Research Centre, University of New South Wales, Sydney, [6]Alfred Hospital, Melbourne, Australia; [7]Merck & Co., Inc., Whitehouse Station, United States*

E-mail: barbara.haber@merck.com

Background and Aims: Grazoprevir (GZR; an NS3/4A protease inhibitor) and elbasvir (EBR; an NS5A inhibitor) are highly potent direct-acting antiviral agents (DAAs) with a high barrier to resistance, and shown to be highly effective for HCV genotype (GT)1 infection in the phase 2 C-WORTHY study. *In vitro*, both compounds have pan-genotypic properties. C-SCAPE is a phase 2 study investigating the efficacy and safety of once-daily GZR ± EBR given with ribavirin for 12 weeks in patients with HCV GT2 infection; and given as GZR + EBR ± ribavirin for 12 weeks in patients with HCV GT4, 5 or 6 infection.

Methods: HCV RNA was assessed using COBAS TaqMan v2.0 (LoQ 15 IU/mL). The primary end point was the proportion of patients with HCV RNA <25 IU/mL 12 weeks after end of treatment (SVR12).

Results: 100 patients were enrolled: 60% had GT2 infection, 20% GT4, 8% GT5 and 12% GT6. 57% were male, and 85% were white. Mean baseline viral load was 6.9 $\log_{10}$ IU/mL and all patients were noncirrhotic. Table 1 shows treatment regimens and efficacy. The first 30 patients with GT2 infection receiving GZR + EBR + RBV were assessed for a polymorphism of the virus based on preclinical data demonstrating a lower potency for EBR in methionine (M) compared with leucine (L) at amino position 31 within NS5A. Four of 30 patients had virologic failure; 4/13 patients with 31M and 0/14 patients with 31L. One patient with GT4 infection discontinued study drug at treatment week 8 with an asymptomatic ALT elevation >10×ULN possibly related to study drug confounded by the concurrent use of etifoxine (a known hepatotoxic drug). Other mild to moderate drug-related adverse events included fatigue (26%), headache (21%) and asthenia (16%).

Conclusions: These data demonstrate high efficacy for patients with HCV GT2 (31L), GT4 and GT6 infection and lower efficacy for patients with GT2 (31 non-L) or GT5 (treated without RBV) infection. These data support the inclusion of patients with GT4 or GT6 infection in the phase 3 GZR/EBR program.

Regimen	Genotype	N	EOT [a]	SVR12 [a]
GZR+EBR+RBV	2	30	93% (28/30)	80% (24/30)
GZR+RBV		30	80% (24/30)	67% (20/30)
GZR+EBR+RBV	4	10	100% (10/10)	100% (10/10)
GZR+EBR		10	90% (9/10)	90% (9/10)
GZR+EBR+RBV	5	4	100% (4/4)	100% (4/4)
GZR+EBR		4	75% (3/4)	25% (1/4)

E-mail: danielle.goffman@articulatescience.com

Background and Aims: The all-oral antiviral regimen using daclatasvir (DCV) + sofosbuvir (SOF) with/without ribavirin (RBV) has demonstrated high response rates along with minimal adverse events (AE) in treatment-naive patients (pts) with hepatitis C genotype (GT) 1, 2 and 3 and prior nonresponders to protease inhibitor-based therapies (GT1). Data in a real world setting especially in difficult-to-treat populations are clinically relevant.

This analysis reports interim findings from a compassionate use program (CUP) of DCV+SOF +/− RBV opened in 5 European countries in pts with severe liver disease.

Methods: This multicenter CUP (ClinicalTrials.gov, NCT02097966) enrolls adult pts with chronic HCV infection who are at a high risk of hepatic decompensation or death within 12 months if left untreated, and who had no available treatment options. Patients received DCV 60 mg + SOF 400 mg QD for 24 weeks, with RBV added at the physician's discretion. This interim analysis includes 413 pts with available data at October 3rd, 2014.

Results: The majority of pts were male (n = 281, 68%), Caucasian (n = 390, 95%), and most had non-CC *IL28B* (140 of 170 pts with available data). Median age was 57 years (range, 27–83). Most pts were infected with HCV GT1 (GT1a, n = 131; GT1b, n = 157) and GT3 (n = 83), with 2 pts GT2, 15 pts GT4, and 1 pt GT5. A total of 42 pts had HIV/HCV coinfection, and 72 were liver transplant recipients. To date, liver biopsy (LB) and/or FibroScan (FS) results are available in 272 pts; of them, 196 had METAVIR F4 or FS >14.6 (Child–Pugh A, n = 111; B, n = 77; C, n = 8). On treatment virological response at Week 12 shows HCV RNA values <LLOQ TD/TND in 193 pts (93%) of 208 pts with available data. Six pts discontinued treatment due to AEs; 3 were considered treatment related (acute renal failure, n = 1; hepatic/renal failure, n = 1; hypersensitivity vasculitis, n = 1). Grade 3/4 laboratory abnormalities were infrequent. Nine pts died (all events were considered non-treatment related). Additional data (including sustained virological response results) will be available for presentation.

Conclusions: In this preliminary analysis, DCV+SOF +/− RBV demonstrated antiviral activity at Wk 12 and was well tolerated in difficult-to-treat pts with severe liver disease.

P0773

THE PREVALENCE AND THE EFFECT OF HCV NS5A RESISTANCE ASSOCIATED VARIANTS IN SUBJECTS WITH COMPENSATED CIRRHOSIS TREATED WITH LEDIPASVIR/SOFOSBUVIR +/− RBV

C. Sarrazin[1], H. Dvory-Sobol[2], E.S. Svarovskaia[2], B. Doehle[2], R. Martin[2], S. Zeuzem[3], E. Lawitz[4], R. Hyland[2], P.S. Pang[2], S. Knox[2], E. Gane[5], R. Reddy[6], N. Afdhal[7], M. Mizokami[8], M. Omata[9], M.D. Miller[2], H. Mo[2], M. Bourlière[10]. *[1]Medizinische Klinik 1, Goethe University Hospital, Frankfurt, Germany; [2]Gilead Sciences, Foster City, United States; [3]Johann Wolfgang Goethe University, Frankfurt am Main, Germany; [4]Texas Liver Institute, University of Texas Health Science Center, San Antonio, TX, United States; [5]New Zealand Liver Transplant Unit, Auckland City Hospital, Auckland, New Zealand; [6]University of Pennsylvania, Philadelphia, PA, [7]Harvard Medical School, Beth Israel Deaconess Medical Center, Boston, MA, United States; [8]Research Center for Hepatitis and Immunology, National Center for Global Health and Medicine, Chiba, [9]Yamanashi Prefectural Hospital Organization, Yamanashi, Japan; [10]Hôpital Saint Joseph, Marseilles, France*
E-mail: Hadas.Dvory-Sobol@Gilead.com

Background and Aims: Here we evaluated the effect of baseline HCV NS5A resistance-associated variants (RAVs) on treatment outcome in 511 cirrhotic subjects treated with ledipasvir/sofosbuvir (LDV/SOF) ± ribavirin (RBV).

Methods: Population (n = 34) or deep (n = 477) sequencing for the HCV NS5A gene was performed at baseline (BL) for all enrolled subjects with cirrhosis in the phase 2 and 3 studies (LONESTAR, ELECTRON, ELECTRON-2, GS-US-337-0113, ION-1, 2 and SIRIUS) and for NS5B at BL in a subset of subjects by deep sequencing (n = 418). Consensus sequences were generated from deep sequences and resistance analysis was performed using 1% and 15% cut-offs (% of total reads).

Results: With a 1% cut-off, 94/511 (18%) cirrhotic subjects were identified as having BL NS5A RAVs. SVR results by regimen and patient group are shown in the table.

	SVR12, % (n/N)			
	LDV/SOF, 12 weeks	LDV/SOF+RBV, 12 weeks	LDV/SOF, 24 weeks	LDV/SOF+RBV, 24 weeks
All subjects				
With NS5A RAVs	88 (23/26)	94 (32/34)	85 (17/20)	100 (14/14)
No NS5A RAVs	95 (86/91)	97 (164/169)	100 (113/113)	100 (44/44)
Treatment-naïve subjects				
With NS5A RAVs	90 (9/10)	100 (8/8)	86 (6/7)	100 (10/10)
No NS5A RAVs	100 (36/36)	97 (36/37)	100 (26/26)	100 (26/26)
Treatment-experienced subjects				
With NS5A RAVs	88 (14/16)	92 (24/26)	85 (11/13)	100 (4/4)
No NS5A RAVs	91 (50/55)	96 (128/133)	100 (87/87)	100 (18/18)

Conclusions: LDV/SOF regimens for 12 and 24 weeks showed high efficacy in treatment naïve cirrhotic subjects with GT1 infection even in the presence of HCV NS5A RAVs at BL.

P0774

LEDIPASVIR/SOFOSBUVIR WITH RIBAVIRIN IS SAFE IN >600 DECOMPENSATED AND POST LIVER TRANSPLANTATION PATIENTS WITH HCV INFECTION: AN INTEGRATED SAFETY ANALYSIS OF THE SOLAR 1 AND SOLAR 2 TRIALS

D. Samuel[1], M. Manns[2], X. Forns[3], S.L. Flamm[4], K.R. Reddy[5], J. Denning[6], S. Arterburn[6], T. Brandt-Sarif[6], P.S. Pang[6], J.G. McHutchison[6], N. Afdhal[7], M. Charlton[8], E. Gane[9], D. Mutimer[10], G.T. Everson[11]. *[1]Université Paris-Sud, Villejuif, France; [2]Hannover Medical School, Hannover, Germany; [3]Liver Unit, IDIBAPS, CIBEREHD, Barcelona, Spain; [4]Northwestern Feinberg School of Medicine, Chicago, [5]University of Pennsylvania School of Medicine, Philadelphia, [6]Gilead Sciences, Inc., Foster City, [7]Beth Israel Deaconess Medical Center, Boston, [8]Intermountain Medical Center, Murray, United States; [9]University of Auckland, Auckland, New Zealand; [10]QE Hospital and University of Birmingham, Birmingham, United Kingdom; [11]University of Colorado Denver, Aurora, United States*
E-mail: jill.denning@gilead.com

Background and Aims: Patients with HCV who have decompensated liver disease or who have recurrent HCV post liver transplantation have substantial rates of morbidity and mortality. The safety of any HCV treatment regimen is therefore critical to evaluate in order to determine if, when and who to treat. The safety of ledipasvir/sofosbuvir (LDV/SOF) + ribavirin (RBV) was evaluated in a pooled analysis of two studies enrolling patients with advanced liver disease in the US (SOLAR 1, NCT01938430) and Europe, Canada, Australia and New Zealand (SOLAR 2, NCT02010255), the largest study of such patients to be evaluated to date.

Methods: Six groups of patients with HCV genotypes 1 or 4 and decompensated liver disease or who were post liver transplantation were randomized to receive 12 or 24 weeks of LDV/SOF + RBV treatment: patients without transplant and either (1) Child–Pugh–Turcotte (CPT) B cirrhosis, or (2) CPT C cirrhosis; or patients who have undergone transplantation and who were either (3) without cirrhosis (F0 to F3), (4) CPT A cirrhosis, (5) CPT B cirrhosis, or (6) CPT C cirrhosis. RBV was administered either at 600 mg/day and escalated as tolerated (decompensated) or weight-based (1000–1200 mg/day; F0–F3, CPT A).

Results: 658 patients were randomized. 392 had HCV genotype 1a, 224 had HCV genotype 1b, and 42 had HCV genotype 4. The major safety findings are included in the table. Of 134 SAEs, only 20 were related to treatment, 11/20 (55%) were due to RBV-associated anemia. RBV-associated anemia was also the most common Grade 3 laboratory AE. There were 18 treatment-emergent (TE) deaths; sepsis (5), GI bleed (3), and myocardial infarct (3) occurred in more than 1 person and none were attributed to LDV/SOF treatment.

Conclusions: In these patient populations treatment with LDV/SOF + RBV was generally safe and well tolerated, irrespective of the degree of decompensation or whether patients were pre- or post-transplantation. The adverse events observed were consistent

with the disease status of the patients; no additional morbidity or mortality, aside from RBV-associated side effects, was associated with treatment. A detailed analysis of RBV dose modification and related safety events for this all oral regimen will be presented.

P0775

FINAL EVALUATION OF 955 HCV PATIENTS TREATED WITH 12 WEEK REGIMENS CONTAINING SOFOSBUVIR +/− SIMEPREVIR IN THE TRIO NETWORK: ACADEMIC AND COMMUNITY TREATMENT OF A REAL-WORLD, HETEROGENEOUS POPULATION

D. Dieterich[1], B. Bacon[2], S. Flamm[3], K. Kowdley[4], S. Milligan[5], N. Tsai[6], Z. Younossi[7], E. Lawitz[8]. *[1]Icahn School of Medicine, Mount Sinai, New York, [2]School of Medicine, St. Louis University, St. Louis, [3]Feinberg School of Medicine, Northwestern University, Chicago, [4]Liver Care Network, Swedish Medical Center, Seattle, [5]Trio Health Analytics, Newton, [6]Queen's Medical Center, University of Hawaii, Honolulu, [7]Center for Liver Diseases, Department of Medicine, Inova Fairfax Hospital, Falls Church, [8]The Texas Liver Institute, University of Texas Health Science Center, San Antonio, United States*
E-mail: scott.milligan@triohealth.com

Background and Aims: Outcomes in a heterogeneous real-world population of hepatitis C (HCV) patients typically fail to match those observed through highly controlled clinical trials. To bridge the knowledge gap between investigation and application, ongoing studies of actual treatment are important to determine clinical effectiveness for patients infected with HCV. Trio Health is a disease management company that works in partnership with academic medical centers, community physicians and specialty pharmacies in the US to optimize care for HCV. Data obtained through the Trio Health program were analysed to evaluate efficacy of 12 week sofosbuvir +/− simeprevir regimens in a real-world HCV population.
Methods: Data were collected from Rx records through the Trio Platform in partnership with specialty pharmacies and was limited to 955 patients who initiated a 12 week course of treatment between Dec 2013 and Mar 2014. Outcomes from 822 patients were previously reported though 133 patients that were not included in these figures will be presented as part of the final evaluation of 955 patients. Treatment commenced in 142 clinics, 30 of which were academic.
Results: Mean age was 57 with 183 patients (19%) 65 years or older, 59% male and mean BMI 28.7. Genotype 1 was seen in 703 patients (74%), genotype 2 in 212 patients (22%), genotype 3 in 7 patients (1%), genotypes 4–6 in 25 patients (3%), and an unknown genotype for 8 patients (1%). Of the 955 patients, 16% were black. HIV co-infection was present in 5% of the population. 16% of patients had a baseline platelet measure of <100k/ul. Baseline Viral load >6MM IU/ml was seen in 19% of patients and ≤800K IU/ml was present in 32% of patients. 43% of patients were previously treated; 35% of which were null responders. Cirrhosis was present in 30% of patients. Treatment evaluation of 955 patients indicates an overall discontinuation rate of 5%. SVR12 rates from 822 patients were previously reported as 79% (Intent to Treat) and 88% (Per Protocol).
Conclusions: Final results, so far paralleling those of clinical trials, of outcomes for a heterogeneous population of 955 patients and sub-groups treated with 12-week regimens containing sofosbuvir +/− simeprevir will be presented.

P0776

EFFICACY OF 12 OR 18 WEEKS OF GRAZOPREVIR PLUS ELBASVIR WITH RIBAVIRIN IN TREATMENT-NAIVE, NONCIRRHOTIC HCV GENOTYPE 3-INFECTED PATIENTS

E. Gane[1], R. Nahass[2], V. Luketic[3], P. Hwang[4], M. Robertson[4], J. Wahl[4], E. Barr[4], B. Haber[4]. *[1]Auckland Clinical Studies, Auckland, New Zealand; [2]ID Care, Hillsborough, [3]Virginia Commonwealth University Medical Center, Richmond, [4]Merck & Co., Inc., Whitehouse Station, United States*
E-mail: barbara.haber@merck.com

Background and Aims: Grazoprevir (GZR) and elbasvir (EBR) are potent NS3/4A protease and NS5A replication complex inhibitors, respectively with pan-genotypic activity in vitro. In patients with HCV genotype (GT)1 infection enrolled in C-WORTHY (parts A B), GZR (100 mg QD) and EBR (50 mg QD) +/− ribavirin (RBV) demonstrated robust efficacy with >95% SVR12 (modified intent to treat). In a phase 1b study, patients with HCV GT3 infection treated with monotherapy EBR (50 mg for 5 days) or GZR (100 mg for 7 days) achieved a >3 log HCV RNA decline. These results supported the initiation of this phase 2 pilot study (PN035 Part D) to assess the safety and efficacy of the combination regimen in treatment-naive, noncirrhotic patients with GT3 infection.
Methods: Treatment-naive, noncirrhotic patients with GT3 infection were randomized to 12 (n = 21) or 18 weeks (n = 20) of GZR (100 mg) + EBR (50 mg) + RBV. The primary end point was HCV RNA <25 IU/mL 12 weeks after end of treatment (SVR12) assessed by COBAS TaqMan v2.0 (lower limit of quantitation <25 IU/mL). Cirrhosis status was determined by either liver biopsy or noninvasive tests.
Results: The study is ongoing: data as of 11/21/2014. Forty-one patients were enrolled: 39% were male, 93% were white, mean age was 46.0 years (range 22–61), and mean viral load was 6.0 $\log_{10}$ (range 2.7–7.4). In the 12-week arm, 10 patients experienced breakthrough or rebound during treatment, 1 patient relapsed and 10 patients achieved SVR4. In the 18-week arm, 7 patients experienced breakthrough or rebound during treatment, 1 patient discontinued unrelated to drug-related adverse event or virologic failure. Of the remaining 12 patients, 1 is TND (HCV RNA target not detected) at follow-up week 4 and 11 are TDu (HCV RNA target detected, unquantifiable, n = 1) or TND (n = 10) on treatment between weeks 12 and 18. Adverse events reported in >10% of patients were fatigue (25%), headache (24%) and asthenia (14%). Final SVR12 results will be presented.
Conclusions: In this pilot study of GZR (100 mg) + EBR (50 mg) + RBV in treatment-naive, noncirrhotic patients with HCV GT3 infection, low efficacy was achieved regardless of duration. Breakthrough or rebound occurred in 17 of 41 patients (41%). GZR and EBR with RBV is inadequate to treat GT3. Further study of this combination will be considered using a triple-drug regimen using GZR, MK-3682 plus either EBR or MK-8408, a pan-genotypic NS5A inhibitor with better GT3 activity.

P0777

SOFOSBUVIR-BASED TREATMENT UNDER REAL LIFE CONDITIONS IN GERMANY (THE SOFGER TRIAL)

P. Buggisch[1], C. Sarrazin[2], S. Mauss[3], H. Hinrichsen[4], K.-G. Simon[5], J. Vermehren[2], D. Hueppe[6], J. Petersen[1]. *[1]Leberzentrum Hamburg, IFI, Hamburg, [2]Johann Wolfgang Goethe University Hospital, Frankfurt, [3]Center for HIV and Gastroenterology, Duesseldorf, [4]Center for Gastroenterology, Kiel, [5]Center for Gastroenterology, Leverkusen, [6]Center for Gastroenterology, Herne, Germany*
E-mail: Buggisch@ifi-medizin.de

Background and Aims: The approval of direct-acting antivirals (DAA) in Germany starting with Sofosbuvir (SOF) in January 2014, Simeprevir (SIM) in May 2014 and Daclatasvir (DCV) in August changed the landscape of HCV-therapy. Recommendations in Germany (BNG/DGVS) were rapidly changed accordingly: first in favour for triple therapy with PEG-IFN, Ribavirin (Riba), SOF, later on for dual therapy with SOF/Riba (GT 2) and SIM/SOF (limited to special cases), and DCV/SOF. Aim of this study was to evaluate the change of treatment modalities following the implementation of recommendation as well as the safety and efficacy of the SOF based therapies under real life conditions.
Methods: In this non-interventional, prospective, multi-center study conducted by the Association of German Gastroenterologists in private practice (BNG) (5 centers) and one academic based center (Frankfurt), SOF-based therapies are currently being evaluated in Germany. Demographic, clinical, virology data and adverse events are collected throughout treatment and post-treatment. This interim analysis shows data about patients with SOF-based treatments from January to October 2014.
Results: 556 patients (319 male, 237 female) received SOF-based treatments. 339 pts with genotype 1 (152 1a, 187 1b), 61 genotype 2, 111 genotype 3, 45 genotype 4. Treatment-naive were 186, 352 had previous treatment (relapse 187, nonresponse 158, 18 unknown), 57% of patients had fibrosis F3–4. 58 pts received SOF/Riba for 12 weeks (all G2), 52 SOF+Riba for 24 weeks. 158 received triple therapy 12 weeks, 181 SOF+DCV +/− Riba (mainly F4, some in compassionate use), 5 SOF+SIM, 102 SIM/SOF. Within 5 months the landscape switched to mostly IFN-free regimen. SVR 12 data in the Triple-therapy group are available so far from 132 patients: 121 SVR12, 7 relapses, 4 pts were lost to follow up. 4 patients with IFN based therapy had to stop treatment because of IFN side effects. Anemia and fatigue were the most reported AEs. No severe side effects occurred. There were 4 deaths (out of 556) reported due to complications of cirrhosis. More SVR 12 data and detailed results for the different treatments will be available at the meeting.
Conclusions: SOF-based triple therapies under real life conditions seems to have comparable results to clinical trials. Following recommendations, there was a fast switch to IFN-free therapies in Germany in 2014. There is a clear trend to treat advanced patients first, but almost 40% were treated without advanced fibrosis. Adverse events and treatment discontinuations were low.

P0778

THE EFFECT OF HCV ANTIVIRAL THERAPY ON FIBROSIS PROGRESSION

M. Lu[1], J. Li[1], L.B. Rupp[1], S.D. Holmberg[2], A.C. Moorman[2], P.R. Spradling[2], E. Tehale[2], F. Xu[2], J.A. Boscarino[3], V. Vijayadeva[2], M.A. Schmidt[4], L.E. Lamerato[1], S. Gordon[1]. *[1]Henry Ford Health System, Detroit, [2]Centers for Disease Control, Atlanta, [3]Geisinger Health System, Danville, [4]Kaiser-Permanente Northwest, Portland, United States*
E-mail: strudea1@hfhs.org

Background and Aims: The extent to which antiviral therapy for hepatitis C virus (HCV) infection alters the course of fibrosis progression is not well understood. We sought to study the impact of antiviral therapy, with and without sustained viral response (SVR), on fibrosis progression as measured by FIB4 trajectory among patients in the Chronic Hepatitis Cohort Study (CHeCS), a longitudinal observational study that draws patients from 4 large US health systems.
Methods: The index date was defined as date of HCV diagnosis or initial treatment, whichever was later. Patients were excluded if they were ever enrolled in an HCV treatment clinical trial, were co-infected with HBV, had received a liver transplant prior to the index date, or were receiving ongoing HCV treatment at end of follow-up. FIB4 scores were derived from routine testing and summarized as median values in 90-day intervals for up to six years after the index date. Only patients with two or more summarized FIB4 scores in addition to index date were included. Multilevel regression for longitudinal logFIB4, univariate followed by the multivariable modeling, was used to test the effects of HCV treatment and SVR on FIB4 trajectory over time. All analyses were adjusted using propensity score. Age, sex, FIB4, diabetes, and history of alcohol abuse at baseline were considered in the propensity score calculation.
Results: A total of 4,148 patients with confirmed HCV infection were included; 1,403 (34%) were treated (92% with dual ribavirin/interferon therapy and 5% with triple therapy), of whom 648 (46%) achieved an SVR. The final multilevel regression model showed significant change in FIB4 based on time, as well as interaction terms indicating that the fibrosis trajectory differed based on sex and timing of treatment response. Over time, men demonstrated consistently higher FIB4 levels than women ($p < 0.01$). For both males and females who achieved SVR, logFIB4 decreased for several years, then leveled off at year 4.5. Non-SVR responders demonstrated slow climbing logFIB4 in the range of 0.5–0.8 for females and 0.7–1.1 for males, while untreated males showed more rapid logFIB4 progression.
Conclusions: Eradication of HCV with antiviral therapy appeared to induce a regression of fibrosis, as measured by the FIB4 biomarker over a 6-year timeframe in a large diverse US cohort. Both absence of treatment and unsuccessful treatment were characterized by a progressive increase in fibrosis progression, with untreated males showing more rapid progression.

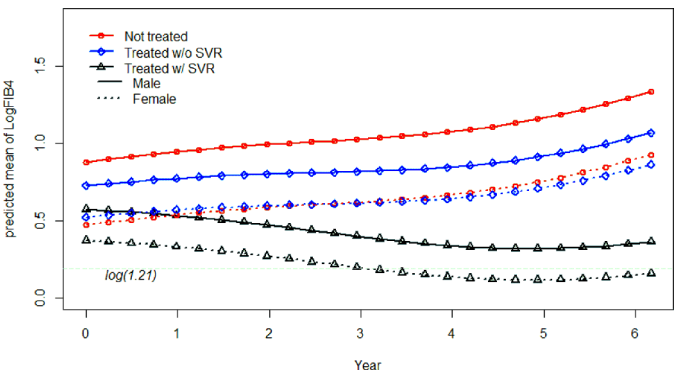

Figure: Predicted log FIB4 over time.

P0779

LEDIPASVIR/SOFOSBUVIR WITH RIBAVIRIN FOR THE TREATMENT OF FIBROSING CHOLESTATIC HEPATITIS C AFTER LIVER TRANSPLANTATION

X. Forns[1], D. Mutimer[2], M. Manns[3], K.R. Reddy[4], G.T. Everson[5], S.L. Flamm[6], J. Denning[7], S. Arterburn[7], T. Brandt-Sarif[7], P.S. Pang[7], J.G. McHutchison[7], N. Afdhal[8], M. Charlton[9], D. Samuel[10], E. Gane[11]. *[1]Liver Unit, IDIBAPS, CIBEREHD, Barcelona, Spain; [2]QE Hospital and University of Birmingham, Birmingham, United Kingdom; [3]Hannover Medical School, Hannover, Germany; [4]University of Pennsylvania School of Medicine, Philadelphia, [5]University of Colorado Denver, Aurora, [6]Northwestern Feinberg School of Medicine, Chicago, [7]Gilead Sciences, Inc., Foster City, [8]Beth Israel Deaconess Medical Center, Boston, [9]Intermountain Medical Center, Murray, United States; [10]Université Paris-Sud, Villejuif, France; [11]University of Auckland, Auckland, New Zealand*
E-mail: jill.denning@gilead.com

Background and Aims: Fibrosing cholestatic hepatitis (FCH) is a rare and severe form of recurrent hepatitis post liver transplantation with high morbidity (e.g., graft loss) and mortality. There are no approved treatments for FCH. This study evaluated ledipasvir/sofosbuvir (LDV/SOF) with ribavirin (RBV) in patients with biopsy-proven FCH.

Methods: In this open-label study, genotype 1 HCV-infected patients within 18 months of transplant, with histologic evidence of FCH (hepatocyte ballooning, periportal or pericellular/sinusoidal fibrosis, cholestasis, cholangiolar proliferation) total bilirubin ≥2.5×ULN and no alternative explanations for cholestasis, were randomized to receive 12 or 24 weeks of LDV/SOF with RBV (weight-based). The primary endpoint is SVR12.

Results: 12 patients have been randomized and treated. Most were male (75%), Caucasian (83%), GT 1a (75%) and had prior HCV treatment (75%). Mean baseline HCV RNA was 6.8 log10 IU/mL [range 4.9–8.0 log10 IU/mL]. 9 patients have completed treatment and 3 are still receiving treatment. There have been no treatment discontinuations. 5 patients (42%) experienced treatment-emergent serious adverse events (SAEs). One SAE, dyspnea, was considered related to study treatment. The most common adverse events were anemia, headache, fatigue and pruritus. Laboratory values at baseline and Week 12 are presented in the table. Bilirubin, GGT and alkaline phosphatase (hallmarks of FCH), as well as albumin, platelets, ALT and INR were all improving with treatment by Week 12.

By on-treatment week 4, eleven of 12 patients had HCV RNA <LLOQ and all 8 of the patients who have reached follow-up week 4 have achieved SVR4. SVR12 data will be presented.

	Normal range	LDV/SOF+RBV (N = 12)	
		Mean, baseline	Mean, Week 12
Bilirubin, mg/dL (range)	0.2–1.2	9.4 (1.5–28.1)	1.7 (0.6–5.2)
GGT, U/L (range)	4–61	554 (47–1332)	139 (15–686)
Alkaline phosphatase, U/L (range)	31–131	218 (114–562)	115 (40–356)
ALT, IU/mL (range)	6–43	161 (62–220)	30 (8–100)
Hemoglobin, g/dL (range)	11.5–18.1	12.5 (8.8–14.5)	11.6 (8.8–13.5)
Platelets $\times 10^3$/uL (range)	130–400	140 (40–217)	165 (53–280)
Albumin, g/dL (range)	3.3–4.9	3.0 (2.2–3.8)	3.7 (2.7–4.6)
INR (range)	0.8–1.2	1.4 (0.9–3.6)	1.1 (0.9–1.3)

Conclusions: Administration of LDV/SOF+RBV in patients with FCH has been well tolerated and resulted in high SVR4 rates in a population with no other options.

P0780

DEEP SEQUENCING ANALYSES IN HCV GENOTYPE 1-INFECTED PATIENTS TREATED WITH SIMEPREVIR PLUS SOFOSBUVIR WITH/WITHOUT RIBAVIRIN IN THE COSMOS STUDY

B. Fevery[1], K. Thys[1], E. Van Rossem[1], T. Verbinnen[1], G. Picchio[2], J. Aerssens[1], S. De Meyer[1], M. Beumont[1], D. Kurland[2], O. Lenz[1]. *[1]Janssen Infectious Diseases BVBA, Beerse, Belgium; [2]Janssen Research & Development, LLC, Titusville, NJ, United States*
E-mail: bfevery@its.jnj.com

Background and Aims: Simeprevir (SMV) and sofosbuvir (SOF) are approved for the treatment of chronic hepatitis C virus (HCV) infection. The presence of minority NS3/NS5B baseline polymorphisms and emerging mutations in HCV genotype 1-infected patients treated with SMV plus SOF with/without ribavirin in the COSMOS study (TMC435HPC2002; NCT01466790) was determined by deep sequencing (DS).

Methods: Illumina® NS3/NS5B DS data (1% cut-off) were available pre-treatment for 73/167 patients and post-baseline for 4/6 relapsers. In addition, early on-treatment NS3 DS data (Day 2–4 with HCV RNA >10,000 IU/mL) were available for 15 patients (including 2 relapsers). Changes at NS3 amino acid positions 43, 80, 122, 155, 156 and 168, and NS5B positions 96, 142, 159, 282, 316, 320, 321, 390 and 415 were analysed.

Results: Minority NS3 and NS5B baseline polymorphisms (i.e., not detected by population sequencing [PS]) were observed in 17.8% (13/73) and 11.0% (8/73) of patients, respectively. In 4/13 and none of the 8 patients carrying minority NS3 and NS5B polymorphisms, these variants were known to affect *in vitro* SMV or SOF activity, respectively. NS3 baseline polymorphism Q80K was detected by both DS and PS in 43/61 (70.5%) genotype 1a patients at a median DS read frequency of 99.6%. Three additional patients (including 1 genotype 1b patient) had Q80K detectable by DS only (read frequency range: 4.6–13.0%); all 3 patients achieved SVR12. One additional patient had minority NS3 baseline polymorphism known to affect *in vitro* SMV activity (D168N at a read frequency of 1.3%) and achieved SVR12. The emerging NS3 mutations observed at time of relapse by PS were not detected at baseline or early on-treatment by DS. No additional emerging NS3 minority mutations were observed at time of relapse by DS. No emerging NS5B mutations were observed by PS or DS.

Conclusions: Relapse in the COSMOS study was not associated with the presence of minority baseline polymorphism and/or early on-treatment emergence of NS3/NS5B minority mutations. No SOF resistance mutations were observed at time of relapse with DS.

HIGH SVR RATES DESPITE MULTIPLE NEGATIVE PREDICTORS IN GENOTYPE 1 PATIENTS RECEIVING OMBITASVIR/PARITAPREVIR/R, DASABUVIR WITH OR WITHOUT RIBAVIRIN FOR 12 AND 24 WEEKS: INTEGRATED ANALYSIS OF SIX PHASE 3 TRIALS

N. Reau[1], M.W. Fried[2], H. Wedemeyer[3], C. Cooper[4], M. Diago[5], A. Craxi[6], S. Strasser[7], J.-F. Dufour[8], W. Xie[9], L. Larsen[9], E.O. Dumas[9], D. Bernstein[10]. *[1]University of Chicago Medical Center, Chicago, [2]University of North Carolina, Chapel Hill, United States; [3]Medizinische Hochschule Hannover, Hannover, Germany; [4]University of Ottawa, Ottawa, Canada; [5]Hospital Quirón de Valencia, Valencia, Spain; [6]A.O.U Policlinico "P. Giaccone" Dip. E-mail: douglas.dylla@abbvie.com

Background and Aims: Phase 3 studies of the 3 direct-acting antiviral (3D) regimen of ombitasvir co-formulated with

paritaprevir/ritonavir (PTV/r, identified by AbbVie and Enanta) and dasabuvir with or without ribavirin (RBV) have demonstrated high efficacy in HCV genotype 1-infected patients regardless of host, viral, and disease characteristics. Whether multiple negative predictors of response have meaningful impact on SVR rates was evaluated using data from six phase 3 studies.

Methods: Multivariate stepwise logistic regression was performed on >2000 HCV genotype 1-infected patients treated with 3D +/− RBV in the SAPPHIRE-I, SAPPHIRE-II, TURQUOISE-II, PEARL-II, PEARL-III, and PEARL-IV studies to identify factors associated with reduced SVR12 rates. Independent continuous variables included age, baseline BMI, weight, HCV RNA, and alanine aminotransferase level; independent categorical variables included HCV subgenotype, IL28B genotype, sex, race, ethnicity, geographic region, fibrosis stage, cirrhosis, treatment regimen (3D vs 3D + RBV), treatment duration (12 vs 24 weeks for patients with cirrhosis), prior HCV treatment experience, and history of diabetes, depression or bipolar disorder, bleeding disorders, and former injection drug use (IDU). Significance level for entering and exiting the model was 0.1.

Results: Five independent variables were associated with lower SVR12 rates: HCV genotype 1a, higher baseline weight, IL28B TT genotype, Hispanic/Latino ethnicity, and higher baseline HCV RNA. The overall SVR12 rate was 96.2% (1964/2041); SVR12 rates were 99% in patients with 0 or 1 negative predictor, and 97% and 95% in those with 2 or 3 negative factors, respectively. SVR rates declined to <95% only among patients with a combination of 4 or 5 negative predictors of response, 86% (106/123) and 82% (9/11) in patients with 4 or 5 negative predictors, respectively.

Conclusions: The 3D +/− RBV regimen achieves high SVR rates across patient populations with multiple negative predictors. SVR12 rates among patients with multiple negative factors using approved treatment regimens will be presented.

E-mail: christiaan.wallett@articulatescience.com

Background and Aims: The phase 3 ALLY-3 study evaluated the all-oral, ribavirin (RBV)-free combination of daclatasvir (DCV; pangenotypic NS5A inhibitor) and sofosbuvir (SOF; NS5B polymerase inhibitor) in patients with GT3 infection. After 12 weeks of treatment, sustained virologic response at posttreatment Week 12 (SVR12) was achieved by 90% and 86% of treatment-naive and -experienced patients, respectively.

Methods: Treatment-naive (N = 101) and experienced (N = 51) patients received open-label DCV 60 mg + SOF 400 mg once daily for 12 weeks. This subanalysis provides further details of efficacy and safety outcomes in the experienced cohort.

Results: Treatment-experienced patients were predominantly male (63%), white (88%) and non-cirrhotic (67%); 75% had baseline HCV RNA ≥800K IU/mL, and 61% had non-CC *IL28B* genotypes. Patients had previously received IFN-based (n = 42), SOF-containing (n = 7, including 7 treated with SOF/RBV and 1 who was retreated with SOF/peg/RBV) and alisporivir-containing (n = 2) regimens. Prior responses included relapse (n = 31), null response (n = 7), partial response (n = 2), and other forms of nonresponse or IFN intolerance (n = 11). All patients completed 12 weeks of study treatment. SVR12 was achieved in 44 patients (86%); all prior null and partial responders, and IFN-intolerant patients achieved SVR12. SVR12 rates were higher in patients without cirrhosis and in those with *IL28B* CC genotype (Table). Treatment failure (relapse) was experienced by 7 patients, including 5 prior IFN/RBV recipients (prior response: relapsers, n = 4; HCV RNA never undetectable, n = 1) and 2 patients who relapsed after prior treatment with SOF/RBV. Of the two prior SOF relapsers, one had cirrhosis with grade 1 steatosis, and one had Fibrotest F3 with grade 2 steatosis, and a baseline NS5A-Y93 resistance-associated variant. There were no serious AEs or AEs leading to discontinuation. Grade 3/4 AEs (a single report of arthralgia) and grade 3/4 lab abnormalities (platelets, n = 1; lipase, n = 1) were uncommon. The most frequent AEs (any grade) were fatigue (26%), headache (20%), nausea (14%) and arthralgia (12%). Safety parameters were similar in those with or without cirrhosis.

Parameter	SVR12, % (n/N)
All treatment-experienced	86 (44/51)
Prior IFN-based regimen	88 (37/42)
Prior sofosbuvir-containing regimen	71 (5/7)
Prior alisporivir-containing regimen	100 (2/2)
Patients without cirrhosis	94 (32/34)
Patients with cirrhosis	69 (9/13)
Fibrotest F0–3	91 (39/43)
Fibrotest F4	63 (5/8)
NS5A-Y93 baseline resistance-associated variant present	71 (5/7)
NS5A-Y93 baseline resistance-associated variant absent	88 (38/43)
IL28B CC	95 (19/20)
IL28B non-CC	81 (25/31)

Conclusions: This all-oral, 12-week combination of DCV+SOF achieved high SVR12 rates in GT3 patients previously treated with all oral DAA or IFN-containing regimens. DCV+SOF was well tolerated.

E-mail: karin.kozbial@meduniwien.ac.at

Background and Aims: Sofosbuvir (SOF), Simeprevir (SMV) and Daclatasvir (DCV) are reimbursed for chronic hepatitis C patients with advanced liver disease (F3, F4) and posttransplant patients in Austria. Real-life data in these patients are scarce and the optimal duration of treatment is still under debate. The aim of this study was to evaluate viral kinetics in patients with advanced liver disease receiving interferon-free treatment regimens.

Methods: We included 181 patients (mean age: 55.8±10.1 years, m/f: 117/64, treatment experienced: 109 [60%], prior failure to protease inhibitors: 23 [13%]) with advanced fibrosis (Metavir score F3: n = 13, F4: n = 168; median platelet count: 98 G/l) who were treated with Sofosbuvir (SOF) 400 mg/day combined with 60 mg/day Daclatasvir (DCV) (GT 1, 3, 4; n = 86) or with Simeprevir (SMV) 150 mg/d (GT1 and 4; n = 49) or weight based ribavirin (RBV; GT 1–4; n = 46). Duration of treatment was at the discretion of the investigator. Viral load was measured after 48 hours, at weeks 1, 2, 3, 4 and then every 4 weeks until the end of treatment by Abbott RealTime HCV quantitative assay (lower limit of quantification [LLOQ]: 12 IU/ml) or by Roche COBAS AmpliPrep/ COBAS TaqMan HCV quantitative assay, Version 2 (LLOQ: 15 IU/ml).

Results: HCV-RNA dropped by a mean log of 2.91 and 3.54 after 48 hours and 7 days, respectively. At weeks 4, 8, 12, and 16 of treatment, 23%, 60%, 84%, and 93% of patients with advanced liver disease had undetectable HCV RNA (TND, target not detected), respectively. Currently 54 patients have reached end of treatment after a treatment duration of 12 weeks (n = 16), 16 weeks (n = 2) or 24 weeks (n = 36). 5 patients discontinued therapy due to psychiatric adverse events (n = 2), death (n = 2, sepsis and multiple organ failure due to decompensation), and non-adherence (n = 1). 29 patients reached follow-up week 4 (23 SVR4, 6 relapsed) and 4 reached follow-up week 12 (all SVR12). All relapsers received SOF/RBV treatment.

Conclusions: Determination of on-treatment response may help to optimize treatment regimen in patients with advanced liver disease. Patients with detectable HCV RNA at treatment week 12 (16%) may need a treatment of 24 weeks.

SOFOSBUVIR IN COMBINATION WITH PEGINTERFERON AND RIBAVIRIN FOR PATIENTS CHRONICALLY INFECTED WITH HEPATITIS C VIRUS GENOTYPE 4: "REAL-LIFE" EXPERIENCE OF TWO LARGE VIRAL HEPATITIS CENTERS IN NORTHERN GERMANY

M.H. Wehmeyer[1], S. Jordan[1], C. Eißing[1], J. Hartl[1], A. Stöhr[2], J. Petersen[2], A.W. Lohse[1], S. Lüth[1], P. Buggisch[2], J. Schulze zur Wiesch[1]. *[1]I. Department of Medicine, University Medical Center Hamburg-Eppendorf, [2]IfI-Institute for Interdisciplinary Medicine, Hamburg, Germany*
E-mail: m.wehmeyer@uke.de

Background and Aims: Sofosbuvir (SOF)-based triple therapy has been approved for all hepatitis C virus (HCV) genotypes. However, real life efficacy data of SOF in patients with genotypes 4 to 6 are limited. Furthermore, SOF-based triple therapy was never directly compared to dual therapy with peginterferon (IFN) and ribavirin (RBV).

Methods: Every patient with HCV genotype 4, 5 or 6 infection who received IFN/RBV/SOF between January and June 2014 at our two centers was included, and patients' data were compared with historical HCV genotype 4 patients treated with IFN/RBV from 01/2001 to 12/2007.

	IFN/RBV/SOF N (%) Mean (±SD) Median (range)	IFN/RBV N (%) Mean (±SD) Median (range)	P-value
Male sex	21 (80.8%)	41 (83.7%)	0.757
Age [years]	47.00 (± 11.02)	42.33 (± 9.29)	0.072
Stage of fibrosis [METAVIR]			0.073
F0–2	13 (50%)	36 (73.5%)	
F3–4	13 (50%)	13 (26.5%)	
Cirrhosis (F4)	6 (23.1%)	6 (12.2%)	0.321
Treatment naïve	13 (50%)	39 (79.6%)	**0.017***
Treatment experienced			
Relapse	7 (26.9%)	3 (6.1%)	**0.017***
Non-response	5 (19.2%)	6 (12.2%)	0.498
Breakthrough	1 (3.8%)	1 (2.0%)	1
Baseline laboratory			
Viral load [U/mL]	645×10^3 (10^2 to 7×10^6)	70×10^3 (0.5×10^3 to 2×10^6)	**<0.001***
Haemoglobin [g/dL]	14.9 (11.8–17.2)	15.2 (11.5–18.3)	0.691
Platelets [billion/L]	200.5 (104–350)	220 (59–392)	0.589
Leucocytes [billion/L]	6 (2.5–10.6)	6.5 (2.9–15.6)	0.853
ALT [U/L]	56 (25–290)	63 (11–346)	0.997
Ribavirin dose reduction	7 (26.9%)	14 (28.6%)	1
Peginterferon dose reduction	1 (3.8%)	11 (22.4%)	**0.048***
RVR (N = 66)	17/24 (70.1%)	16/42 (38.1%)	**0.020***
EOTR	25/26 (96.2%)	30/49 (61.2%)	**0.002***
SVR12	19/22 (86.4%)	21/49 (42.9%)	**0.001***

Results: We included 75 patients in our study. 26 patients received SOF-based triple therapy and 49 patients were treated with IFN/RBV. Baseline characteristics of both groups are provided in the accompanying table. Sustained virological response (SVR12) was achieved in 19/22 (86.4%) patients who received IFN/RBV/SOF and in 21/49 patients (42.9%) of the control group (P = 0.001). Rapid virological response (RVR) was a predictor of SVR12 in the control group (13/16 with RVR compared to 4/26 patients without RVR achieved SVR12; P < 0.001), whilst patients with SOF-based therapy achieved SVR12 regardless of reaching RVR (SVR12 in 6/6 patients with RVR and in 13/15 patients without RVR; P = 1). All cirrhotic patients with SOF-based triple therapy achieved SVR12. Notably, adverse events (AEs) of any kind more frequently occurred in the control group than in the SOF group (95.9% vs. 69.2%; P = 0.002). Particularly gastrointestinal (P < 0.001), dermatologic (P = 0.003) and psychiatric (P = 0.030) AEs were more frequent in IFN/RBV patients than in patients receiving IFN/RBV/SOF. SVR data of 4 patients are pending, but will be provided in April 2015.

Conclusions: A 12 week course of IFN/RBV/SOF was significantly more effective than dual therapy for 48 weeks. Furthermore,

patients who received dual therapy displayed a higher risk to experience side-effects than patients with SOF-based triple therapy. Combination of sofosbuvir, peginterferon and ribavirin should be considered as first-line therapy for patients chronically infected with HCV genotypes 4 to 6, if all-oral therapy is not available.

P0785

FIRST REAL CLINICAL PRACTICE DATA IN SPAIN ON SOFOSBUVIR, SIMEPREVIR AND DACLATASVIR IN POST-TRANSPLANT HCV RECURRENCE: THE HepatiC REGISTRY EXPERIENCE

M. Prieto[1], M. Carlota Londoño[2], J.M. Pascasio[3], M. Salcedo[4], J. Crespo[5], J.L. Montero[6], I. Baños[7], I. Fernández[8], C. Vinaixa[9], C. Fernández-Carrillo[7], J.L. Calleja[7], X. Forns[2], on behalf of HepatiC Registry. *[1]Hospital Universitari i Politècnic La Fe de Valencia, Valencia, [2]Hospital Clínic de Barcelona, Barcelona, [3]Digestive diseases, Hospital Universitario Virgen del Rocío, Sevilla, [4]Hospital General Universitario Gregorio Marañón, Madrid, [5]Hospital Universitario Marqués de Valdecilla, Santander, [6]Hospital Universitario Reina Sofía, Córdoba, [7]Hospital Universitario Puerta de Hierro-Majadahonda, Majadahonda (Madrid), [8]Hospital Universitario 12 de Octubre, Madrid, [9]Universitari i Politècnic La Fe de Valencia, Valencia, Spain*
E-mail: cfernandezc@idiphim.org

Background and Aims: Direct-acting antivirals (DAA) have become elective treatment for HCV chronic infection. After phase III trials, sofosbuvir (SOF), simeprevir (SIM) and daclatasvir (DCV) have recently started their use in Spain in different combinations. The aim of this study is to analyse the initial experience in Spain on these new treatments in liver transplant (LT) patients.
Methods: AEEH's HepatiC is a multicentric monitored registry including HCV-infected patients under DAA. We selected 106 LT patients with post-LT HCV-recurrence under compassionate use. The main basal characteristics and safety data regarding SVR at week 4 post-end of treatment (SVR4) were assessed.
Results: Eighty-nine percent of the patients had G1 and the others G3–4. Cholestatic recurrence was present in 30% of patients and 34% had F4 fibrosis stage. At treatment onset, 26% had ascites (median MELD 12, 6–31). The most part of the patients (69%) were treatment-experienced, including new DAA (5%). Treatment groups: SOF/PR (n = 16), SOF/R (n = 52), SOF/DCV±R (n = 28), SIM/DCV±R (n = 10). Currently, 46/106 patients have data on SVR4. With complete data pending, global SVR is 80%. SVR4 by groups was: SOF/PR, 89% (8/9); SOF/R, 72% (21/29); SOF/DCV±R, 100% (6/6); SIM/DCV±R, 100% (1/1). No difference in SVR4 was found for patients with cholestatic recurrence (88.2% *vs* 71%, p = 0.284). Among patients with F4, those with liver decompensation had lower SVR4 than compensated ones (56% *vs* 88%, p < 0.05). Albumin and bilirubin levels significantly improved after treatment (Alb, 3.4 *vs* 4 g/dL, p < 0.001; Bil, 1.8 *vs* 1 mg/dL, p < 0.001), unlike platelets (88 *vs* 107×10^9/L, p = 0.207). Regarding safety, 36% of the patients experienced severe adverse events (SAE) during treatment, mainly transfusion-requiring anemia (22/38, 58%). Patients on ribavirin had more need for transfusion (24% *vs* 5%, p < 0.05). No association was observed between interferon use and SAE (38% *vs* 36%, p = 0.785), yet this group is small (n = 16). During treatment, 8/106 (8%) cases of grade 3–4 infection were registered. Nevertheless, only 7/106 (7%) patients required early discontinuation due to SAE.
Conclusions: First data on real clinical practice show that new DAA induce high RVS4 and improve hepatic function in a difficult-to-treat population as LT recipients. While SAE are still present, DAA discontinuation was necessary in a low proportion of patients. Complete data on SVR12 will be presented, including SOF+DCV and SIM+DCV with and without R, 12 vs 24 weeks.

P0786

100% SVR12 WITH LEDIPASVIR/SOFOSBUVIR±RIBAVIRIN FOR 12 WEEKS IN JAPANESE PATIENTS WITH CHRONIC GENOTYPE 1 HEPATITIS C VIRUS WHO PREVIOUSLY FAILED THERAPY WITH PROTEASE INHIBITOR + PEGYLATED INTERFERONα + RIBAVIRIN

E-mail: shampa.de-oertel@gilead.com

Background and Aims: Patients with HCV who have previously failed other therapies have lower rates of SVR12 than treatment naïve patients. This open-label, Phase 3 study evaluated the efficacy and safety of ledipasvir 90 mg/sofosbuvir 400 mg Fixed-Dose Combination (LDV/SOF FDC) ± ribavirin (RBV) administered orally, once daily for 12 weeks in Japanese patients with HCV GT1.
Methods: Patients were included if: age ≥20 years; HCV-RNA ≥10^5 IU/mL; platelets ≥50,000/μL. Primary endpoint was Sustained Virologic Response 12 weeks after treatment completion (SVR12). Here we present a post-hoc subgroup analysis of patients who failed previous therapy with a protease inhibitor (PI) plus pegylated interferon (Peg-IFNα) and RBV.
Results: Out of the total study population of 341 patients, 40 (12%) had previously failed treatment with PI+Peg-IFNα+RBV. In this subpopulation, the mean age was 60 years and 40% were male. In terms of their HCV disease characteristics, 93% were HCV GT1b, 25% were IL28 CC, 18% had cirrhosis and mean HCV RNA was 6.5 log10 IU/mL. Prior PI treatment included telaprevir (n = 14), simeprevir (n = 13), vaniprevir (n = 8), and faldaprevir (n = 5). Most (31/40) had previously relapsed, five were non-responders, and four were IFN intolerant.
All patients who had previously failed PI+ Peg-IFNα+RBV therapy (40/40) achieved SVR12 after 12 weeks of treatment with LDV/SOF±RBV. LDV/SOF±RBV was also safe to use in this population. In the LDV/SOF group, 8/17 (47%) patients reported a treatment-emergent adverse event (TEAE). All of these were mild and only one was considered related to study drug. In the

LDV/SOF+RBV group, 18/23 (78%) reported a TEAE. All were mild to moderate in severity and most were considered related to study drug. The most common AE in both arms was nasopharyngitis. In the LDV/SOF+RBV arm, RBV-related AEs such as anemia, nausea and rash were also reported. There were no Grade 3 or 4 AEs nor discontinuations due to AE in either arm.

Conclusions: LDV/SOF FDC±RBV for 12 weeks achieved SVR12 in 100% of Japanese patients who had previously failed PI+ Peg-IFNα+RBV. LDV/SOF FDC for 12 weeks provides a highly effective, well-tolerated, IFN- and RBV-free treatment for Japanese patients with chronic HCV GT1 infection.

P0787

COMPARISON OF SOFOSBUVIR +/− SIMEPREVIR IN HETEROGENEOUS, REAL-WORLD POPULATIONS OF HCV PATIENTS OVER 70 YEARS OF AGE VS YOUNGER HCV PATIENTS; DATA FROM THE TRIO NETWORK

N. Tsai[1], K. Kowdley[2], B. Bacon[3], S. Flamm[4], E. Lawitz[5], S. Milligan[6], Z. Younossi[7], D. Dieterich[8]. *[1]Queen's Medical Center, University of Hawaii, Honolulu, [2]Liver Care Network, Swedish Medical Center, Seattle, [3]School of Medicine, St. Louis University, St. Louis, [4]Feinberg School of Medicine, Northwestern University, Chicago, [5]The Texas Liver Institute, University of Texas Health Science Center, San Antonio, [6]Trio Health Analytics, Newton, [7]Center for Liver Diseases, Department of Medicine, Inova Fairfax Hospital, Falls Church, [8]Icahn School of Medicine, Mount Sinai, New York, United States*
E-mail: scott.milligan@triohealth.com

Background and Aims: Clinical trials often exclude significant numbers of patients over the age of 65 years and data on treatment of older patients with HCV is lacking. Trio Health is a disease management company that works in partnership with academic medical centres, community physicians and specialty pharmacies in the US to optimize care for Hepatitis C. Data obtained through the Trio Health program were used to evaluate efficacy and tolerability of regimens containing sofosbuvir or simeprevir in HCV patients over 70 years of age in comparison to HCV patients 70 years or younger.

Methods: Data were collected from Rx records through the Trio Platform in partnership with specialty pharmacies. Analyses were limited to 955 patients who initiated treatment with 12 week regimens between December 2013 and March 2014. Patients were treated in 142 clinics, 30 of which were academic-based. 55 of the 955 patients were over 70 years of age.

Table 1. Patient demographics and clinical characteristics at baseline

	Age ≤70 years, N = 900 (94%)	Age >70 years, N = 55 (6%)
Age, mean (range)	56 (17–70)	74 (71–86)
Male, no. (%)	535 (59%)	30 (55%)
Black, no. (%)	141 (16%)	10 (18%)
Platelets <100K/ul, no. (%)	122 (16%)	10 (20%)
Treatment experienced, no. (%)	392 (44%)	15 (27%)
Cirrhosis, no. (%)	268 (30%)	23 (42%)
Genotype, no. (%)		
1	61 (7%)	1 (2%)
1a	448 (50%)	14 (25%)
1b	159 (18%)	20 (36%)
2	194 (22%)	18 (33%)
3	7 (1%)	0 (0%)
4–6	24 (3%)	1 (2%)
mixed	7 (1%)	1 (2%)
Initial viral load, no. (%)		
≤800,000 IU/ml	283 (31%)	26 (47%)
>6MM IU/ml	169 (19%)	9 (16%)
Regimen, no. (%)[a]		
PEG + RBV + SOF	377 (42%)	7 (13%)
RBV + SOF	207 (23%)	20 (36%)
SMV + SOF +/− RBV	292 (32%)	28 (51%)

[a] 24 patients received other therapies.

Results: Patient demographics and baseline clinical measures are provided in Table 1. In the over 70 years old group, the discontinuation rate was 7% and SVR12 rates were 79% and 95% for the Intent to Treat (ITT) and Per Protocol (PP) populations, respectively, with results pending for 8 patients. In comparison and without balancing for disease, treatment and/or patient characteristics, outcomes for ≤70 year old patients (n = 900) from the same time period were 4% discontinuation, 80% SVR12 (ITT) and 87% SVR12 (PP), with results pending for 119 patients. None of the rates were significantly different between the age groups, though the SVR12 PP rate difference approached significance at p = 0.056.

Conclusions: All oral DAA therapy is well tolerated in patients over 70 years old with SVR rates >80% similar to that seen in younger populations.

P0788

ESTIMATING THE COST-EFFECTIVENESS OF DACLATASVIR PLUS SOFOSBUVIR IN TREATMENT-NAÏVE, TREATMENT-EXPERIENCED AND INTERFERON-INELIGIBLE/INTOLERANT PATIENTS WITH ADVANCED CHRONIC HEPATITIS C GENOTYPE 1 INFECTION

P. McEwan[1,2], S. Webster[1], T. Ward[1], A. Kalsekar[3], Y. Yuan[3], M. Brenner[4]. *[1]HEOR, HEOR Ltd, Monmouth, [2]School of Human & Health Sciences, Swansea University, Swansea, United Kingdom; [3]World Wide Health Economics and Outcomes Research, Bristol-Myers Squibb Pharmaceuticals Ltd, Princeton, United States; [4]UK HEOR, Bristol-Myers Squibb Pharmaceuticals Ltd, Uxbridge, United Kingdom*
E-mail: samantha.webster@heor.co.uk

Background and Aims: The availability of effective treatment for chronic hepatitis C patients with advanced disease has been considered an area of unmet medical need due to the limited efficacy and sub-optimal safety of historical treatments. However, the treatment landscape for chronic hepatitis C is rapidly evolving. Presented herein is a cost-effectiveness analysis of licensed regimens for treatment-naïve, treatment-experienced and interferon-ineligible/intolerant patients infected with hepatitis C virus (HCV) genotype 1 with advanced disease (METAVIR score ≥F3).

Methods: A published Markov model was used to estimate the relative cost-effectiveness of chronic hepatitis C treatments over a lifetime horizon in a cohort that had a mean age of 50 years and were 67% male. Patients progress through disease stages using published transition rates. Patients were distributed across fibrosis stages F3 and F4 at therapy initiation according to UK data (78.62% and 21.38%, respectively). Disease state costs were obtained from 2013 UK data and discounting was set to 3.5%. Weekly treatment costs were as follows: daclatasvir (DCV): £2,083.13; sofosbuvir (SOF): £2,915.24; simeprevir (SMV): £1,866.50; telaprevir (TVR): £1,866.50; boceprevir (BOC): £700.00; ribavirin (RBV): £66.95;

Population	Regimen	SVR (%)	ICER (£) versus DCV+SOF
Naive	DCV+SOF	100	
	TVR+PR	66	7,851
	BOC+PR	41	1,346
	SOF+PR	80	14,240
	SMV+PR	68	12,265
	PR	41	8,861
	No treatment	0	4,263
Experienced	DCV+SOF	100	–
	No treatment	0	4,263
Interferon-ineligible/intolerant	DCV+SOF	100	–
	SOF+RBV	36	Dominant[a]
	SMV+SOF	93	Dominant[a]
	No treatment	0	4,263

[a] DCV+SOF is associated with improved quality of life and reduced total cost.

pegylated interferon-alfa+ribavirin (PR): £191.35. Clinical inputs were obtained from pivotal studies for all treatment regimens, as reported in respective Summaries of Product Characteristics (SPCs) or published articles.
Results: Predicted incremental cost-effectiveness results are presented in Table 1.
Conclusions: Treatment with DCV+SOF is likely to be cost-effective (at the £20,000/QALY threshold) and associated with improved quality of life against all available comparators in treatment-naïve, treatment-experienced and interferon-ineligible/intolerant HCV genotype 1 patients with advanced disease; further, DCV+SOF is expected to be associated with reduced total medical costs in interferon-ineligible/intolerant patients versus active comparators.

P0789
EFFECTIVENESS, SAFETY AND COST PER SVR IN GT4 HEPATITIS C PATIENTS TREATED WITH SOFOSBUVIR-BASED THERAPIES IN REAL CLINICAL PRACTICE: A FRANCO-GERMAN EXPERIENCE (SOFEX-4)

R. Pais[1], P. Buggisch[2], J. Moussalli[1], Y. Benhamou[1], H. Wedemeyer[3], T. Asselah[4], M. Bec[5], J. Schwarzbard[5], V. Ratziu[1], J. Petersen[2].
[1]Hepatogastroenterology, La Pitié-Salpêtrière Hospital, Paris, France; [2]Hepatology, Asklepios Klinik St Georg, Hamburg, [3]Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany; [4]Hepatology, Beaujon Hospital, Clichy, France; [5]Amaris, London, United Kingdom
E-mail: agauthier@amaris.com

Background and Aims: Sofosbuvir (SOF) is approved for treatment of chronic hepatitis C (CHC) patients genotypes (GT) 1–6 but clinical trial data with SOF regimens in GT4 is limited. In the real-world (RW) setting, very limited clinical data was recently presented (Buggisch et al. AASLD 2014 n = 18, TRIO AASLD 2014 n = 16), and no study to date has simultaneously evaluated the clinical and economic outcomes of SOF-based therapies in GT4 patients in Europe. The aim of this study was to estimate the total costs, RW effectiveness, safety and cost per SVR of CHC patients treated with SOF-based therapies in a Franco-German collaboration.
Methods: This is a retrospective multicentre cohort study including 160 GT4 patients treated in 5 centers (3 in France and 2 in Germany). All patients who received at least 1 week of SOF from January 17th 2014 (date of SOF approval by EMA) to October 31st 2014, are included. SVR rates (ITT), overall and by subgroup, along with incidence of adverse events (AE) requiring intervention, were estimated. Total cost incurred from therapy initiation to 12 weeks after treatment was estimated by summing drug costs, lab costs, patient care costs including AE (treatment related only) management costs. Cost per SVR was calculated as median cost divided by the SVR rate. Subgroup analysis included treatment experience and fibrosis stage.
Results: Complete results will be available at the time of presentation. Recruitment is on-going and preliminary results are based on 51 patients with 49% receiving SOF+PR, 33% SOF+SIM, 10% SOF+R and 8% SOF+DCV. Mean age was 54 years, and 88% were male. At study entry, 57% of patients were cirrhotic and 73% had received at least one prior therapy (from the 31 patients with data available, 61% did not respond to prior therapy and 29% relapsed). Overall the SVR rate was 92% with 86% in treatment-naïve patients and 94% in treatment-experienced patients. A total of 11 patients (22%) experienced AEs (7 patients on SOF+PR). One patient discontinued due to AE. Cost per SVR results, overall and per subgroup will be estimated once patients have completed treatment and SVR12 is available.
Conclusions: Preliminary data indicates high levels of SVR in this difficult to treat mostly cirrhotic and experienced GT4 patients.

P0790
THE EFFECT OF RENAL IMPAIRMENT ON MULTIPLE-DOSE PHARMACOKINETICS OF THE FIXED-DOSE COMBINATION OF DACLATASVIR/ASUNAPREVIR/BECLABUVIR

R. Adamczyk[1], K. Sims[1], M. Hesney[1], M. Wind-Rotolo[1], M. Stonier[1], R. Penn[2], L. Reynolds[2], F. LaCreta[1], M. AbuTarif[1]. *[1]Bristol-Myers Squibb Research and Development, Princeton, [2]ICON, Development Solutions, Hanover, United States*
E-mail: neslihan.oz@articulatescience.com

Background and Aims: Daclatasvir (DCV; NS5A inhibitor), asunaprevir (ASV; NS3 inhibitor), and beclabuvir (BCV [BMS-791325]; nonnucleoside NS5B inhibitor) are in phase 3 evaluation for chronic hepatitis C as a fixed-dose combination (FDC) of DCV/ASV/BCV (30/200/75 mg BID). As a subset of HCV patients have some degree of renal impairment due to age and comorbidities, this open-label, multiple-dose study (AI443–110) assessed the pharmacokinetics (PK) and safety of DCV/ASV/BCV FDC in HCV-uninfected subjects with normal renal function and renal impairment (RI) of varying degree.
Methods: All subjects were scheduled to receive DCV/ASV/BCV FDC + additional 75 mg BCV (to adjust for higher BCV exposures in HCV-infected patients) BID with food. Subjects were grouped based on renal function: normal renal function (creatinine clearance [CrCl] by Cockcroft-Gault of ≥90 mL/min), mild RI (CrCl 60 to <90 mL/min), moderate RI (CrCl 30 to <60 mL/min), severe RI (CrCl <30 mL/min) and end-stage renal dysfunction (ESRD) on hemodialysis (HD). All subjects received the regimen for 9 days with a single morning dose on Day 10. Noncompartmental PK parameters were derived and linear regression was used to estimate the relationship between Cmax (ng/mL) and AUC_{TAU} (ng·.h/mL) and CrCl. Predicted values for each PK parameter and associated 90% CIs were presented for CrCl equal to 15, 30, 60, and 90 mL/min. Safety was assessed and reported.
Results: A total of 41 subjects received study drug across normal renal function (n = 8), mild RI (n = 9), moderate RI (n = 8), severe RI (n = 8), and ESRD on HD (n = 8) groups. Values of PK parameters relative to the normal renal function group predicted from the regression analysis of CrCl are shown in the table. Regression analysis indicated that Cmax and AUC_{TAU} increased with decreasing CrCl for all 3 drugs. For subjects with ESRD on HD, exposures were similar to subjects with normal renal function. Multiple doses of study drug were generally well tolerated in all subjects. There were no deaths or SAEs. There was 1 discontinuation due to an AE (in moderate RI group) due to increased blood uric acid in a subject with baseline abnormalities, which was assessed as moderate and study drug-related.
Conclusions: No dose adjustment is recommended for renal impairment except for severe RI subjects that are not on HD, where QD dosing of the FDC is recommended instead of BID dosing.

Group	Adjusted Geometric Mean Ratio (90% CI) (vs Normal)						Dose adjustment
	DCV		ASV		BCV		
	Cmax	AUC_{TAU}	Cmax	AUC_{TAU}	Cmax	AUC_{TAU}	
Mild [a]	1.16 (1.03, 1.31)	1.22 (1.09, 1.37)	1.29 (0.98, 1.69)	1.33 (1.12, 1.59)	1.15 (1.02, 1.29)	1.28 (1.14, 1.45)	No
Moderate [a]	1.35 (1.19, 1.52)	1.50 (1.33, 1.68)	1.65 (1.26, 2.17)	1.76 (1.47, 2.11)	1.32 (1.17, 1.49)	1.65 (1.45, 1.86)	No
Severe [a]	1.45 (1.29, 1.63)	1.65 (1.47, 1.86)	1.88 (1.43, 2.47)	2.03 (1.69, 2.43)	1.42 (1.26, 1.60)	1.86 (1.65, 2.11)	QD instead of BID
ESRD [b]	0.95 (0.72, 1.25)	1.00 (0.76, 1.33)	0.89 (0.45, 1.73)	0.84 (0.52, 1.35)	0.93 (0.70, 1.23)	1.03 (0.75, 1.40)	No

[a] Estimated by linear regression analysis.
[b] Estimated by categorical analysis.

E-mail: kamilah.amir@meditechmedia.com

Background and Aims: Interferon-based therapies are poorly tolerated in LT recipients with recurrent HCV. DCV, a potent NS5A inhibitor, has shown promising efficacy when combined with SOF or SMV + ribavirin (RBV). The aim of this study was to describe the results of an ongoing study of DCV-based therapy in LT recipients.
Methods: DCV 60 mg/day was administered for up to 24 weeks as part of a compassionate use protocol. Safety and efficacy laboratory results, as well as clinical data, were obtained from local site investigators.
Results: As of 22/11/14, 108 patients (pts) had enrolled, and end of treatment (EOT) data were available for 64 eligible pts. The mean time from LT to initiation of DCV was 42.6±56.9 months (33% <1 year). Mean age was 59.3±8.8 years, 66% were male, 44% had fibrosing cholestatic HCV, 30% had cirrhosis, 8% had HIV co-infection, and 67% had received prior antiviral therapy. The % CTP A/B/C score was 52%/27%/16%; mean MELD score was 12.8±6.3. Most pts had HCV genotype 1 (34% 1a, 59% 1b). Mean baseline HCV RNA was $18\times6\log_{10}$ IU/mL. Oral antiviral regimens included DCV+SOF (n = 48), DCV + SMV (n = 14), and DCV+SMV+SOF (n = 2), and 34% overall received RBV. Five pts died between 0 and 16 weeks of DCV therapy from liver failure or sepsis not attributed to DCV (all in the DCV + SOF group). In the 59 survivors, 3 pts (5%) had virologic breakthrough at weeks 12, 16, and 21 after DCV start, and 2 EOT responder pts (3%) had a virologic relapse 5 and 13 weeks after EOT (all 5 pts received DCV + SMV ± RBV). Twenty pts were observed ≥12 weeks after EOT; at the first measurement ≥12 weeks, 85% of these 20 pts were HCV-RNA (−), 10% were HCV-RNA (+) but <43 IU/mL, and 1 pt had 15,400 IU/mL; the second pt who relapsed had 13,510 IU/mL at the last measurement at week 5 post-EOT. The mean CTP and MELD scores improved from baseline to last follow-up (CTP: 6.9 vs 5.7, $P < 0.0001$, MELD: 11.9 vs 10.0, $P = 0.0006$) in 50 (CTP) and 52 (MELD) evaluable pts with a median follow-up of 29 weeks.
Conclusions: A 24-week course of DCV-based oral antiviral therapy was well tolerated and resulted in a high EOT virologic response rate in LT recipients with severe recurrent HCV. The majority of DCV-treated pts experienced stabilisation or improvement in their laboratory results and clinical status. However, the optimal DCV-based all-oral antiviral combination regimen that will maximise the likelihood of SVR12 in LT recipients requires further study.

BASELINE FACTORS ASSOCIATED WITH INCREASED SVR RATES IN 123 TREATMENT-NAÏVE CHRONIC HCV GENOTYPE 1 PATIENTS TREATED WITH A SHORTENED 12-WEEK SIMEPREVIR PLUS PEGYLATED INTERFERON AND RIBAVIRIN REGIMEN: A MULTIVARIATE ANALYSIS

T. Asselah[1], C. Moreno[2], C. Sarrazin[3], M. Gschwantler[4], G.R. Foster[5], A. Craxi[6], P. Buggisch[7], R. Ryan[8], O. Lenz[9], G. Van Dooren[9], I. Lonjon-Domanec[10], M. Schlag[11], M. Buti[12]. *[1]Beaujon Hospital University of Paris, Paris, France; [2]CUB Hôpital Erasme, Université Libre de Bruxelles, Brussels, Belgium; [3]Johann Wolfgang Goethe University Hospital, Frankfurt am Main, Germany; [4]Wilhelminenspital, Vienna, Austria; [55]Queen Mary Hospital, University of London, Barts Health, London, United Kingdom; [6]University of Palermo, Palermo, Italy; [7]Institute for Interdisciplinary Medicine, Hamburg, Germany; [8]Janssen Research & Development, Titusville, United States; [9]Janssen Infectious Diseases BVBA, Beerse, Belgium; [10]Janssen Pharmaceuticals, Paris, France; [11]Janssen-Cilag, Vienna, Austria; [12]Hospital Valle Hebron and Ciberehd del Institut Carlos III, Barcelona, Spain*
E-mail: tarik.asselah@bjn.aphp.fr

Background and Aims: A Phase 3, open-label study of SMV (150 mg QD) + PR was conducted in Europe, in 163 treatment-naïve chronic HCV genotype 1 patients with mild-to-moderate fibrosis (F0–F2, Metavir score) to investigate safety and efficacy of a 12-week SMV+PR regimen. This pre-planned, multivariate analysis aimed to determine baseline factors associated with SVR12, and identify patients who may benefit from shorter interferon-based therapy.
Methods: Patients with HCV RNA <25 IU/mL (detectable/undetectable [using Roche COBAS® Taqman® assay, LLOQ: 25 IU/mL, LLOD: 15 IU/mL]) at Week 2, and <25 IU/mL undetectable at Week 4 and 8 fulfilled criteria for stopping all therapy at Week 12. If these criteria were not met, PR was continued to Week 24. Patients eligible to stop therapy at Week 12 were included in the univariate/multivariate analyses to determine factors influencing either SVR or relapse.
Results: Overall, 75% (123/163) of patients were eligible for 12 weeks of therapy. Of these, 65% (80/123) achieved SVR12; 39 patients relapsed and 4 did not have SVR12 data. SVR varied according to baseline parameters, e.g. 94% (30/32), 53% (39/73) and 61% (11/18) for *IL28B* CC, CT and TT, respectively, and 82% (27/33) and 59% (53/90) for HCV RNA ≤800,000 and >800,000 IU/mL, respectively. In univariate/multivariate analyses, baseline HCV RNA, *IL28B* CC genotype, and mild fibrosis (F0/F1) were associated with SVR and relapse (Table). Baseline HCV RNA and mild fibrosis were associated with SVR and relapse when considering the non-CC population (N = 91) (Table). HCV genotype subtype, race, sex and baseline BMI were not associated with SVR in either the full or non-CC patient populations. Although Week 2 viral response was associated with SVR in the univariate analysis of the full population (odds ratio 2.52 [1.13, 5.60], P = 0.0235) this was not the case in the multivariate analysis (odds ratio 1.92 [0.70, 5.29], P = 0.2068). Similar results were found for the association of Week 2 viral response with SVR in the non-CC population and with relapse in both populations analysed. The safety profile was similar to previous SMV+PR studies.
Conclusions: Early on-treatment response patients with *IL28B* CC genotype, mild fibrosis (F0/F1), and lower baseline HCV RNA levels are more likely to achieve SVR12 when stopping all therapy after 12 weeks of SMV+PR. In the non-CC patient population, mild fibrosis

and lower baseline HCV RNA levels were associated with SVR on this shortened regimen.

Table: Factors associated with SVR and viral relapse determined by univariate and multivariate analyses in patients eligible for 12 weeks of therapy

Baseline factor	N	Univariate analysis		Final multivariate analysis	
		Odds ratio (95% CI)	P-value	Odds ratio (95% CI)	P-value

P0793
ESTIMATING THE NUMBER OF CHRONIC HEPATITIS C PATIENTS IN NEED OF TREATMENT AND PROJECTING THE DISEASE BURDEN DURING 2015–2030 UNDER THE INTERFERON-FREE TREATMENT REGIMENS IN GREECE

V. Sypsa[1], I. Gountas[1], G. Papatheodoridis[2], K. Souliotis[3], H. Razavi[4], A. Hatzakis[1]. *[1]Dept. of Hygiene, Epidemiology and Medical Statistics, [2]Department of Gastroenterology, Athens University Medical School, Athens, [3]Centre for Health Services Research; Faculty of Social and Political Sciences, University of Peloponnese, Korinnth, Greece; [4]Center for Disease Analysis, Louisville, Colorado, United States*
E-mail: vsipsa@med.uoa.gr

Background and Aims: The treatment of hepatitis C with IFN-free Direct-Acting Antivirals (DAAs) is anticipated to change the future burden of disease. Aim of this study is to estimate the current number of diagnosed patients in need of treatment and to assess the impact of IFN-free DAAs on HCV-related morbidity and mortality in Greece.
Methods: A previously described model has been used (Razavi et al, Hatzakis et al, J Viral Hepat 2014) to estimate the current number of patients in each fibrosis stage and to make projections for the future disease burden up to 2030. We used a previously published estimate that 19.2% of Greek HCV-infected patients have been diagnosed (Papatheodoridis et al, J Viral Hepat 2014) to calculate the number of diagnosed cases per fibrosis stage. We projected the future disease burden under: (A) Base scenario: treatment of approximately 2,000 patients/year (30–69 years old, independently of fibrosis stage) with Peg-interferon+Ribavirin with or without Boceprevir/Telaprevir, (B) IFN-free scenario: treatment of 3,000 patients/year for 2015 and 2016 and approximately 2000/year for the subsequent years with IFN-free DAAs (30–69 years old, F3–F4 only).
Results: The number of diagnosed patients with chronic hepatitis C in 2014 in Greece is estimated to be 25600. Of those, 2650, 2850, 4100, 7150, 6750 and 2100 are diagnosed with F0, F1, F2, F3, F4-compensated and F4-decompensated cirrhosis, respectively. Under the base scenario, no decline is predicted by 2030 in HCV-related morbidity and mortality. Under the IFN-free scenario, the number of patients with F4-compensated or F4-decompensated cirrhosis, HCC and the number of deaths in 2030 are predicted to be 34–46% lower than the base scenario. Furthermore, from 2024 and onwards, patients in earlier fibrosis stages could be treated due to the exhaustion of diagnosed F3–F4 cases. In total, 31460 and 30920 will have received treatment during 2015–2030 under the base and the IFN-free scenario, respectively.
Conclusions: Current guidelines suggest that treatment should be prioritized depending on the fibrosis stage. Estimates of the number of diagnosed patients per fibrosis stage are necessary for appropriate public health planning. In Greece, there are approximately 16000 diagnosed patients with fibrosis stage ≥F3 that should be prioritised for treatment. If those patients are given access to the new treatment regimens, a considerable decline is predicted in HCV-related morbidity and mortality by 2030.

P0794
RELATIONSHIP BETWEEN HCV GENOTYPE, LIVER CO-MORBIDITIES AND FIBROSIS IN THE FRENCH COHORT ANRS CO22 HEPATHER

E-mail: helene.fontaine@cch.aphp.fr

Background and Aims: ANRS CO22 HEPATHER is a French multicenter cohort (32 centres) aiming to include 15,000 HCV- and 10,000 HBV-infected patients. We analyzed the factors associated with a specific HCV genotype, especially the fibrosis stage and the liver comorbidities.
Methods: 14,698 patients were included on November 19th 2014; 10,197 had HCV hepatitis, 8519 had a chronic hepatitis including 4403 patients with complete data regarding the viral genotype, liver comorbidities and general characteristics at baseline. The association between the viral genotype, liver comorbidities and

fibrosis was assessed by multinomial logistic regression adjusted on age, gender, duration of diagnosis and treatment status at baseline; genotype 1-infected patients were considered as the reference category.

Results: Genotype 3- or 4-infected patients were younger and genotype 2- or 5-infected patients were older than genotype 1-infected patients. The proportion of men was higher in genotype 3 and 4 and lower in genotype 2 (Table). Treatment-naïve patients were more frequent in genotypes 2 and 5 and less frequent in genotypes 4. The viral load at baseline did not significantly differ between genotypes. Extensive fibrosis or cirrhosis (F3/4) were more frequent in genotypes 3 (60% and 42%, respectively) and less frequent in genotypes 2 (33% and 21%), and 5 (34% and 24%), than in genotypes 1 (51% and 34%). Hazardous alcohol consumption was 2-fold higher in genotype 3 and could be an additional risk factor for fibrosis, while metabolic comorbidities were less prevalent.

Table: General characteristics of the first 4403 HCV patients of the French HEPATHER ANRS CO22 cohort according to the genotype at inclusion.

Variable	Geno1 (ref) (n = 2919)	Geno2 (n = 245)	Geno3 (n = 577)	Geno4 (n = 571)	Geno5 (n = 91)
Age (yr)	58	**59**↑	**53**↓	**54**↓	**62**↑
Duration since diagnosis (yr)	14	**12**↓	13	**12**↓	12
Sex M (%)	55	**43**↓	**69**↑	**65**↑	45
Treatment-Naïve (%)	33	**52**↑	38	**33**↓	**53**↑
Viral load at inclusion (log_{10} IU/ml)	5.64	5.66	5.51	5.64	5.69
F3-F4 (%)	51	**33**↓	**60**↑	49	**34**↓
Suspicion of cirrhosis (%)	34	**21**↓	**42**↑	34	24
Obesity/overweight (%)	23	24	19	26	31
Diabetes (%)	14	14	11	15	15
Hypercholesterolemia (%)	7	10	**4**↓	6	**16**↑
Arterial hypertension (%)	30	33	**17**↓	**30**↑	37
Vasculitis with manifestations (%)	10	**4**↓	8	**6**↓	8
Renal failure (%)	3	**5**↑	2	**5**↑	5
Hazardous alcohol consumption (%)	3	3	**6**↑	4	2

A number in **bold** followed by ↓ (←) indicates a statistically significant **decrease** (**increase**) compared to genotype 1-infected patients.

Conclusions: HCV genotype3 chronic hepatitis is associated with more severe fibrosis than other genotypes.

E-mail: helene.fontaine@cch.aphp.fr

Background and Aims: The French cohort ANRS CO22 HEPATHER aims to identify prognosis factors, including response to treatments, in 10,000 HBV and 15,000 HCV-infected patients with a 8 years follow-up. In November 2014, 10,197 HCV patients from 32 centers were included. The aim of this analysis was to describe the profile of patients who started a Sofosbuvir (SOF)-containing regimen before May 25th, 2014 in the cohort and to evaluate the virological efficacy and safety of such regimens.

Methods: Demographics, history of liver disease were collected at entry in the cohort. Clinical, adverse events, and virological data were collected throughout treatment and post-treatment follow-up. Patients with prior liver transplantation, HCV therapy without SOF or participating in clinical trials were excluded.

Results: 619 patients in the cohort started a treatment with a SOF-containing regimen. Compared with 4523 patients who did not start a treatment; treated patients were older (57 vs 56 years), more frequently male (65% vs 54%), with a higher BMI (26 vs 25 kg/m^2), with a more advanced disease (cirrhosis 69% vs 14%; decompensated cirrhosis 5% vs 2%), more associated comorbidities (diabetes 19% vs 12%) and were more frequently treatment-experienced (previous PEG/RBV +/− 1st generation protease inhibitor 68% vs 30%). Regimens distribution according to HCV genotype is described in the table.

The baseline characteristics did not differ according to the regimen but decompensated cirrhosis was more frequent in patients starting a SOF/DCV +/− RBV regimen than in others (11% vs 2%). To date, the end-of-treatment response rates were >90% in all regimens, and the sustained virological response rates at week 4 were 77% with SOF/RBV, 79% with SOF/PEG/RBV, 89% with SOF/DCV, 100% with SOF/DCV/RBV, 95% with SOF/SMV and 100% with SOF/SMV/RBV; 78 SAE (7 of which considered treatment-related) were reported in 54 (8.5%) patients and 3 deaths (SOF/RBV: 1 hepatic failure, SOF/DCV: 1 cerebral haemorrhage and 1 septic shock). Only 20 patients (3%) have discontinued treatment prematurely (follow-up ongoing).

	HCV genotype			
	1	2	3	4
N	332	64	129	89
Treatment – n				
SOF/RBV	42	62	58	27
SOF/PEG/RBV	56	1	43	23
SOF/DCV	157	1	18	14
SOF/DCV/RBV	58	0	10	8
SOF/SMV	16	0	0	13
SOF/SMV/RBV	3	0	0	4

DCV: daclatasvir, SMV: simeprevir. 5 patients with genotype 5 infection not shown.

Conclusions: Sofosbuvir-containing regimens are highly efficient and fairly tolerated in "priority" patients. SVR12 and safety data will be reported for each regimen at the meeting.

E-mail: alex.pariente@free.fr

Background and Aims: New direct antiviral agents (NDAAs) appear as a striking progress in hepatitis C treatment but have not largely been evaluated in real-life settings. The aim of this study was to evaluate the efficacy and safety in patients with chronic hepatitis C treated with NDAAs in general hospitals in France.

Methods: APROVVIE 2 is a longitudinal observational study of patients treated with NDAAs in French general hospitals (first in early access programs, then following market authorizations). Demographic, clinical, adverse events, biological and virological data are prospectively collected throughout treatment and post treatment follow-up from willing patients by their responsible physicians, voluntary investigators, members of the Association Nationale des Gastroentérologues des Hôpitaux généraux (ANGH).

Results: Since March, 2014, 287 patients with chronic hepatitis C starting treatment including NDAAs were included by 18 investigators in 16 centers. Main characteristics of the patients were: male gender 64%, median age 54 years, cirrhosis (C) 47%, F3 fibrosis stage 41%, high viremia 72%, patients naïve 29%, treatment-experienced 71% (non responders 39%, relapsers 32%), genotype (G) 1: 65%, genotype 2: 5%, genotype 3: 14%, genotype 4: 14%, genotype 5: 2%. Prescribed drugs were sofosbuvir (So) 97%, daclatasvir (Da) 49%, simeprevir (Si) 23%, peginterferon (IF) 18%, ribavirin (Riba) 32%.

G1 (n = 187): C 45%, Naive Pts 28%, IF-So-Riba 16%, IF-Si-Riba 3%, So-Si 20%, So-Da 56%, So-Riba 5%, HCV-RNA undetectable at week 4 (VR4) 77%.

G2 (n = 13): C 20%, Naive Pts 38%, IF-So-Riba 15%, So-Si 8%, So-Riba 77%, VR4 100%.

G3 (n = 40): C 62%, Naive Pts 30%, IF-So-Riba 15%, I So-Si 3%, So-Da 53%, So-Riba 30%, VR4 68%.

G4 (n = 40): C 41%, Naive Pts 23%, IF-So-Riba 13%, IF-Si-Riba 8%, So-Si 43%, So-Da 25%, So-Riba 13%, VR4 80%.

G5 (n = 7): C 60%, Naïve Pts 43%, IF-So-Riba 14%, So-Da 71%, So-Riba 14%, VR4 77%.

To date, on-treatment response (undetectable HCV-RNA) was observed in 42% and 76% of patients at week 2 and week 4, respectively. Grade 3–4 adverse effects have been so far reported in 6/52 patients receiving interferon-ribavrin, and 2/235 patients not receiving these drugs.

Conclusions: To date, patients treated in French general hospitals are mostly treatment-experienced ones with severe fibrosis/cirrhosis. Complete SVR and safety data will be presented.

P0797

LATE RELAPSE IN PATIENTS WITH CHRONIC HEPATITIS C TREATED WITH TRIPLE THERAPY BASED ON FIRST GENERATION PROTEASE INHIBITORS

A. Madejón[1], M. Romero[1], L. Martín-Carbonero[2], M. Sánchez-Carrillo[1], A.I. Gil[1], I. Francisco[1], J. García-Samaniego[1]. *[1]Hepatology Unit, Hospital Universitario La Paz-Carlos III. CIBERehd. IdiPAZ, [2]Infectious Diseases Unit. Department of Internal Medicine, Hospital Universitario La Paz-Carlos III, Madrid, Spain*
E-mail: amadejon@yahoo.com

Background and Aims: Sustained virological response 12 (SVR-12) or 24 (SVR-24) is the clinical event that defines chronic hepatitis C (CHC) cure and is considered equivalent to the eradication of the virus. Maintaining the response is the rule (>99%) and late relapses are exceptional. The aim was to analyze the incidence of late relapses in patients treated with first-generation protease inhibitors (PIs) [telaprevir (TVR) and boceprevir (BOC)] and to investigate whether relapse in patients with SVR-24 is due to re-infection or "real" late viral relapse.

Methods: We included 146 patients (54 HIV+) with CHC treated with first-generation PIs who had reached SVR-24 in our hospital. In patients with late relapse (after SVR-24) a phylogenetic analysis of the ENV gene of HCV by clonal sequencing (10 clones/sample) in baseline and relapse samples was performed. HCV-RNA was determined in peripheral blood mononuclear cells (PBMCs) samples.

Results: Only 2/92 (2.2%) HCV and 1/54 (1.8%) HCV/HIV patients experienced late relapse. The clinical features (fibrosis, genotype, treatment schedule) were: Case 1: F3; HCV-1b (12 weeks of triple therapy with PR/TVR and 24 weeks of double therapy with PR); Case 2: F2; HCV-1b (12 weeks of PR/PR and 12 of TVR); Case 3 (HIV+): F4; HCV-1a (4-weeks lead-in with PR and 44 of PR/BOC). All patients achieved extended rapid virological response. Relapse occurred between 6–15 months after SVR-24. Adherence to treatment was good in all cases. A high homology between baseline and relapse samples sequences was found (Case 1: 95%; Case 2: 95%; Case 3: 94%). Phylogenetic bootstrap analysis (90% significance) showed that baseline and relapse HCV-RNA sequences from each patient were always grouped together in a separate branch, showing a close relationship of both populations in all cases. Additionally, the complexity of baseline samples was always higher [different colonies (baseline vs relapse): 9/10 vs 2/10, 8/10 vs 2/10 and 10/10 vs 0/10 in cases 1, 2 and 3, respectively]. PBMCs samples (cases 1 and 2) taken at SVR-12 point were HCV-RNA positive.

Conclusions: These results confirm that late relapse, although a rare event, may occur in patients treated with first-generation PIs. Once re-infection is discarded, relapse may be due to a reactivation of residual viral strains, as demonstrated by sequence homology and low complexity of the emerging population. The persistence of HCV-RNA in PBMC may play a role in the relapse of these patients.

THE COST-EFFECTIVENESS OF SOFOSBUVIR- AND SIMEPREVIR-BASED THERAPIES FOR HCV GENOTYPE 1 INFECTION

B.P. Linas[1], J.R. Morgan[2], M.T. Pho[3], J.A. Leff[4], B.R. Schackman[4], S.A. Assoumou[1], J.A. Salomon[5], K.A. Freedberg[6], A.Y. Kim[7]. *[1]School of Medicine, [2]School of Public Health, Boston University, Boston, [3]School of Medicine, University of Chicago, Chicago, [4]Weill Cornell School of Medicine, Cornell University, New York, [5]School of Public Health, Harvard University, [6]Medical Practice Evaluation Center, [7]Department of Medicine, Massachusetts General Hospital, Boston, United States*
E-mail: benjamin.linas@bmc.org

Background and Aims: New regimens to treat HCV genotype 1 are highly effective, but costly. We estimated quality-adjusted life expectancy (QALE), costs, and incremental cost-effectiveness ratios (ICERs) for strategies to treating HCV genotype 1 treatment-naïve and treatment-experienced patients with and without cirrhosis.

Table: Cost-effectiveness of treatment regimens for HCV genotype 1 in treatment naïve and experienced patients with and without cirrhosis

Strategy	Cost	QALY	ICER [a]
Naïve No Cirrhosis, RNA <6 Million (8 weeks SOF/LDV)			
No treatment	161,000	8.5	–
PEG/RBV 48 weeks	202,000	11.0	dominated
PEG/RBV/SMV 24 weeks	227,000	13.8	dominated
SOF/LDV 8 weeks	229,000	14.3	11,800
PEG/RBV/SOF 12 weeks	260,000	14.1	dominated
Naïve No Cirrhosis, RNA ≥6 Million (12 weeks SOF/LDV)			
No treatment	161,000	8.5	–
PEG/RBV 48 weeks	202,000	11.1	dominated
PEG/RBV/SMV 24 weeks	227,000	13.8	12,400
SOF/LDV 12 weeks	257,000	14.3	63,900
PEG/RBV/SOF 12 weeks	260,000	14.1	dominated
Naïve Cirrhosis (12 weeks SOF/LDV)			
No treatment	96,000	4.8	–
PEG/RBV 48 weeks	156,000	7.0	dominated
PEG/RBV/SMV 24 weeks	201,000	10.9	dominated
PEG/RBV/SOF 12 weeks	248,000	12.3	dominated
SOF/LDV 12 weeks	252,000	13.9	17,000
Experienced No Cirrhosis (12 weeks SOF/LDV)			
No treatment	160,000	8.5	–
SOF/LDV 12 weeks	259,000	14.3	17,100
PEG/RBV/SOF 12 weeks	261,000	14.1	dominated
SOF/SMV 12 weeks	324,000	14.1	dominated
Experienced Cirrhosis (24 weeks SOF/LDV)			
No treatment	96,000	4.8	–
PEG/RBV/SOF 12 weeks	245,000	11.9	21,000
SOF/SMV 12 weeks	315,000	13.5	43,800
SOF/LDV 24 weeks	336,000	13.9	55,600

[a] dominated = a strategy that provides lower QALE at either higher cost, or a higher cost per QALY gained.

Methods: Monte Carlo simulation of HCV disease comparing current U.S. FDA approved regimens for HCV genotype 1 infection. We stratified patients by treatment experience, cirrhosis status and HCV RNA to model appropriate treatment course.
Treatment naïve patients (% SVR with/without cirrhosis, treatment course cost):
1. No treatment
2. Pegylated interferon (PEG) and ribavirin (RBV) 48 weeks (23/44%, $53,000)
3. PEG/RBV and simeprevir (SMV) 12 weeks (65/90%, $37,000)
4. PEG/RBV and sofosbuvir (SOF) 12 weeks (78/92%, $90,000)
5. SOF/ledipasvir (LDV) 8–12 weeks depending on cirrhosis and HCV RNA (96/96%, $58,000–87,000)

Treatment experienced patients:
1. No treatment
2. PEG/RBV/SOF 12 weeks (74/92%, $53,000)
3. SOF/SMV 12 weeks (91/93%, $139,000)
4. SOF/LDV 12–24 weeks depending on cirrhosis (96%/96%, $87,000–175,000)

In sensitivity analyses we considered only treating patients with SOF/LDV when they developed metavir F2 fibrosis.
Results: *Treatment naïve patients with and without cirrhosis:* SOF/LDV increased QALE (0.5–9.1 QALY) and cost ($29,676-$68,118), resulting in ICERs $11,800–63,900/QALY (Table). Short SOF/LDV treatment (8 weeks) in non-cirrhotic patients with HCV RNA <6 million resulted in SOF/LDV being cost saving compared to other regimens.
Treatment-experienced patients without cirrhosis: SOF/LDV was cost saving compared to other regimens.
Treatment-experienced patients with cirrhosis: Compared to SOF/SMV 12 weeks, SOF/LDV 24 weeks increased cost by $20,975 and had an ICER <$100,000/QALY.
Sensitivity analyses: Including the SOF/LDV F2 strategy did not change cost-effectiveness conclusions. Waiting for F2 disease resulted in lower QALE than treating all patients due to quality of life decrements while waiting for treatment and was a dominated strategy.
Conclusions: SOF/LDV improves outcomes and has an ICER <$100,000/QALY for treatment naïve and experienced patients with and without cirrhosis. Limiting SOF/LDV access to only F2 disease results in lower QALE than simply treating all patients, at either higher total cost, or a higher cost per QALY gained.

P0799

THE PHARMACOKINETICS OF BECLABUVIR (BMS-791325) WHEN ADMINISTERED IN COMBINATION WITH DACLATASVIR AND ASUNAPREVIR IN TREATMENT-NAIVE PATIENTS WITH OR WITHOUT CIRRHOSIS INFECTED WITH HCV GENOTYPE 1

B. He[1], K. Sims[1], E. Chung[1], W.-L. Luo[1], J. Pursley[1], M. Wind-Rotolo[1], F. LaCreta[1], R. Bertz[1], M. AbuTarif[1]. *[1]Research and Development, Bristol-Myers Squibb, Princeton, United States*
E-mail: danielle.goffman@articulatescience.com

Background and Aims: Daclatasvir 30 mg (DCV; NS5A inhibitor), asunaprevir 200 mg (ASV; NS3 inhibitor), and beclabuvir 75 mg (BCV, BMS-791325; non-nucleoside NS5B inhibitor), administered twice daily (BID) as a fixed-dose combination (DCV/ASV/BCV) is currently in phase 3 development for the treatment of hepatitis C virus (HCV) infection. This DCV/ASV/BCV regimen administered for 12 weeks achieved a 100% sustained virologic response rate in HCV genotype (GT) 1-infected treatment-naive patients with compensated cirrhosis (Child–Pugh A) in an open-label, multiple-dose phase 2 study (AI443014); pharmacokinetics (PK) of DCV, ASV, BCV, and BMS-794712, an active metabolite of BCV in patients with and without cirrhosis are presented here.
Methods: Patients (age, 18–70 years; BMI, 18–35 kg/m^2) infected with HCV GT1 with (n = 8) or without (n = 73) biopsy-confirmed compensated cirrhosis (Child–Pugh A; capped at 10% of treatment group) received DCV/ASV/BCV for 12 weeks. Blood samples (0–12 h) were collected post-AM dose on days 1 and 14 from the first 20 non-cirrhotic patients and all cirrhotic patients for analysis by LC-MS/MS; standard non-compartmental PK parameters were calculated and summarized by descriptive statistics. Comparisons of (1) DCV and ASV PK descriptive statistics with PK data from Study AI447011 (DCV + ASV administered in combination in HCV-infected patients without cirrhosis), and (2) BCV and BMS-794712 PK descriptive statistics with PK data from Study AI443012 (BCV + pegIFNα/RBV in HCV-infected patients) will also be presented. In addition, data from patients receiving a DCV/ASV/BCV regimen containing BCV 150 mg BID will be presented.
Results: BCV and BMS-794712 steady state exposures were similar between patients with and without compensated cirrhosis (Table). The results of DCV and ASV steady state exposures in cirrhotic versus non-cirrhotic patients were consistent with historical

observations. DCV/ASV/BCV treatment was generally well tolerated in patients with and without compensated cirrhosis.
Conclusions: Data indicate that the presence of compensated cirrhosis (Child–Pugh A) does not have any clinically meaningful effect on exposures of BCV and BMS-794712, and similar safety profiles were observed in patients with or without cirrhosis.

Analyte	Study AI443014 AUC_{TAU}, ng·h/mL (Day 14)	
	Non-cirrhotic, n = 18	Cirrhotic, n = 8
BCV	9711 (44)	8304 (38)
BMS-794712	2145 (42)	2783 (50)

Data are geometric mean (CV%). AUC_{TAU}, area under the plasma concentration time curve during the dosing interval (0–12 h).

P0800
EFFECTIVENESS AND SAFETY OF COMBINATION NEW REGIMENS BASED ON SOFOSBUVIR (SOFO) WITH RIBAVIRIN (RBV), DACLATASVIR (DAC) OR SIMEPREVIR (SIM) IN DIFFICULT PATIENTS TO TREAT INFECTED WITH CHRONIC HEPATITIS C (CHC)

B. Kutala[1], F. Mourri[1], N. Boyer[1], V. Sitruk[1], N. Giuily[1], C. Castelnau[1], P. Marcellin[1], T. Asselah[1]. [1]*Hepatologie, Hôpital Beaujon, Clichy, France*
E-mail: blaise.kutala@bjn.aphp.fr

Background and Aims: SOFO, DAC and SIM have been approved for treatment of CHC patients with advanced fibrosis in combination with or without Ribavirin (RBV). Beside study results, limited data are available for these drugs during treatment under real life conditions. Further data are necessary to reflect the effectivity and safety of IFN-free therapy in difficult to treat patients (pts).
Methods: This prospective study conducted by the referral hospital Beaujon, France including 317 CHC pts between Jan to 20 November 2014, 29 pts excluded for missing data and 288 treated with SOFO+RBV (n = 136), SOFO+DAC (n = 104) or SOFO+SIM (n = 48). This cross sectional analysis included HCV monoinfected with G1/4 with fibrosis F3–F4 in each combination respectively (n = 92/ 60), (n = 72/32), (n = 29 and 19). At point of time of analysis, 288 pts reached week 12, 55 completed treatment, and 138 pts at follow up week +4.
Results: Baseline characteristics in total were age of 51 yrs, 72% male, BMI 25 kg/m^2, median HCV-RNA (5.4 log), GT-1 (70%), Fibrosis stage F3–F4 (64%). Responses to treatments and side effects are reported in the table.
Conclusions: Despite of the severity of liver disease combinations of IFN free regimens based Sofosbuvir seems to be effective with a good tolerability in this real-life. Patients accede to new IFN free regimens with less adverse events compared to IFN regimen. Effective management of new treatment combinations is necessary to reach optimal results in clinical practice.

	SOFO + RBV (n = 136)	SOFO + DAC (n = 104)	SOFO + SIM (n = 48)
Response to different antiviral regimens			
SVR at Week 12	134/136 (98%)	104/104 (100%)	45/48 (94%)
SVR at Week +4 of follow up	75/80 (94%)	41/42 (98%)	14/16 (87%)
Main side effects reported during treatment			
Photosensitivity reaction			6 (12%)
Asthenia	11 (8%)	6 (6%)	
memory problems	3 (2%)	5 (5%)	
Irritability	5 (4%)	4 (4%)	2 (4%)

P0801
ERADICATE HCV: TREATMENT AS PREVENTION IN CHAOTIC DRUG USERS

F. Ahmad[1], L. Johnston[1], B. Stephens[1], J. Dillon[1]. [1]*Gastroenterology, NHS Tayside, Dundee, United Kingdom*
E-mail: farsana.ahmad@nhs.net

Background and Aims: Approximately 1% of the Scottish population have been infected with hepatitis C compared to around 0.5% in other parts of the UK. Prevalence of Hepatitis C virus (HCV) in people who inject drugs (PWID) in Tayside has been found to be consistently around 30%. Modelling work of Martin et al (2011) raises the possibility that prevalence of HCV may be reduced by treating relatively small numbers of active drug users and therefore preventing onward transmission. The model illustrates that treating as few as 10 per 1000 drug users per year can significantly impact on prevalence rates.
This group has been previously thought to be too chaotic to adhere to therapy. The first step to "Treatment as Prevention" is to treat these patients.
Objectives: To recruit 100 hepatitis C positive PWID, offer HCV treatment, record sustained virological response (SVR) rates obtained and monitor any long term population prevalence changes.
Methods: To engage PWID at the needle exchange centres in Tayside. Incentivise suitable participants to comply with treatment of Interferon/Ribavirin and a protease inhibitor, if required. Giving them £5–10 grocery vouchers and high protein drinks to attend on a weekly basis throughout the course of their treatment and follow up.
Results: In the initial 20 month study period, 119 patients discussed the study with the specialist nurses. Of those, 46 were not eligible for treatment. Reasons for ineligibility; 20 were PCR negative, 15 had no contraceptive, 3 were HCV anti-body negative, 2 had no genotype, 2 were drug free, 2 were previously treated, 1 became pregnant and 1 had unstable mental health. Of the 73 eligible patients, 51 agreed to participate and were consented. Of the 51 consented, 38 (74.5%) were male. 41 have since commenced treatment, 3 being lost to follow up, 2 are in prison, 1 has a start date pending, 2 are now drug free and are on treatment via the standard pathway, 1 in hospital and 1 had no contraception.

Table 1. Basic demographics and results

	Total (n)
Total number	51
Genotype 1	17 (33.3%)
Genotype 3	34 (66.7%)
Viral load <600,000 iu/ml	37/51 (72.5%)
Treatment started	41
PCR(week 4)	41/41 ≤16 iu/ml
Treatment stopped	3 (2 obtained SVR)
Treatment completed	22
Non-responder/relapser	2
3 month SVR	17/20 (85%)
6 month SVR	12/15 (80%)

Conclusions: The results to date show that it is possible to connect with this chaotic PWID population. All of this population reached HCV PCR ≤16 iu/ml by week 4, culminating in an SVR rate of 80% at 6 months post treatment. The incentivisation scheme is effective in the initial engagement stage, however once on treatment the paramount importance of becoming cured becomes the primary focus.

P0802

SAFETY AND EFFICACY OF SOFOSBUVIR + SIMEPREVIR WITHOUT RIBAVIRIN IN HEPATITIS C GENOTYPE 1-INFECTED PATIENTS WITH END-STAGE RENAL DISEASE OR GFR <30 mL/min

H.E. Nazario[1], M. Ndungu[1], A. Modi[2]. [1]*The Liver Institute, Methodist Dallas Medical Center, Dallas,* [2]*Liver Consultants of Texas, Baylor All Saints Medical Center, Fort Worth, United States*
E-mail: HectorNazario@mhd.com

Background and Aims: Treatment of chronic hepatitis C (CHC) in the setting of ESRD and/or severe renal impairment has historically been limited by poor tolerability and low cure rates regardless of the regimen used. Combination antiviral therapy using sofosbuvir & simeprevir is now an approved treatment option in patients with genotype 1 CHC; however, the safety and efficacy of this regimen in patients with ESRD on HD or with GFR <30 mL/min is not known. Interim data from a combined treatment cohort of two large hepatology referral centers were evaluated to assess for safety and efficacy of full dose sofosbuvir + simeprevir without ribavirin in this special patient population.
Methods: All (n = 12) patients included in the analysis had severe renal impairment including ESRD on HD (n = 11) or GFR <30 mL/min (n = 1). All received sofosbuvir 400 mg daily + simeprevir 150 mg daily without ribavirin, for anticipated course of 12 weeks. Interim safety and efficacy data are presented. SVR4 and SVR12 data for all patients to follow.
Results: Of the 12 patients in this cohort, 11 (92%) were male, 7 (58%) were cirrhotic, 3 (25%) had stage 3 liver fibrosis, 10 (83%) were genotype 1A, and 10 (83%) were treatment naïve. Eight patients (67%) have completed 12 weeks of therapy. The remaining 4 patients have been treated for a median of 9 weeks (range 3–11). The mean baseline hemoglobin was 11.6 g/dL and 6 patients were on Epoetin since prior to starting therapy. Treatment was overall well tolerated with no treatment discontinuations reported. Five (41%) patients reported adverse events (AE), 4 of which were rated as mild clinical manifestations, and one a laboratory abnormality. These AEs were insomnia (n = 2), headache (n = 1), nausea (n = 1), and worsening anemia requiring blood transfusion (n = 1). All 8 (100%) patients who completed 12 weeks of therapy achieved end of treatment response (negative HCV RNA at week 12). Of the 7 patients that have reached post-treatment week-4 follow up, 100% were HCV RNA negative (SVR4). All 5 (100%) patients who reached post-treatment week-12 follow up, achieved SVR12 or virologic cure.
Conclusions: Daily, full dose of sofosbuvir plus simeprevir for 12 weeks of therapy appears to be well tolerated in patients with ESRD on HD or GFR <30 mL/min. Most common AEs resembled those of healthier CHC patients without significant renal impairment. 100% of patients who completed therapy had EOT.

P0803

COST-EFFECTIVENESS OF LEDIPASVIR/SOFOSBUVIR FOR THE TREATMENT OF GENOTYPE 1 OR 4 CHRONIC HEPATITIS C IN SCOTLAND

J. Dillon[1], C. Treharne[2], R. Howells[3]. [1]*Ninewells Hospital, Dundee,* [2]*Abacus International, London,* [3]*Abacus International, Manchester, United Kingdom*
E-mail: michaela.lion@gilead.com

Background and Aims: Ledipasvir/sofosbuvir (LDV/SOF) is a new all-oral fixed-dose combination tablet indicated for the treatment of chronic hepatitis C (CHC) in adults. LDV/SOF has demonstrated overall SVR rates of >94% and discontinuation rates <1% in the phase 3 clinical trial programme. As part of the Health Technology Appraisal (HTA) process in Scotland an economic model was developed to estimate the cost-effectiveness of LDV/SOF for genotype (GT) 1 or 4 compared to standard of care regimens.
Methods: A decision-analytic Markov model was used to evaluate the cost-effectiveness of LDV/SOF for 8, 12 or 24 weeks compared to sofosbuvir (SOF) or simeprevir (SMV) in combination with pegylated interferon (PEG-IFN) and ribavirin (RBV) for 12 or 24–48 weeks duration, respectively. In addition, a comparison was made versus SMV+SOF for patients who are ineligible for interferon. The model was constructed based on precedent models for the treatment of CHC, and evaluated treatment naïve and treatment experienced patients separately. Patients entered the model in either a non-cirrhotic or cirrhotic disease state. Patients who were successfully treated, and therefore achieved an SVR, moved to the corresponding SVR state. Patients who did not achieve an SVR were exposed to a risk of CHC disease progression, liver transplant or liver-related mortality. Cost and utility data were included in the model associated with the treatment phase and disease state. The model outcomes included the incremental cost-effectiveness ratio (ICER) reported in terms of cost per incremental quality-adjusted life year (QALY) in accordance with Scottish guidelines.
Results: In CHC GT1 treatment naïve patients, LDV/SOF dominated SOF+PEG-IFN+RBV and SMV+PEG-IFN+RBV, achieving both cost-savings and higher QALYs. In GT4 treatment naive patients, LDV/SOF was cost-effective compared to SOF+PEG-IFN+IFN and SMV+PEG-IFN+RBV with ICERs of £4,088 and £12,651 respectively. In treatment experienced GT1 and GT4 patients, LDV/SOF had ICERs of £5,894 compared to SOF+PEG-IFN+RBV and £9,788 compared to SMV+PEG-IFN+RBV. LDV/SOF dominated SMV+SOF in all scenarios.
Conclusions: LDV/SOF is a highly effective and cost-effective single tablet regimen for patients with CHC GT1 or GT4 in Scotland compared to SOF+PEG-IFN+RBV and SMV-based regimens. The first generation protease inhibitors were not included as they have similar efficacy and cost compared to SMV, therefore LDV/SOF is also cost-effective compared to these medicines.

EFFICACY OF SOFOSBUVIR-BASED TREATMENT REGIMENS IN HIV/HCV CO-INFECTED PATIENTS AFTER LIVER TRANSPLANTATION: THE ANRS CO23 CUPILT STUDY

T.M. Antonini[1,2,3,4], A. Coilly[1,2,3,4], S. Radenne[5], A. Veislinger[6], D. Botta-Fridlund[7], F. Durand[8], P. Houssel-Debry[9], N. Kamar[10], V. Canva[11], P. Perre[12], I. Bertucci[13], J. Dumortier[14], V. Leroy[15], D. Samuel[1,2,3,4], G.-P. Pageaux[16], J.-C. Duclos-Vallee[1,2,3,4]. [1]*AP-HP Hôpital Paul Brousse,* [2]*Unit 785, INSERM,* [3]*UMR-S 785, Univ Paris-Sud,* [4]*DHU Hepatinov, Villejuif,* [5]*HCL – Hôpital de la Croix Rousse, Lyon,* [6]*CHU de Rennes – Hôpital Pontchaillou, Rennes,* [7]*AP-HM CHU La Conception, Marseille,* [8]*AP-HP Hôpital Beaujon, Clichy,* [9]*CHU de Rennes, Rennes,* [10]*CHU de Toulouse, Toulouse,* [11]*CHRU de Lille, Lille,* [12]*Centre hospitalier departemental de Vendee, La Roche sur Yon,* [13]*ANRS, Paris,* [14]*HCL – Hôpital Edouard Herriot, Lyon,* [15]*CHU de Grenoble, Grenoble,* [16]*CHU de Montpellier – Hôpital Saint Eloi, Montpellier, France*
E-mail: jean-charles.duclos-vallee@pbr.aphp.fr

Background and Aims: Severe hepatitis C virus (HCV) recurrence after liver transplantation (LT) affects post-transplant survival in HIV/HCV co-infected patients. The recent approval of interferon-free regimen using direct antiviral agents (DAA) has radically changed the management of recipients. Study aims were to assess efficacy and safety of based sofosbuvir (SOF)-based treatment regimens in HIV/HCV coinfected patients after LT.
Methods: The CUPILT study is a prospective nationwide cohort including patients with HCV-recurrence following LT treated by new antivirals. The present work focused on 16 HIV/HCV coinfected patients and included between August 2013 and August 2014 in 10 centers. Treatment regimens were prescribed at investigator's discretion.
Results: This cohort study enrolled 16 liver transplant patients (male: 81%, mean age 53±5 years [46–62]). Seven patients (43%)

were non-responders to a previous course of therapy post-LT (Peg-IFN/RBV n = 5; 1st generation PI based regimen n = 2). At W0 the proportion of G1, G3, G4, and median levels of gGT, haemoglobin, HCV viral load (VL), HIV VL and CD4 count were: 56%, 6%, 19%, 476.2±328.2 IU/L [49–939], 12.8±2 g/dL [9.2–15.3], 7.0±0.6 $\log_{10}$ IU/mL [6.2–8.4], <40 cp/ml and 301±177 cells/mm^3 [122–671], respectively. Indication for treatment was HCV recurrence (≥F1, n = 12) or fibrosing cholestatic hepatitis (n = 4). Anti HCV-therapy started at 29.2±33.8 months [3.2–126.3] post LT. The regimens used were as follows: Peg-IFNa + SOF + RBV (n = 1), SOF + RBV (n = 3), SOF + DCV (n = 3) and SOF + DCV + RBV (n = 9) for 24 weeks (n = 13). RBV was combined to SOF + DCV in 13 patients. At W4, HCV VL was <15 IU/mL in 3 patients (19%). To date, 10 patients (53%) have stopped treatment and all of them have an undetectable HCV VL (<15 IU/mL). Seven patients (44%) acquired SVR12. Five patients (31%) developed serious adverse events (haematological n = 7, sepsis n = 2 and renal insufficiency n = 1). No significant drug–drug interaction was observed. Complete results of safety and efficacy with SVR 24 for all patients will be presented.

Conclusions: Anti HCV treatment with sofosbuvir and daclatasvir show excellent results in HIV/HCV coinfected patients after liver transplantation.

P0805

ACHIEVEMENT OF SVR12 DESPITE THE PRESENCE OF HCV VARIANTS RESISTANT TO FIRST GENERATION NS5A INHIBITORS IN GENOTYPE-1 HEPATITIS C PATIENTS AFTER 8-WEEK THERAPY OF ACH-3102 IN COMBINATION WITH SOFOSBUVIR

D. Patel[1], Y. Zhao[1], J. Fabrycki[1], G. Yang[1], S. Podos[1], H. Kocinsk[1], M. Mader[1], E. Gane[2], C. Schwabe[3], D. Apelian[1], M. Huang[1], W. Yang[1]. *[1]Achillion Pharmaceuticals, New Haven, United States; [2]New Zealand Liver Transplant Unit, Auckland Hospital, Auckland, [3]Auckland Clinical Studies Ltd, Grafton, New Zealand*
E-mail: mhuang@achillion.com

Background and Aims: ACH-3102 is a second-generation HCV NS5A inhibitor that retains activity against multiple variants resistant to first-generation NS5A inhibitors such as ledipasvir. In a phase 2a study, sustained virologic response 12 weeks after therapy (SVR12) was achieved by 100% of genotype-1 hepatitis C patients after 8-week administration of ACH-3102 and sofosbuvir. Here we report genotypic and phenotypic analyses of baseline samples collected from patients in this study.

Methods: NS5A fragments were PCR-amplified from patient plasma samples collected at baseline and sequenced either directly or after cloning. Chimeric replicons incorporating NS5A fragments from patient plasma samples were used for phenotypic analyses.

Results: Mutations at positions associated with viral resistance to first-generation NS5A inhibitors were detected in baseline samples. In particular, mutations at positions associated with virologic failures of ledipasvir and sofosbuvir combination treatment were detected as major species by population sequencing in 50% of both genotype-1a (5 out of 10) and genotype-1b (1 out 2) baseline samples. These positions include NS5A amino acid residues 24, 28, 30, 31 and 58. Phenotypic analysis confirmed that genotype-1a and 1b mutations at these positions as well as genotype-1b mutations at NS5A amino acid residue 93 retain significantly greater susceptibility to ACH-3102 than to ledipasvir. This greater susceptibility may have contributed to the success of the ACH-3102-containing regimen, although additional confirmatory studies are needed, especially in types of hepatitis C patients whose viral baseline NS5A sequences compromise virologic responses to ledipasvir and sofosbuvir combination treatment.

Conclusions: Despite the presence of viral variants resistant to ledipasvir as major species at baseline, 100% SVR12 was achieved in genotype-1 hepatitis C patients after 8-week administration of ACH-3102 and sofosbuvir. These results suggest that ACH-3102 in combination with an NS5B nucleotide inhibitor may improve clinical efficacy against HCV variants with resistance to first-generation NS5A inhibitors.

P0806

THE VALUE OF SURVIVAL BENEFITS FROM TREATING HEPATITIS C AT DIFFERENT FIBROSIS STAGES WITH ALL-ORAL, INTERFERON-FREE THERAPY RELATIVE TO 'WATCHFUL WAITING'

S. Johnson[1], H. Parisé[1], Y. Sanchez Gonzalez[2], A. Wang[2], S. Virabhak[1], T. Juday[2], S. Saab[3]. *[1]Medicus Economics Inc., Milton, [2]AbbVie Inc., North Chicago, [3]Pfleger Liver Institute, UCLA, Los Angeles, United States*
E-mail: yuri.sanchezgonzalez@abbvie.com

Background and Aims: Chronic infection with the hepatitis C virus (HCV) may lead to complications that negatively affect the length and quality of life. The AbbVie 3D regimen is an all-oral, interferon-free therapy for treating patients with chronic genotype 1 (GT1) HCV that has demonstrated high effectiveness in achieving a sustained virologic response (SVR) in Phase III clinical trials. However, the survival benefits of treatment with this regimen

Table (abstract P0806): Survival benefits of AbbVie 3D regimen versus no treatment among patients with chronic GT1 HCV

	Discounted LYs				Discounted QALYs			
	AbbVie 3D	No treatment	Difference (AbbVie 3D – No treatment)	Survival benefit evaluated at $100k/LY	AbbVie 3D	No treatment	Difference (AbbVie 3D – No treatment)	Survival benefit evaluated at $100k/QALY
Treatment naive								
F0	18.20	17.57	0.63	$62,987	17.98	16.18	1.80	$180,460

Treatment experienced								
F0	17.43	16.81	0.61	$61,432	17.23	15.44	1.78	$178,367
F1	17.36	16.25	1.11	$111,220	17.08	14.29	2.79	$278,951
F2	17.26	15.40	1.86	$186,350	15.86	12.71	3.16	$315,912
F3	17.10	13.97	3.12	$312,360	15.70	11.34	4.36	$436,084
F4	15.11	11.34	3.77	$376,524	13.77	8.89	4.88	$487,885
Overall**	16.67	14.58	2.09	$209,343	15.84	12.43	3.41	$340,716

*Based on a distribution of 27% F0, 36% F1, 17% F2, 9% F3 and 11% F4 among treatment-naive patients with HCV.
**Based on a distribution of 20% F0, 27% F1, 13% F2, 10% F3 and 30% F4 among treatment-experienced patients with HCV.

relative to 'watchful waiting' (i.e. no HCV treatment) at different fibrosis stages are not well understood. The aim of this study is to quantify these survival benefits in terms of life-years (LYs) and quality-adjusted life years (QALYs) and to monetize their value.

Methods: A Markov disease utility state-transition model was developed to estimate survival benefits accruing from no HCV treatment and treatment with the AbbVie regimen from the perspective of a private US payer. Survival outcomes were evaluated over a lifetime horizon with annual cycles and discounted at 3% per year. Transition probabilities and health utilities associated with 14 health states were obtained from published literature. The model population was composed of treatment-naïve patients aged 52 years and treatment experienced patients aged 54 years with GT1 chronic hepatitis C. About 60% of the patient population was male. Clinical efficacy and disutilities associated with HCV treatment were extracted from AbbVie trials. Survival benefits were monetized based on an assumed valuation of $100,000 per LY or QALY suggested in the literature.

Results: Compared to watchful waiting, the lifetime survival benefits of HCV treatment with the AbbVie regimen vary substantially by stage of treatment initiation. For treatment-naive patients, the value of survival benefits increases six-fold from $62,987 with initiation at F0 to $398,766 with initiation at F4 (see Table). The quality-adjusted value of these survival benefits increases nearly three-fold from $180,460 with initiation at F0 to $508,723 with initiation at F4. Regardless of the fibrosis stage when treatment is initiated, treatment-experienced patients have 1%>6% less survival benefits than treatment-naïve patients.

Conclusions: The AbbVie 3D regimen prolongs the survival of chronic HCV patients and improves quality of life. The survival costs of watchful waiting are substantially greater at more advanced levels of liver fibrosis.

P0807

THE QUALITY OF LIFE JOURNEY FOR PATIENTS WITH CHRONIC HEPATITIS C: FROM INTERFERON AND RIBAVIRIN TO INTERFERON-FREE AND RIBAVIRIN-FREE REGIMENS

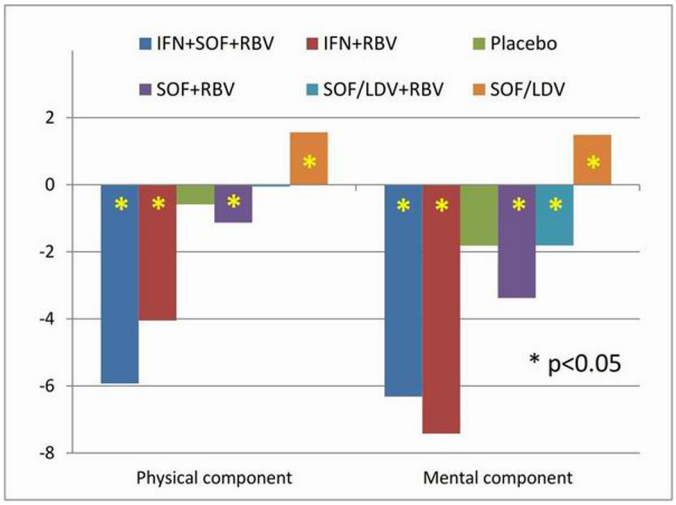
Z. Younossi[1,2], M. Stepanova[1,2], L. Henry[1,2], F. Nader[1,2], H. Park[3], B. Lam[1,2], H. Pham[1], S. Hunt[1,2]. *[1]Center for Liver Diseases, Department of Medicine, Inova Fairfax Hospital, [2]Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church, VA, [3]College of Pharmacy, University of Florida, Gainesville, FL, United States*
E-mail: zobair.younossi@inova.org

Background and Aims: Interferon (IFN) and ribavirin (RBV) negatively impact health-related quality of life (HRQL) during treatment. The aim is to compare the impact of IFN- and/or RBV-containing regimens on HRQL to that of IFN- and RBV-free regimens.

Methods: HRQL data from nine multicenter multinational phase 3 clinical trials of sofosbuvir (SOF)-based regimens with and without ledipasvir (LDV), IFN, or RBV (POSITRON, FISSION, FUSION, NEUTRINO, VALENCE, PHOTON-1, ION-1, ION-2, and ION-3) were used. The Short Form-36 (SF-36) HRQL questionnaire was administered to subjects at baseline, during and 12 weeks after treatment.

Results: A total of 3,506 CH-C patients were included (age: 52.2±10.2 years old, 62.2% male, 75.8% enrolled in the U.S., 73.7% treatment-naïve, 15.1% cirrhotic). Of these, 327 received IFN+RBV+SOF, 110 received IFN+RBV, 1,046 received SOF+RBV, 872 received SOF/LDV+RBV, 1,080 received SOF/LDV and 71 received placebo. At the last day of treatment, severe decrements in HRQL were noted in IFN+RBV±SOF [Physical component score (PCS): −11.6 to −16.9%, $p < 0.0001$; mental component score (MCS): −13.2% to −15.6%, $p < 0.0001$], while moderate decrements were noted in SOF+RBV±LDV [PCS: −3.2% $p < 0.0001$, MCS: −3.8 to −7.1%, $p < 0.0001$] (Figure 1). In contrast, in SOF/LDV regimen, improvements in PCS (+4.8%) and MCS (+4.3%) were noted ($p < 0.0001$). By SVR12, HRQL returned to baseline in IFN+RBV±SOF ($p > 0.05$) and improved in all IFN-free arms: PCS +3.6% to +4.8%, and MCS +2.9% to +4.5% (all $p < 0.0001$). Post-SVR12 improvements were noted in all individual scales of SF-36 in SOF/LDV, ranging between +2.9% (role emotional) and +7.8% (vitality) (all $p < 0.0001$). In multivariate analysis, end of treatment PCS score was lower in IFN+RBV±SOF (beta −10.4 to −15.9%, $p < 0.0001$), and higher in SOF/LDV (beta +6.0%, $p < 0.0001$) compared to the reference (SOF+RBV). Similarly, end of treatment MCS score was lower in IFN+RBV-containing regimens (beta −6.4% to −9.2%), slightly higher in SOF/LDV+RBV (beta +3.3%), and substantially higher in SOF/LDV (beta +10.2%) (all $p < 0.001$). Finally, by SVR12, SOF/LDV was associated with higher MCS (+2.5%, $p < 0.001$).

Conclusions: Removing IFN and RBV has led to substantial improvement of HRQL during treatment. Treatment with IFN- and RBV-free anti-HCV treatment (LDV/SOF) is independently associated with better HRQL during and after treatment.



P0808

IMPROVEMENT IN LIVER FUNCTION AND NON-INVASIVE ESTIMATES OF LIVER FIBROSIS 48 WEEKS AFTER TREATMENT WITH OMBITASVIR/PARITAPREVIR/R, DASABUVIR AND RIBAVIRIN IN HCV GENOTYPE 1 PATIENTS WITH CIRRHOSIS

H. Wedemeyer[1], T. Berg[2], S.L. Flamm[3], G.R. Foster[4], A. Craxi[5], D. Larrey[6], T.R. Morgan[7], M.W. Fried[8], F. Poordad[9], R. Trinh[10], S. Lovell[10], Y. Tang[10], M. Pedrosa[10], J.-C. Lopez-Talavera[10], I.M. Jacobson[11]. *[1]Medizinische Hochschule Hannover, Hannover, [2]Universitätsklinikum Leipzig, Leipzig, Germany; [3]Northwestern Feinberg School of Medicine, Chicago, United States; [4]Queen Marys University of London, Barts Health, London, United Kingdom; [5]A.O.U Policlinico "P. Giaccone" Dip. E-mail: douglas.dylla@abbvie.com

Background and Aims: Viral eradication in individuals with chronic HCV infection and cirrhosis may result in improvement in hepatic synthetic function and reduce portal hypertension. The interferon-free 3 direct-acting antiviral (3D) regimen of ombitasvir, paritaprevir (identified by AbbVie and Enanta, dosed with ritonavir [r]), and dasabuvir with ribavirin (RBV) has shown high rates of sustained virologic response rates 12 weeks post-treatment (SVR12) in HCV genotype 1-infected patients with cirrhosis in the TURQUOISE-II trial. We evaluated various non-invasive markers of liver function and fibrosis 48 weeks after treatment with 3D + RBV.

Methods: In this open-label trial, patients were randomized to receive 3D + RBV for 12 or 24 weeks. Changes in non-invasive estimates of liver fibrosis [AST to platelet ratio (APRI), FIB-4, Forns Index, FibroTest], laboratory surrogates for hepatic synthetic function [international normalized ratio (INR), albumin, platelet count], and alpha fetoprotein (AFP) levels were measured over time.

Results: Among 380 patients randomized to 12 or 24 weeks of 3D + RBV, SVR12 rates were 92% and 97%, respectively. In general, mean non-invasive estimates of liver fibrosis, surrogates for hepatic synthetic function, and AFP improved from baseline to post-treatment week 12 (PTW12), and further improved by post-treatment week 48 (PTW48; Table). In patients treated for 12 and 24 weeks who achieved an SVR12, mean FibroTest scores improved to 0.64 and 0.65 at PTW48, respectively. Conversely, in patients who did not achieve SVR12 after 12 and 24 week treatment, mean FibroTest scores increased to 0.89 and 0.89, respectively. Results by baseline disease severity will be presented.

Conclusions: In the phase 3 TURQUOISE-II trial of patients with HCV genotype 1 and cirrhosis, treatment with the 3D + RBV regimen improved surrogates of hepatic synthetic function, AFP levels, and FibroTest scores after completion of antiviral therapy in patients with HCV genotype 1 infection and cirrhosis.

98% SVR12 IN KOREAN AND TAIWANESE PATIENTS WITH CHRONIC GENOTYPE 2 HCV INFECTION RECEIVING 12 WEEKS OF SOFOSBUVIR PLUS RIBAVIRIN: RESULTS FROM AN INTERNATIONAL, MULTICENTER PHASE 3 STUDY

J.-H. Kao[1], S.-H. Ahn[2], R.-N. Chien[3], S.-H. Jeong[4], C.-Y. Peng[5], Y.-S. Lim[6], J.C. Yang[7], H. Mo[7], L.-L. Han[7], D. Brainard[7], S.J. Knox[7], J.G. McHutchison[7], Y.-J. Lee[8], T.-T. Chang[9], S.-W. Paik[10], C.-J. Chu[11], W.-L. Chuang[12], K.-H. Han[2]. *[1]National Taiwan University Hospital, Taipei, Taiwan; [2]Severance Hospital, Yonsei University Health System, Seoul, Korea, South; [3]Gastroenterology, Chang Gung Memorial Hospital-Keelung, Keelung, Taiwan; [4]Seoul National University Bundang Hospital, Seoul, Korea, South; [5]China Medical University Hospital, Taichung, Taiwan; [6]Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, South; [7]Gilead Sciences, Foster City, CA, United States; [8]Inje University, Pusan Paik Hospital, Busan, Korea, South; [9]National Cheng Kung University Hospital, Tainan, Taiwan; [10]Samsung Medical Center, Seoul, Korea, South; [11]Taipei Veterans General Hospital, Taipei, [12]Kaohsiung Medical University Hospital, Kaohsiung, Taiwan*
E-mail: jenny.yang@gilead.com

Background and Aims: Infection with genotype (GT) 2 hepatitis C virus (HCV) accounts for approximately half of all cases of chronic HCV infection in Korea and Taiwan. Patients have often failed to respond to prior interferon (IFN)-based therapy and may be ineligible for, or intolerant of current available therapy. There is a significant unmet medical need for highly effective, safe and well-tolerated IFN-free therapies for use in this aging population and those with advanced liver disease.

Methods: An open-label, Phase 3 study was conducted to evaluate the efficacy and safety of sofosbuvir (SOF) 400 mg once daily plus weight-based ribavirin (RBV; 1000–1200 mg/day) administered for 12 weeks in treatment-naïve and treatment-experienced Korean and Taiwanese adults with chronic GT2 HCV infection, with and without cirrhosis. No upper age limit was applied and in order to support enrollment of patients with cirrhosis no entry restriction applied for neutrophils and the minimum platelet count was 50,000/μL. NS5B resistance associated variants were evaluated by deep sequencing. The primary efficacy endpoint was SVR12.

Results: 216 patients were enrolled. The mean (range) age was 54 (22–82) years old, BMI 24 (18–38) kg/m^2, and baseline HCV RNA 6.2 (2.1–7.7) $\log_{10}$ IU/mL. The majority of patients were treatment-naïve (69%), non-cirrhotic (88%), female (57%), and had IL28B CC genotype (84%). Table 1 shows the overall SVR12 rates. A total of 4 patients (2%) failed to achieve SVR12: 1 patient had on-treatment breakthrough, 1 patient relapsed and 2 patients' were lost to follow-up. No S282T or SOF treatment emergent variants (L159F or V321A) were detected in the 2 virologic failure patients at baseline or at the time of virologic failure. Adverse events (AE) reported in ≥10% of patients were pruritus, headache, and insomnia. Six patients (3%) had treatment-emergent SAEs all unrelated to study drug. No patients discontinued therapy due to an AE. Overall, 11% of patients had hemoglobin <10 g/dL and 1% had hemoglobin <8.5 g/dL during treatment. No other laboratory abnormalities were observed. Baseline viral sequencing results will also be presented.

Table 1. SVR12 rates in GT2-infected patients and difficult-to-treat subgroups

	Korea (N = 129)	Taiwan (N = 87)	Overall (N = 216)
Virologic response (ITT)			
Overall, SVR12, n (%)	125 (97)	87 (100)	212 (98)
On-treatment failure, n (%)	1 (1)	0	1 (<1)
Relapse, n (%)	1 (1)	0	1 (<1)
Lost to follow-up, n (%)	2 (2)	0	2 (1)
SVR12 by subgroup			
Treatment-experienced (TE), n/N (%)	24/24 (100)	44/44 (100)	68/68 (100)
Cirrhotic, n/N (%)	13/13 (100)	13/13 (100)	26/26 (100)
TE with cirrhosis, n/N (%)	7/7 (100)	9/9 (100)	16/16 (100)

Conclusions: Sofosbuvir plus RBV for 12 weeks is highly effective and well tolerated in Korean and Taiwanese patients with GT2 HCV infection, including those with cirrhosis.

P0810

SOFOSBUVIR AND DACLATASVIR COMBINED TREATMENT FOR CHRONIC HEPATITIS C: FIRST-YEAR EFFICACY AND SAFETY DATA IN A REAL-LIFE SETTING

E-mail: alex.pariente@free.fr

Background and Aims: The combination of sofosbuvir and daclatasvir (SoDa) has not largely been evaluated in real-life settings. The aim of this study was to evaluate the efficacy and safety in patients with chronic hepatitis C treated with SoDa in general hospitals in France.

Methods: APROVVIE 2 is a longitudinal observational study of patients treated with new direct antiviral agents in French general hospitals (first in early access programs, then following market authorizations). Demographic, clinical, adverse events, biological and virological data are prospectively collected throughout treatment and post treatment follow-up from willing patients by their responsible physicians, voluntary investigators, members of the Association Nationale des Gastroentérologues des Hôpitaux généraux (ANGH).

Results: Since March, 2014, 140 patients with chronic hepatitis C starting treatment with SoDa were included by 13 investigators in 12 centers. Main characteristics of the patients were: male gender 58%, median age 57 years, cirrhosis (C) 54% (Child A 85%, Child B 9%), F3 fibrosis stage 32%, high viremia 68%, patients naïve 22%, treatment-experienced 78% [non-responders 43% (including null responders 15%), relapsers 35%], genotype (G) 1: 74%, G 3: 15%, G 4: 7%, G 5: 4%.

Daily doses were 400 mg/j of sofosbuvir and 60 mg of daclatasvir, except in the 7 HIV-coinfected patients in whom daclatavir dosage was modified according to the antiretroviral combination used; ribavirin was prescribed in only 2 patients.

Available on-treatment responses, similar in patients with or without cirrhosis, are described below.

G 1 + 5 (n = 109): C 56% (Child A/B: 91%/9%), Patients (Pts) naïve 21%, Viral response (undetectable HCV-RNA) week 2 (VR2) 33%, Viral Response week 4 (VR4) 75%, Viral response week 12 (VR12) 89%.

G 3 (n = 21): C 50% (Child A/B: 86%/4%), Pts naïve 29%, VR2 55%, VR4 64%, VR12 100%.

G 4 (n = 10): C 40% (Child A 100%), Pts naïve 20%, VR2 50%, VR4 75%, VR12 100%.

To date, no grade 3–4 adverse effect has been reported.

Conclusions: In a population of patients mainly treatment-experienced and with cirrhosis or severe fibrosis, treated with sofosbuvir and daclatasvir initial tolerance and efficacy data seem to be in the range of phase II studies. Complete SVR and safety data will be presented.

P0811

SOFOSBUVIR-BASED DIRECT-ACTING ANTIVIRALS TREATMENT FOR ELDERLY CHRONIC HEPATITIS C PATIENTS: A COST-EFFECTIVENESS ANALYSIS

A. Ciaccio[1], P.A. Cortesi[2], G. Bellelli[3], Matteo Rota[4], Monica Rota[1], S. Okolicsanyi[1], L.G. Mantovani[2], G. Annoni[3], M. Strazzabosco[1,5]. *[1]Department of Surgery and Translational Medicine, [2]Research Centre on Public Health (CESP), [3]Department of Health Sciences, Geriatric Medicine, [4]Department of Health Sciences, Centre of Biostatistics for Clinical Epidemiology, University of Milan-Bicocca, Milan, Italy; [5]Liver Center & Section of Digestive Diseases, Department of Internal Medicine, Yale University School of Medicine, New Haven, CT, United States*
E-mail: mario.strazzabosco@yale.edu

Background and Aims: A relevant proportion of patients affected by Chronic Hepatitis C (CHC) is older than 65 years. In the interferon era, comorbidities and a higher susceptibility to interferon/ribavirin adverse events have historically limited treatment in these patients. Recent approval of interferon-free regimens, characterized by high efficacy and limited toxicity, provide unprecedented chances for these patients to receive curative treatments. However, the cost-effectiveness of all-oral Direct-Acting Antivirals (DAAs) has not been addressed in the elderly population. We have performed a cost-effectiveness analysis taking into account the severity of liver disease, the age of the patient and the geriatric (frailty) status.

Methods: A semi-Markov model of CHC natural history was built. The study focuses on CHC patients older than 65 years, stratified according to liver fibrosis (METAVIR F3 and F4), age (65 to 85 years old) and frailty phenotype defined by Fried's (not frail, pre-frail and frail) for a total of 30 cohorts simulated. Treatment with sofosbuvir plus simeprevir (SOF/SMV) combination versus no treatment was assessed for each cohort population. The model estimated costs, Life Years and Quality Adjusted Life Years (QALY) using a lifetime time horizon and the Health System perspective. Results are presented as incremental cost-effectiveness ratios (ICERs) per QALY gained. Cost-effectiveness was defined as an ICER under the willingness-to-pay threshold of €37,000 per QALY gained.

Results: At each fibrosis score, ICER increased with age and frailty index. Among patients with F3 fibrosis, ICER ranged from €13,934/QALY in not-frail 65 years old and €79,354 in frail 85 years old patients. Among F4 patients ICER ranged from €13,873/QALY in not frail 65 years old and €115,965 in frail 85 years old patients. In both F3 and F4 cohorts ICER was below €37,000/QALY up to age 80 in non-frail pts, up to age 75 in pre-frail patients, up to age 70 in frail patients. Adopting an alternative scenario with a 20% discount of SOF/SMV treatment, the number of cohort population simulated with an ICER below € 37,000/QALY increased.

Conclusions: SOF/SMV treatment is cost-effective in most CHC patients older than 65 years, however a careful assessment of the patient geriatric status is mandatory. This cost-effectiveness analysis should promote a prospective clinical study to verify efficacy and side effects in elderly HCV patients.

P0812

IMPACT OF SVRW12 IN THE DEVELOPMENT OF COMPLICATIONS AND FIBROSIS REGRESSION IN PATIENTS TREATED WITH TRIPLE THERAPY WITH BOCEPREVIR AND TELAPREVIR

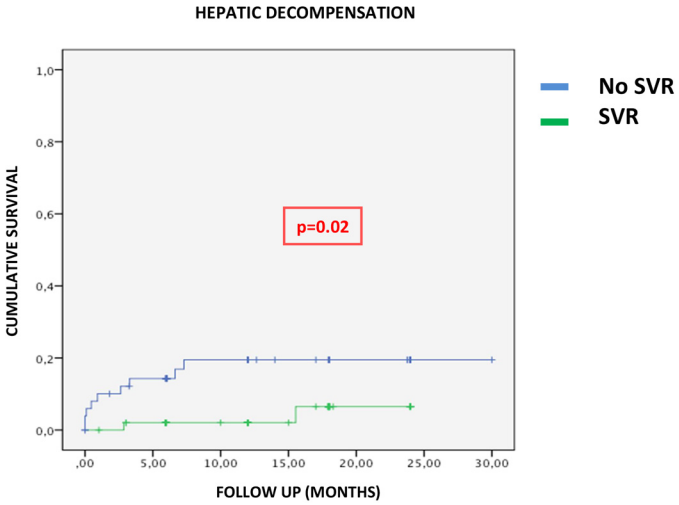
C. Perelló[1], J. Cabezas[2], E. Llop[3], S. Menéndez[2], J. De La Revilla[3], J. Crespo[2], J.L. Calleja[3]. *[1]Gastroenterology, Hepatology Unit, University Hospital Puerta de Hierro, Majadahonda, [2]Gastroenterology and Hepatology, University Hospital Marqués de Valdecilla, Santander, [3]Gastroenterology and Hepatology. CYBERehd, University Hospital Puerta de Hierro, Majadahonda, Spain*
E-mail: csperello@hotmail.com

Background and Aims: Antiviral treatment with triple therapy achieved a sustained viral response (SVR12) in a significant number of patients with advanced fibrosis. The aim of this study was to evaluate the development of complications and the evolution of fibrosis after treatment

Methods: Hepatic decompensation (HD) data were collected prospectively until the end of follow up or liver transplantation (LT) and FibroScan® at 6 and 12 months after treatment in two university hospitals.

Results: A total of 226 consecutive patients with SVR12 (59.2%) were included. 112 patients were classified as F4, the baseline characteristics were: Age 64.6 (SD 9.2), ALT 109.5 (SD 64.8), Bilirubin 1.0 (SD 0.6), Albumin 4.2 (SD 0.4), Platelets 138.5×10^9 (SD 50.3×10^9), INR 2.4 (SD 10.7), Fibroscan (kPa) 21.6 (SD 11.6).
The SVR12 was 47.3% (53 patients). 21 patients presented HD (18.8%), of these 10 (8.9%) during treatment and 11 (9.7%) at the end. The most frequent complications were ascites 11 (9.8%) and hepatocarcinoma 8 (7.1%). 8 patients (7.1%) required liver transplantation (LT) and 4 patients (3.5%) died. The mean follow up to the HD or end of follow-up was 12.6 months (SD 7.6). SVR12 patients had lower frequency of HD (4% vs 17.3%; p = 0.03). The cumulative probability of HD year post treatment SVR12 group was significantly lower (2% vs 19.5%; p = 0.02) (Figure 1). In the group of SVR12 the need for LT was significantly lower (0% vs 9.6%; p = 0.03). Were significantly related to the presence of HD the values of albumin [4.3 (SD 0.4) vs 3.7 (SD 0.3); p < 0.001] and fibroscan [20.5 (SD 10.7) vs 32.1 (15.6); p = 0.02]; patients with SVR12 showed a greater decrease of fibrosis in a significantly higher percentage (60% vs 31.6%; p = 0.04).

Conclusions: The SVR12 in patients with advanced liver disease was associated with an improvement in fibrosis stage and a lower rate of decompensation and liver transplantation.



P0813

ALL ORAL THERAPY (SOFOSBUVIR–RIBAVIRIN) COMBINATION IN SEVERE HCV-MIXED CRYOGLOBULINEMIA VASCULITIS, THE VASCUVALDIC STUDY

D. Saadoun[1], V. Thibault[2], G. Pialoux[3], L. Elkrief[4], M. Mallet[5], L. Musset[6], D. Bazin Kara[7], C. Cazorla[8], S. Pol[9], P. Cacoub[1]. *[1]Internal medicine, [2]Virology, GHPS, [3]Infectious disease, Tenon hospital, [4]Hepatology, Beaujon hospital, [5]Hepatology, [6]Immunology, GHPS, Paris, [7]Nephrology, Strasbourg hospital, Strasbourg, [8]Internal medicine, Noumea Hospital, Noumea, [9]Hepatology, Cochin, Paris, France*
E-mail: dsaadoun@wanadoo.fr

Background and Aims: The standard of care treatment of patients with HCV-mixed cryoglobulinemia vasculitis (MC) includes Peg-IFN alpha plus Ribavirin, w/wo Rituximab. Thirty to 40% of patients are non-responders, relapsers or intolerant to such combination. Our aim was to analyze the safety and efficacy of a Sofosbuvir/Ribavirin combination in active severe and/or refractory HCV-MC.

Methods: Open label prospective single-center cohort study including 18 patients with HCV-MC vasculitis. All patients received Sofosbuvir 400 mg/d and Ribavirin (200 to 1200 mg daily), for 24 weeks.

Results: Median age 61.5 years (28–88), 50% women, HCV genotype 1 (n = 12), 2 (n = 2), 4 (n = 3) and 5 (n = 1). Eleven patients (61%) were non-responders to previous antiviral therapy, including Peg-IFN alpha/Ribavirin/Protease inhibitor (n = 6). Three patients had been also previously treated with Rituximab.
At baseline, mean HCV RNA level was 5.9 log copies/mL; Metavir fibrosis score was stage 4 in 8 cases, stage 3 in 2 cases, stage 2 in 5 cases, stage 1 in 1 case and stage 0 in 2 cases. Eleven patients had a type II IgMk MC. Main HCV-MC manifestations included purpura (n = 13), polyneuropathy (n = 9), arthralgia (n = 12), and kidney involvement (n = 3). The median serum MC, C4 and rheumatoid factor levels were 0.17 g/l, 0.10 g/l and 26 IU/ml, respectively.
At week 24 (end of treatment), 14 patients (78%) were complete clinical responders of cryoglobulinemia vasculitis. Negative viremia i.e. <12 IU/ml (at week 24) was evidenced in 13 out of 16 (81%) cases. The cryoglobulin level decreased from 0.17 to 0.05 g/l (p < 0.05) while the C4 serum level increased from 0.10 to 0.15 g/l (p < 0.05). The alanine aminotransferase level dropped from 50 to 17 IU/ml (p < 0.05). Adverse events occurred in 13 patients (72%) and included anemia (n = 6), insomnia (n = 4), asthenia (n = 3), infection (n = 3) (herpes, pneumonia and prostatitis) and nausea (n = 1).

Conclusions: Sofosbuvir plus ribavirin combination is highly effective in active severe and/or refractory HCV-MC with an acceptable safety profile. Virological (SVR12) and clinical responses at week 36 will be presented at the meeting.

P0814

HEPATIC IMPROVEMENT IN RESPONSE TO LEDIPASVIR/SOFOSBUVIR/RIBAVIRIN AS MEASURED BY THE HEPQUANT® (HQ)-SHUNT TEST IN LIVER TRANSPLANT (LT) RECIPIENTS WITH ALLOGRAFT FIBROSIS OR CIRRHOSIS AND NON-LT PATIENTS WITH DECOMPENSATED CIRRHOSIS

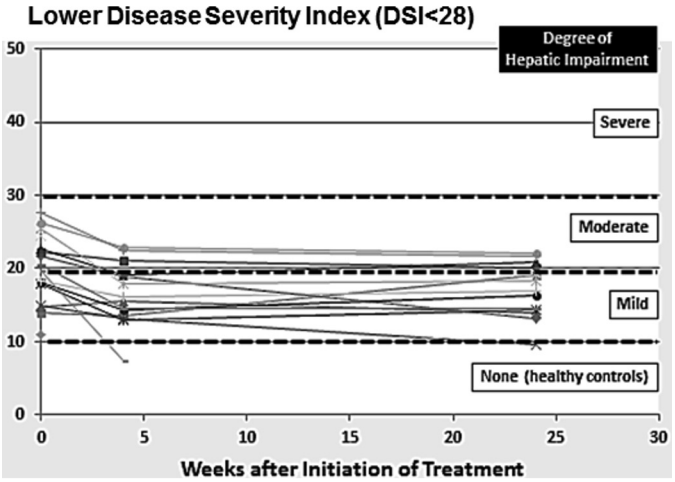
J.R. Burton[1], J.G. O'Leary[2], S. Helmke[1], A. Herman[1], M. Cookson[1], S. Lauriski[1], J.F. Trotter[2], J. Denning[3], P. Pang[3], J. McHutchison[3], M.P. Curry[4], G.T. Everson[1]. *[1]Section of Hepatology, University of Colorado Denver, Aurora, [2]Baylor University Medical Center, Dallas, [3]Gilead Sciences Inc, Foster City, [4]Beth Israel Deaconess Medical Center, Boston, United States*
E-mail: greg.everson@ucdenver.edu

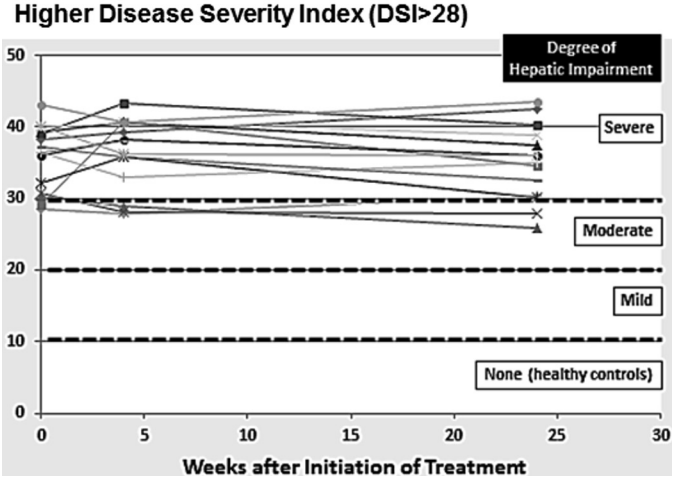
Background and Aims: A primary goal of the treatment of advanced HCV is normalization of hepatic function and the portal circulation. In SOLAR-1, recipients of liver transplantation (LT) with either fibrosis or cirrhosis, and non-LT patients with decompensated cirrhosis were treated with ledipasvir/sofosbuvir/ribavirin

(LDV/SOF/RBV) for 12 or 24 weeks. We assessed changes in hepatic function and the portal circulation during, and after LDV/SOF/RBV using HQ-SHUNT, a test employing dual cholates labeled with stable isotopes and given simultaneously both orally (po) and intravenously (iv). Baseline, Week 4, and Week 24 results were available. Completed results through Week 48 will be presented.

Methods: The study included 31 patients enrolled in SOLAR-1: 10 with LT and F0–F3 fibrosis, 11 with LT and cirrhosis (3 CTP A, 6 CTP B, 2 CTP C) and 10 non-LT patients with decompensated cirrhosis (4 CTP B, 6 CTP C). The HQ-SHUNT test involves serum sampling prior to, and at 5, 20, 45, 60, and 90 minutes after administering the cholates. Clearance of po D4-cholate defines Portal Hepatic Filtration Rate (HFR). Clearance of iv ^{13}C-cholate defines Systemic HFR. The ratio of Systemic to Portal HFR defines SHUNT. HFRs and SHUNT have been modeled in other studies to derive a disease severity index (DSI) predictive of clinical outcomes. A DSI >28 signifies severe hepatic impairment. Healthy controls have DSI ≤10.

Results: At baseline, HFRs were higher and SHUNT and DSI were lower in non-cirrhotic LT recipients compared to cirrhotic LT recipients, and in cirrhotic LT recipients compared to the decompensated non-LT patients. Median baseline DSI was 27.6 – 16 patients had DSI <28 (10 F0–F3, 1 CTP A, 5 CTP B) and 15 had DSI >28 (2 CTP A, 5 CTP B, 8 CTP C). By Week 4, HCV RNA was <LLOQ and patients with baseline DSI <28 had significant drop in DSI. Patients with DSI >28 did not improve. DSI, HFRs and SHUNT did not change between Weeks 4 and 24 in either DSI group. One patient with SBP between Weeks 0 and 4, had marked increase in DSI at Week 4, and decline in DSI by Week 24 (dotted line in right panel).





Conclusions: A DSI cutoff of 28 correlates with severity of liver disease and identifies patients with (DSI <28) and without (DSI >28) early hepatic improvement during LDV/SOF/RBV. Early hepatic improvement is likely related to improvement in hepatocyte perfusion and function. Further hepatic improvement beyond Week 4, as measured by decline in DSI, will likely require resolution of hepatic fibrosis – a much slower natural process.

P0815

COST-EFFECTIVENESS OF TREATING DIFFERENT STAGES OF GENOTYPE 1 HEPATITIS C VIRUS (HCV) WITH ABBVIE 3D (ABT-450/RITONAVIR/OMBITASVIR AND DASABUVIR) +/− RIBAVIRIN COMPARED TO NO TREATMENT IN THE UNITED STATES

S.J. Johnson[1], D.A. Misurski[2], T.R. Juday[2], J.C. Samp[2], S.E. Marx[2], H. Parisé[1], S. Virabhak[1], S. Saab[3]. [1]*Medicus Economics, Milton,* [2]*Global Health Economics and Outcomes Research, AbbVie, Mettawa,* [3]*Pfleger Liver Institute, Los Angeles, United States*
E-mail: jensamp@gmail.com

Background and Aims: New interferon (IFN)-free therapies for the treatment of hepatitis C virus (HCV) offer better viral clearance rates and safety profiles than older therapies but are priced higher. As a result, payers have questioned the value of treating all HCV patients with IFN-free therapies and have proposed reserving treatment for patients with more advanced liver disease. The objective of this study was to determine the cost-effectiveness of treating genotype 1 HCV patients with the AbbVie 3D (ABT-450/ritonavir/ombitasvir and dasabuvir) +/− ribavirin regimen compared to no treatment at different fibrosis stages in the United States.

Methods: A Markov model was developed to determine the cost-effectiveness of HCV treatment with AbbVie 3D compared to no treatment. The model population, dosing, and efficacy information were based on the AbbVie 3D phase 3 clinical trials. Disease stage was grouped based on fibrosis score (F0, F1, F2, F3, and F4). A hypothetical cost of AbbVie 3D was assumed to be equal to the cost of sofosbuvir. Effects were measured in quality-adjusted life-years (QALYs) and cost-effectiveness was quantified as an incremental cost-effectiveness ratio (ICER). The ICER was calculated for patients across all stages (F0–F4) and compared to the ICER for treating patients with more severe disease, separately for treatment naïve and experienced patients.

Table 1. Cost-effectiveness of treating different stages of HCV with AbbVie 3D compared to no treatment

Treatment strategy	ICER of AbbVie 3D compared to no treatment
Treatment naive	
Treat F0–F4 patients	$19,193/QALY
Treat F1–F4 patients	$15,701
Treat F2–F4 patients	$12,612
Treat F3–F4 patients	$11,792
Treat F4 patients	$16,181
Treatment experienced	
Treat F0–F4 patients	$18,411/QALY
Treat F1–F4 patients	$16,081
Treat F2–F4 patients	$14,523
Treat F3–F4 patients	$14,519
Treat F4 patients	$16,956

Results: It is cost-effective to treat treatment naïve patients across all stages (F0–F4) at $19,193/QALY. The ICER is more favorable with treatment of F1–F4 patients ($15,701), F2–F4 ($12,612), and F3–F4 ($11,792) but increases if treatment is restricted to only F4 patients ($16,181) (Table 1). Treatment experienced patients also have favorable cost-effectiveness ratios. The ICER for treating F0–F4 treatment experienced patients is $18,411/QALY. Similarly to the treatment naïve group, the ICER is slightly more favorable when restricting treatment to F1–F4 ($16,081), F2–F4 ($14,523), F3–F4

($14,519) but increases if treatment is restricted to only F4 patients ($16,956). Results were robust to variation in model parameters including costs, efficacy, health utilities, discount rates, and fibrosis and disease progression rates.
Conclusions: It is cost-effective to treat HCV patients across all disease stages and treatment histories. All incremental cost-effectiveness ratios are well below the cost per QALY threshold of $50,000.

P0816
REDUCTION IN ANNUAL MEDICAL COSTS WITH EARLY TREATMENT OF HCV USING ABBVIE 3D (ABT-450/RITONAVIR/ OMBITASVIR AND DASABUVIR) +/− RIBAVIRIN IN THE UNITED STATES

D.A. Misurski[1], S.J. Johnson[2], J.C. Samp[1], S.E. Marx[1], T.R. Juday[1], S. Virabhak[2], H. Parisé[2], S. Saab[3]. *[1]Global Health Economics and Outcomes Research, AbbVie, Mettawa, [2]Medicus Economics, Milton, [3]Pfleger Liver Institute, Los Angeles, United States*
E-mail: jensamp@gmail.com

Background and Aims: Treating and curing patients with hepatitis C virus (HCV) is believed to reduce future medical costs; however, the timing and stage at which to treat HCV has been a topic of debate. Early treatment has been associated with greater viral clearance rates while treating HCV patients in later disease stages has been shown to leave patients at excess risk for liver complications including hepatocellular carcinoma and liver transplant. The aim of this study was to determine the average annual lifetime post-treatment medical costs for patients treated at varying stages of liver disease in the United States.
Methods: A Markov model of the natural history of HCV was developed based on previous HCV models. The model population and efficacy rates were based on AbbVie 3D (ABT-450/ritonavir/ombitasvir and dasabuvir) phase 3 clinical trials. Disease stage was classified into 5 groups based on METAVIR score (F0, F1, F2, F3, and F4). Costs were in US dollars and based on a systematic literature review of US costs in HCV. All direct medical costs, with the exception of HCV drug costs, were included in the model. Analyses were run with costs and life years undiscounted and discounted at a rate of 3%. The model was run over a life time horizon with patients entering the model at each fibrosis stage and receiving treatment with AbbVie 3D. Annual medical costs were calculated by dividing lifetime costs by life years. Analyses were run separately for treatment naïve and experienced patients.

Table 1. Average annual lifetime direct medical costs after treatment with AbbVie 3D

Stage of disease at treatment	Average annual lifetime direct medical costs post-treatment	
	Undiscounted	Discounted
Treatment naive		
F0	$314	$228
F1	$441	$320
F2	$597	$445
F3	$806	$633
F4	$3,266	$2,938
Treatment experienced		
F0	$298	$221
F1	$417	$308
F2	$564	$427
F3	$760	$604
F4	$3,128	$2,823

Results: Initiation of treatment at later stages of fibrosis resulted in an increase in average annual lifetime post-treatment costs increase while the life years saved decreased. This result occurred in both treatment naïve and experienced patients. Treatment naïve patients treated in F0 stage had average annual medical costs of $314 ($228 discounted) post-treatment. This value gradually increased for patients in F1, F2, and F3 stages. Patients treated in F4 stage had significantly greater annual medical costs that were over 10-fold greater that annual medical costs for patients treated in F0.
Conclusions: Our model suggests that HCV patients who are treated earlier in the disease process incur lower average annual lifetime post-treatment annual medical costs compared to patients treated later in the disease process. Consistent with existing literature, annual post-treatment medical costs are much higher for patients in F4 stage compared to other stages.

P0817
COST-EFFECTIVENESS OF TREATING CHRONIC HEPATITIS C GENOTYPE-1 WITH LEDIPASVIR AND SOFOSBUVIR IN GERMANY

J.T. Stahmeyer[1], S. Rossol[2], F. Bert[2], I.M. Guerra[3], C. Krauth[1]. *[1]Institute for Epidemiology, Social Medicine and Health Systems Reserach, Hannover Medical School, Hannover, [2]Department of Medicine, Krankenhaus Nordwest, Frankfurt a.M., Germany; [3]OptumInsight, Uxbridge, United Kingdom*
E-mail: Stahmeyer.Jona@mh-hannover.de

Background and Aims: Treatment of chronic hepatitis C has significantly improved with the introduction of recent direct acting antivirals (DAAs) allowing more than 90% of patients to be cured. Increased effectiveness was accompanied by significantly higher treatment costs, especially for interferon-free treatment regimens. The aim of the present study was to analyze the cost-effectiveness of treating patients with the new released DAA combination of ledipasvir/sofosbuvir (LDV/SOF).
Methods: A decision-analytic markov model was used to evaluate the long-term cost-effectiveness of LDV/SOF treatment compared to current available treatment regimens for genotype-1 patients: peginterferon/ribavirin (PR); telaprevir/PR (TVR/PR); boceprevir/PR (BOC/PR); simeprevir/PR (SMV/PR); sofosbuvir/PR (SOF/PR); sofosbuvir/R (SOF/R), sofosbuvir/daclatasvir (SOF/DAC) and SOF/SMV. Analyses were conducted for treatment-naive (TN) patients receiving LDV/SOF for 8 or 12 weeks and treatment-experienced (TE) patients receiving 12 weeks of LDV/SOF(+R). Payers perspective, discount-rate of 3%, lifetime horizon were used and a proportion of 19% cirrhotic patients in both TN and TE patients was assumed. Sustained virological response (SVR) was based on clinical trials. Other model parameters such as transition probabilities, quality-of-life and costs were derived from published literature or public sources.

Table 1. Total costs and QALYs for alternative treatment regimens and ICER of LDV/SOF compared to other treatment regimens

Treatment	Total costs	Total QALYs	ICER
Treatment-naive			
LDV/SOF (8 or 12 weeks)	58,631 €	18.963	reference
No treatment	19,533 €	15.914	12,821 €/QALY
PR (48 weeks)	32,107 €	16.994	13,472€/QALY
BOC/PR (RGT)	49,414 €	17.779	7,285 €/QALY
TVR/PR (RGT)	52,503 €	17.982	6,247 €/QALY
SMV/PR (24 weeks)	66,663 €	18.159	dominated
SOF/PR (12 weeks)	69,787 €	18.611	dominated
SOF/R (24 weeks)	129,764 €	17.589	dominated
DAC/SOF (12 or 24 weeks)	119,412 €	19.065	595,455 €/QALY
SOF/SMV (12 weeks)[a]	110,742 €	18.831	dominated
Treatment-experienced			
LDV/SOF(+R) (12 weeks)	70,449 €	17.720	reference
No treatment	18,448 €	15.052	19,492 €/QALY
SOF/PR (12 weeks)	70,605 €	17.108	dominated
SMV/PR (48 weeks)[b]	75,861 €	16.999	dominated
DAC/SOF (24 weeks)	195,087 €	17.642	910,792 €/QALY
SOF/SMV (12 weeks)[a,b]	110,036 €	17.857	dominated

[a] SMV/SOF should only be used in patients intolerant to or ineligible for interferon therapy; [b] only for P/R failures.

Results: Treating TN patients with LDV/SOF resulted in average lifetime costs of €58,631 while achieving 18.96 QALYs. Incremental cost-effectiveness ratios were €13,472/QALY compared to PR for 48 weeks; €7,285/QALY compared to BOC/PR RGT; €6,247/QALY compared to TVR/PR RGT and €12,821/QALY compared to no treatment. LDV/SOF was more effective and had lower total costs compared to SOF/PR for 12 weeks, SOF/R for 24 weeks, SMV/PR for 24 weeks and SOF/SMV for 12 weeks. Total QALYs in LDV/SOF were slightly lower compared to SOF/DAC treatment, but also resulted in considerably lower costs. Results for TE patients are shown in Table 1.
Conclusions: This analysis showed LDV/SOF treatment is cost-effective considering international thresholds. Considering SVR-rates in current DAAs, model results are mainly influenced by costs for antiviral treatment. Average LDV/SOF treatment costs have been reduced in TN patients and are almost equivalent for TE patients compared to SOF/PR. Outcomes and average treatment costs should be verified in analyses using real-life data since many trials relate on small patient numbers.

P0818
ANALYSIS OF NS3 PROTEASE RESISTANCE-ASSOCIATED VARIANTS AND PHENOTYPES FOR THE PREDICTION OF TREATMENT RESPONSE TO HCV TRIPLE THERAPY

J. Dietz[1], D. Rupp[2], D. Perner[1], C. Berkowski[1], M. Räder[1], S. Susser[1], S. Mauss[3], T. Kuntzen[4], S. Zeuzem[1], R. Bartenschlager[2], C. Sarrazin[1]. *[1]Department of Internal Medicine 1, Goethe University Hospital, Frankfurt, [2]Department of Infectious Diseases, Molecular Virology, Heidelberg University, Heidelberg, [3]Gastroenterologische Schwerpunktpraxis, Düsseldorf, Germany; [4]Klinik für Gastroenterologie und Hepatologie, Universitätsspital Zürich, Zürich, Switzerland*
E-mail: julia.dietz@em.uni-frankfurt.de

Background and Aims: Triple therapies with NS3 protease inhibitors (PI) Telaprevir (TVR) or Boceprevir (BOC) were widely used for treatment of HCV (hepatitis C virus) genotype 1 infected patients in the past 3 years and this treatment is still the standard of care in many countries. In the present study, several viral and host factors like pre-existing RAVs, phenotypic drug susceptibility, viral load, viral subtype, cirrhosis, treatment history, IP10 levels (interferon-gamma inducible protein) and *IL28B* genotype were investigated in association with response to triple therapy.
Methods: Patients were enrolled in a prospective multicenter study to analyze baseline resistance (PIRB, n = 211) and resistance after treatment failure (PISA, n = 92) together with clinical parameters. Patient NS3 RAVs were studied at positions V36, T54, V55, V107, R117, R155, A156, V158, V170, M175 by population-based sequencing. For phenotypic resistance characterization, we created subgenomic replicon-based NS3-libraries of patients with virologic failure (n = 30) and a corresponding cohort with SVR (sustained virologic response) (n = 21).
Results: Within 24 weeks after treatment failure, RAVs appeared frequently (62%) with the combined mutation V36M+R155K as most prevalent variant (49%). Investigations on the association of baseline RAVs with phenotypes and clinical parameters were conducted in a group of 41 patients with virologic failure and 115 individuals with SVR. RAVs occurred rarely at baseline [n = 2 (5%), virologic failure; n = 10 (9%), SVR] and correlated not with treatment response. We detected sensitive (n = 28, <1-fold change IC_{50} compared to wildtype replicon) and resistant (n = 23, >1-fold change) phenotypes not correlating with the presence of RAVs. The number of resistant phenotypes was comparable in both groups (48% SVR, 43% virologic failure). Other predictors of treatment response were not (HCV viral load, subtype) or weakly (IL28B, prior null response, cirrhosis, IP10 levels; $P < 0.05$) associated with outcome as single parameters. In combined analyses, we detected a highly significant correlation of a higher number of negative predictors in patients with virologic failure compared to SVR (mean 3.6 versus 2.3, $P < 0.001$).
Conclusions: Failure to first generation PI-based triple therapy is a multifactorial event shown by a lack of correlation with single predictors but with the number of negative predictors including RAVs, viral phenotype, viral load and HCV subtype, prior null response, IL28B genotype, IP10 levels and cirrhosis.

P0819
SIMEPREVIR AND SOFOSBUVIR WITH MODIFIED DOSES OF RIBAVIRIN (RBV) THERAPY ON TELAPREVIR EXPERIENCED CO INFECTED (WITH HIV) CIRRHOTICS WITH CHRONIC HEPATITIS C (CHC). A RANDOMIZED OPEN LABEL CLINICAL PILOT STUDY: STOP C

P.P. Basu[1,2], N.J. Shah[3], R. Brown Jr.[1]. *[1]Columbia University College of Physicians and Surgeons, NY, [2]King's County Hospital Medical Center, Brooklyn, NY, [3]James J. Peters VA Medical Center, Icahn School of Medicine at Mount Sinai, NY, United States*
E-mail: basu.patrick@gmail.com

Background and Aims: Cirrhotics with CHC still remains a challenge. Co-infected cirrhotics (HIV+CHC) are at a greater risk for rapid decompensation affecting QOL and have a higher transplant risk burden. Interferon based therapy entails a longer duration with an increased susceptibility of infections and marrow suppression warranting use of growth factors and even discontinuation of therapy/treatment failure. Telaprevir; a protease inhibitor (PI) based therapy have proved efficacious in co-infected patients. Newer generation PI coupled with polymerase inhibitors and adjusted doses of RBV have shown favorable outcomes. To evaluate the efficacy of Simeprevir, Sofosbuvir with RBV in prior Telaprevir experienced co-infected cirrhotics.
Methods: Fifty (n = 50) co-infected (HIV+CHC, non AIDS) cirrhotics with mean MELD 16, HIV RNA undetectable, mean CD4 count 439, Hb 10.7, HCV RNA 1.7 million copies, mean platelet count 104, albumin 2.9 and WBC 4600. 18 genotype 1a and 32 genotype 1b.
Exclusion criteria: HBV, decompensated cirrhosis, hemolytic disease, heart failure, AIDS, Alcohol consumption >30 g/day, CrCl <50%, uncontrolled diabetes, portal hypertension, Patients on any herbal medications.
Group A: Simeprevir 150 mg + Sofosbuvir 400 mg + RBV for 24 weeks
Group B: Simeprevir 150 mg + Sofosbuvir 400 mg + RBV 1000 mg for 16 weeks
Results: See the table.

Undetectable	Group A (n = 22)	Group B (n = 28)
48 hours	2/22 (9%)	4/28 (14%)
1 week	3/22 (14%)	7/28 (25%)
4 weeks	16/22 (73%)	19/28 (68%)
8 weeks	17/22 (77%)	22/28 (78%)
12 weeks	17/22 (77%)	23/28 (82%)
16 weeks	17/22 (77%)	23/28 (82%)
24 weeks	18/22 (83%)	
28 weeks		23/28 (82%) [SVR 12]
36 weeks	18/22 (83%) [SVR 12]	
40 weeks	18/22 (83%)	23/28 (82%)

Conclusions: The combination of Interferon free regimen in special population with prior experienced PI demonstrated no difference of SVR in 16th week over 24th weeks. Group A 83% compared to Group B 82% responders were noted. This regimen was well tolerated and has a better safety profile than conventional trials.

P0820

PHARMACOKINETICS OF PARITAPREVIR, OMBITASVIR, DASABUVIR, RITONAVIR AND RIBAVIRIN IN SUBJECTS WITH HCV GENOTYPE 1 INFECTION IN PHASE 3 STUDIES

S. Mensing[1], S. Sharma[2], D. Eckert[1], A. Polepally[3], A. Khatri[3], T. Podsadecki[3], W. Awni[3], R. Menon[3], S. Dutta[3]. [1]*AbbVie Deutschland GmbH & Co. KG, Ludwigshafen am Rhein, Germany;* [2]*Former AbbVie employee,* [3]*AbbVie, North Chicago, United States*
E-mail: sven.mensing@abbvie.com

Background and Aims: AbbVie currently has 3 direct acting antiviral agents (DAAs) in clinical development for the treatment of HCV genotype 1 (GT1) infection, paritaprevir, an HCV NS3/4A protease inhibitor identified by AbbVie and Enanta as a lead compound for clinical development, (administered with ritonavir, a pharmacokinetic enhancer), ombitasvir, a NS5A inhibitor and dasabuvir a NS5B non-nucleoside polymerase inhibitor. Objectives of these analyses were to characterize the pharmacokinetics of the 3 DAAs, ritonavir and ribavirin (RBV) to identify patient-specific covariates affecting exposure.

Table 1. Covariates evaluated for effect on pharmacokinetics of DAAs, Ritonavir and RBV

Patient-specific covariates
On apparent clearance: age, sex, black race, body weight, body mass index, body surface area, creatinine clearance, non-responders/naïve, genotype 1 a/b, Hispanic/Latino ethnicity, Asian, cirrhosis, use of methadone/buprenorphine, use of ribavirin and comedications (see below for the drug classes and categories).
On apparent volume parameters: age, sex, body weight, body surface area and body mass index.
Drug Classes
Proton pump inhibitors/GI agents (those that interfere with stomach pH, and does not include laxatives)
Opioids
Antidepressants/Anxiolytics/Benzodiazepines/Barbiturates
Antihypertensives
PDE5 inhibitors
Non-opioid analgesics
Statins (HMG Co-A inhibitors) and lipid-lowering agents
Antipsychotics
Antiepileptic drugs (AEDs)/anticonvulsants
Antidiabetics
Antihistamines/antiallergics/respiratory agents
Hormonal contraceptives
Hormonal replacement therapies
Steroids
Anti-infectives
Drug categories: Inhibitors and/or inducers of metabolic enzymes and transporters
CYP 3A4/5/7
CYP 2C8
CYP 2D6
CYP 1A2
CYP 2C9
CYP 2C19
CYP 2B6
UGTs
P-gp
MRP2
BCRP
OATP1B1
OATP1B3

Methods: Pharmacokinetic data of all 3 DAAs ± RBV were obtained for 2348 HCV GT1-infected patients who enrolled in one Phase 2 and six Phase 3 trials (1841 of them received RBV). Population pharmacokinetic models were built using the program NONMEM 7.3. Effect of patient-specific covariates (demographics, compensated cirrhosis Child–Pugh class A, renal impairment, and treatment experience), RBV and 15 comedication drug classes and/or 19 enzyme/transporter inhibitor/inducer categories (see table) on pharmacokinetics were evaluated.

Results: A one-compartment model best described paritaprevir, ritonavir and ombitasvir concentration-time profiles, while a two-compartment model best described dasabuvir and RBV concentration time profiles. Steady-state Cmax (ng/mL) and AUC24 (ng·h/mL) values, respectively, for the reference population included paritaprevir: 97 and 1130; ritonavir: 396 and 3400; ombitasvir: 49 and 857; dasabuvir: 533 and 8150; and RBV: 1450 and 38200. Changes in age (by 10 years) and body weight (by 10 kg) showed minimal impact on exposures (<20% change). Females had higher exposures (15%>100%) of the DAAs and RBV than males. Subjects with cirrhosis had higher paritaprevir (140%) and dasabuvir (40%) exposures, but comparable ombitasvir, RBV and ritonavir exposures as noncirrhotic patients. Mild renal impairment did not affect paritaprevir and ombitasvir, while having a <15% impact on dasabuvir, RBV and ritonavir exposures. Subjects on concomitant anti-diabetics or opioids had up to approximately 50% higher exposures of paritaprevir than without these concomitant medications. None of the other DAAs, ritonavir or ribavirin were influenced by comedications. RBV did not significantly impact DAA or ritonavir pharmacokinetics.

Conclusions: Based on the broad therapeutic range and tolerability of the 3DAA regimen, no dose adjustments of the DAAs are required for the evaluated covariates.

P0821

ARE EXTENDED DURATIONS AND/OR RIBAVIRIN USEFUL FOR GENOTYPE 1 (G1) CIRRHOTIC PATIENTS WHO RECEIVE DAAS COMBINATION? A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS (RCTS)

V. Di Martino[1], C. Richou[1], J.-P. Cervoni[1], D. Weil[1], C. Vanlemmens[1], T. Thévenot[1]. [1]*Service d'Hépatologie, CHU Jean Minjoz, Besançon, France*
E-mail: vdimartino@chu-besancon.fr

Background and Aims: The use of ribavirin and a treatment duration longer than 12 weeks have been suggested to increase SVR12 rates in G1 cirrhotic patients receiving DAAs, especially G1 treatment-experienced (TE) cirrhotic patients. The aim of this meta-analysis was to address this issue.

Methods: All phase II and phase III RCTs published or communicated to date which included GI naïve (TN) or TE cirrhotics and contained arms with or without ribavirin and/or compared 12 weeks vs. extended (i.e., 18 or 24 weeks) treatment durations were included. All DAAs regimen were analyzed together. For TN and TE patients, 2 analyses evaluated the ribavirin use (regardless of the treatment duration and for a fixed 12 weeks treatment duration) and 3 analyses evaluated the treatment duration (regardless of, with, or without ribavirin). Meta-analyses were performed according to the Der Simonian and Laird method and reported weight-adjusted SVR12 gains.

Results: 10 RCTs including 1307 G1 cirrhotic patients (573 TN, 734 TE) were selected for this meta-analysis. The distribution of DAA combinations was as follows: SIM+SOF (COSMOS, N = 168), 3D Abbvie (TURQUOISE II, N = 380), DCV-TRIO BMS (UNITY 2, N = 202), GPV+EBV (C-WORTHY, N = 253), and LDV+SOF (6 RCTs, N = 496). In G1 TN cirrhotic patients, the use of ribavirin (ΔSVR = +2.45%; 95% CI: −1.27% to +6.16%, NS, N = 411) or an extended duration (ΔSVR = +0.64%; 95% CI: −3.03% to +4.32%, NS, N = 434) did not increase SVR12. In G1 TE cirrhotic patients, the use of ribavirin did not increase SVR12 (ΔSVR = −0.04%; 95% CI: −3.84% to +3.74%, NS, N = 503), even in analyses restricted to 12 wks treatment duration (ΔSVR = +1.77%; 95% CI: −3.85% to +7.38%, NS, N = 267). Conversely, extended duration was associated with higher SVR rates (ΔSVR = +7.98%; 95% CI: +1.26 to +14.70%, p = 0.019, N = 539), even with ribavirin use (ΔSVR = +12.87%; 95% CI: +0.39 to +25.35%,

p = 0.008, N = 280). The magnitude of SVR gain was similar between the different DAA regimen but was higher in studies incorporating patients who experienced failure to previous PI+P/R regimen (+9.17% vs. +6.90%).

Conclusions: The use of ribavirin does not increase SVR12 rates in TN and TE G1 cirrhotic patients. In TN G1 cirrhotic patients, treatment durations >12 weeks are not useful. In TE G1 cirrhotic patients, treatment durations >12 weeks increase SVR12 rates by 8% and thus should be recommended.

P0822

SAFETY AND EFFICACY OF SOFOSBUVIR CONTAINING REGIMENS FOR HEPATITIS C: COMMUNITY TREATMENT OF A REAL WORLD POPULATION WITH ADVANCED LIVER FIBROSIS

E-mail: denis.ouzan@wanadoo.fr

Background and Aims: The use of direct-acting antivirals (DAAs) such as sofosbuvir (SOF), simeprevir (SIM) and daclatasvir (DAC) created a major paradigm shift in the treatment of chronic hepatitis C. The aim of this study was to evaluate the safety and efficacy of DAAs utilized in clinical practice in experienced patients with advanced liver fibrosis

Methods: AVD LIB is a longitudinal observational study of patients treated with DDAs at community medical centers (n = 13). Demographic, clinical, adverse events and virological data were collected during treatment and post treatment follow-up.

Results: Since March 2014, 209 patients have started treatment according to restrictive French guidelines (interferon based regimen failure and/or fibrosis F3 or F4) and were included in this study. Mean age was 59 years, 58% male. Genotype 1 was seen in 167 patients (71%), genotype 2 in 4 (2%), genotype 3 in 34 (16%) genotype 4 in 24 (11%). Comorbidities included diabetes in 10% and anxiety and depression in 15%. Viral load >800,000 was seen in 70%, 21% were treatment naïve and 79% have failed on interferon bases regimen including patients with 1 generation protease inhibitors failure. Cirrhosis was present in 66% (Child A in 91%, B in 9% of cases).

Treatment regimens: 12 weeks regimen for genotype 1 included PEG + RBV + SOF in 23 (16%), SOF + SIM +/− RBV in 47 (32%), SOF + DAC in 11 (7%); 24 weeks regimens for genotype 1 included SOF + RBV in 11 (7%) and SOF + DAC +/− RBV in 53 (36%). 12 weeks regimen of PEG + RBV + SOF and of SOF + RBV were used in respectively 2 patients with genotype 2. Among patients with genotype 3, 8 (24%) received 12 weeks of PEG + RBV + SOF, 8 (24%) 24 weeks of SOF + RBV and 18 (53%) 24 weeks of SOF + DAC. Among patients with genotype 4, 4 (17%) received 12 weeks of PEG + RBV + SOF, 12 (50%) 12 weeks of SOF + SIM and 8 (33%) 24 weeks of SOF + DAC +/− RBV.

Any serious adverse event was reported, the most common side effect was asthenia (26 patients). Normal life with any side effects was seen in 37% of patients. At week 4, HCV RNA was undetected in 93% of patients. SVR12 weeks after treatment was available in 29 patients who received 12 weeks of PEG + RBV + SOF. Relapse occurred in 8 of these patients. The SVR12 rate in experienced patients receiving PEG + RBV + SOF was 72%.

Conclusions: An examination of real life advanced hepatitis C in community medical practice: AVD LIB study is underway and SVR and safety data will be available at the meeting

P0823

PHARMACOKINETICS OF PARITAPREVIR, OMBITASVIR, RITONAVIR AND RIBAVIRIN IN SUBJECTS WITH HCV GENOTYPE 4 INFECTION

D. Eckert[1], T. Wang[2], S. Mensing[1], A. Khatri[2], S. Dutta[2], R. Menon[2]. *[1]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen am Rhein, Germany; [2]AbbVie, North Chicago, United States*
E-mail: sven.mensing@abbvie.com

Background and Aims: Paritaprevir is an HCV NS3/4A protease inhibitor identified by AbbVie and Enanta as a lead compound for clinical development, [administered with ritonavir (RTV), a pharmacokinetic (PK) enhancer] and ombitasvir is a NS5A inhibitor. A recently completed study evaluated these two direct acting antivirals (DAA) in combination (2DAA), with and without ribavirin (RBV) in non-cirrhotic patients with HCV Genotype 4 (GT4) infection. SVR rates of 91% (40/44) and 100% (91/91) were observed in the RBV-free and RBV-containing regimens respectively. No patient discontinued due to adverse events. Objectives of these analyses were to characterize the pharmacokinetics of the two DAAs, RTV and RBV to identify patient-specific covariates affecting exposure in GT4 infected subjects.

Methods: PK data were obtained from 135 HCV GT4-infected patients without cirrhosis who received 2DAA with RBV (N = 91) or without (N = 44) in a Phase 2b trial. Population PK models were built using the program NONMEM 7.3. Effect of patient-specific covariates (demographics, creatinine clearance and treatment experience), and the coadministration with RBV on pharmacokinetics were evaluated.

Results: A one-compartment model best described paritaprevir and RTV concentration-time profiles, while a two-compartment model best described ombitasvir and RBV concentration-time profiles. Age, weight, sex, prior treatment experience and creatinine clearance did not affect paritaprevir and RTV exposures. Female subjects had 15–48% higher ombitasvir exposures than male subjects, while subjects with mild renal impairment (creatinine clearance 75–105 mL/min) had 8–25% higher ombitasvir exposures than subjects with normal renal function (creatinine clearance 105 mL/min). Renal impairment also affected RBV exposures as subjects with mild renal impairment had 8% higher exposure compared to subjects with normal renal function. RBV did not significantly impact DAA or RTV PK.

Conclusions: Based on the broad therapeutic range and tolerability of the 2DAA regimen, no dose adjustments of the DAAs are required based on the evaluated covariates.

Table 1. Model-predicted steady-state exposure [a] at normal renal function [b]

	AUC_{ss} (ng·h/mL)	$C_{max,ss}$ (ng/mL)	$C_{min,ss}$ (ng/mL)
Paritaprevir	2210	189	13.2
Ombitasvir	1080–1340	72.2–83.1	17.4–25.7
Ritonavir	3360	280	21.8
Ribavirin	18600	1690	1330

[a] Calculated over 24 hours steady state profiles for paritaprevir, ombitasvir, RTV QD regimens and over 12 hours for RBV BID regimen.
[b] Creatinine clearance of 105 mL/min.

P0824

A PHASE 1 STUDY TO EVALUATE THE INTERACTION OF HCV NS5B INHIBITOR MK-3682 WITH HCV NS3/4A PROTEASE INHIBITOR MK-5172 AND HCV NS5A INHIBITOR MK-8408 IN HEALTHY SUBJECTS

X.-J. Zhou[1], E. Sicard[2], J. Chen[1], D. Frank[1], W. Gao[3], M.L. Rizk[3], E.G. Rhee[3], J.R. Butterton[3], J. Sullivan-Bolyai[1]. *[1]Idenix Pharmaceuticals, Inc., Cambridge, MA, United States; [2]Algorithme Pharma, Montreal, Quebec, Canada; [3]Merck & Co., Inc., Whitehouse Station, NJ, United States*
E-mail: elizabeth.rhee@merck.com

Background and Aims: MK-3682 is a potent and selective pan-genotypic uridine nucleoside monophosphate prodrug inhibitor of the HCV NS5B RNA polymerase being developed with MK-5172, a potent and selective HCV NS3/4A protease inhibitor and MK-8408, a novel HCV NS5A inhibitor, as potential components of a once-daily (QD) all-oral direct-acting antiviral regimen for the treatment of chronic HCV infection. This study evaluated the safety and PK of coadministration of MK-3682 with MK-5172 and MK-8408.
Methods: This was a 3-period, fixed-sequence, open-label drug-interaction study in 18 healthy subjects. In period 1, subjects received MK-5172 200 mg and MK-8408 60 mg QD on days 1–7 followed by a washout on days 8–14. In period 2, subjects received MK-3682 300 mg QD on days 15–21 followed immediately by period 3, in which subjects received MK-3682 300 mg, MK-5172 200 mg and MK-8408 60 mg QD on days 22–28. Blood samples were collected for MK-3682 and its circulating metabolites IDX20664 and IDX23267, MK-5172 and MK-8408. PK parameters were calculated by non-compartmental analysis. Geometric mean ratios (GMR) and 90% confidence intervals (CI) were calculated from the log transformed AUC0–24 and Cmax for all analytes using mixed effect modeling. Safety assessments included ECGs, vital signs, clinical laboratory tests, physical examination and adverse event monitoring.
Results: 18 healthy male and female subjects were enrolled and 17 completed the study. Coadministration with MK-5172 and MK-8408 modestly increased MK-3682 exposures with AUC0–24 and Cmax GMRs [90%CI] of 1.27 [1.16–1.39] and 1.21 [1.03–1.42] and decreased IDX20664 exposures with AUC0–24 and Cmax GMRs [90% CI] of 0.85 [0.81–0.89] and 0.75 [0.72–0.79]. IDX23267 exposures were not affected by MK-5172 and MK-8408. MK-3682 increased MK-5172 exposures but not to a clinically meaningful degree (AUC0–24 and Cmax GMRs [90% CI] of 1.36 [1.11–1.68] and 1.56 [1.19–2.03]) and did not affect MK-8408 exposures (AUC_{0-24} and C_{max} GMRs [90% CI] of 0.99 [0.94–1.04] and 0.99 [0.92–1.06]). Coadministration of MK-3682 with MK-5172 and MK-8408 was well tolerated. One subject was discontinued for a non-drug-related Grade 1 elevation in direct bilirubin.
Conclusions: Coadministration of MK-3682 with MK-5172 and MK-8408 in healthy subjects did not result in clinically significant drug interactions. These results suggest that no dose adjustments of MK-3682, MK-5172 or MK-8408 are needed for coadministration and support further studies of this regimen in HCV patients.

P0825

VARYING EFFICACY OF SOFOSBUVIR TREATMENT REGIMENS IN REAL LIFE SETTINGS

E. Huchet[1], C. Galanakis[1], B. Trottier[1], M. Poliquin[1], S. Lavoie[1], D. Longpré[1], S. Vézina[1], C. Bédard[1], N. Machouf[1], R. Thomas[1]. *[1]Clinique médicale l'Actuel, Montréal, Canada*
E-mail: nima.machouf@lactuel.ca

Background and Aims: The efficacy and safety of Sofosbuvir (SOF) in HCV treatment has been demonstrated in several clinical trials. Nevertheless, few studies have examined its effectiveness in clinical settings. The aim of this study therefore was to evaluate the impact of SOF on treatment outcomes in real life settings.
Methods: We prospectively assessed all genotype 1 (a,b) HCV infected patients attending our clinic who were receiving SOF-based treatments. According with our mDOT model of care, during their treatment period patients were followed each week at the clinic and had a consultation with a nurse, physician and pharmacist; and they had lab tests. Patients enrolled in RCTs were excluded. The primary outcome was sustained virologic response (SVR) at 12 weeks post-treatment by intent-to-treat analysis. Comparisons among treatment groups were assessed by Chi square.
Results: 56 patients were included. They were mainly male (71%), treatment naïve (57%), their mean age was 54 y (IQR 49–58) at treatment initiation, 86% were infected by HCV genotype 1a and 14% by genotype 1b. More than half of patients (64%) were cirrhotic at baseline and 29% were co-infected with HIV. Patients were receiving 3 types of SOF-based regimens: Simeprevir (SIM) + SOF (61%); followed by SOF+PEGINF+Riba (30%); and SOF+Riba (9%). The majority of treatment regimens were 12 and 24 weeks long (91% and 7% respectively) with only 1 patient undergoing a 48 week treatment. 17 patients completed their treatment period and 12 weeks post treatment FU. 16/17 (94%) completed treatment and had undetectable viral loads at the end of treatment, and one died from decompensated liver cirrhosis. However, 12/17 (71% ITT analysis) achieved SVR 12 weeks post-treatment. The rate of SVR varied by regimen, treatment status at baseline and by presence of cirrhosis. SVR was 89% with SIM+SOF, 25% with SOF+Riba and 75% with SOF+Riba+PEGINF ($p = 0.07$). SVR was 100% (3/3) for relapsers; 78% (7/9) for naïve patients and 40% (2/5) for nulls responders ($p = 0.11$). 8/13 (62%) of patients with cirrhosis and 4/4 (100%) without cirrhosis had a SVR ($p = 0.21$). Patients on SIM+SOF were more likely to achieve SVR even after controlling for cirrhosis ($p = 0.08$). No patient had been lost to FU during the study period.
Conclusions: In real life settings, SOF offers a variable rate of SVR. The combination SIM+SOF was the most effective HCV treatment, including for patients with cirrhosis. An mDOT model of care, and close FU, could assure a good adherence to medication.

P0826

EFFECTIVENESS OF SIMEPREVIR (SMV)-CONTAINING REGIMENS AMONG PATIENTS WITH CHRONIC HEPATITIS C VIRUS (HCV) IN VARIOUS US PRACTICE SETTINGS: INTERIM ANALYSIS OF THE SONET STUDY

I. Alam[1], R. Manch[2], S. Naggie[3], R. Reindollar[4], J. Slim[5], A. Prabhakar[6], K. Lauwers[7], C. Donovan[6], N. Tandon[6], J. Forlenza[6], K. Brown[6]. *[1]Austin Hepatitis Center, Austin, TX, [2]St. Joseph's Hospital & Medical Center, Phoenix, AZ, [3]Durham VA Medical Center/Duke University School of Medicine, Durham, NC, [4]Piedmont Healthcare, Gastroenterology and Hepatology, Statesville, NC, [5]Saint Michael's Medical Center, Newark, NJ, [6]Janssen Scientific Affairs, Titusville, NJ, United States; [7]Janssen R&D, Beerse, Belgium*
E-mail: jforlenz@its.jnj.com

Background and Aims: SMV is an oral, once-daily, HCV NS3/4A protease inhibitor approved in various countries for the treatment of chronic HCV infection as part of combination antiviral therapy. Since efficacy and safety in real world practice may vary from clinical trials, SONET evaluates effectiveness of SMV-containing regimens.
Methods: This ongoing, observational, US-based study (N = 300) includes patients aged ≥18 years with chronic HCV G1 infection and a healthcare provider (HCP) decision to treat with SMV; patients with prior direct-acting antiviral use were excluded. Treatment decisions and clinical management were at HCP discretion. The primary endpoint was sustained virologic response (SVR12); secondary endpoints included patient characteristics, prognostic factors of virologic response, SVR4, virologic failure and safety. This planned interim analysis (IA) was conducted when ≥100 patients had Week 4 on-treatment HCV RNA results.

Table 1. IA outcomes

	SMV/SOF (n = 152)	SMV/SOF/RBV (n = 10)	SMV/PegIFN/RBV (n = 6)
HCV RNA outcomes			
RVR	57.7% (56/97)	55.6% (5/9)	100% (5/5)
EOT	100% (38/38)	100% (6/6)	–
SVR4	91.3% (21/23)	100% (1/1)	–
Viral breakthrough	0.7% (1/152)	0	0
Relapse	0.7% (1/152)	0	0
Treatment status			
Discontinuation of all HCV treatment	2.0% (3/152)	10.0% (1/10)	16.7% (1/6)

EOT, end of treatment; PegIFN/RBV, pegylated interferon plus ribavirin; RBV, ribavirin; RVR, rapid virologic response at week 4; SMV, simeprevir; SOF, sofosbuvir; SVR4, sustained virologic response 4 weeks after treatment end.
–, Data not available.

Results: This IA included 168 patients (intent-to-treat population) receiving care in academic centers (15.5%; n = 26), private practice (75.6%; n = 127), and/or integrated health networks (13.1%; n = 22). Median age=58.0 years; 58.9% (99/168) male; 58.9% (99/168) white; 36.3% (61/168) black/African-American; 13.7% (23/168) Hispanic/Latino. HCV G1a and G1b comprised 81.0% (119/147) and 19.0% (28/147) of the population, respectively. At baseline, 16.0% (26/163) of patients reported active alcohol use; 25.3% (42/166) reported a household income of <$10,000 USD. Approximately 29% (49/168) were treatment-experienced; 11.9% (20/168) were prior null-responders; 2.4% (4/168) were prior partial responders. Cirrhosis was reported in 41.0% (68/166) of patients; 13.8% (23/167) had documented varices, 7.2% (12/167) ascites, and 4.8% (8/167) hepatic encephalopathy. Overall, 90.5% (152/168) received SMV+sofosbuvir (SOF), 6.0% (10/168) received SMV+SOF+ribavirin (RBV) and 3.6% (6/168) received SMV+peginterferon (PegIFN)+RBV. At IA, 47 patients completed therapy and 8 patients discontinued ≥1 medication. Table 1 shows outcomes by treatment regimen. At IA, the most common (>5% patients) adverse events (AEs) were headache, nausea and rash; 4.2% (7/168) had serious AEs.
Conclusions: In this IA, SMV+SOF was the most common regimen; of the patients who had this regimen and evaluable SVR4 results, 91.3% achieved SVR4. SVR 12 rates, duration of therapy, outcomes by subgroups (e.g. cirrhotics), and additional safety information will be presented at the meeting.

P0827
A DESCRIPTIVE ANALYSIS OF A REAL-WORLD POPULATION WITH CHRONIC HEPATITIS C (CHC) TREATED WITH SIMEPREVIR (SMV)- AND/OR SOFOSBUVIR (SOF)-BASED REGIMENS: FINDINGS FROM A US PAYER DATABASE

J.B. Forlenza[1], J. Fortier[2], F. Laliberté[2], P. Lefebvre[2], N. Tandon[1].
[1]Janssen Scientific Affairs, LLC, Titusville, NJ, United States; [2]Groupe d'analyse, Ltée, Montréal, QC, Canada
E-mail: jforlenz@its.jnj.com

Background and Aims: Real-world evaluations of newer direct-acting antivirals (DAAs) in CHC patients are needed from large US payer perspectives.
Methods: Medical and pharmacy claims linked to lab data from the Humana Database were analyzed for Medicare Advantage or commercially-insured adults with ≥2 CHC claims (ICD-9 070.44; 070.54) who received therapy containing SMV and/or SOF through 6/2014; those with HIV were excluded. Patients were grouped based on most common regimens in the data: SMV/SOF, SMV/SOF/ribavirin (RBV), SOF/RBV, or SOF/interferon (IFN)/RBV; <3% received other regimens. At time of analysis, baseline (BL) demographics, selected comorbidities and clinical characteristics (e.g., claims-based cirrhosis or end stage liver disease [ESLD], FIB-4 scores) were described and post-treatment follow-up time measured. Methods to control for treatment selection bias were not performed, and comparative analyses were not conducted.

Table: Pre-treatment comorbidities and disease severity

	SMV/SOF (n = 184)	SMV/SOF/RBV (n = 37)	SOF/RBV (n = 269)	SOF/IFN/RBV (n = 225)
Select comorbidities:				
Substance abuse	20%	32%	25%	30%
Anemia	22%	22%	16%	12%
Psychiatric disease	21%	27%	25%	22%
Depression	21%	16%	25%	25%
Diabetes	28%	27%	25%	26%
COPD	14%	16%	19%	22%
Liver disease severity:				
Non-cirrhotic	25%	35%	55%	64%
Cirrhotic	27%	27%	17%	24%
ESLD	48%	38%	27%	12%

COPD, Chronic obstructive pulmonary disease.

Results: There were 715 CHC patients who received therapy with SMV/SOF (n = 184), SMV/SOF/RBV (n = 37), SOF/RBV (n = 269) or SOF/IFN/RBV (n = 225); mean age for cohorts was between 60–62 years; 58%, 68%, 62% and 70% were male; most (85%, 78%, 81% and 80%) had Medicare. BL cirrhosis and ESLD were evaluated as well as selected comorbidities such as substance abuse, anemia, psychiatric disease, depression, diabetes, and chronic obstructive pulmonary disease (Table). Slightly over half in each cohort had calculable FIB-4 scores, of which, 56%, 54%, 34% and 35%, respectively, had scores >3.25. Among those with genotype data, 100% (78/78) SMV/SOF, 94.7% (18/19) SMV/SOF/RBV, 24.4% (29/119) SOF/RBV and 95.8% (92/96) SOF/IFN/RBV were genotype 1. Using prior claims history, 10%, 19%, 12% and 17% of respective cohorts were treatment-experienced, of which 74%, 71%, 28% and 79% had protease inhibitor/IFN/RBV therapy. At time of analysis, less than half of each cohort had post-treatment data ≥1 week.
Conclusions: This analysis of CHC patients predominantly insured through Medicare found that the majority of those who received SMV/SOF±RBV had either cirrhosis or ESLD claims prior to therapy and, using lab data, over half had FIB-4 scores >3.25. These results along with findings on BL comorbidities and prior treatment history offer insight into the real-world characteristics of CHC patients treated with newer DAAs from a US payer perspective. Further analysis with additional follow-up data will provide insights into post-treatment outcomes.
This research was supported by Janssen Scientific Affairs, LLC

P0828
RELAPSERS TO NON-INTERFERON, SOVALDI BASED TREATMENT OF G1 CHRONIC HCV WERE INADEQUATELY TREATED

J.C. Hoefs[1], L.T. Tran[2], B.B. Babaknia[2]. *[1]Medicine, University of California Irvine, [2]Medicine, Liver Specialty Center, Irvine, United States*
E-mail: jchoefs@uci.edu

Background and Aims: Treatment duration can be an important factor in cure of HCV1 and recent studies have shown that longer treatment for 6 months is required for some patients when using Harvoni (Sovaldi + Ledepisvir) and this may also be true of Sovaldi (S) and Olysio (O). We have applied the treatment duration criteria for Harvoni to HCV1 patients treated with the combination of Sovaldi (S) and Olysio (O) in a single community practice since January 2014.
Methods: *Patients:* 35 G1 patients were started on treatment since January 2014. The SVR rate of the 35 patients reaching 4 Weeks (SVR4) and 24 patients at 12 weeks (SVR12) is reported. G1a was present in 19, G1b 14, and G1 2. The response to the last pegasys (P) based treatment (NR non-response, R relapse) with double therapy (P+R) (DT) and triple therapy (P+R+DAA) (TT) was assessed. IL28B CC and cirrhosis was assessed. Harvoni Criteria for treatment duration

was applied to this population: 2 months – naïve non-cirrhotic, RNA <6M IU/ml; 3 months – naïve cirrhosis or non-cirrhosis with >6M IU/ml; 6 months – cirrhosis, treatment experienced.
Results: The overall SVR4 was 91.4% and SVR12 83.3%. IL28B-CC was present in 14 patients (SVR4 100%), G1b in 14 patients (SVR4 100%), 14 naïve patients (SVR4 92.9%) and Q80K in 6/28 patients tested (SVR4 75%). 5 patients had cirrhosis with 1 of these having recurrent HCV with ascites after liver transplant (SVR 4 and 12 40%). The poster table shows the treatment duration recommended if Harvoni had been used compared to the actual 3 months treatment duration with S+O in all patients. Regardless of any other factor, those patients meeting criteria for 2–3 mo treatment duration had a 100% SVR4 and 94% SVR12. All relapse patients had combinations of cirrhosis (4/4), Q80K positive (2/4), and/or prior non-response to DT and TT (3/4).
Conclusions: Based on Harvoni treatment duration criteria, patients qualifying for 2–3 mo treatment had an SVR4 of 100% and SVR12 of 95% with S+O comparable to that expected with Harvoni. The 3/4 patients who relapsed would have qualified for 6 months of Harvoni treatment suggesting that most relapse patients were inadequately treated.

P0829

ON-TREATMENT HCV RNA AS A PREDICTOR OF SUSTAINED VIROLOGIC RESPONSE IN HCV GENOTYPE 3 INFECTED PATIENTS TREATED WITH DACLATASVIR AND SOFOSBUVIR: ANALYSIS OF PHASE 3 ALLY-3 STUDY

K. Kowdley[1], D. Nelson[2], J. Lalezari[3], T. Box[4], N. Gitlin[5], G. Poleynard[6], M. Rabinovitz[7], N. Ravendhran[8], A. Sheikh[9], A. Siddique[10], R. Bhore[11], P.D. Yin[12], S. Noviello[11], K. Rana[12].
[1]Swedish Medical Center, Seattle, [2]University of Florida, Gainesville, [3]Quest Clinical Research, San Francisco, [4]Clinical Research Centers of America LLC, Murray, [5]Atlanta Gastroenterology Associates, Atlanta, [6]Digestive Health Specialists, Winston-Salem, [7]University of Pittsburgh, Pittsburgh, [8]Digestive Disease Associates, Baltimore, [9]Gastrointestinal Specialists of Georgia, Marietta, [10]Virginia Mason, Seattle, [11]Research and Development, Bristol-Myers Squibb, Princeton, [12]Research and Development, Bristol-Myers Squibb, Wallingford, United States
E-mail: christiaan.wallett@articulatescience.com

Background and Aims: The use of response-guided therapy (RGT) with some peginterferon/ribavirin-based HCV regimens has improved outcomes for GT-1 treatment, but also complicates patient management. Here, we investigate the utility of RGT in HCV GT-3-infected patients by analysing data from the Phase 3 ALLY-3 Study, in which a 12-week combination of daclatasvir (DCV; NS5A inhibitor) and sofosbuvir (SOF; NS5B polymerase inhibitor) achieved SVR12 rates of 90% and 86% in HCV GT3-infected treatment-naive and -experienced patients, respectively.
Methods: This retrospective analysis included 152 HCV GT3-infected patients who were treatment-naive (N = 101, 66%) or -experienced (N = 51, 34%) and received open-label DCV 60 mg + SOF 400 mg QD for 12 weeks (ALLY-3). Serum HCV RNA levels were quantified using the COBAS Taqman v2.0 (LLOQ=25 IU/mL). Positive and negative predictive values (PPVs and NPVs, respectively) were calculated at Weeks 1, 2, 4, 6, and end of treatment (Week 12) based on HCV RNA
Results: Early decreases in HCV RNA were observed on-treatment, with 34%, 74%, and 95% of total patients having HCV RNA <LLOQ by treatment Week 1, 2, and 4 respectively. The early on-treatment response of <LLOQ at Week 4 in patients with cirrhosis was 91% (29/32). PPVs and NPVs are shown for the total population at Weeks 1, 2, and 4 (Table). As demonstrated by the high PPVs, there was strong concordance between those achieving undetectable HCV RNA at early timepoints and subsequent achievement of SVR12. More than 90% of patients with undetectable HCV RNA at Weeks 1, 2, and/or 4 achieved SVR12. In contrast, as demonstrated by the low NPVs, patients failing to achieve undetectable HCV RNA at early timepoints were still likely to achieve SVR12. Similar results were observed when patients were analysed based on treatment-naive or -experienced status.
Conclusions: Achieving early virologic milestones was associated with a high probability of achieving SVR12 whereas failure to achieve early virologic milestones did not appear to impact outcome. These data do not support the use of early futility rules such as achievement of rapid virologic response to inform on-treatment decisions in HCV GT3-infected patients receiving DCV+SOF.

Table: PPV and NPV data for the total population (N = 152)

	SVR12, n/N (%)

EARLY HCV KINETICS DURING DUAL ORAL THERAPY WITH DACLATASVIR AND ASUNAPREVIR

M. Nakamuta[1], M. Kohjima[1], K. Motomura[1], S. Tabata[1], T. Koyanagi[1], N. Yamashita[1], T. Sato[1], M. Yokota[1], N. Higuchi[1], T. Yoshimoto[1], T. Kurashige[1], M. Kawamoto[1], K. Fukuizumi[1], K. Kotoh[1], Fukuoka Kanzo Treatment study (FKT) group. *[1]Fukuoka Kanzo Treatment study (FKT) group, Fukuoka, Japan*
E-mail: kohjima@kyumed.jp

Background and Aims: The dual oral therapy with the first-in-class NS5A replication complex inhibitor Daclatasvir (DCV) and the potent NS3 protease inhibitor Asunaprevir (ASV) has recently approved for the treatment of chronic hepatitis C genotype 1 patients. Previous trials for the treatment was shown promising results for improving SVR to more than 80% in patients with HCV genotype 1b. We conducted a prospective, multicenter study to investigate the effectiveness and safety of the dual oral therapy with DVC and ASV and evaluate the early HCV kinetics during the treatment.
Methods: The patients with HCV genotype 1b have been treated with DCV and ASV since Sep. 2014 (n = 206). The enrolled population was generally older (median 69 years old) that was consistent with HCV epidemiology in Japan and predominantly female (63%). HCV genotype and IL-28B polymorphisms were determined by PCR amplification and sequencing. HCV resistant associated polymorphisms were analyzed by direct sequence of the HCV NS3 and NS5A domains.
Results: HCV-RNA declined rapidly after the initiation of the DCV + ASV treatment, and the reduction of HCV-RNA was comparable with the peg-IFN + RBV + Telaprevir or Simeprevir treatment. HCV-RNA was lower than detection sensitivity limit in 71% of the patients after 2 weeks and 78% of patients achieved RVR. The viral response of HCV was not affected by age, sex, liver fibrosis, previous treatment response, or IL-28B SNPs. Most of the patients enrolled for the study had no resistance-associated

polymorphism in NS3 or NS5A, while two patients with the polymorphism experienced viral breakthrough. Except for the two patients, patients with NS5A Y93H/N or L31M showed similar viral response until 4 weeks of the therapy. The frequently reported adverse events were mild headache, fever, or elevations of ALT, g-GTP or ALP and one patient stopped the therapy because of the onset of brain infarction. There were no further serious adverse events during early course of the treatment.

Conclusions: The response of HCV-RNA was favorable enough during the DCV + ASV therapy, even for women, aged patients, patients with liver cirrhosis or patients with intractable IL-28B polymorphism. However, resistance-associated polymorphism of HCV could affect treatment response, and further examination for absolute quantity of the resistance-associated polymorphism is desired to evaluate the effectiveness for the DCV + ASV treatment.

P0831

SAFETY AND EFFICACY OF SOFOSBUVIR-BASED TREATMENT REGIMENS FOR CHRONIC HEPATITIS C VIRUS INFECTION: A "REAL-LIFE", SINGLE-CENTER EXPERIENCE IN 117 PATIENTS

M.H. Wehmeyer[1], C. Eißing[1], S. Jordan[1], A.W. Lohse[1], J. Schulze zur Wiesch[1], S. Lüth[1]. *[1]I. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*
E-mail: m.wehmeyer@uke.de

Background and Aims: In clinical phase III trials sofosbuvir (SOF)-based treatment regimens in chronic HCV infections achieve high rates of sustained virological response (SVR). The safety profile of SOF seems to be favourable. There are only limited "real-life" data on safety and efficacy of SOF-based therapy in unselected patients outside clinical trials.

Methods: Every patient who started SOF-based therapy [with or without peginterferon (IFN), ribavirin (RBV), simeprevir (SIM) and/or daclatasvir (DAC)] between 01/2014 and 10/2014 was included in the study. Demographical, clinical, laboratory and virological data were collected throughout the entire treatment period. Severe adverse events (SAE) were defined as any grade 3 or 4 laboratory events or any condition leading to prolonged invalidity, hospitalization or death. Potential predictors for SAE and SVR12 were analysed by Fisher's exact test, t-test or rank sum test.

Results: We included 117 patients in our study, of which 60 were infected with genotype (GT) 1 (51.3%), 11 with GT2 (9.4%), 24 with GT3 (20.5%), 20 with GT4 (17.1%), and each 1 with GT5 or GT6 (0.9%, each). In total, 62 patients received IFN/RBV/SOF (53.0%), 18 patients SOF/RBV (15.4%), 12 patients SOF/SIM (10.3%) and 25 patients SOF/DAC±RBV (21.4%). Cirrhosis was diagnosed in 65 patients (55.6%; 25 cirrhotic patients were treated with IFN/RBV/SOF, 8 with SOF/RBV, 12 with SOF/SIM and 20 with SOF/DAC±RBV). 20 SAE occurred in 15 patients (12.8%). No fatal outcome was reported. Use of IFN was no risk factor for SAE (P = 0.219). Age (P = 0.049), MELD score (P = 0.001), cirrhosis (29.3% vs. 6.8%; P = 0.009), baseline thrombocytopenia <100 billion/l (46.7% vs. 11.4%; P = 0.004) and low baseline serum albumin <35 g/l (36.8% vs. 12.1%; P = 0.035) were identified as risk factors for SAE. Non-GT1 infected patients receiving IFN/RBV/SOF achieved SVR12 more often than GT1 patients with IFN/RBV/SOF [20/22 (90.9%) vs. 15/24 (62.5%); P = 0.038]. On-treatment safety data of the entire cohort and SVR12 data of all patients treated with IFN/RBV/SOF, SOF/RBV or SOF/SIM will be available in April 2015.

Conclusions: SOF-based treatment regimens are generally safe and well tolerated. Risk for SAE is not necessarily higher in patients treated with IFN/RBV/SOF compared to patients (with generally more advanced cirrhosis) receiving IFN-free therapy. According to our "real-life" data, IFN/RBV/SOF will remain a reasonable treatment option for patients infected with HCV GT3 or GT4.

SIMEPREVIR- AND TELAPREVIR-BASED TRIPLE THERAPIES FOR GENOTYPE 1B CHRONIC HEPATITIS C PATIENTS AGED 70 AND OVER IN A MULTICENTRE COHORT STUDY

N. Furusyo[1], E. Ogawa[1], E. Kajiwara[2], H. Nomura[3], A. Kawano[4], K. Takahashi[5], K. Dohmen[6], T. Satoh[7], K. Azuma[8], M. Nakamuta[9], T. Koyanagi[10], K. Kotoh[11], S. Shimoda[12], J. Hayashi[13], The Kyushu University Liver Disease Study (KULDS) Group. *[1]Department of General Internal Medicine, Kyushu University Hospital, Fukuoka, [2]Department of Hepatology, Steel Memorial Yawata Hospital, [3]The Center for Liver Disease, Shin-Kokura Hospital, [4]Department of Medicine, Kitakyushu Municipal Medical Center, Kitakyushu, [5]Department of Medicine, Hamanomachi Hospital, [6]Department of Internal Medicine, Chihaya Hospital, Fukuoka, [7]Center for Liver Disease, National Hospital Organization Kokura Medical Center, Kitakyushu, [8]Department of Medicine, Kyushu Central Hospital, [9]Department of Gastroenterology, Kyushu Medical Center, National Hospital Organization, [10]Department of Medicine, Fukuoka City Hospital, [11]Department of Medicine and Bioregulatory Science, [12]Department of Medicine and Biosystemic Science, Graduate School of Medical Sciences, Kyushu University, [13]Kyushu General Internal Medicine Center, Haradoi Hospital, Fukuoka, Japan*
E-mail: furusyo@gim.med.kyushu-u.ac.jp

Background and Aims: Increasing age has been associated with developing advanced liver fibrosis and hepatocellular carcinoma for chronic hepatitis C. The aim of this study was to evaluate the efficacy analysis in patients aged ≥70 treated with simeprevir and telaprevir-based triple therapies in a prospective, multicenter cohort study.

Methods: This prospective, multicenter study has enrolled 885 genotype 1b patients with chronic hepatitis C who received 12-week triple therapy that included simeprevir (n = 345) or telaprevir (n = 540) combined with pegylated interferon α2b (PEG-IFNα2b) and ribavirin (RBV) followed by a 12-week dual therapy that included PEG-IFNα2b and RBV. A total of 144 patients aged ≥70 were analyzed, 74 and 70 receiving simeprevir and telaprevir-based therapies, respectively. Serum HCV RNA level was measured by COBAS TaqMan HCV test. The undetectable HCV RNA at week 4 (RVR) and sustained virological response at 12 weeks after therapy (SVR_{12W}) was done based on intention-treat-analysis.

Results: The overall rates of RVR and SVR_{12W} were 76.4% and 77.8%, respectively. Of the patients with RVR, 83.6% achieved an SVR_{12W}. While significant differences in RVR rates were found between simeprevir- and telaprevir-based triple therapies (83.8% vs. 68.6%, P = 0.031), SVR rates did not differ between the two therapies (79.7% vs. 75.7%, P = 0.562). The overall treatment discontinuation was 17.4%, but no significant differences were found between the two therapies (14.9% vs. 20%, P = 0.416). The SVR_{12W} rate for interleukin 28B (IL28B) (rs8099917) TT (86.7%) was significantly higher than for IL28B TG/GG (36.9%) (P < 0.001). The rate for no or mild advanced fibrosis (F0–2) (87.3%) was significantly higher than for advanced fibrosis (F3–4) (48.1%) (P < 0.001). The rate for no treatment discontinuation (84.9%) was significantly higher than for treatment discontinuation (44.0%) (P < 0.001). Multivariate analysis extracted IL28B TT (Odds ratio 7.3, P = 0.015), no or mild advanced fibrosis (Odds ratio 12.7. P = 0.003), and no treatment discontinuation (Odds ratio 21.4, P = 0.004) as independent factors associated with SVR_{12W}, but did not RVR. No episode of death or hepatic decompensation was observed.

Conclusions: Simeprevir- and telaprevir-based triple therapies can be used successfully and safely to treat elderly patients with genotype 1b chronic hepatitis C. Treatment discontinuation indicates low effectiveness in these elderly patients.

P0834

SIGNIFICANT DRUG–DRUG INTERACTION BETWEEN SIMEPREVIR AND CYCLOSPORINE A BUT NOT TACROLIMUS IN PATIENTS WITH RECURRENT CHRONIC HCV INFECTION AFTER ORTHOTOPIC LIVER TRANSPLANTATION: THE SATURN STUDY

S. Ouwerkerk-Mahadevan[1], I. Vanwelkenhuysen[1], M. Peeters[2], M. Simonts[2], I. Ilsbroux[2], A. Simion[2], J. Witek[3]. *[1]Janssen Research & Development, LLC, [2]Janssen Infectious Diseases BVBA, Beerse, Belgium; [3]Janssen Research and Development, LLC, Titusville, NJ, United States*
E-mail: SOUWERKE@its.jnj.com

Background and Aims: SATURN (TMC435HPC3016) is an ongoing Phase II open-label study investigating the combination of simeprevir (SMV), daclatasvir (DCV) and ribavirin (RBV) in patients with recurrent chronic hepatitis C virus (HCV) genotype (GT)1b infection after orthotopic liver transplantation. Data from a planned interim 4-week pharmacokinetic (PK)/safety analysis are reported.
Methods: Patients with recurrent chronic HCV GT1b infection (METAVIR score F1–F2) received SMV (150 mg once-daily [QD]), DCV (60 mg QD), and RBV (1–1.2 g/day) and concomitant stable immunosuppressive therapy with cyclosporine A (CsA) or tacrolimus (TAC). Serial PK SMV sampling followed by noncompartmental analysis occurred on day (D)14. PK data were compared with historic noncompartmental Phase II data and Phase III population PK data. Final data from 35 patients, including those with METAVIR score F3–F4, will be available at the time of presentation.
Results: Twenty patients were included in this analysis: CsA, n = 9 (METAVIR F1 n = 4, F2 n = 5); TAC, n = 11 (METAVIR F1 n = 6, F2 n = 5). PK data for SMV on D14 and comparisons with Phase II studies are presented in the Table. When coadministered with CsA, SMV exposure was highly variable and the least squares mean (LSM) ratio was 4.74 for C_{max} and 5.81 for area under the curve (AUC) compared with historic data (SMV without CsA). Although there were no significant safety findings, the SMV dose was reduced to 150 mg every other day in 7/9 patients with high SMV exposures receiving concomitant CsA based on individual patient SMV exposures. On D14 post-dose adjustment, plasma exposures of SMV in those patients were within the range of exposures observed in Phase III studies. When SMV was coadministered with TAC, LSM ratios for C_{max} and AUC were 79% and 85% higher, respectively, than historic data (SMV without TAC) and no SMV dose adjustment was required. Coadministration with SMV did not affect CsA and TAC PK. Grade 3 adverse events (AEs) occurred in 2 patients receiving CsA (hyperbilirubinemia, n = 1; anaemia, n = 1) and 1 patient receiving TAC (pneumonia, hyperbilirubinemia, anaemia). No grade 4 AEs occurred.
Conclusions: In patients with recurrent chronic HCV infection after orthotopic liver transplantation, concomitant use of SMV with CsA resulted in significantly increased plasma SMV concentrations. TAC did not result in a clinically significant increase of SMV exposure. No new safety signals for SMV were identified.

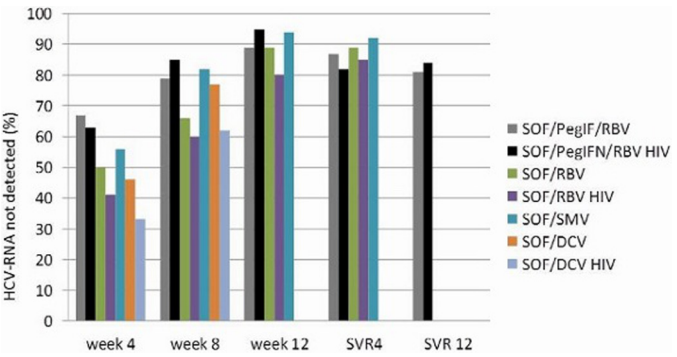
GERMAN MULTICENTER COHORT ON SOFOSBUVIR-BASED TREATMENTS IN HCV MONO- AND HIV/HCV CO-INFECTED PATIENTS (GECOSO)

P. Ingiliz[1], S. Christensen[2], D. Hueppe[3], T. Lutz[4], K. Schewe[5], C. Boesecke[6], K.G. Simon[7], G. Schmutz[8], A. Baumgarten[1], H. Busch[2], S. Mauss[8]. *[1]MIB, Berlin, [2]CIM, Muenster, [3]Practice for Gastroenterology, Herne, [4]Infektiologikum, Frankfurt, [5]ICH, Hamburg, [6]Medical Department 1, University Hospital Bonn, Bonn, [7]Practice for Gastroenterology, Leverkusen, [8]Center for HIV and Hepatogastroenterology, Duesseldorf, Germany*
E-mail: stefan.mauss@center-duesseldorf.de

Background and Aims: Sofosbuvir (SOF) and later on simeprevir (SMV) and daclatasvir (DCV) were approved in Europe in 2014 with limited study data. In particular HIV/HCV co-infection and pre-treated patients were not systematically studied. Here, we present real-life data on sofosbuvir-based HCV treatment from Germany.
Methods: In this ongoing multicenter cohort, all patients receiving the following treatment regimens were documented: SOF/ribavirin (RBV), SOF/DCV, SOF/SMV, and SOF/pegylated Interferon (PegIFN)/RBV. For the current analysis due to the limited observational period SVR12 data are pending for all regimens with the exception of SOF/PegIFN/RBV. In April 2015 SVR 12 results for all regimens will be available.
Results: Overall, 395 patients have been enrolled so far. Of those, 288 were HCV-mono-infected and 107 HIV/HCV-co-infected. The HCV genotype (GT) pattern was: GT1 n = 254 (64%), GT2 n = 24 (6%), GT3 n = 85 (21%), GT4 n = 29 (7%). Liver cirrhosis was present in 152/395 (38%) patients. 202/395 (50%) patients were pre-treated with interferon based therapy. Patients were treated as follows (HCV mono-infection/HIV/HCV co-infection): SOF/PegIFN/RBV n = 117/n = 52, SOF/RBV n = 55/n = 19, SOF/DCV n = 87/n = 31, SOF/SMV n = 28/n = 5. The on treatment viral response did not differ substantially between HIV/HCV co-infection and HCV-mono-infection (figure 1). However the preliminary analysis of the data indicates a difference in the on treatment viral kinetics depending on the regimen (figure 1). SOF/PegIFN/RBV showed an SVR12 of 84% in HCV mono-infection compared to 81% in HIV/HCV co-infection. So far <5% of patients discontinued therapy prematurely or were lost to follow up.



Conclusions: In this preliminary analysis, HIV/HCV co-infected and HCVmono-infected patients treated with SOF based therapies showed similar on treatment viral kinetics with different SOF based regimens. For SOF/PegIFN/RBV the SVR12 rate showed no difference between HIV/HCV-coinfected and HCV-monoinfected individuals. However SVR12 seems to be lower in GECOSO than in the NEUTRINO study despite a low discontinuation rate. The lower SVR rate may be attributable to the cohort population containing more difficult-to-treat patients as reported from the HCV-TARGET cohort.

P0836

TREATMENT RESPONSE RATES IN A REAL LIFE COHORT OF PATIENTS WITH ADVANCED LIVER DISEASE AND ORGAN TRANSPLANTATION

S. Hametner[1], R. Schöfl[1], A. Ziachehabi[1], A. Maieron[1].
[1]*Gastroenterology and Hepatology, Elisabethinen Hospital, Linz, Austria*
E-mail: andreas.maieron@elisabethinen.or.at

Background and Aims: Interferon free treatments (i-free) containing regimes of Simeprevir (SIM), Sofosbuvir (SOF) and Daclatasvir (DCV) +/− Ribavirin are reimbursed in patients with advanced liver disease (F3–F4) and in post transplantation setting due to Hepatitis C in Austria. Although real life data are emerging from the US, real life data for Europe are still lacking. Therefore we analysed our HCV cohort treated with i-free therapy.
Methods: 94 patients applied to treatment, 9 cases approval refused, 8 waiting for approval, 1 died, 17 approval passed and waiting for start of therapy and 59 started so far. Viral load was measured using COBAS TaqMan HCV quantitative assay, Version 2 (LLOQ: 15 IU/ml) at weeks 1, 2, 3, 4, 8, 12 (24) and follow up 4 and 12. All patients are treated for 12 weeks n = 38 (64.4%) or 24 weeks n = 19 (32.2%) with a combination of SOV+SIM n = 37 (62.7%), SOV+DCV n = 13 (22%), SOV+RBV n = 6 (10.2%) or SOV n = 3 (5.1%).
Results: 59 patients, 42 (71.2%) male, 17 (28.8%) female, median age 57 (IQR: 53–63 years). Distribution of genotype: 1a n = 16 (27.1%), 1b n = 34 (57.7%), 2 n = 1 (1.7%), 3 n = 6 (10.2%) and 4 n = 2 (3.4%). 43 patients have cirrhosis (73%). 35 (81.4%) are compensated, 8 (18.6%) are decompensated. CPS A n = 32 (74.4%), CPS B n = 7 (16.3%), CPS C n = 2 (4.6%). 14 patients (23.7%) are treatment naive, 27 (45.8%) are PegINF based therapy failures and 18 (30.5%) are PI failures. 6 patients (10.2%) are IL28B polymorphism CC, 38 patients (64.4%) are non-CC, 25.8% missing.
HCV PCR results are shown in Table 1.
In our cohort on treatment response at week 4 is not different in patients with a platelet count $<100\times10^9$ or $>100\times10^9$ (p = 0.2). There is also no difference between patients with or without cirrhosis (p = 0.092), IL28B polymorphism CC vs. Non-CC (p = 0.36), compensated and decompensated patients (p = 0.58) and type of prior therapy PegINF based therapy failures vs. PI failures (p = 0.52).
24 out of 59 patients finished therapy, all of them reached an EOT SVR.
10 patients who underwent therapy had prior organ transplantation: OLTX n = 7, NTX n = 2, OLTX+TX n = 1. 7 patients reached EOT SVR, 3 patients are still under therapy, one of them is already HCV PCR negative.
No severe adverse events occurred under therapy. 6 patients (10.1%) got a mild sunburn during outdoor activity.
Conclusions: EOT SVR rates and FUP SVR rates are outstanding independent of patients' baseline characteristics and severity of disease. At EASL we will be able to present data of approximately 120 patients under i-free therapy.

Time of therapy	n	Pos. HCV-PCR	Neg. HCV-PCR
Week 1	48	47	1
Week 2	46	38	8
Week 3	45	30	15
Week 4	44	14	30
Week 8	39	2	37
Week 12	32	0	32
Week 24	6	0	6
Follow up, 4	6	0	6

E-mail: jean-charles.duclos-vallee@pbr.aphp.fr

Background and Aims: The aim of this study was to assess efficacy and safety of sofosbuvir (SOF) and daclatasvir (DCV) in HIV/HCV coinfected with advanced fibrosis.
Methods: Nineteen patients (3 naive and 16 experienced) with advanced fibrosis received SOF and DCV with or without ribavirin (RVB) (12 and 7 patients respectively) for 24 weeks.
Results: All patients had F4 fibrosis (Fibroscan >12.5 kPa or histological evidence) except one who had F3 fibrosis. Eight (42%) patients had signs of portal hypertension (oesophageal varices and/or ascites). Three patients were listed for liver transplantation. At week 0, the average ALT, bilirubin, platelet count, HCV viral load, fibrosis, MELD score and CD4 count were respectively: 82 IU/L [14–229], 38 μmol/L, 96,000 cells/μL, 5.9 log IU/mL [2.3–7.1], 32 kPa [12–68], 10 [6–15] and 575 cells/mm^3 [204–1618]. Hepatitis C genotype was G1, G3 and G4 in 9, 4 and 6 patients respectively. HIV viral load was lower than 20 cp/mL in all patients. To avoid drug–drug interaction with DCV, cART was changed in 3 (16%) patients or DCV doses adjusted in 6 patients when required. Concerning tolerance, 5 (42%) patients treated with ribavirin developed anaemia, requiring RBV reduction (n = 5) and erythropoietin (n = 2). Four (21%) patients developed infection (urinary tract infection n = 1, herpes n = 1, bronchitis n = 1 and severe pneumonia n = 1). At week 4, HCV viral load was lower than 15 IU/mL in 14 (74%) patients, and it was lower than 15 IU/mL in all patients (100%) at week 8 and week 12. To date, 11 (59%) patients have stopped treatment and all of them have an undetectable HCV viral load (lower than 15 IU/mL). Two listed patients discontinued anti-HCV therapy at week 7 and week 20 and maintained sustained virological response 12 weeks after liver transplantation. Complete results of safety and efficacy with sustained virological response at week 4 and week 12 will be presented.
Conclusions: The association of sofosbuvir and daclatasvir is very effective and safe in HIV/HCV coinfected patients with advanced fibrosis.

P0838

PROGRESSION TO ADVANCED LIVER FIBROSIS IN HIV/HCV-COINFECTED PATIENTS AND PRIORITIZATION OF NEW HEPATITIS C THERAPIES

P. Labarga[1], P. Barreiro[2], C. de Mendoza[3], V. Soriano[2,2]. [1]*Internal Medicine, La Luz Clinic,* [2]*Infectious Diseases, La Paz University Hospital, Madrid,* [3]*Internal Medicine, Puerta de Hierro Research Institute, Majadahonda, Spain*
E-mail: vsoriano@dragonet.es

Background and Aims: Because of their high cost, the use of direct-acting antivirals (DAA) is being restricted by many governments to chronic HCV-infected individuals with advanced liver fibrosis. However, response rates are lower and toxicities more frequent in this subset of patients.
Methods: All HCV/HIV-coinfected patients followed for at least 3 years at one reference clinic were identified. Liver fibrosis progression (LFP) was defined as a shift from Metavir F0–F2 to F3–F4 estimates (>9.5 kPa) using elastometry.

Results: A total of 527 HIV/HCV-coinfected patients were identified, of whom 344 had F0–F2 at baseline. Peginterferon-ribavirin therapy was given to 205 patients with null-mild fibrosis, of whom 92 (44.9%) achieved sustained virological response (SVR). After a mean follow-up of 53 months, LFP occurred in 5.4% SVR, 25.7% non-SVR and 18% untreated patients (p = 0.005). In multivariate analysis, only achievement of SVR prevented LFP (adjusted hazard ratio 2.1; 95% confidence interval 1.1–4.1; p = 0.01).
In 139 untreated patients, only greater baseline elastometry values predicted LFP in multivariate analysis (adjusted hazard ratio 1.84; 95% CI: 1.03–3.3; p = 0.03). The area under the receiver operating characteristic (AUROC) curve was 79%. A discriminant threshold of 7.1 kPa gave 68% sensitivity and 82% specificity.
Conclusions: In the absence of successful treatment, more than 20% of HIV/HCV-coinfected patients with null-mild liver fibrosis progress to advanced fibrosis within 5 years. Patients with >7.1 kPa (Metavir F2) display the highest risk. Therefore, all coinfected patients with any significant liver fibrosis should be considered as candidates for new DAA-based therapies.

EVALUATION OF DRUG–DRUG INTERACTIONS BETWEEN THE FIXED-DOSE COMBINATION OF DACLATASVIR/ASUNAPREVIR/BECLABUVIR AND METHADONE OR BUPRENORPHINE/NALOXONE

X. Tao[1], K. Sims[1], M. Hesney[1], S. Lubin[1], M. Stonier[1], M. Wind-Rotolo[1], L. Reynolds[2], D. Liang[2], J. Pursley[1], M. AbuTarif[1].
[1]Bristol-Myers Squibb Research and Development, Princeton, [2]ICON Development Solutions, Hannover, United States
E-mail: neslihan.oz@articulatescience.com

Background and Aims: Daclatasvir (DCV; NS5A inhibitor), asunaprevir (ASV; NS3 inhibitor) and beclabuvir (BCV [BMS-791325]; nonnucleoside NS5B inhibitor) are in phase 3 evaluation for hepatitis C virus (HCV) infection as a twice-daily (BID) fixed-dose combination (DCV/ASV/BCV, 30/200/75 mg). HCV is common among injection drug users, and often medically managed with the opioids methadone (MET), or buprenorphine (BUP) + naloxone (NAL) The effect of DCV/ASV/BCV on the pharmacokinetics (PK) of MET or BUP/NAL was assessed.
Methods: An open-label study of the effect of steady-state DCV/ASV/BCV BID on the PK of MET (Part 1; N = 16) or BUP/NAL (Part 2; N = 16) was conducted in HCV-uninfected subjects on stable opioid maintenance. Subjects received daily oral MET (40–120 mg) or BUP/NAL (8/2–24/6 mg), plus DCV/ASV/BCV BID on Days 2–12 plus additional BCV (75 mg BID) to adjust for higher systemic BCV exposure in HCV patients. Serial PK sampling was on Days 1 (opioid alone) and 12. Dose-normalized PK parameters for *R*-, *S*-, and total-MET, BUP and its metabolite norBUP were derived. Geometric mean ratios (GMR; Day12:Day 1) and 90% confidence intervals (90%CI) for C_{max} and AUC_{tau} of each analyte were derived from linear mixed-effect models. No clinically relevant interaction was to be inferred if C_{max} and AUC_{tau} 90%CI were within literature-derived boundaries (R-MET: 0.7–1.43; BUP/norBUP: 0.5–2.0). Safety and opioid pharmacodynamics (PD, withdrawal scales and overdose assessment) were assessed.
Results: Opioid PK parameters are shown. Steady-state DCV/ASV/BCV (+ BCV) BID resulted in a ~30% reduction in dose-normalized R-, S- and total-MET systemic exposures with 90%CI outside prespecified boundaries. However, no loss of MET maintenance efficacy was observed by investigator or PD assessment throughout dosing. No relevant effects were observed on BUP or norBUP PK. All-cause adverse events (AEs, mild/moderate) occurred in: Part 1, 10 subjects (63%); Part 2, 6 subjects (38%). There were no deaths, serious AEs, withdrawal/overdose AEs or discontinuations for AEs. All AEs resolved without sequelae.
Conclusions: Steady-state DCV/ASV/BCV (+ BCV 75 mg) BID was generally well tolerated and had no clinically meaningful effect on the PK of BUP/NAL. A reduction in MET systemic exposure was observed but was not associated with loss of clinical maintenance. No a priori dose adjustments appear warranted when DCV/ASV/BCV is administered to HCV patients on MET or BUP/NAL maintenance.

		Adj. Geo. Mean		GMR (90% CI)

E-mail: salqaht1@jhmi.edu

Background and Aims: HCV genotype (GT) 3 and 4 are common in many regions of the world and optimal treatment regimens continue to evolve. The real-world safety and efficacy of available antiviral options in clinical practice has not been reported. The aim of this study is to evaluate the safety and efficacy of sofosbuvir (SOF) containing regimens for the treatment of patients with GT 3 and 4 in HCV-TARGET (HCVT), a multicentre, prospective, observational cohort study.
Methods: Patients who initiated HCV treatment in clinical practice were enrolled and treated according to the regional standards of care at academic (n = 43) and community medical centres (n = 13) in North America (n = 51) and in Europe (n = 5). Information was collected from the medical records and abstracted into a unique centralized data core. Independent data monitors systematically review data entries for completeness and accuracy. Demographic, clinical, adverse events (AEs) and virological data were collected throughout treatment and post-treatment follow-up
Results: Of 202 patients with GT 3 and 47 with GT4, 110 (54%) and 31 (66%) have completed treatment, respectively. Demographic and treatment regimens are shown in the Table. The majority of patients with GT 3 (91%) were treated with SOF/ribavirin (RBV) whereas patients with GT 4 received peginterferon (PEG) plus SOF/RBV (49%), SOF/RBV (25%) or Simeprevir (SMV)/SOF±RBV (26%). 132 (106 GT 3 and 26 GT 4) patients experienced at least one AE, although most were mild. Among patients with GT 3, five discontinued due to AEs (anemia, flu-like symptoms, nausea, vision loss and intolerance) and 4 for lack of efficacy; 1 was lost to follow-up and 1 underwent liver transplant. One patient with GT 4 stopped due to worsening encephalopathy. As of most recent follow-up, 144/162 GT3 and 34/37 GT 4 had HCV RNA below level of quantitation. Among patients for whom post-treatment data is

Table (abstract P0840): Demographics of all HCV genotype 3 and 4 infection patients who started treatment

Variable	HCV genotype 3			HCV genotype 4				
Treatment regimen	SOF/PEG/RBV	SOF/RBV	Total	SOF/PEG/RBV	SOF/RBV	SOF/SMV	SOF/SMV/RBV	Total
Subjects	18	184	202	23	12	6	6	47
Male, n (%)	12 (67)	114 (62)	126 (62)	18 (78)	11 (92)	4 (67)	4 (67)	37 (79)

White race, n (%)	14 (78)	147 (80)	161 (80)	10 (44)	6 (50)	2 (33)	3 (50)	21 (45)
Treatment-experienced, n (%)	10 (56)	92 (50)	102 (50)	16 (70)	9 (75)	3 (50)	5 (83)	33 (70)
Cirrhosis, n (%)	9 (50)	94 (51)	103 (51)	7 (30)	6 (50)	3 (50)	2 (33)	18 (38)
Post-Liver transplant, n (%)	1 (6)	18 (10)	19 (9)	0 (0.0)	1 (8)	0 (0.0)	(0.0)	1 (2)

currently available, 22/38 (58%) and 5/5 (100%) of GT3 patients treated with SOF/RBV and SOF/RBV/PEG, respectively, achieved SVR4 and 14/16 (88%) and 4/4 (100%) of GT4 patients treated with SOF/PEG/RBV and SOF/SIMSMV±RBV, respectively, achieved SVR4. Complete efficacy data will be presented

Conclusions: Preliminary safety and efficacy data from HCVT for patients with HCV genotype 3 and 4 infections suggests that sofosbuvir-containing treatment regimens are generally safe and well tolerated across a broad spectrum of patients and clinical practices.

P0841
SUCCESSFUL COMMUNITY BASED TREATMENT OF HEPATITIS C IN PEOPLE WHO INJECT DRUGS

A.J. Wade[1,2,3], D. Macdonald[4], J.S. Doyle[1,2,4], A.J. Thompson[5], S.K. Roberts[6,7], M.E. Hellard[1,2,4]. *[1]Centre for Population Health, Burnet Institute, [2]School of Public Health and Preventive Medicine, Monash University, Melbourne, [3]Infectious Diseases Department, Barwon Health, Geelong, [4]Department of Infectious Diseases, The Alfred, [5]Department of Gastroenterology, St Vincents Hospital, [6]Department of Gastroenterology, The Alfred, [7]Department of Medicine, Monash University, Melbourne, Australia*
E-mail: amanda.wade@me.com

Background and Aims: Hepatitis C virus (HCV) treatment uptake is <2% in Australia. A new nurse led service was developed linking The Alfred Hospital to community clinics. The service aimed to increase access to care, targeting current and past people who inject drugs (PWID). A hepatology nurse and specialist physicians attended 3 primary care clinics; all offered opiate substitution therapy (OST). Assessment and management was nurse led. We aim to describe the success of this service engaging and treating PWID.

Methods: A retrospective audit of the service was undertaken. All patients referred to the nurse from service inception in 2010 until 1/8/14 were determined by accessing clinic appointment scheduling. Data collected included; patient demographics, drug, alcohol and psychiatric history, results, treatment uptake and outcome and retention in care.

Results: 462 patients were referred to the community hepatitis nurse service – 344 attended. 279 patients had chronic HCV infection, of these; 184 (66%) were male, 208 (75%) had a psychiatric diagnosis, 145 (52%) were on psychotropic medication, 257 (92%) were current or past PWID, 147 (53%) were on OST, and 99 (35%) reported current injecting drug use (IDU). 203 (73%) had a fibroscan. 15 (5%) patients had significant fibrosis (fibroscan score >9.0 kPa, or clinical evidence such as oesophageal varices).

Fifty-five patients (20%) commenced HCV treatment; 47 had pegylated interferon (PEG) based regimens and 8 were enrolled in PEG-free directly acting antiviral (DAA) trials. Of the 55 patients who commenced treatment, 18 (33%) reported current IDU, 32 (58%) were on OST and 35 (64%) were on psychotropic medication. 14 patients are still undergoing treatment or are <3 months post treatment. Of the remaining 41 patients, 28 completed treatment, 6 ceased due to side effects, 6 fulfilled treatment futility criteria and 1 was lost to follow up. Of the 28 patients who completed therapy, 23 (56%) had a sustained virologic response (SVR). Factors associated with treatment uptake included OST and being on psychotropic medication. Of the 256 patients with chronic HCV who have not had an SVR, 95 (37%) remain engaged in care.

Conclusions: This community based program successfully provided care and interferon based treatment to a significant number of PWID, with an SVR rate comparable to patients treated in tertiary institutions. With the advent of DAAs it highlights the benefits of community based HCV services in managing PWID, a group with a high prevalence of HCV infection.

P0842
MALACHITE-I: PHASE 3B TRIAL OF OMBITASVIR/PARITAPREVIR/R AND DASABUVIR +/− RIBAVIRIN OR TELAPREVIR + PEGINTERFERON/RIBAVIRIN IN TREATMENT-NAÏVE ADULTS WITH HCV GENOTYPE 1

B. Conway[1], E. Janczewska[2], Y. Luo[3], M. Curescu[4], S. Greenbloom[5], A. Streinu-Cercel[6,7], F.A. Caruntu[6], W. Ghesquiere[8], B. Knysz[9], W. Mazur[10], F. Fuster[11], A. Motoc[12], A. Soza[13], V. Arama[6,7], O. Dalgard[14], D. Sullivan[3], X. Liu[3], T. Podsadecki[3]. *[1]Vancouver ID Research and Care Centre, Vancouver, Canada; [2]ID Clinic, Mysłowice, Poland; [3]AbbVie Inc., North Chicago, United States; [4]Life Search SRL, Timisoara, Romania; [5]Toronto Digestive Disease Associates, Toronto, Canada; [6]National Institute for Infectious Diseases "Prof. Dr. Matei Bals", [7]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [8]Island Health Authority, Section of Infectious Diseases, Victoria, Canada; [9]Wrocław Medical University, Wrocław, [10]Clinical Department of Infectious Disease, Medical University of Silesia, Katowice, Poland; [11]Instituto Oncologico, Viña del Mar, Chile; [12]Hospital of Infectious Diseases Dr. Victor Babes, Bucharest, Romania; [13]Department of Gastroenterology, Pontificia Universidad Catolica de Chile, Santiago, Chile; [14]Akershus University Hospital, Lorenskog, Norway*
E-mail: christine.ratajczak@abbvie.com

Background and Aims: In phase 3 trials, regimens of co-formulated ombitasvir/paritaprevir/r (paritaprevir [formerly ABT-450] identified by AbbVie and Enanta, co-dosed with ritonavir [r]) and dasabuvir +/− ribavirin (3D±RBV) demonstrated high efficacy rates and low rates of drug discontinuation due to adverse events (AEs) in patients with chronic HCV genotype (GT) 1 infection. Telaprevir (TPV) plus peginterferon (pegIFN)/RBV remains the standard of care for chronic HCV GT1 infection in many regions. However, this regimen is associated with long treatment duration, suboptimal efficacy, and treatment-limiting AEs related to pegIFN/RBV and exacerbated by TPV-associated rash and anemia. MALACHITE-I is the first multicenter trial to directly compare efficacy and safety of an all-oral direct-acting antiviral regimen (3D±RBV) and TPV+pegIFN/RBV in treatment-naive HCV GT1-infected pts without cirrhosis.

Methods: This multicenter, open-label trial included 311 HCV GT1-infected treatment-naive patients without cirrhosis. Patients received 3D+RBV for 12 weeks, 3D for 12 weeks, or TPV+pegIFN/RBV for 12 weeks and pegIFN/RBV for an additional 12–36 weeks (total treatment duration of 24–48 weeks). Patients with GT1a infection

Rash	12 (7.8)*	0*	16 (21.3)

*P-value ≤0.05 for the comparison with the TPV+pegIFN/RBV arm. Fisher's exact test was used for comparison of AE frequency.

were randomized 2:1 to 3D+RBV and TPV+pegIFN/RBV. Patients with GT1b infection were randomized 2:2:1 to 3D+RBV, 3D, and TPV+pegIFN/RBV. The primary endpoint was SVR12. Patients will be followed for 48 weeks post-treatment.

Results: Patient baseline characteristics are in Table 1. For patients receiving 3D+RBV or 3D, SVR4 and SVR12 rates were 97.1–98.8%; 3 patients had on-treatment failure and 1 patient had post-treatment relapse (Table 1). SVR4 rates were 82.9–85.3% for patients receiving TPV+pegIFN/RBV; SVR12 rates for the TPV+pegIFN/RBV arm will be presented. Rates of common AEs (including anemia, nausea, and pruritus), AEs leading to drug discontinuation or RBV dose modification, and serious AEs were significantly lower in patients receiving 3D±RBV compared to patients receiving TPV+pegIFN/RBV (Table 2). The frequency of RBV-associated AEs, such as anemia, was significantly lower in the 3D±RBV arms compared to the TPV+pegIFN/RBV arm.

Conclusions: In this trial, 12 weeks of 3D±RBV resulted in SVR12 rates of 97.1–98.8% while 12 weeks of TPV with 24–48 weeks of pegIFN/RBV resulted in SVR4 rates of 82.9–85.3% in treatment-naive patients with chronic HCV GT1 infection without cirrhosis. 3D±RBV also demonstrated better tolerability, with ≤0.7% of patients experiencing an AE leading to treatment discontinuation.

P0843

ON-TREATMENT VIRAL KINETICS DO NOT PREDICT SVR IN PATIENTS WITH ADVANCED LIVER DISEASE RECEIVING SOFOSBUVIR IN COMBINATION WITH DACLATASVIR OR SIMEPREVIR FOR 12 WEEKS

C. Hezode[1,2], S. Chevaliez[2,3], G. Scoazec[1], M. Bouvier-Alias[2,3], I. Ruiz[2], M. Francois[1], A. Mallat[1,2], C. Feray[1,2], J.-M. Pawlotsky[2,3]. *[1]Hepatology, [2]INSERM U955, [3]Virology, Hôpital Henri Mondor, Creteil, France*
E-mail: christophe.hezode@hmn.aphp.fr

Background and Aims: New direct-acting antiviral (DAA) drugs, including sofosbuvir (SOF), daclatasvir (DCV) and simeprevir (SMV), are available for the IFN-free treatment of patients with chronic HCV infection with advanced fibrosis or cirrhosis. We investigated the predictive role of on-treatment viral kinetics on the virological outcome of IFN-free SOF/DCV and SOF/SMV regimens in the real-life setting

Methods: 240 HCV mono-infected patients with advanced fibrosis (Fibroscan 9.6–12.4 kPa, 42%) or compensated cirrhosis (Fibroscan >12.5 kPa, 58%) received SOF/DCV (78%) or SOF/SMV (22%) for 12 weeks without RBV, regardless of their genotype (GT). The majority of patients were males (63%) and treatment-experienced (68%). The GT distribution was GT1b (31%), GT1a (25%), GT4 (24%), GT3 (17%) and other GTs (3%). SVR was available at post-treatment week 4 (SVR4) in 86 patients.

Results: Overall, 94% (81/86) of patients achieved SVR4. Three different patterns of virologic response were observed: (a) Rapid response: HCV RNA <12 IU/mL (detected or not) at week 4, n = 41 (48%); (b) Early response: HCV RNA >12 IU/mL at week 4 and HCV RNA <12 IU/mL (target detected or not) at week 8, n = 23 (27%); (c) Slow response: HCV RNA >12 IU/mL at weeks 4 and 8 and HCV RNA still detectable at week 12, i.e. end-of-treatment (EOT), n = 22 (25%). In the latter group, all but one patient with an HCV RNA=23 IU/mL had a detectable HCV RNA <12 IU/mL. In the

slow responder group, the proportion of treatment-experienced patients and GT4 tended to be higher than in the overall population, 82% (18/22) and 41% (9/22), respectively. The other baseline characteristics were similar, male 55% (12/22), cirrhosis 59% (13/22). As shown in the Table, SVR4 did not vary according to the on-treatment viral kinetics. Strikingly, 20/22 (91%) slow responders who still had detectable HCV RNA at EOT achieved an SVR4.

Conclusions: Based on our results in a cohort of real-life patients with advanced liver disease or cirrhosis, on-treatment viral kinetics do not predict the virological outcome of the new IFN-free SOF-based regimens. Thus, viral kinetics monitoring should not be used to alter the planned treatment regimen. In particular, most patients with detectable low-level HCV RNA at the end of treatment at week 12 achieve an SVR, raising the question as to the mechanisms involved in post-treatment clearance. SVR12 results and multivariate analysis of outcome predictors will be presented for the 240 patients.

	Rapid response N = 41	Early response N = 23	Slow response N = 22

IS DUAL INTERFERON AND RIBAVIRIN TREATMENT SAFE AND EFFICACIOUS AMONG THE CUPIC COHORT? – A RETROSPECTIVE COHORT STUDY

D. Schmidt-Martin[1], O. El-Sherif[1], O. Crosbie[2], S. Corbett[2], S. McKiernan[1], S. Norris[1]. *[1]Hepatology, St James Hospital, Dublin, [2]Hepatology, Cork University Hospital, Cork, Ireland*
E-mail: danscma@yahoo.com

Background and Aims: Hepatitis C virus is an RNA virus capable of establishing chronic infection which is associated with a significant risk of developing cirrhosis. The introduction of triple therapy protease inhibitors promised markedly improved sustained viral response rates albeit with a slightly worsened side effect profile. The promise of improved response and the already known poor response to interferon and ribavirin based dual therapy among cirrhotic patients prompted many physicians to defer treatment, a process which became known as warehousing.

The recent publication of the French Early access programme also known as the CUPIC study which targeted patients with advanced liver disease identified worryingly high rates of serious complications and a number of deaths among cirrhotic patients with platelet counts below 100,000 and albumin <35 g/L who were treated with triple therapy. We noted that two of these deaths occurred in patients who had commenced dual therapy but prior to commencing treatment with protease inhibitors.

We hypothesised that dual therapy may have had similar outcomes to triple therapy.

Methods: We performed a multicentre retrospective review of treatment outcomes among cirrhotic patients in the period between 2003 and 2012 in two of the leading centres for HCV treatment in the Republic of Ireland.

We identified 153 cirrhotic patients who had undergone treatment with dual therapy in that period.

Results: Our results are summarised in Table 1.

There were no mortalities among our cohort of patients. Although our cohort was only one third the size of the CUPIC study our discontinuation rate due to either death or adverse drug effects was 9% among patients with both low platelets and albumin levels which contrasts with a discontinuation rate of 44% among the CUPIC cohort. Among genotype 1 patients with low platelets and albumin had a non response rate of 86% and an SVR rate of 14%. SVR rates were markedly lower among patients with both low platelet and albumin levels. Conversely, SVR rates among subjects with preserved platelets counts and albumin levels were comparable to published rates for non cirrhotic patients and this was also true for when analysed by genotype.

Conclusions: Dual therapy has an acceptable safety profile among cirrhotic patients. There appears to be an associated between low platelets and albumin levels and poor lower rates of SVR.

These findings suggest that the adverse outcomes reported in CUPIC may have been the result of protease inhibitor use.

Hayashi[13]. *[1]Department of General Internal Medicine, Kyushu University Hospital, Fukuoka, [2]Department of Hepatology, Steel Memorial Yawata Hospital, [3]The Center for Liver Diseas, Shin-Kokura Hospital, [4]Department of Medicine, Kitakyushu Municipal Medical Cente, Kitakyushu, [5]Department of Medicine, Hamanomachi Hospital, [6]Department of Internal Medicine, Chihaya Hospital, Fukuoka, [7]Center for Liver Disease, National Hospital Organization Kokura Medical Center, Kitakyushu, [8]Department of Medicine, Kyushu Central Hospital, [9]Department of Gastroenterology, National Hospital Organization Kyushu Medical Center, [10]Department of Medicine, Fukuoka City Hospital, [11]Department of Medicine and Bioregulatory Science, [12]Department of Medicine and Biosystemic Science, Kyushu University, [13]Kyushu General Internal Medicine Center, Haradoi Hospital, Fukuoka, Japan*
E-mail: eogawa@gim.med.kyushu-u.ac.jp

Background and Aims: The addition of hepatitis C virus (HCV) NS3/4A protease inhibitors to the peginterferon and ribavirin (triple therapy) has greatly improved treatment outcome, but there has not been adequate study of the difference in effectiveness of the first- and second-generation of NS3/4A protease inhibitors. The aim of this study was to compare the treatment outcome of simeprevir (SMV)- or telaprevir (TVR)-based triple therapy.

Methods: This multicenter cohort study consisted of 835 consecutive Japanese HCV genotype 1b patients treated in a clinical setting, 808 of whom were enrolled (SMV 283 and TVR 525). The

interleukin-28B (IL28B) genotype at rs8099917 was determined for all studied patients and mild fibrosis was determined by METAVIR score F0–2 or FIB-4 index <3.25. Logistic regression was done after propensity score matching to assess the sustained virological response at week 12 after the end of treatment (SVR12).
Results: The SVR12 rates of the patients treated with SMV- or TVR-based triple therapy were 82.3% and 81.1%, respectively, by intention-to-treat analysis. Propensity score matching of the entire study population yielded 275 matched pairs. No significant difference was found between the SVR12 rates of the SMV (81.8%) and TVR (80.0%) groups (P = 0.59). Moreover, no significant difference in the SVR12 rate was found for treatment-naïve patients (SMV: 86.6% and TVR: 84.5%) or those with prior relapse (92.5% and 88.5%), prior partial response (64.0% and 61.5%), or prior null response (30.4% and 41.7%). For treatment-naïve patients, IL28B TT genotype (odds ratio [OR] 6.29; P < 0.0001) and mild fibrosis (OR 2.81; P = 0.0091) were independent pretreatment predictors of SVR12. For patients with prior relapse, the SVR12 rate by per-protocol analysis was extremely high for both SMV (96.3%) and TVR (91.8%) groups. In analysis of difficult-to-treat groups with prior partial/null response, IL28B TT genotype (OR 5.41; P = 0.015) and mild fibrosis (OR 6.34; P = 0.0047) for the prior partial response group and mild fibrosis (OR 6.50; P = 0.0038) for the prior null response group were independent predictors of SVR12, irrespective of the NS3/4A protease inhibitor used.
Conclusions: The treatment outcome and predictors of SVR12 by NS3/4A protease inhibitor-based triple therapy were very similar between groups treated with SMV or TVR for chronic HCV genotype 1b infection. When considering the choice of triple therapy for difficult-to-treat patients, fibrosis status may be the most useful factor.

EVALUATION OF ADHERENCE TO TELAPREVIR (TVR) AND BOCEPREVIR (BOC) USING DIFFERENT THRESHOLDS

E. González-Colominas[1], T. Broquetas[2], A. Retamero[1], M. García-Retortillo[2], N. Cañete[2], M. Puigvehí[2], R. Pellicer[1], D. Giménez[2], B. Cabrero[2], F. Bory[2], E. Salas[1], R. Solà[2], J.A. Carrión[2]. *[1]Pharmacy Department, Hospital del Mar, [2]Liver Section, Gastroenterology Service, Hospital del Mar, IMIM, Barcelona, Spain*
E-mail: 95565@parcdesalutmar.cat

Background and Aims: Information about optimal adherence to protease inhibitors (PIs) in patients with chronic hepatitis C (CHC) receiving triple therapy is very scarce.
The aim of our study was to analyse the sustained virological response at week 12 (SVR12) according to adherence in patients receiving boceprevir (BOC) or telaprevir (TVR) using different thresholds. Secondary aim was to establish the factors related to non-adherence.
Methods: Patients receiving BOC or TVR between May 2012 and April 2014 were included. We excluded those patients with HIV-coinfection. Demographic, virological and clinical data were analysed. Current outpatient medication was collected and Charlson comorbidity index was calculated. Non-adherent patients were defined as those receiving less than 80% of peg-interferon or ribavirin. For PIs, 80, 85, 90 and 95% adherence thresholds were analysed. Discontinuation of treatment in non-responders was not considered as lack of adherence. We compared the percentage of adherent and non-adherent patients achieving the SVR12 and the factors related to a low adherence.
Results: Fifty-seven patients were included: 44 (77.2%) received TVR. The percentage of adherent patients for each threshold was: 73.7% (n = 42) for 80/80/80 or 80/80/85 or 80/80/90 and 71.9% (n = 41) for 80/80/95. The rate of SVR12 in adherent vs. non-adherent patients was: 69% vs. 40% for 80/80/80 or 80/80/85 or 80/80/90 (p = 0.066 for the three thresholds) and 70.7% vs. 37.5% (p = 0.033) for 80/80/95. Advanced fibrosis stage (F3–F4) (p = 0.030), a Charlson index ≥2 (p = 0.003) and the number of concomitant drugs (p = 0.085) were related to low (<80/80/95) adherence. Only the Charlson index ≥2 (OR = 0.120: 95% CI: 0.029–0.491) was independently associated with a low adherence (<80/80/95).
Conclusions: An adherence threshold of 95% for BOC and TVR had the best predictive value for SVR12. Moreover, one third of the patients treated with TVR or BOC were non-adherent due to the presence of comorbidities and advanced disease.

E-mail: christine.ratajczak@abbvie.com

Background and Aims: Telaprevir (TPV) plus peginterferon (pegIFN)/ribavirin (RBV) remains a standard therapy for chronic HCV genotype (GT) 1 infection in many regions although its efficacy is suboptimal in treatment-experienced patients (pts), particularly prior null responders. In addition, pegIFN/RBV toxicity is often treatment-limiting and TPV is associated with rash and increased risk of anemia. In phase 3 trials, IFN-free regimens of co-formulated ombitasvir/paritaprevir/r (paritaprevir [formerly ABT-450] identified by AbbVie and Enanta, co-dosed with ritonavir [r]) and dasabuvir+ribavirin (3D+RBV) demonstrated high efficacy rates and low rates of drug discontinuation due to adverse events (AEs) in pegIFN/RBV-experienced pts with chronic HCV GT1 infection. MALACHITE-II is the first multicenter trial to directly compare efficacy and safety of an all-oral direct-acting antiviral regimen (3D+RBV) and TPV+pegIFN/RBV in pegIFN/RBV-experienced HCV GT1-infected pts without cirrhosis.
Methods: This open-label trial included 148 HCV GT1-infected prior pegIFN/RBV relapsers, partial responders, and null responders without cirrhosis. Pts received 3D+RBV for 12 weeks or TPV+pegIFN/RBV for 12 weeks and pegIFN/RBV for an additional 12–36 weeks (total treatment duration 24–48 weeks). Pts were randomized 2:1 to 3D+RBV or TPV+pegIFN/RBV. Primary endpoint was SVR12. Pts will be followed for 48 weeks post-treatment.
Results: Pts were stratified by HCV subtype (1a, 1b) and prior pegIFN/RBV response. Demographic/baseline characteristics were balanced between arms. SVR4 and SVR12 rate was 99.0% for 3D+RBV (Table). SVR4 rate was 68.1% for TPV+pegIFN/RBV; SVR12 rate for TPV+pegIFN/RBV will be presented. In each arm, nearly half the pts were prior null responders to previous pegIFN/RBV treatment. In prior null responders, SVR4/SVR12 rate was 100% (49/49) for 3D+RBV and SVR4 rate was 56.5% (13/23) for TPV+pegIFN/RBV. Rates of any AE, serious AE, AE leading to discontinuation, and AE leading to RBV dose modification were significantly lower for 3D+RBV compared to TPV+pegIFN/RBV (Table). Frequency and severity of RBV-associated AEs, such as anemia, were significantly lower for 3D+RBV compared to TPV+pegIFN/RBV.

Conclusions: In this trial, 12 weeks of 3D+RBV resulted in an SVR12 rate of 99.0% and TPV+pegIFN/RBV resulted in an SVR4 rate of 68.1% in pegIFN/RBV-experienced pts with chronic HCV GT1 infection without cirrhosis. 3D+RBV also demonstrated better tolerability, with no pt experiencing AEs leading to treatment discontinuation.

Table: Baseline characteristics, efficacy and treatment-emergent adverse events

	3D+RBV (N = 101)	TPV+pegIFN/RBV (N = 47)
Male, n (%)	55 (54.5)	28 (59.6)

Non-virologic treatment failure [c], n	1	4
Any AE, n (%)	63 (62.4)*	43 (91.5)
Serious AE, n (%)	1 (1.0)*	5 (10.6)
AE leading to drug discontinuation, n (%)	0*	5 (10.6)
AE leading to RBV dose modification, n (%)	2 (2.0)*	15 (31.9)
Common AEs, n (%)		
Headache	29 (28.7)	21 (44.7)
Nausea	10 (9.9)*	20 (42.6)
Pruritus	13 (12.9)*	19 (40.4)
Asthenia	8 (7.9)*	16 (34.0)
Anemia	3 (3.0)*	15 (31.9)
Pyrexia	2 (2.0)*	14 (29.8)
Neutropenia	1 (1.0)*	13 (27.7)
Anal pruritus	0*	12 (25.5)
Cough	7 (6.9)*	12 (25.5)
Fatigue	12 (11.9)	12 (25.5)
Rash	3 (3.0)*	12 (25.5)

*P-value ≤0.05 for the comparison with the TPV+pegIFN/RBV arm. For SVR4, P-value is based on logistic regression. Fisher's exact test was used for comparison of AE frequency.

[a] Fibrosis stage was assessed by liver biopsy scores, FibroScan scores, or FibroTest scores.

[b] Post-treatment relapse shown through post-treatment week 12 for 3D+RBV arm and through post-treatment week 4 for TPV+pegIFN/RBV arm.

[c] Non-virologic treatment failure includes premature drug discontinuation and missing SVR data.

P0848

EFFICACY OF RESPONSE-GUIDED PEGYLATED INTERFERON AND RIBAVIRIN THERAPY FOR PEOPLE WHO INJECT DRUGS WITH HCV GENOTYPE 2/3 INFECTION: THE ACTIVATE STUDY

J. Grebely[1], O. Dalgard[2], B. Conway[3], G. Foster[4], P. Bruggmann[5], M. Backmund[6], G. Robaeys[7,8,9], T. Swan[10], B. Hajarizadeh[1], J. Amin[1], P. Marks[1], S. Quiene[1], M. Weltman[11], D. E-mail: jgrebely@kirby.unsw.edu.au

Background and Aims: Despite HCV guidelines advocating for treatment among people who inject drugs (PWID), treatment uptake remains low. The aim of this study was to evaluate response-guided PEG-IFN alfa-2b/RBV treatment for chronic HCV genotypes 2/3 infection among PWID.

Methods: ACTIVATE is a phase IV open-label, multicentre, international trial. Participants with chronic HCV genotype 2/3 and active (previous 24 weeks) injecting drug use or receiving opioid substitution treatment (OST) were recruited between 2012 and 2014. Participants received directly observed PEG-IFN (1.5 μg/kg/week) and self-administered RBV (800–1400 mg daily, weight-based). Participants with a rapid virological response (RVR) received 12 weeks (shortened duration) and those without RVR received 24 weeks (standard duration) therapy. The primary efficacy endpoint was SVR at 12 weeks (SVR12) by ITT analysis. A preliminary ITT analysis included only patients having completed follow-up to SVR12 or having discontinued therapy prior to that time-point.

Results: Overall, 93 participants initiated treatment (mean age 42 years; 82% men; 87% HCV genotype 3). At baseline, 35% (n = 33) were receiving OST [15 (16%) with injecting in the previous 12 weeks], 43% (n = 40) had injected in the past 4–12 weeks and 22% (n = 20) had injected in the last month. In follow up, 66% (n = 61) achieved RVR (shortened treatment), 28% (n = 26) did not (standard treatment), and 6% (n = 6) discontinued therapy prior to week 4. In the preliminary ITT population (n = 75), the ETR and SVR were 83% (n = 62) and 59% (n = 44), respectively. SVR was 69% (38 of 55) in those with an RVR (shortened treatment) compared to 43% (6 of 14) in those without an RVR (standard treatment). SVR was similar among OST (52%, n = 12), non-OST injecting in past 4–12 weeks (79%, n = 11) and non-OST injecting in past month (55%, n = 21, $P = 0.238$) sub-groups. In multivariate analyses, after adjusting for age, gender, HCV genotype, baseline HCV RNA level and baseline injecting risk behaviour (OST vs. non-OST), RVR was the only factor associated with SVR (adjusted OR = 4.38; 95% CI: 1.05, 18.31; $P = 0.043$).

Conclusions: Among PWID with chronic HCV genotypes 2/3, on-treatment RVR was a strong predictor of SVR in patients receiving a 12 week course of PEG-IFN/RBV combination therapy, even in patients actively injecting drugs when treatment was initiated. These data provide further support for recommendations advocating HCV treatment in active PWID and the use of innovative shorter therapies in this context.

P0849

REAL-WORLD EFFECTIVENESS OF SOFOSBUVIR (SOF), TELAPREVIR, AND BOCEPREVIR (T, B) BASED THERAPY FOR HEPATITIS C VIRUS (HCV): AN ANALYSIS IN A LARGE INTEGRATED HEALTH CARE SYSTEM

J.B. Lai[1], D.J. Witt[1], M.A. Witt[1]. [1]*Infectious Disease, Kaiser Permanente Medical Center, San Rafael, United States*
E-mail: david.j.witt@kp.org

Background and Aims: New direct-acting antiviral (DAA) agents have become an integral component of treatment for HCV infection but little is known about their real-world effectiveness particularly in community practice. To optimize therapy, Kaiser Permanente Northern California (KPNC) established an HCV care team at each of 21 medical centers, which included a Gastroenterologist or Infectious Disease specialist, Clinical Pharmacist, Nurse and Hepatologist at each medical center. We compared virologic responses of patients receiving DAA-based therapy to those reported in clinical trials, including FDA approval documents.
Methods: Approval was obtained from the KPNC Institutional Review Board. HCV patients who completed T or B by 30AUG13 or SOF [with ribavirin (RBV) for genotype (GT) 2 or PEG-interferon (PEG-IFN)/RBV for non-GT2] based therapy by 30SEP14 were identified and analyzed on an intent-to-treat basis. Sustained viral response 12 (SVR12) was defined as undetectable (UD) HCV RNA 12 weeks after completing therapy.
Results: For GT1 treatment naïve (TN) patients treated with SOF/PEG-IFN/RBV, we found an SVR12 of 73.3%. For GT2 TN with SOF/RBV, we found the SVR12 was 92.6%. For GT1 with T/PEG-IFN/RBV, we found SVR12's of 65% and 59%, for TN and treatment experienced (TE), respectively, and for GT1 with B/PEG-IFN/RBV, the SVR12's were 56% and 61%, for TN and TE, respectively. Detailed results and comparisons to published clinical trials are located in Figure 1.
Conclusions: Our purely community-based results were similar to those observed in randomized controlled trials and included comparisons of the more difficult to tolerate interferon-based regimens. We believe our multidisciplinary care team provided a similar framework to the intense support often provided in clinical trials.

DAA	Genotype	Treatment History	Study	SVR 12 %	N	P Value (Fisher's Exact Test)
Sofosbuvir PEG-Interferon Ribavirin	1	Naïve	NEUTRINO	89.4	292	0.77

P0850

PERCENT OF SUBJECTS EXPERIENCING LIVER MORBIDITY OVER A LIFETIME HORIZON WITH ABBVIE 3D (ABT-450/RITONAVIR/OMBITASVIR AND DASABUVIR) VERSUS NO TREATMENT

S.J. Johnson[1], H. Parisé[1], S. Virabhak[1], D.A. Misurski[2], T.R. Juday[2], J.C. Samp[2,2,2], S.E. Marx[2], S. Saab[3]. [1]*Medicus Economics, Milton,* [2]*Global Health Economics and Outcomes Research, AbbVie, Mettawa,* [3]*Pfleger Liver Institute, Los Angeles, United States*
E-mail: jensamp@gmail.com

Background and Aims: Treating and curing patients with hepatitis C virus (HCV) is associated with reductions in long-term morbidity. Additionally, earlier HCV treatment is thought to reduce morbidity compared to treatment of HCV in later disease stages. Newer therapies for HCV are available that offer substantially improved sustained virologic response (SVR) rates. It is unclear what the impact these drugs will be on long-term morbidity and mortality. The aim of this study was to compare liver disease morbidity rates for HCV patients in varying disease stages who are treated with AbbVie 3D (ABT-450/ritonavir/ombitasvir and dasabuvir) +/− ribavirin compared to no treatment.
Methods: A Markov health state model estimated lifetime outcomes for patients treated with the AbbVie 3D regimen and no treatment. The model had 13 states including 8 disease progression states (F0–F4, decompensated cirrhosis [DCC], hepatocellular carcinoma [HCC], and liver transplant [LT]), 3 SVR states (based on baseline fibrosis score), and 2 mortality states (liver-related and non-liver-related death). Transition rates were derived from previous models. Population characteristics and efficacy rates were based on the AbbVie 3D phase 3 clinical trials. The model was run over a lifetime horizon. Analyses were run separately for each fibrosis score and for treatment naïve and treatment experienced patients. Rates of DCC, HCC, and LT were analyzed.
Results: Lower rates of DCC, HCC, and LT were seen across all fibrosis stages (F0–F4) in HCV patients treated with AbbVie 3D compared to no treatment (Table 1). Rates were 5 to 7 fold lower in the treated HCV patients compared to untreated patients, with an except in HCC among the F4 patients (e.g., 28.5% versus 28.9% for untreated and treated naïve patients, respectively). Rates of HCC were similar between the treated and untreated F4 patients likely due to the excess risk of HCC that remains for compensated patients despite viral clearance. Morbidity rates were similar among treatment naïve and treatment experienced patients of the same disease stage and rates of morbidity rose with increasing baseline disease severity.
Conclusions: The percent of HCV patients experiencing liver morbidity – DCC, HCC, and LT – was significantly reduced with AbbVie 3D treatment compared to HCV patients who were not treated. Rates of morbidity were higher when treatment was deferred to patients with greater baseline disease severity.

Table 1. Percent of subjects experiencing liver morbidity over a lifetime horizon with AbbVie 3D versus no treatment

Fibrosis stage	Liver morbidity					
	Decompensated cirrhosis		Hepatocellular carcinoma		Liver transplant	
	No treatment	AbbVie 3D	No treatment	AbbVie 3D	No treatment	AbbVie 3D
Treatment naive						
F0 (100%)	18.2%	2.9%	10.0%	1.6%	4.0%	0.6%
F1 (100%)	26.0%	4.4%	14.3%	2.4%	5.9%	0.9%
F2 (100%)	33.4%	6.0%	18.5%	3.3%	7.8%	1.3%
F3 (100%)	41.7%	7.9%	23.1%	4.3%	10.1%	1.8%
F4 (100%)	51.2%	9.7%	28.5%	28.9%	12.8%	6.8%
Treatment experienced						
F0 (100%)	17.6%	2.6%	9.6%	1.4%	3.8%	0.5%
F1 (100%)	25.1%	3.9%	13.8%	2.1%	5.6%	0.8%
F2 (100%)	32.3%	5.3%	17.9%	2.9%	7.5%	1.2%
F3 (100%)	40.4%	7.1%	22.4%	3.9%	7.9%	1.6%
F4 (100%)	49.7%	8.5%	27.7%	27.4%	12.3%	6.3%

P0851

EFFECTIVENESS OF SOFOSBUVIR AND RIBAVIRIN FOR GENOTYPE 2 AND 3 HCV AMONG NON-CIRRHOTIC, CIRRHOTIC, AND POST-TRANSPLANT PATIENTS AT 3 US MEDICAL CENTERS

M. Leise[1], B. Rodriguez[2], S. Pungpapong[2], B. Aqel[3], A. Chervenak[3], T. Werner[3], J. Murphy[2], T.M. Henry[2], K. Ryland[2], A. Keaveny[2], H. Vargas[3], K. Watt[1]. [1]*Gastroenterology and Hepatology, Mayo Clinic, Rochester MN,* [2]*Transplantation, Mayo Clinic, Jacksonville, FL,* [3]*Hepatology, Mayo Clinic, Phoenix, AZ, United States*
E-mail: leise.michael@mayo.edu

Background and Aims: Sofosbuvir (SOF) and Ribavirin (RBV) are effective for Genotype 2 and 3 Hepatitis C (HCV) but randomized controlled trials demonstrated variability in the response rates for this group, especially those with cirrhosis and prior treatment. The aim of this work is to evaluate the virological response and safety of SOF+RBV in treating G2 and G3 HCV including cirrhotics, liver transplant (LT) wait-list and LT recipients.

Methods: This multicenter effort analyzed data from 3 academic medical centers in the United States. Relevant demographic, clinical, and virologic data was evaluated in patients who have completed or continue on HCV treatment.

Results: At present, 94 patients (56% male, 7% non-white, 52% genotype 3, 48% genotype 2, 48% with cirrhosis, 14% decompensated) have been treated with SOF+RBV, approximately 70% have completed treatment. The mean MELD and CTP scores were 9 (range 6–18) and 6 (range 5–10), respectively. 21% (10/46) of the cirrhotic patients were awaiting LT and 17 (18%) were post LT. In total, 40% previously failed or did not tolerate peginterferon-based treatments. All patients had estimated GFR >30 mL/min. To date, 97% (56/58) patients completing treatment achieved an end of treatment response (EOTR). Two patients (3%) relapsed immediately after treatment, both cirrhotic. Twenty-six additional patients continue on treatment with 82% achieving treatement week 4 HCV negativity or were below the lower limit of quantification. One pre-transplant cirrhotic stopped SOF+RBV at week 8 due to viral breakthrough. Five other cirrhotics did not complete treatment (1 variceal bleed, 1 persistent nausea/vomiting, 1 hyperbilirubinemia post TIPS, 2 non-compliance). Among the decompensated cirrhotics, 4 patients developed complications (1 SBP, 1 variceal bleed, 1 hyperbilirubinemia post TIPS, 1 overt HE), and 1 compensated cirrhotic developed ascites. One patient who was able to stop diuretics and another was able to reduce diuretic doses. There was not a significant change in mean MELD (9 vs 10) or CTP (5.6 vs 5.6) from drug initiation to end of treatment in cirrhotics.

Conclusions: SOF+RBV was effective for this G2 and G3 HCV population enriched with difficult to treat patients including cirrhotics and post-LT patients. Significant improvement in ascites and/or hepatic encephalopathy was not observed in this population. SVR12 data will be reported when available.

P0852

CLINICAL CHARACTERISTICS AND OUTCOMES OF CHRONIC HEPATITIS C (CHC) PATIENTS TREATED WITH NEWER DIRECT-ACTING ANTIVIRAL (DAA)-BASED REGIMENS FROM A LARGE US PAYER PERSPECTIVE

N. Tandon[1], J. Forlenza[1], A. Goolsby Hunter[2], S.D. Korrer[2], A. Buikema[2]. [1]*Janssen Scientific Affairs, LLC, Titusville, NJ,* [2]*Optum, Eden Prairie, MN, United States*
E-mail: jforlenz@its.jnj.com

Background and Aims: To describe, from a large US payer-perspective, current clinical characteristics, health care utilization and cost per sustained virologic response (SVR) of CHC patients treated with newer DAA-based regimens using claims-linked lab data.

Methods: The Optum Research Database (ORD) with medical and pharmacy claims-linked lab data for commercially-insured patients and Medicare Advantage beneficiaries was used. Patients with CHC aged ≥18 years treated with simeprevir (SMV) and/or sofosbuvir (SOF) regimens after Nov2013 and with 6-months baseline health plan enrollment were followed from treatment initiation until Jun2014. ORD contained 123.1M cumulative lives as of Jun2014.

Results: 1,844 CHC patients were treated with SOF+RBV (33%) SOF +PEG+RBV (32%), SMV+SOF (29%) and SMV+SOF+RBV (6%) (n = 51 were treated with other regimens and excluded from this analysis). Less than half of patients had a diagnosis of cirrhosis (37%). 24% had claims-based evidence of end-stage liver disease. Over half (65%) were male; 68% white and 14% black; and mean age was 57.5 years (SD=9.5 years). One-third (33%) of patients were Medicare beneficiaries and 67% were commercially insured.

Table: Baseline liver disease severity by treatment regimen

Liver disease severity	Total (N = 1,844)		SOF + RBV (N = 615)		SOF + RBV + PEG (N = 581)		SMV + SOF (N = 534)		SMV + SOF + RBV (N = 114)		p-value
	n	%	n	%	n	%	n	%	n	%	
Claims-based evidence of cirrhosis or ESLD	778	42.20	238	38.70	180	30.98	286	53.56	74	64.91	<0.001
Baseline APRI [a,b]											
0 to <0.5	225	34.19	68	31.19	94	43.72	50	27.03	13	32.50	0.003
0.5–1.5	240	36.47	82	37.61	76	35.35	69	37.30	13	32.50	0.904
>1.5	193	29.33	68	31.19	45	20.93	66	35.68	14	35.00	0.008
Baseline FIB-4 [b,c]											
0 to <1.45	196	29.79	65	29.82	81	37.67	36	19.46	14	35.00	<0.001
1.45–3.25	242	36.78	74	33.94	88	40.93	73	39.46	7	17.50	0.009
>3.25	220	33.43	79	36.24	46	21.40	76	41.08	19	47.50	<0.001
No valid APRI or FIB-4 value	1,186	64.32	397	64.55	366	62.99	349	65.36	74	64.91	0.867

[a] APRI = (AST / normality upper limit) / platelet [10^9/L] ×100. AST and platelet values must occur within 30 days of each other.

[b] FIB-4 = (age [years] × AST [IU/L]) / (platelets [10^9/L] × sqrt(ALT [IU/L]). AST, platelet and ALT values must occur within 30 days of each other.

[c] When percentages are presented for valid values for APRI or FIB-4, patients without available values for the result in the denominator are not included.

Mean treatment duration among those with completed regimens (n = 339) was 10.7 weeks; over half of regimens had treatment durations of >11 to ≤15 weeks (57%). Most common prescribing provider type was gastroenterology (54%). Among patients with genotype (GT) results available (n = 597), 1a (51%) was most common, followed by 1b (18%) and 2 (17%). Percentage of patients by GT with SOF+PEG+RBV, SOF+RBV and SMV+SOF±RBV regimens were: GT1a – 44%, 7% and 49%, respectively; GT1b – 41%, 10%, 49%; GT2 – 1%, 99%, 0%; GT4 – 94%, 6%, 0%. Approximately one-third of patients with liver function test results (n = 658) had baseline advanced liver fibrosis (29% with APRI >1.5; 33% with FIB-4 >3.25). Significant variations in treatment regimen were seen across liver disease severity subgroups, including those with advanced liver fibrosis most often being treated with SMV+SOF±RBV (see table). Health care resource utilization and cost per SVR will be examined when post-treatment outcomes data are available.

Conclusions: The analysis provides current CHC treatment patterns in a large US payer database, evidence of potential variation in newer DAA treatment utilization by clinical characteristics, and suggests that a significantly higher proportion of patients receiving SMV+SOF±RBV had advanced liver fibrosis.

SERUM CYSTATIN C AND NGAL LEVELS AT THE OUTSET OF PROTEASE INHIBITOR ANTIVIRAL THERAPY POSITIVELY PREDICT RENAL DYSFUNCTION DEVELOPMENT AND ANAEMIA SEVERITY

S. Verma[1], I. Kraslova[1], K. Agarwal[1]. [1]*Institute of Liver Studies, King's College Hospital, London, United Kingdom*
E-mail: suman.verma@kcl.ac.uk

Background and Aims: The PAN study reported renal dysfunction in 4.7% and 6.6% of patients on Hepatitis C (HCV) antiviral protease inhibitors (PI) therapy. Risk factors associated with eGFR decline to <60 mL/min at treatment week 12 (TW12) were diabetes and arterial hypertension. Additionally, this eGFR was associated with lower TW12 haemoglobin (Hb) levels.

Serum NGAL is a biomarker for renal tubular cell injury and red blood cell production suppressant, while Cystatin C is a biomarker of glomerular function. Thus could NGAL and Cystatin C predict renal function decline and anaemia severity in cirrhotic and non-cirrhotic patients on PI therapy.

Methods: 33 patients with HCV genotype 1 undergoing PI (bocepravir or telaprevir) based therapy had serum NGAL and Cystatin C measurements at the following time points: treatment initiaton (TW0), TW12, end of treatment (EOT) (median 41 weeks) and 24 weeks post treatment (FUW24), using commercially available Quantikine ELISA kits from R&D systems. Absorbance measured at 450 nm on a microplate reader. Renin, creatinine, eGFR and Hb measurements were also made at these time points. Statistical analysis was performed using SPSS.

Results: Of the 33 patients (median age 50.32 years), 22 had cirrhosis, with 9 having renal risk factors (diabetes and hypertension). The remainder were neither cirrhotic nor had renal risk factors. Sustained viriologic response (SVR) rates were comparable between the telaprevir and bocepravir groups (75% and 70.5% respectively).

Serum NGAL levels showed no significant differences based on PI, SVR or level of fibrosis. However, in cirrhotics regardless of PI, a statistically significant rise in NGAL levels from TW0 until EOT with subsequent resolution was observed. TW0 NGAL levels >70 ng/ml were associated with >4 g/dl Hb decline at TW12 (PPV 89%) necessitating erythropoetin initiation.

Cystatin C levels were higher at TW0 in cirrhotics vs. non-cirrhotics (933 vs. 791, p = 0.04) but only increased during therapy in cirrhotic patients. Baseline Cystatin C levels (>900 ng/ml) were linked to >20% decline in eGFR by TW12 (PPV 86%). Renin and creatinine levels did not correspond to Cystatin C levels, thus suggesting dehydration was not a contributory factor to these changes.

Conclusions: TW0 Cystatin C levels (>900 ng/ml) can determine which patients will have significant renal dysfuntion during therapy, whilst serum NGAL levels >70 ng/ml identifies those requiring EPO support, regardless of cirrhosis, thus facilitating safer delivery of PI based therapy.

P0854

ESTIMATING THE COST OFFSETS AND IMPACT ON QUALITY-ADJUSTED LIFE EXPECTANCY ASSOCIATED WITH INCREASING SVR IN UK PATIENTS WITH HEPATITIS C-RELATED ADVANCED LIVER DISEASE

T. Ward[1], P. McEwan[1,2], S. Webster[1], D. Sugrue[1], Y. Yuan[3], A. Kalsekar[3]. [1]*HEOR, HEOR Ltd, Monmouth,* [2]*School of Human & Health Sciences, Swansea University, Swansea, United Kingdom;* [3]*World Wide Health Economics and Outcomes Research, Bristol-Myers Squibb Pharmaceuticals Ltd, Princeton, United States*
E-mail: samantha.webster@heor.co.uk

Background and Aims: Most health economic models for hepatitis C consider the value of treating chronically infected patients; however, few have been designed to model treatment in those with advanced liver disease (ALD). Described herein is an adaptation to the MONARCH model to allow modeling of those with ALD with significantly more granularity, including pre- and post-transplant stages. MONARCH ALD was used to estimate the potential benefit of increased efficacy associated with novel direct-acting antivirals (DAAs) over conventional treatment with pegylated interferon-alfa plus ribavirin (PR) when treating patients from the following disease stages: compensated cirrhosis (CC); decompensated cirrhosis (DC); and post-liver transplant fibrosis stage F2 (pLTx-F2).

Methods: A systematic literature review informed the structural framework of the model and key parameters for modeling patients with ALD. Transition rates between health states were obtained from published sources. Costs and mortality estimates were obtained from UK-specific sources. Baseline sustained virologic response (SVR) rates of 30.0%, 14.3% and 45.6% for PR (extracted from published sources) were utilised, with future costs and health benefits discounted at 3.5%. An SVR of 90% was used for comparison to a hypothetical novel DAA. Total complication costs and quality-adjusted life expectancy (QALE) of patients aged 55 with HCV therapy commencing from CC, DC or pLTx-F2 were estimated.

Results: Predicted complication costs and QALEs utilising base case and improved SVR rates are presented in Table 1.

Table 1.

Stage of treatment initiation	Cost of complications (£)			QALE		
	PR	DAA	Cost-offset	PR	DAA	Incremental QALE
CC	32,444	7,801	24,642	8.28	11.23	2.95
DC	104,949	93,230	11,719	7.31	7.96	0.65
pLTx-F2	81,352	47,035	34,317	10.56	12.2	1.63

Conclusions: With the introduction of new therapies with higher rates of SVR, it is likely that significant benefits, in terms of reducing complication costs and increasing QALEs, over conventional therapies will be realised. The greatest cost offset due to the increase in SVR was observed in those that initiated treatment from the pLTx-F2 health state. The greatest improvement in QALE was observed in patients that initiated treatment from the CC health state.

P0855

PHARMACOKINETICS OF ABT-493 AND ABT-530 IS SIMILAR IN HEALTHY CAUCASIAN, CHINESE, AND JAPANESE ADULT SUBJECTS

T. Wang[1], W. Liu[1], A. Asatryan[1], J. Wu[1], A. Campbell[1], J. Kort[1], S. Dutta[1]. [1]*AbbVie Inc, North Chicago, United States*
E-mail: tlwang2011@gmail.com

Background and Aims: A next generation direct acting antiviral (DAA) combination of ABT-493 (NS3/4A protease inhibitor discovered by AbbVie and Enanta) + ABT-530 (NS5A inhibitor) is being developed for the treatment of chronic hepatitis C infection. This study assessed pharmacokinetics (PK) and safety of multiple oral doses of ABT-493 and ABT-530 administered alone and in combination in healthy Han Chinese, Japanese, and Caucasian subjects.

Methods: This Phase 1, single center, multiple-dose, open-label study consisted of 11 Han Chinese, 12 Japanese, and 12 Caucasian subjects randomized into 2 cohorts with stratification by race (Figure). Intensive PK assessments were performed on Days 1, 7, 8 and 14. PK parameters were estimated by noncompartmental analyses. Safety [adverse events (AEs), clinical labs, vital signs, ECG] was assessed throughout the study.

Results: ABT-493 and ABT-530 exposures (difference ≤32% and ≤58%, respectively) were comparable in Japanese, Chinese and Caucasians when administered alone. When taking DAAs in combination, three ethnic groups also had similar ABT-493 and ABT-530 exposures: the geometric means for ABT-493 C_{max} were 15300, 13900, and 16700 ng/mL, and for AUC were 66000, 49400, and 67500 ng·h/mL, respectively in Caucasian, Chinese, and Japanese; for ABT-530 C_{max} were 289, 288, and 326 ng/mL, and for AUC were 2910, 2570, and 3070 ng·h/mL, respectively in Caucasian, Chinese, and Japanese. Interaction between ABT-493 and ABT-530 were also comparable among ethnicities: on average ABT-493 AUC and C_{max} were increased by 17–61% and 16–30%, respectively, in presence of steady-state ABT-530; ABT-530 AUC and C_{max} were increased to 5.1- to 7.5-fold and 3.1- to 5.0-fold, respectively in presence of steady-state ABT-493. Elimination half-lives of ABT-493 and ABT-530 were similar among Japanese, Chinese, and Caucasian.

Asymptomatic Grade 3 ALT and Grade 2 AST elevation (without concurrent bilirubin elevations) were observed in a Caucasian subject, and 2 additional subjects (Chinese and Caucasian) developed isolated asymptomatic Grade 3 total bilirubin elevations with predominantly indirect fraction. Overall the regimens were well tolerated. There were no serious AEs, premature discontinuations and described laboratory abnormalities normalized/improved following completion of dosing.

	Days 1 to 7	Days 8 to 14
Cohort 1 (N = 18)	ABT-493 700 mg QD	ABT-493 700 mg QD ABT-530 160 mg QD
Cohort 2 (N = 17)	ABT-530 160 mg QD	ABT-493 700 mg QD ABT-530 160 mg QD

Conclusions: Ethnicity does not have much impact on the exposures, safety and tolerability of ABT-493 or ABT-530 alone, or ABT-493 + ABT-530 combination.

P0856

OMBITASVIR/PARITAPREVIR/RITONAVIR AND DASABUVIR WITH RIBAVIRIN (RBV) HAS MILD IMPACT ON HEALTH-RELATED QUALITY OF LIFE (HRQOL) COMPARED WITH PLACEBO DURING 12-WEEK TREATMENT IN TREATMENT-EXPERIENCED ADULTS WITH CHRONIC HEPATITIS C (CHC)

Y. Liu[1], L. Larsen[1], M. Bourliere[2], R. Baran[1], T. Juday[1]. *[1]Abbvie Inc, North Chicago, United States; [2]Hôpital Saint Joseph, Marseille, France*
E-mail: Yan.Liu@abbvie.com

Background and Aims: Interferon can negatively impact patient HRQoL during CHC treatment. We assessed the HRQoL impact of an interferon-free all-oral CHC therapy – ombitasvir/paritaprevir (identified by AbbVie and Enanta)/ritonavir and dasabuvir with RBV (3D+RBV) – compared with placebo in treatment experienced, non-cirrhotic, Genotype 1 (GT1) adults during 12 weeks of treatment in the Phase 3 trial SAPPHIRE-II.

Methods: Patients were randomized in a 3:1 ratio to 3D+RBV or placebo and treated during a 12-week double-blind period. HRQoL was assessed using the SF-36 v2 Health Survey (SF-36) which was administered at baseline, during treatment, and at end of treatment (EOT) for both treatment groups, and at post-treatment (PT) visits for the 3D+RBV group only. Physical Component Summary (PCS) and Mental Component Summary (MCS) scores were calculated for the SF-36. Summary statistics of change from baseline, including mean and standard deviation (SD), were generated for each visit by treatment group. A repeated measures analysis of covariance (RM-ANCOVA) was carried out for PCS and MCS, respectively, to determine the mean difference in adjusted scores between treatment groups during the 12-week treatment period. The factors in the RM-ANCOVA analysis were treatment group and visit and covariates were baseline PCS score, MCS score, and patient characteristics.

Table: Mean baseline (SD) and change from baseline (SD) HRQoL scores by treatment group

		Baseline	Wk 4	Wk 8	EOT	PT Wk 4	PT Wk 12
PCS	3D+RBV	50.7 (8.46)	−2.2 (6.67)	−3.0 (7.47)	−2.8 (7.74)	0.0 (6.46)	0.8 (6.36)
	Placebo	50.7 (8.03)	−1.2 (4.59)	−0.6 (5.26)	−1.3 (6.27)	n.a.	n.a.
MCS	3D+RBV	50.0 (9.86)	−2.4 (7.91)	−3.9 (9.37)	−3.7 (9.74)	−0.3 (8.41)	0.8 (8.54)
	Placebo	48.6 (11.08)	0.5 (7.55)	−0.5 (7.78)	−0.6 (9.04)	n.a.	n.a.

Results: The analysis included 297 patients on 3D+RBV and 97 on placebo. HRQoL results are summarized in Table. At EOT, greater changes from baseline PCS and MCS scores were observed in the 3D+RBV group (−2.8 in PCS and −3.7 in MCS) compared with the placebo group (−1.3 for PCS and −0.6 for MCS). At PT Wk 12 visit, PCS and MCS scores for 3D+RBV patients were improved over baseline (PCS: +0.8 and MCS: +0.8). Results from RM-ANCOVA demonstrated that the adjusted mean decrements in PCS and MCS scores over the 12 week treatment period in the 3D+RBV group were greater than in the placebo group, and both differences were statistically significant – 1.57 greater decrement in PCS (95% CI, 0.31 to 2.84) and 2.45 greater decrement in MCS (95% CI, 0.83 to 4.07).

Conclusions: During the 12-week treatment period in SAPPHIRE-II, the interferon-free all-oral 3D+RBV regimen had mild impact on patient HRQoL compared with placebo. Post-treatment scores for 3D+RBV showed improvement over baseline.

P0857

98% SVR12 IN KOREAN AND TAIWANESE PATIENTS WITH CHRONIC GENOTYPE 1 HCV INFECTION RECEIVING 12 WEEKS OF LEDIPASVIR/SOFOSBUVIR: RESULTS FROM AN INTERNATIONAL, MULTICENTER PHASE 3 STUDY

Y.-S. Lim[1], W.-L. Chuang[2], S.-H. Ahn[3], C.-Y. Peng[4], S.-W. Paik[5], R.-N. Chien[6], C.-J. Chu[7], J.C. Yang[8], H. Mo[8], B. Gao[8], P.S. Pang[8], S.J. Knox[8], J.G. McHutchison[8], Y.-J. Lee[9], T.-T. Chang[10], S.-H. Jeong[11], K.-H. Han[3], J.-H. Kao[12]. *[1]Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, South; [2]Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [3]Severance Hospital, Yonsei University Health System, Seoul, Korea, South; [4]China Medical University Hospital, Taichung, Taiwan; [5]Samsung Medical Center, Seoul, Korea, South; [6]Gastroenterology, Chang Gung Memorial Hospital-Keelong, Keelung, [7]Taipei Veterans General Hospital, Taipei, Taiwan; [8]Gilead Sciences, Foster City, CA, United States; [9]Inje University, Pusan Paik Hospital, Busan, Korea, South; [10]National Cheng Kung University Hospital, Tainan, Taiwan; [11]Seoul National University Bundang Hospital, Seoul, Korea, South; [12]National Taiwan University Hospital, Taipei, Taiwan*
E-mail: jenny.yang@gilead.com

Background and Aims: Approximately half of the patients with chronic hepatitis C virus (HCV) infection in Korea and Taiwan are infected with HCV genotype (GT) 1. The majority of these patients have often failed to respond to prior interferon (IFN)-based therapy. Frequently, patients may be ineligible for, or intolerant of current treatment options. Highly effective, safe and well-tolerated IFN- and ribavirin-free therapies are needed to address the burden of HCV-related liver disease in Korea and Taiwan.

Methods: An open-label, Phase 3 study was conducted to evaluate the efficacy and safety of the ledipasvir (LDV) 90 mg/sofosbuvir (SOF) 400 mg fixed-dose combination (FDC) tablet administered orally, once daily for 12 weeks in Korean and Taiwanese adults with chronic GT1 HCV infection, with and without cirrhosis. There was no upper age limit, we included patients with cirrhosis, no entry restriction applied for neutrophils and the minimum platelet count was 50,000/μL. NS5A and NS5B resistance associated variants (RAVs) were evaluated by deep sequencing. The primary efficacy endpoint was SVR12.

Table 1. SVR12 rates in GT 1-infected patients and difficult-to-treat subgroups

	Korea (N = 93)	Taiwan (N = 85)	Overall (N = 178)
Virologic response (ITT):			
Overall, SVR12, n (%)	92 (99)	83 (98)	175 (98)
On-treatment failure, n (%)	0	0	0
Relapse, n (%)	1 (1)	1 (1)	2 (1)
Withdrew consent, n (%)	0	1 (1)	1 (<1)
SVR12 by subgroup:			
Treatment-experienced (TE), n/N (%)	46/47 (98)	41/43 (95)	87/90 (97)
Cirrhotic, n/N (%)	17/17 (100)	9/9 (100)	26/26 (100)
TE with cirrhosis, n/N (%)	13/13 (100)	4/4 (100)	17/17 (100)

Results: 178 patients were enrolled. The mean (range) age was 54 (20–75) years old, BMI 24 (18–38) kg/m^2, and baseline HCV RNA 6.7 (3.7–7.6) $\log_{10}$ IU/mL. The majority of patients were treatment-experienced (51%), non-cirrhotic (85%), GT1b infected (93%), female (56%), and had IL28B CC genotype (72%). Table 1 shows the overall SVR12 rates. A total of 38 subjects were identified as having baseline NS5A RAVs, of which 37/38 (97%) achieved SVR12. Three (2%) patients failed to achieve SVR12: 2 patients' relapsed and 1 patient withdrew consent. Both relapse patients had detectable NS5A RAVs, but no detectable S282T at the time of relapse. Headache was the only adverse event (AE) reported in ≥10% of patients. Five patients (3%) had treatment-emergent SAEs all unrelated to study drug. Two patients (1%) discontinued therapy due to an AE. No AE leading to

discontinuation occurred in >1 patient. No significant laboratory abnormalities were observed

Conclusions: A single tablet regimen of ledipasvir/sofosbuvir administered once daily for 12 weeks is highly effective and well tolerated in Korean and Taiwanese patients with genotype 1-infection, including those with cirrhosis.

P0858

EARLY HCV RNA DECLINE BY BASELINE CHARACTERISTICS IN HCV INFECTED PATIENTS RECEIVING SOFOSBUVIR-BASED TREATMENT: AN ITALIAN SINGLE CENTER EXPERIENCE

A. Mangia[1], V. Piazzolla[1], R. Santoro[1], L. Mottola[1], D. Petruzzellis[1], M. Ripoli[1], F. Leone[1], D. Facciorusso[1]. [1]*Liver Unit, IRCCS "Casa Sollievo della Sofferenza", San Giovanni Rotondo, Italy*
E-mail: a.mangia@tin.it

Background and Aims: In Italy, experience with IFN free regimens is yet mostly related to nominal drug use. Therefore, early virologic response in pts with different genotypes on Sofosbuvir (SOF)-based treatment is available in real life in limited numbers of pts.

Methods: All pts starting SOF-based regimens at our center and expected to have completed at least 4 weeks post treatment at the time of the meeting were evaluated regardless of genotype and treatment regimen. Used regimens included: SOF + PegIFN + ribavirin (RBV), SOF + RBV, SOF + Simeprevir (S), SOF + Daclatasvir (DAC), SOF + ledipasvir (LDV). We assessed HCV RNA at wk 2 and wk 4 by Abbot RealTime (LOQ 12 UI/ml). Liver disease was assessed by both fibroscan and APRI. Univariate and multivariate analysis of baseline characteristics associated with undetectable HCV RNA at week 4 was performed.

Results: Due to the lack of week 2 available HCV RNA results in 6 pts, 89 of 95 starting SOF-based regimens, are analysed here. 54 were NR, 10 PI failure, and the remaining naive. Only 11 patients received PegIFN in combination with SOF + RBV. IFN free regimens were SOF + RBV in 37, SOF + S +/− RBV in 7, SOF + DAC +/− RBV in 37 and SOF + LDV in 7. PI failures received only SOF + DAC. Overall, 67% were male, 85% >45 yr-old, 55% genotype 1, 20% genotype 2, 24% genotype 3 and 1% genotype 4, 80% cirrhotics, 43% with BMI ≥26. Baseline HCV RNA <800,000 IU/ml in 64%, and IL28B CC in 15% were observed. HCV RNA was undetectable or among genotype 2>3>1 both at week 2 ($p = 0.047$) and week 4 ($p = 0.26$). By week 12, all but one, genotype 3 infected, were HCV RNA undetectable (Table). 90% of pts either cirrhotic or not achieved undetectable/or not achieved undetectable/or <LOQ at week 4 ($p = 0.64$). Although not statistically different, week 4 HCV RNA response was lower in previous PI failure than in PegIFN + RBV NR (78% vs 95%, $p = 0.17$)

	HCV RNA undetectable, n/N (%)		
	Week 2	Week 4	Week 12
Genotype 1	19/32 (39%)	29/33 (88%)	33/33 (100%)
Genotype 2	14/15 (93%)	16/16 (100%)	16/16 (100%)
Genotype 3	16/21 (76%)	20/21 (95%)	20/21 (95%)

Conclusions: SOF-based regimens induce wk 4 virologic response regardless of genotype and treatment regimens. The only on treatment failure was related to genotype 3. The vast majority of Genotype 1 PegIFN and RBV NR showed on treatment successful responses after 4 wks of either SOF + PegIFN + RBV or SOF + S.

P0859

GENOTYPE 1 AND 4 CIRRHOTICS: WHAT IS THE SVR RATE IN COMMUNITY CLINICS USING SIMEPREVIR AND SOFOSBUVIR?

A.M. Hefner[1], I. Suliman[1], R. Hassanein[1], C. Hill[1], R. Pozza[1], T.A. Couturier[1], P.A. Reshamwala[1], T.I. Hassanein[1]. [1]*Southern California Liver Centers, Coronado, United States*
E-mail: kbiando@livercenters.com

Background and Aims: Combination Simeprevir and Sofosbuvir (SIM/SOF) achieved high SVR rates in Clinical Trials. This combination is currently approved by the FDA and recommended by the AASLD as a treatment option for Genotype 1 infection. The treatment efficacy is not known in patients with cirrhosis in real life experiences. Our aim was to evaluate the safety, tolerability, and efficacy of SIM/SOF in treating chronic Hepatitis C in cirrhotic patients with Genotype 1 and 4 in liver specialized community based clinics. The community clinics were run by nurse practitioners following a standardized protocol.

Methods: 32 patients with liver cirrhosis commenced therapy with Simeprevir 150 mg daily and Sofosbuvir 400 mg daily for 12 weeks. 23 (71.0%) were males with mean age of 61.2±6.4 years. 23 patients (71%) were Peg-IFN treatment experienced. Genotype 1 accounted for 87% of the subjects and 13% had Genotype 4. Baseline platelet levels were $113.4 \pm 46 \times 10^3/\mu L$, albumin 3.7±1.9 g/dL, bilirubin 1.35±1.5 mg/dL and ALT/AST were 82.31±55.1 IU/L and 80.9±70.6 IU/L respectively. 30 patients were Child A; 2 patients were Child B with no clinical signs of liver decompensation. HCV PCR was obtained before, during, and after treatment using commercial assays. Safety data was collected and laboratory tests were performed every 2–4 weeks according to the standard treatment protocol.

Results: 23 (72%) patients achieved HCV below detectable levels by W4. 24/25 (98%) patients completing 12 weeks are negative at end of treatment. SIM/SOF was well tolerated with no signs or laboratory tests indicating liver decompensation. Mean ALT/AST dropped significantly in 68.0% of patients by W4. Platelet counts increased 2%>4% during therapy. SVR12 was achieved in 12/15 (80%) of the patients. 3 patients relapsed within the first 2 weeks after end of therapy.

	Naïve	Treatment experienced
Week 4	n = 5 (71%)	n = 18 (86%)
Week 8	n = 7 (100%)	n = 20 (100%)
Week 12	n = 6 (100%)	n = 18 (95%)
SVR 4	n = 5 (100%)	n = 10 (71%)
SVR 12	n = 4 (80%)	n = 13 (81%)

Conclusions: (1) The combination of SIM/SOF is well tolerated. (2) Not all patients achieve week 4 negativity. (3) Cirrhotic patients who finished 12 weeks of treatment have high SVR12 response rates. (4) All Genotype 4 patients who finished 12 weeks of follow-up achieved viral cure. The remaining patients continue on treatment.

Summary: Though this is a limited study in community clinics, it provides high response rates in a real-life setting of cirrhotic patients using the combination of Simeprevir/Sofosbuvir. Thus far, SIM/SOF has shown to be safe, tolerable, and effective. Data collection continues with more cirrhotic patients being treated with this combination.

P0860

THE IMPACT OF INTERFERON-FREE REGIMENS ON EMPLOYMENT RATE DURING TREATMENT IN PATIENTS WITH CHRONIC HEPATITIS C

B. Kutala[1], F. Mourri[1], N. Boyer[1], C. Castelnau[1], V. Sitruk[1], N. Giuily[1], T. Asselah[1], P. Marcellin[1]. [1]*Hepatologie, Hôpital Beaujon, Clichy, France*
E-mail: blaise.kutala@bjn.aphp.fr

Background and Aims: The current standard-of-care newly approved therapies, Sofosbuvir (Sofo), Daclastavir (Dacla) and Simeprevir (sime) lead to hight rate of sustained response (SVR). However, the impact of these news regimens on unemployment rate is unknown. Purpose: to determine changes in employment status of patients who underwent the new treatments for hepatitis C (HCV) and to identify predictors of employment during treatment.

Methods: 117 patients who had completed HCV therapy (Sofo + ribavirin or sofo + Dacla or sofo+Sime) were consecutively recruited from the referral hospital Beaujon, France between January 2014 and November 2014. A questionnaire was administered prospectively for all patients. Chart review was conducted for labs and biopsy results. A binomial test was conducted to find if antiviral therapy affects on the employment rate. We compared our current truancy rate against the null hypothesis that p = 1. We tested each study charateristic's effect on the employment rate. Our data is categorical. The chi-square test or exact test could be used according the assumption of normality due to the sample size under the null hypothesis that the correlation is 0 to test if each study characteristic has a relationship with the employment rate.
Results: Eighty-nine patients were male (76%), the median age was 53 (range 43–76), 74 (63%) patients worked prior to treatment and 63 (54%) worked during treatment. Five patients (3%) attributed a decrease in work hours to HCV therapy. Six of the seventeen patients who did not return to work with health concerns as the reason. Variables associated with employment during treatment included the following: safety and tolerability during of treatment ($p \leq 0.001$), working conditions ($p = 0.041$), age ($p = 0.001$) and lack of compliance to treatment ($p = 0.08$). Fibrosis stage was not associated with employment ($p = 0.174$). The binomial test is 0.143, indicating that antiviral therapies do not affect employment rates during treatment.
Conclusions: The use of new antiviral therapy seems to be compatible with the maintains employment in a tertiary care referral center. The improved safety and tolerability decreased unemployment rates seen in patients treated regimen based interferon or in general population. This is the first study to our knowledge to focus on the main outcome variable of employment status during HCV treatment. More studies are needed for global assessments of QOL with extrapolation to effects on work productivity.

P0861
EVALUATION OF THE PAN-GENOTYPIC HCV NS3/4A PROTEASE INHIBITOR GS-9857 IN HEALTHY VOLUNTEERS

B. Kirby[1], J. Yang[1], C. Yang[1], Q. Song[1], Y. Wang[1], J. Taylor[1], L. Stamm[1], A. Mathias[1]. [1]*Gilead Sciences, Foster City, United States*
E-mail: brian.kirby@gilead.com

Background and Aims: GS-9857 is a pan-genotypic HCV NS3/4A protease inhibitor (PI), in development for the treatment of chronic HCV infection, with potent antiviral activity against HCV genotypes 1–6 and an improved resistance profile compared to previous HCV PIs. In pre-clinical studies, GS-9857 exhibited high metabolic stability, low systemic clearance, and low potential for metabolic drug–drug interactions. This Phase 1 first-in-human study evaluated the safety, tolerability and pharmacokinetics of GS-9857 in healthy volunteers.
Methods: This was a randomized, double-blind, placebo-controlled study with 3 staggered dose-escalation cohorts. Within each cohort, unique healthy subjects were randomized to receive single (SD) and multiple (MD) daily doses (10 days) of GS-9857 (N = 12/cohort) or matching placebo (N = 3/cohort) of 30 mg, 100 mg or 300 mg in the fasted state, with a 6-day washout between SD and MD. Safety was examined throughout the study. SD and MD GS-9857 PK parameters were estimated.
Results: 45 subjects were enrolled and completed the study: 36 subjects received GS-9857 and 9 subjects received placebo. The most frequently reported adverse events (>1 subject) in subjects administered GS-9857 were constipation (n = 2) and diarrhea (n = 2). All treatment emergent AEs were mild in severity. No notable laboratory abnormalities were observed. GS-9857 was absorbed quickly with Cmax occurring 2 to 5 hours post-dose. Across the doses tested, GS-9857 exhibited a median steady-state half-life of 28 to 41 hours. Steady-state GS-9857 exposure was achieved after 7 days of repeated dosing. In general, GS-9857 exposure increased linearly from 30 mg to 300 mg upon SD and MD (Table 1). Accumulation ratios of 2.1 to 4.2 were observed for GS-9857 AUC, Cmax and C24, with slightly greater accumulation (~2-fold) upon multiple dosing of 100 or 300 mg than predicted from single dose data (AUCtau vs. AUCinf).

Table 1. GS-9857 PK parameter summary (N = 12)

PK parameter	30 mg		100 mg		300 mg	
	SD	MD	SD	MD	SD	MD
$AUC_{inf\ or\ tau}$ (h·ng/mL)	56.9 (107)	74.2 (40.7)	195 (92.8)	364 (81.3)	485 (58.1)	1030 (77.3)
C_{max} (ng/mL)	3.7 (56.9)	7.3 (57.6)	12.6 (80.7)	46.0 (126)	34.5 (54.2)	155 (99.6)
$C_{24\ or\ tau}$ (ng/mL)	0.5 (56.5)	1.9 (50.6)	2.0 (123)	5.7 (44.9)	4.4 (67.9)	10.0 (56.2)
$T_{1/2}$ (h), median (Q1, Q3)	–	41.0 (30.1, 46.5)	25.8 (18.4, 39.4)	30.5 (27.3, 32.0)	35.5 (28.8, 46.3)	27.6 (25.1, 34.1)

PK parameters are presented as Mean (%CV) to 3 significant digits as applicable.

Conclusions: GS-9857 was well tolerated as single or multiple daily doses in healthy subjects. The in-vitro antiviral potency, safety and PK profile of GS-9857 supports once-daily dosing for further evaluation of its antiviral activity in HCV-infected subjects.

P0862
FIRST REAL CLINICAL PRACTICE DATA ON SOFOSBUVIR, SIMEPREVIR AND DACLATASVIR WITH HCV-CHRONICALLY INFECTED PATIENTS IN SPAIN: THE HepatiC REGISTRY EXPERIENCE

C. Fernández-Carrillo[1], J.M. Pascasio[2], S. Lens[3], C. Vinaixa[4], E. Fraga[5], M. Buti[6], M. Romero-Gómez[7], J. García-Samaniego[8], J. Crespo[9], D. Rincón[10], J.L. Calleja[1], on behalf of HepatiC Registry. [1]*Hospital Universitario Puerta de Hierro-Majadahonda, Majadahonda (Madrid),* [2]*Digestive diseases, Hospital Universitario Virgen del Rocío, Sevilla,* [3]*Hospital Clínic de Barcelona, Barcelona,* [4]*Universitari i Politècnic La Fe de Valencia, Valencia,* [5]*Hospital Universitario Reina Sofía, Córdoba,* [6]*Hospital Vall d'Hebron, Barcelona,* [7]*Hospital Ntra. Sra. de Valme, Sevilla,* [8]*Hospital Carlos III/La Paz, Madrid,* [9]*Hospital Universitario Marqués de Valdecilla, Santander,* [10]*Hospital General Universitario Gregorio Marañón, Madrid, Spain*
E-mail: cfernandezc@idiphim.org

Background and Aims: Direct-acting antivirals (DAA) have become elective treatment for HCV chronic infection, especially in patients with advanced liver disease. After phase III trials, sofosbuvir (SOF), simeprevir (SIM) and daclatasvir (DCV) have recently started their use in Spain in different combinations under compassionate regimen. The aim of this study is to analyse the initial experience in Spain on these new treatments in real clinical practice.
Methods: AEEH's HepatiC is a multicentric monitored registry including HCV-infected patients under DAA. Sixty-nine non-liver transplant patients were selected on treatment under compassionate use. The main basal characteristics and safety data regarding SVR at week 4 post-end of treatment (SVR4) were assessed.
Results: Eighty-four percent of the patients had G1 and the others had G3–4. Fibrosis stage was F3/F4 in 96% (F4 88%), and 25% had ascitic decompensation at treatment onset (median MELD 12, 6–21). The most part of the patients (67%) were treatment-experienced, including new DAA (2%). Treatment groups: SOF/PR (n = 4), SOF/R (n = 29), DCV/PR (n = 1), SOF/DCV±R (n = 34), SIM/DCV±R (n = 1). Currently, 20/69 patients have data on SVR4. With complete data pending, global SVR is 80%. SVR4 by group is: SOF/PR, 100% (3/3); SOF/R, 85% (11/13); DCV/PR, 0% (0/1); SOF/DCV±R, 67% (2/3). Patients with ascites at treatment had lower SVR4 (33% *vs* 88%, $p < 0.05$). Albumin levels improved after treatment (3.3 *vs* 3.9 mg/dL, $p = 0.05$), unlike bilirubin (1.75 *vs* 1.15 g/dL, $p = 0.232$) or platelets (69 *vs* 72×10^9/L, $p = 0.264$). Regarding safety, 20% of the patients experienced severe adverse events (SAE) during treatment, mainly liver decompensation (9/14, 64%), transfusion-requiring anemia (4/14, 29%) and grade 3–4 infection (2/14, 14%). Nevertheless, only 9% required discontinuation due to SAE. No association was observer between interferon use and SAE ($p = 0.785$), yet this group is

small (n = 4). Finally, 17% of the patients were liver transplanted on treatment, with available data on SVR4 in 4 of them (SVR4 100%).
Conclusions: With complete data pending, first data in real clinical practice show that new DAA are highly effective even in patients with advanced and decompensated liver disease, improving liver function and being able to prevent post-transplant recurrence. While SAE are still present, DAA discontinuation was necessary in a low proportion of patients. Complete data on SVR12 will be presented, including SOF+DCV and SIM+DCV with and without R, 12 vs 24 weeks.

P0863
"REAL-LIFE"-EXPERIENCE WITH SECOND GENERATION DIRECT ACTING ANTIVIRAL (DAA) TREATMENT IN HCV PATIENTS (N = 149)

C.R. Werner[1], D.P. Egetemeyr[1], N.P. Malek[1], U.M. Lauer[1], C.P. Berg[1]. [1]*Department of Gastroenterology, Hepatology, and Infectiology, Universitätsklinikum Tübingen, Tübingen, Germany*
E-mail: christoph.werner@med.uni-tuebingen.de

Background and Aims: In 2014, the second generation DAA, Sofosbuvir (SOF), Simeprevir (SMP), and Daclatasvir (DAC) were approved by the authorities. This single center retrospective analysis was conducted to assess the efficacy and safety of 2nd generation DAA treatment in HCV patients.
Methods: 149 consecutive patients infected with HCV were treated with (i) SOF, Ribavirin (RBV) +/− PEG-IFN (n = 55), (ii) SOF, DAC +/− RBV (n = 65), (iii) SOF, SMP +/− RBV (n = 29). 67 patients were treatment naïve, 82 patients had been pretreated either with PEG-IFN/RBV +/− 1st generation protease inhibitors (Telaprevir, Boceprevir), or with SOF/PEG-IFN/RBV (n = 1). Distribution of HCV genotypes (GT): GT 1a: 24%, GT 1b: 42%, GT 2: 3%, GT 3: 22%, GT 4: 6%, GT 6: 1%. Median baseline viral load was 1,335,000 IU/ml HCV RNA. 38% had liver cirrhosis. 10 patients were treated after liver transplantation, 2 of those with a cholestatic recurrence of HCV, one with advanced graft failure. 1 patient was treated post-kidney transplantation.
Results: *Efficacy:* At treatment week (TW) 2, 9% (6/66) were HCV negative, while at TW 4, 69% (59/86) were HCV negative [subgroup analysis TW 4: SOF/RBV +/− PEG-IFN: 80% (32/40) HCV negativity; SOF, DAC +/− RBV: 60% (15/25) HCV negativity; SOF, SMP +/− RBV: 57% (12/21) HCV negativity]. Notably, 49/149 patients already have reached end of treatment, 11 of these patients have reached SVR12.
Safety: 1 patient with relapse after SOF/RBV/PEG-IFN had liver cirrhosis and developed liver failure after relapse, but could be retreated with SOF-DAC, and now is HCV negative again. 1 patient being treated in the course of an advanced graft failure after liver transplantation died due to complications of transplant failure during treatment.
Conclusions: New DAA are highly effective with respect to early viral kinetics. Groups of patients with advanced cirrhosis, or previous treatment failure now can be treated effectively and savely with IFN-free treatment regimens. Most patients will have reached SVR 4, or SVR 12 until March, 2015. These data will be presented at the ILC 2015.

P0864
THE IMPACT OF RIBAVIRIN ON REAL WORLD ADHERENCE AND DISCONTINUATION RATES IN HCV PATIENTS TREATED WITH SOFOSBUVIR + SIMEPREVIR

D.R. Walker[1], T.R. Juday[1], S.R. Manthena[1], Y. Jing[1], V. Sood[1]. [1]*Health Economics and Outcomes Research, Abbvie, North Chicago, United States*
E-mail: david.r.walker@abbvie.com

Background and Aims: The all-oral combination of sofosbuvir (SOF) and simeprevir (SIM) is used extensively in the United States to treat patients with hepatitis C virus (HCV) infection. A recent analysis of real world data in the US by CVS Health found a four-fold increase in the discontinuation of SOF regimens compared to that in clinical trials. In addition, discontinuation rates varied by type of SOF regimen. Unknown, however, from the CVS analysis is whether the addition of ribavirin (RBV) to SOF+SIM, which raises the pill count of the regimen from 2 pills (2 pills once a day) to 8 pills (2 pills once a day plus 3 pills twice a day), has an impact on adherence and persistence to SOF+SIM. The aim of this study is to examine real-world adherence and discontinuation rates in SOF+SIM patients with and without ribavirin.
Methods: This retrospective study assessed real world adherence (proportion of days covered) and discontinuation (pill gap of >15 days during a 12 week treatment period) for HCV patients in the US initiating SOF-based treatment regimens between December 2013 and March 2014. Analyses were conducted using MarketScan US commercial pharmacy claims and enrollment data for December 2013 through June 2014. Two SOF-based treatment regimens were analyzed: SOF+SIM and SOF+SIM+RBV. Index date was first fill date for SOF. Inclusion criteria included continuous enrollment from the month of index date through the following three months. An exclusion criterion was an 84 day supply of SOF on initial fill. Statistical analyses were conducted using population proportion z-tests. Generalized linear modeling was used to adjust adherence by age, gender and copay (includes copays for SOF, SIM and RBV).
Results: Patient sample size was 286 for SOF+SIM and 65 for SOF+SIM+RBV. The mean age and percent male were not statistically different between cohorts – 56.6 years and 65.0% male for SOF+SIM and 56.7 years and 72.3% male for SOF+SIM+RBV. Differences in unadjusted adherence and discontinuation rates between SOF+SIM (90.6%, 19.2%) and SOF+SIM+RBV (88.2%, 21.5%) were not statistically significant ($p > 0.05$). After adjusting for age, gender and copay, adjusted adherence was 90.2% for SOF+SIM and 87.7% for SOF+SIM+RBV ($p = 0.2915$).
Conclusions: These findings indicate that, in spite of the greater number of pills and more frequent dosing, adding ribavirin to an all-oral regimen of SOF+SIM does not appear to impact HCV medication adherence or persistence in hepatitis C patients.

P0865
THE USE OF SOFOSBUVIR BASED REGIMENS AMONGST TREATMENT NAIVE AND EXPERIENCED PATIENTS WITH ADVANCED FIBROSIS/CIRRHOSIS: REAL WORLD RESULTS FROM A DIFFICULT TO TREAT COHORT

D. Sutherland[1], S. Datta[2], E.H. Forrest[1], R. Fox[3], M. Heydtmann[4], M. Priest[5], P.R. Mills[5], J. Morris[6], A.J. Stanley[1], S.T. Barclay[1]. [1]*Walton Liver Clinic, Glasgow Royal Infirmary,* [2]*Gastroenterology, Victoria Infirmary,* [3]*The Brownlee Centre, Gartnavel General,* [4]*Gastroenterology, Royal Alexandra Hospital,* [5]*Gastroenterology, Gartnavel General,* [6]*Gastroenterology, Southern General, Glasgow, United Kingdom*
E-mail: stephenbarclay@nhs.net

Background and Aims: Phase 3 trials of Sofosbuvir (Sof) have included patients with cirrhosis at a rate of 17–23%, however, trial inclusion/exclusion criteria may make outcomes less reproducible in routine clinical care. Data is lacking for GT1 treatment experienced (TE) patients, and data for treating GT3 patients with pegylated interferon (IFN) based regimens limited. We sought to establish the tolerability and effectiveness of Sof based regimens to treat naive and TE patients with advanced fibrosis/cirrhosis in routine practice.
Methods: We analysed the Scottish HCV Database to identify patients with a liver stiffness ≥9.5 kPa starting a Sof based regimen [with Ribavirin (RBV) +/− IFN] in Glasgow treatment centres. Data were obtained on demographics, liver stiffness, cirrhosis status, treatment status, baseline laboratory measurements, Child's score, presence of varices, and history of drug and alcohol abuse. Data were compared with phase 3 trial inclusion/exclusion criteria.

Baseline viral load, week 4 PCR, EOTR and SVR12 were recorded. Discontinuation rates and reasons were recorded.

Results: 122 patients, were treated with either Sof/IFN/RBV (n = 107) or Sof/RBV (n = 15). Baseline characteristics are summarised per treatment regimen in Table 1. 97 (79.5%) patients were cirrhotic, with a median liver stiffness of 20.8 (IQR 14.8–35.5). The majority were GT3 (69, 56.5%) or GT1 (45, 36.8%). Around half (47.6%) were TE, including 9 Protease Inhibitor failures. 65 (53.2%) patients would have failed at least one trial exclusion criterion [37 (30.3%) of the cohort due to baseline labs, 30 (24.6%) recent drug/alcohol misuse, 1 (0.8%) schizophrenia].

Table 1.

Patient characteristics	Sof/IFN/Rib (n = 107)	Sof/Rib (n = 15)
Mean age (range)	48 (23–76)	50 (39–69)
Male (%)	83 (77.5)	8 (53.3)
Previous IVDU (%)		
Never	43 (40.1)	5 (33)
>12 months	51 (47.6)	9 (62)
Within last 12 months	10 (9.3)	1 (5)
Unknown	3 (2.8)	–
Former alcohol excess (%)	42 (38.9)	8 (53.3)
In 12 months prior to Tx	18 (16.8)	1 (5)
Treatment experienced (%)	50 (46.7)	10 (66.6)
Median viral load (IQR)	5.69 (5.22–6.31)	5.58 (4.64–6.37)
Genotype (%)		
1	43 (40.1)	2 (13.3)
2	1 (0.9)	3 (20)
3	59 (55.1)	10 (66.6)
4	4 (3.7)	–
Cirrhosis (%)	83 (77.5)	14 (93.3)
Child A/B/C	76 (91.5) / 7 (8.4) / –	7 (50) / 7 (50) / –
Platelets <90	22 (26.5)	3 (21.4)
Platelets <50	–	3 (21.4)
Varices	16 (19.2)	6 (42.9)
Median LSM (IQR)	20.9 (14.3–34.3)	30.4 (25.1–37.5)

To date 1 patient has been lost to follow up and one stopped due to non compliance. 1 patient died suddenly at home (post mortem pending, not clearly related to treatment). No other patient discontinued due to adverse events.

106 patients had week 4 results, of whom 30 (28.3%) had undetectable RNA (RealTime HCV, Abbott Laboratories). 45 (42%) were detectable below the lower limit of quantification (LLOQ) of 12 IU/ml, and 31 (29.%) had quantifiable RNA (median 24 IU/ml, IQR 15–58). 34/35 (97.1%) patients were PCR negative at the end of treatment, with one positive.

Conclusions: Patients with advanced fibrosis/cirrhosis and unfavourable baseline characteristics can be treated with Sofosbuvir based regimens. High numbers of such patients had detectable HCV RNA at week 4, however, this does not appear to impact on end of treatment response. SVR12 data will be presented.

P0866

COMPARATIVE EFFICACY AND TOLERABILITY OF DACLATASVIR + SOFOSBUVIR VERSUS SOFOSBUVIR + RIBAVIRIN FOR HEPATITIS C GENOTYPE 3: A MATCHING-ADJUSTED INDIRECT COMPARISON

E. Swallow[1], J. Song[1], Y. Yuan[2], A. Kalsekar[2], C. Kelley[1], F. Mu[1], S. Kim[1], S. Noviello[2], J. Signorovitch[1]. *[1]Analysis Group, Boston, [2]Bristol-Myers Squibb, Princeton, United States*
E-mail: fan.mu@analysisgroup.com

Background and Aims: To compare the efficacy and tolerability of 12 weeks of daclatasvir and sofosbuvir (DCV+SOF) versus 24 weeks of SOF and ribavirin (R) in both treatment-naïve and treatment-experienced patients infected with chronic hepatitis C (HCV) genotype 3.

Methods: A systematic literature review was conducted to identify Phase 3 trials of SOF+R in genotype 3 patients with HCV. One trial with the approved regimen of SOF+R (VALENCE) was identified for the comparison with the DCV+SOF trial (ALLY-3). Individual patient data from ALLY-3 were available (n = 144); published summary data were extracted from the 24-week SOF+R-treated arm from VALENCE (n = 250). To adjust for cross-trial differences, ALLY-3 patients were weighted to match all available summary baseline characteristics reported in both ALLY-3 and VALENCE; specifically, age, BMI, gender, race, ethnicity, HCV RNA level, alanine aminotransferase level, IL28B genotype, cirrhosis status, prior treatment status, and response type to prior treatment were included in the analysis. Sustained virologic response (SVR) at week 12 post-treatment (overall and stratified by prior treatment experience), discontinuation due to adverse events (AEs), and rates of specific AEs (with an incidence of >10%) were compared between the treatments.

Results: After adjustment for baseline characteristics, SVR12 was comparable in the overall, treatment-naïve, and treatment-experienced populations in ALLY-3 and VALENCE (Table 1). In the overall population, the rate of discontinuation due to AEs was similar in patients treated with DCV+SOF and patients treated with SOF+R. Rates of asthenia, cough, dry skin, dyspnea, irritability, nasopharyngitis, and pruritus were significantly lower in patients treated with DCV+SOF compared to patients treated with SOF+R. Rates of all other assessed AEs were similar between the treatment regimens.

Table 1. Comparison of SVR12 rates in overall, treatment-naïve, and treatment-experienced patients

Group	SVR 12 (%)		
	DCV + SOF		SOF + R
	Pre-adjustment	Post-adjustment	
Overall	89.6	88.8	85.2
Treatment-naïve patients	90.1	96.4	94.3
Treatment-experienced patients	88.4	83.2	78.6

Conclusions: After adjustment for cross-trial differences in baseline characteristics, 12 weeks of DCV+SOF was associated with similar rates of SVR12 in the overall, treatment-naïve, and treatment-experienced populations, and with similar or lower rates of discontinuation and AEs in the overall population, compared with 24 weeks of SOF+R in HCV genotype 3 patients.

P0867

EFFICACY EVALUATION OF 24 WEEK SOF + RBV IN A HETEROGENEOUS, REAL-WORLD POPULATION OF GENOTYPE 3 HCV PATIENTS; DATA FROM THE TRIO NETWORK

K. Kowdley[1], B. Bacon[2], D. Dieterich[3], E. Lawitz[4], S. Milligan[5], N. Tsai[6], Z. Younossi[7], S. Flamm[8]. *[1]Liver Care Network, Swedish Medical Center, Seattle, [2]School of Medicine, St. Louis University, St. Louis, [3]Icahn School of Medicine, Mount Sinai, New York, [4]The Texas Liver Institute, University of Texas Health Science Center, San Antonio, [5]Trio Health Analytics, Newton, [6]Queen's Medical Center, University of Hawaii, Honolulu, [7]Center for Liver Diseases, Department of Medicine, Inova Fairfax Hospital, Falls Church, [8]Feinberg School of Medicine, Northwestern University, Chicago, United States*
E-mail: scott.milligan@triohealth.com

Background and Aims: HCV genotype 3 has proven difficult to treat in clinical trials and understanding the therapies used in a heterogeneous real-world population and the outcomes of these treatments are important for patients and physicians. Trio Health is a disease management company that works in partnership with academic medical centres, community physicians and specialty pharmacies in the US to optimize care for Hepatitis C. Data obtained through the Trio Health program were used to evaluate 24 week sofosbuvir plus ribavirin (SOF + RBV) for HCV genotype 3 patients.

Methods: Data were collected from Rx records through the Trio Platform in partnership with specialty pharmacies. Analyses were limited to 96 patients who initiated a 24 week course of SOF + RBV between December 2013 and March 2014. These 96 patients were

treated in 35 practices, 17 of which were community based and 18 that were academic.
Results: Mean age was 54 with 11% of patients 65 years or older, 56% male and mean BMI 30.0. Of the 96 patients, 7% were Asian, 3% black, 7% Hispanic and 68% white. HIV co-infection was present in 7% of the population. Mean lab measures at baseline were AST 89 IU/l, ALT 97 IU/l, Hb 14.2 mg/dl, and platelets 158K/ul (range 38K–429K). Baseline Viral load >6MM IU/ml was seen in 15% of patients and ≤800K IU/ml was present in 41% of patients. 39% of patients were previously treated, 41% of whom were null responders. Cirrhosis was present in 30% of patients. Treatment evaluation indicates an overall discontinuation rate of 9%.
Conclusions: An examination of 24 week SOF + RBV in a heterogeneous population with genotype 3 HCV is underway; SVR results will be available at the meeting.

P0868
MODELING COST-EFFECTIVENESS DURING ANTIVIRAL THERAPY FOR CHRONIC HEPATITIS C IN REAL-LIFE PRACTICE BY GENETIC TESTS AND VIRAL KINETIC PROFILE

L. Chemello[1], E. Bugin[2], G. Furneri[3], K. Bortolozzo[2], A. Gatta[1], L. Cavalletto[1]. *[1]Dept. of Medicine, Hospital-University od Padua, [2]Molecular Biology, ABanalitica srl, Padova, [3]Health Economics & Pharmaceutical Market Consultant, Melegnano (MI), Italy*
E-mail: liliana.chemello@unipd.it

Background and Aims: The association between host (IL28B/ITPA SNPs) and viral (genotype and kinetic) are determining factors for sustained virologic response (SVR). We propose a novel model to identify subjects with favorable profile of response and drug-tolerance to tailor therapy strategies, especially with DAAs, based on SVR-probabilitity (pSVR) at week 4 of therapy (4WT) (lead-in phase).
Methods: Prospective-observational study on 1194 cases (773M/421F;aged 46±10 yrs) with chronic hepatitis C, that underwent to determination of: (a) multiplex PCR for detecting IL28B and ITPA SNPs (GeneQuality IL28B-ITPA, AB Analitica) (b) quantitative HCV-RNA test (VL), (c) calculation of per-SVR costs (pharmacoeconomics model).
Results: The HCV1–4 (688 cases) and HCV2–3 (506 cases) IL28B-ITPA SNPs distribution were: rs12979860-CC (29%) and TT (16%); rs8099917-TT (50%) and GG (7%); rs7270101-AA (78%) and CC (2%); rs1127354-CC (87%) and AA (2%). By multivariate analysis, the: VL reduction (>3LogUI/mL) at 4WT, IL28B wild-type, genotype, disease stage, therapy duration/intensity and age were predictive of SVR, while the ITPA variant, was strongly associated with a lower Hb-reduction (<30 mg/dL) at 4WT. Different pSVR groups allowed to determine cost-effectiveness of therapy strategies (table 1) with 86% specificity and 78% sensitivity.

Model at 4WT pSVR (%)	Treated cases (%)	Strategy	SVR cases (%)	Cost (€)/SVR
>60	654 (55)	Continue Peg-IFN + RBV	551 (84)	6,289
40–60	184 (15)	Add BOC, TEL or SOF	140 (76)	31,540
20–40	150 (13)	Add BOC, TEL or SOF	70 (47)	51,400
0–20	206 (17)	Stopping rule	12 (6)	49,878

Conclusions: Our pharmacoeconomic model allows the choice of the best cost-effectiveness strategy to: apply a stopping-rule, add DAAs, or continue Peg-IFN+RBV in cases with low, moderate or high pSVR, avoiding futile therapy and optimizing costs.

P0869
EARLY VERSUS DELAYED USE OF SOFOSBUVIR PLUS PEGINTERFERON/RIBAVIRIN THERAPY IN FIBROSIS PATIENTS WITH HEPATITIS C VIRUS: A COST-EFFECTIVENESS ANALYSIS

M. Buti[1], R. Domínguez-Hernández[2], I. Oyagüez[2], M. Rueda[3], M.Á. Casado[2]. *[1]Hospital Vall d' Hebrón, Barcelona, [2]Pharmacoeconomics & Outcomes Research Iberia, [3]Medical Department, Gilead Sciences, Madrid, Spain*
E-mail: rdominguez@porib.com

Background and Aims: The administration of treatment in patients with chronic hepatitis C virus (HCV) in different disease stages is associated with a variation in the therapy's effectiveness. The aim of the analysis was assessed the cost-effectiveness of sofosbuvir combined with peginterferon alfa-2a and ribavirin (SOF/PEG-IFN/RBV) at early versus delayed fibrosis disease stage, in previously untreated patients with HCV genotype 1, 52 years aged, from the Spanish National Health System perspective.
Methods: A Markov model with ten health states was developed to compare lifetime cost and outcomes (life-years gained-LYG and quality-adjusted life-years-QALY) of two treatment strategies: early SOF/PEG-IFN/RBV at mild-moderate fibrosis (F2–F3) or delayed treatment at compensated cirrhosis (F4). The efficacy was measured as sustained virology response (SVR) at 12-weeks after the end of therapy (NEUTRINO study). Annual transition probabilities, disease management costs and utilities were obtained from literature. Only direct cost (pharmaceutical and disease cost by health state) were considered. Drug cost for the SOF/PEG-IFN/RBV 12-weeks regimen was calculated with the publicly available local ex-factory prices with applicable mandatory discounts for marketed drugs. Costs were expressed in Euro (€) 2014. A 3% annual discount rate was applied to cost and outcomes. Probabilistic sensitivity analysis (PSA) was performed.
Results: Early SOF/PEG-IFN/RBV therapy at F2–F3 was more effective (19.12 LYG and 14.14 QALY) than delayed administration at F4 (16.36 LYG and 9.27 QALY). In a 1,000 patient cohort, SOF/PEG-IFN/RBV at F2–F3 avoided 66 cases of decompensated cirrhosis, 60 hepatocellular carcinoma and 4 liver-transplantation compared to delayed therapy in F4 patients. Total cost of early therapy at F2–F3 (€56,012.51) was lower than the cost of delayed treatment in F4 patients (€61,767.92). Early versus delayed therapy was a dominant strategy (more effective and less costly). In PSA, early use of SOF/PEG-IFN/RBV remained dominant in 100% of simulations.
Conclusions: Compared to delayed administration of therapy at F4, initiating SOF/PEG-IFN/RBV treatment at early disease stages (F2–F3) reduced the incidence of new cases of liver-disease complications and it was associated to cost savings for the Spanish National Health System in previously untreated genotype 1 HCV-infected patients.

P0870
ESTIMATING THE COST-EFFECTIVENESS OF 12 WEEKS OF TREATMENT WITH DACLATASVIR + SOFOSBUVIR IN PATIENTS CHRONICALLY INFECTED WITH HCV GENOTYPE 3

P. McEwan[1,2], T. Ward[1], S. Webster[1], A. Kalsekar[3], M. Brenner[4], Y. Yuan[3]. *[1]HEOR, HEOR Ltd, Monmouth, [2]School of Human & Health Sciences, Swansea University, Swansea, United Kingdom; [3]World Wide Health Economics and Outcomes Research, Bristol-Myers Squibb Pharmaceuticals Ltd, Princeton, United States; [4]UK HEOR, Bristol-Myers Squibb Pharmaceuticals Ltd, Uxbridge, United Kingdom*
E-mail: samantha.webster@heor.co.uk

Background and Aims: Chronic infection with hepatitis C virus (HCV) genotype 3 is associated with increased rates of disease progression and is considered to be difficult to treat. Further, historically, patients that are ineligible for or intolerant to interferon had no available treatment option. The objective of this investigation was to compare the cost-effectiveness of two all-oral, interferon-free treatment regimens that have recently been licensed

for the treatment of patients with HCV genotype 3: daclatasvir plus sofosbuvir (DCV+SOF) and sofosbuvir plus ribavirin (SOF+RBV). A comparison to no treatment was also made for those that are ineligible for or intolerant to interferon.

Methods: A published Markov model was used to estimate the cost-effectiveness of interferon-free HCV genotype 3 treatment regimens over a lifetime horizon. It was assumed patients were evenly distributed across fibrosis stages F0–F4 upon treatment initiation. Patients progress from chronic infection through disease stages using published transition rates. Disease state costs were obtained from 2013 UK data and discounting was set to 3.5%. The weekly costs of DCV, SOF and RBV were £2,038.13, £2,915.24 and £66.95, respectively. Clinical inputs were obtained from a matching-adjusted indirect comparison (MAIC) of the ALLY-3 and VALENCE studies for DCV+SOF and SOF+RBV, which adjusts for baseline differences between trials.

Results: Predicted incremental costs, quality-adjusted life years (QALYs) and cost-effectiveness results are presented in Table 1.

Conclusions: Historically, HCV genotype 3 patients that were unable to receive interferon had no available treatment option. Based upon a willingness-to-pay threshold of £20,000/QALY, 12 weeks of DCV+SOF appears a cost-effective treatment option for patients chronically infected with HCV genotype 3 in all scenarios. When compared to 24 weeks of SOF+RBV, the DCV+SOF regimen results in improved quality of life and reduced total costs.

Pop.	Regimen	Incremental		ICER (£) versus DCV+SOF
		Cost (£)	QALY	
N	DCV+SOF		–	
	SOF+RBV	−12,963	0.13	Dominant [a]
E	DCV+SOF		–	
	SOF+RBV	−13,761	0.24	Dominant [a]
I	DCV+SOF		–	
	SOF+RBV	−13,442	0.2	Dominant [a]
	No treatment	31,815	4.12	7,728

E, Experienced; I, Interferon-ineligible/intolerant; N, Naïve; Pop., Treatment population.

[a] DCV+SOF is associated with improved quality of life and reduced total costs.

REAL LIFE EXPERIENCE WITH INTERFERON/RIBAVIRIN-FREE ANTIVIRAL TREATMENT IN RENAL TRANSPLANT RECIPIENTS AND ENDSTAGE RENAL DISEASE-PATIENTS ON DIALYSIS INFECTED WITH HEPATITIS C VIRUS

S. Beinhardt[1], K. Kozbial[1], A. Schmidt[2], C. Freissmuth[1], M. Mandorfer[1], R. Strassl[3], R. al Zoairy[4], R. Stauber[5], M. Strasser[6], G. Sunder-Plassmann[7], M. Trauner[1], M. Peck-Radosavljevic[1], W. Vogel[4], H. Hofer[1], P. Ferenci[1]. *[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, [2]Department of Internal Medicine III, Division of Nephrology and Dialysis, [3]Department of Laboratory Medicine; Division of Clinical Virology, Medical University of Vienna, Vienna, [4]Division of Gastroenterology and Hepatology; Department of Internal Medicine II, Medical University of Innsbruck, Innsbruck, [5]Department of Internal Medicine; Division of Gastroenterology and Hepatology, Medical University of Graz, Graz, [6]Department of Gastroenterology and Hepatology, Paracelsus Medical University of Salzburg, Salzburg, [7]Division of Nephrology; Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria*

E-mail: sandra.beinhardt@meduniwien.ac.at

Background and Aims: Since introduction of all-oral interferon-free treatment-regimens for hepatitis C virus infection (HCV), former “difficult to treat” patient-groups, like end-stage renal disease (ESRD)-patients or patients after renal transplant (NTx) are focused on recently, as treatment of those represented an area of unmet therapeutically need. As real-life data of sofosbuvir-based all-oral treatment-regimens is scarce, we investigated on-treatment viral response (otVR) and clinical profiles in ESRD- and NTx-patients.

Patients and Methods: Fifteen patients with chronic HCV-infection (2 GT1; 2 GT1a, 7 GT1b; 1 GT3a; 1 GT4; 1 GT4a/c/d; 1 GT1b/3a; Cirrhosis: 8/53%) after NTx (11/73%) or on dialysis (5/33%) due to ESRD are being treated with sofosbuvir (SOF)/daclatasvir (DCV; N = 9), SOF/simeprevir (SIM; N = 5) or DCV/SIM (N = 1); 24 h-dosage: N = 14/93%, 48 h-dosage: N = 1/7% patient(s).

Viral-load was measured by Abbott RealTime HCV-quantitative assay (lower limit of quantification [LLOQ]: 12 IU/ml); treatment-response (defined as: TND [target not detected) evaluated at weeks: 4/8/12(EoT)/16/24(EoT)/SVR4/SVR12. Continuous variables were reported as mean±SD or median (interquartile range).

Results: 15 patients (male: 11; age: 52.4±13.4 [31–71] years mean±SD [range]) were evaluated. On-treatment response was: week 4 – TND: 4/36.4%, LLOQ: 5/45.5%; week 12 – TND: 5/100%; EoT – TND: 5/100%. SVR 12: 1. Treatment-duration was reduced in 1 patient to 12 weeks due to worsening of renal function (creatinine: BL: 3.01/WE12: 4.16 mg/dl; otVR: WE4: LLOQ; EoT: TND). One SOF/SIM-patient developed pancytopenia at week 7; as a result treatment-regimen had to be re-evaluated and switched from 24 h- to 48 h-dosage with consecutive increase in HCV RNA (week 4: LLOQ – week 8: 200 IU/ml). No patient required dose-adjustment of immuno-suppressive treatment or discontinuation due to further (severe) adverse events (clinical or laboratory) as far. Final SVR12-results, safety-data as well as subgroup-analyses will be presented.

Conclusions: On-treatment virological response rates with interferon free therapy-regimens in ESRD- and renal transplant-patients are promising and resulted in rapid viral on-treatment suppression.

Overall SOF-based treatment-regimens were safe in patients with ESRD or after NTx; no interactions with immuno-suppressive regimens were observed.

P0872

EARLY VIRAL KINETICS DO NOT DIFFER IN PATIENTS WITH VARYING DEGREES OF FIBROSIS AND CIRRHOSIS IN THE SOLAR 1 TRIAL

T.W. Welzel[1], K.R. Reddy[2], S.L. Flamm[3], J. Denning[4], S. Arterburn[4], T. Brandt-Sarif[4], P.S. Pang[4], J.G. McHutchison[4], M. Charlton[5], G.T. Everson[6], S. Zeuzem[1], N. Afdhal[7]. *[1]Johann Wolfgang Goethe University Medical Center, Frankfurt am Main, Germany; [2]University of Pennsylvania School of Medicine, Philadelphia, [3]Northwestern Feinberg School of Medicine, Chicago, [4]Gilead Sciences, Inc., Foster City, [5]Intermountain Medical Center, Murray, [6]University of Colorado Denver, Aurora, [7]Beth Israel Deaconess Medical Center, Boston, United States*

E-mail: jill.denning@gilead.com

Background and Aims: Ledipasvir/sofosbuvir (LDV/SOF) + RBV for 12 or 24 weeks led to high SVR rates in patients with genotype 1 or 4 HCV and advanced liver disease or those who were post liver transplantation. We analyzed the viral kinetics in decompensated and post-transplant patients to determine whether on-treatment response varied by patient population.

Methods: Six groups of patients with HCV genotypes 1 or 4 and decompensated liver disease or who were post liver transplantation were randomized to receive 12 or 24 weeks of LDV/SOF+RBV treatment: patients without transplant and either (1) Child–Pugh–Turcotte (CPT) B cirrhosis, or (2) CPT C cirrhosis; or patients who have undergone transplantation and who were either (3) without cirrhosis (F0 to F3), (4) CPT A cirrhosis, (5) CPT B cirrhosis, or (6) CPT C cirrhosis. HCV RNA was measured using the Roche COBAS® Ampliprep®/Cobas TaqMan HCV Test, Version 2.0 (CAP/CTM HCV v2.0) with a lower limit of quantification (LLOQ) <15 IU/mL detected or HCV RNA not detected.

Table (abstract P0872).

	Advanced liver disease pre-transplantation (N = 108)		Post-transplantation (N = 223)			
	CPT B (N = 59)	CPT C (N = 49)	F0–F3 (N = 111)	CPT A (N = 51)	CPT B (N = 52)	CPT C (N = 9)
Overall SVR12, n/N (%)	50/57 (88)	37/42 (88)	108/111 (97)	49/51 (96)	37/44 (84)	5/8 (63)
Week 2 <LLOQ, n/N (%)	23/59 (39)	19/49 (39)	50/110 (45)	16/51 (31)	13/51 (25)	3/9 (33)
Week 2 TND, n/N (%)	7/59 (12)	5/49 (10)	28/110 (25)	6/51 (12)	6/51 (12)	0/9 (0)
Week 4 <LLOQ, n/N (%)	49/59 (83)	45/49 (92)	98/110 (89)	43/51 (84)	41/51 (80)	9/9 (100)
Week 4 TND, n/N (%)	25/59 (42)	28/49 (57)	69/110 (63)	24/51 (47)	24/51 (47)	5/9 (56)
Week 6 <LLOQ, n/N (%)	59/59 (100)	47/48 (98)	108/110 (98)	50/50 (100)	51/51 (100)	9/9 (100)
Week 6 TND, n/N (%)	51/59 (86)	42/48 (88)	97/110 (88)	44/50 (88)	45/51 (88)	8/9 (89)

Results: The percent of patients who were LLOQ by Weeks 2, 4 and 6 is shown in the table.
Conclusions: 12 or 24 weeks of treatment with LDV/SOF+RBV was highly efficacious in patients with advanced liver disease or who were post transplantation. The majority of subjects achieved HCV RNA target not detected (TND) at Week 4. Early on-treatment viral kinetics were similar among patient groups: advanced liver disease CPT class B or C, and in patients post transplantation with varying degrees of fibrosis and cirrhosis. An analysis of the relationship between viral decline at on-treatment weeks 2, 4, and 6, presence of NS5A RAVs, and relapse will be presented.

P0873
OMBITASVIR/PARITAPREVIR/RITONAVIR AND DASABUVIR WITH RIBAVIRIN (RBV) HAS MINIMAL IMPACT ON HEALTH-RELATED QUALITY OF LIFE (HRQOL) COMPARED WITH PLACEBO DURING 12-WEEK TREATMENT IN TREATMENT-NAÏVE ADULTS WITH CHRONIC HEPATITIS C (CHC)

Y. Liu[1], L. Larsen[1], S. Zeuzem[2], E. Coakley[1], R. Baran[1], T. Juday[1].
[1]Abbvie Inc, North Chicago, United States; [2]Wolfgang Goethe University Hospital, Frankfurt, Germany
E-mail: Yan.Liu@abbvie.com

Background and Aims: Interferon can negatively impact patient HRQoL during CHC treatment. We assessed the HRQoL impact of an interferon-free all-oral CHC therapy – ombitasvir/paritaprevir (identified by AbbVie and Enanta)/ritonavir and dasabuvir with RBV (3D+RBV) – compared with placebo in treatment naïve, non-cirrhotic, Genotype 1 (GT1) adults during 12 weeks of treatment in the Phase 3 trial SAPPHIRE-I.
Methods: Patients were randomized in a 3:1 ratio to 3D+RBV or placebo and treated during a 12-week double-blind period. HRQoL was assessed using the SF-36 v2 Health Survey (SF-36) which was administered at baseline, during treatment, and at end of treatment (EOT) for both treatment groups, and at post-treatment (PT) visits for the 3D+RBV group only. Physical Component Summary (PCS) and Mental Component Summary (MCS) scores were calculated for the SF-36. Summary statistics of change from baseline, including mean and standard deviation (SD), were generated for each visit by treatment group. A repeated measures analysis of covariance (RM-ANCOVA) was carried out for PCS and MCS, respectively, to determine the mean difference in adjusted scores between treatment groups during the 12-week treatment period. The factors in the RM-ANCOVA analysis were treatment group and visit and covariates were baseline PCS score, MCS score, and patient characteristics.
Results: The analysis included 473 patients on 3D+RBV and 158 on placebo. HRQoL results are summarized in Table. At EOT, greater changes from baseline PCS and MCS scores were observed in the 3D+RBV group (−1.3 in PCS and −3.7 in MCS) compared with the placebo group (+0.7 for PCS and −2.0 for MCS). At both PT visits, PCS and MCS scores for 3D+RBV patients were improved over baseline (PCS: +0.5 at week 4 and +1.4 at week 12; MCS: +0.3 at week 4 and +2.0 at week 12). Results from RM-ANCOVA demonstrated that the adjusted mean decrements in PCS and MCS scores over the 12 week treatment period in the 3D+RBV group were greater than in the placebo group, but neither difference was statistically significant – 0.98 greater decrement in PCS (95% CI, −0.11 to 2.07) and 1.39 greater decrement in MCS (95% CI, −0.00 to 2.77).
Conclusions: During the 12-week treatment period in SAPPHIRE-I, the interferon-free all-oral 3D+RBV regimen had minimal impact on patient HRQoL compared with placebo. Post-treatment scores for 3D+RBV showed improvement over baseline.

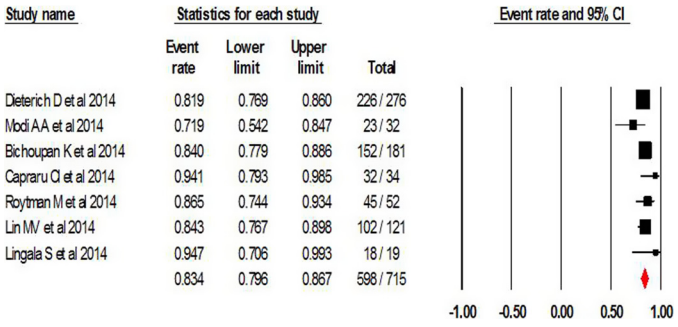
P0874
OUTCOMES OF 12-WEEK THERAPY WITH SIMEPREVIR + SOFOSBUVIR +/− RIBAVIRIN (SMV+SOF±RBV): A META-ANALYSIS OF 7 STUDIES AND 715 HCV GENOTYPE 1 (HCV-1) PATIENTS

B.E. Yee[1], N.H. Nguyen[1], G.A. Lutchman[2], J.K. Lim[3], M.H. Nguyen[2].
[1]School of Medicine, University of California, San Diego, La Jolla, [2]Department of Gastroenterology and Hepatology, Stanford University Medical Center, Palo Alto, [3]Yale Liver Center, Yale University School of Medicine, New Haven, United States
E-mail: mindiehn@stanford.edu

Background and Aims: SVR12 with 12-week SMV+SOF±RBV therapy was shown to be high for HCV GT1 patients in COSMOS study, but its generalizability is limited due to small sample size in a highly controlled clinical trial. Less is known about the effectiveness of the regimen in a real-life setting. Our goal was to perform a meta-analysis of real-world data evaluating the effectiveness of SMV+SOF±RBV.
Methods: A comprehensive literature search for 'simeprevir' in MEDLINE and major liver meetings in 2014 (AASLD, APASL, DDW, EASL, and World Transplant Congress) was performed and data was extracted in November 2014 by two authors using a case report form (BY and NN) with discrepancies resolved by consensus with a third author (MN). We included studies with SVR12 data that had ≥5 HCV GT1 patients treated with SMV+SOF±RBV for 12 weeks. Those who had prior liver transplantation or were co-infected with HIV or HBV were excluded. Primary endpoint was pooled effect sizes for SVR12 with random effects modeling. To evaluate study heterogeneity, Cochrane Q-test (p-value <0.10) with I^2 statistic (>50%) was determined.
Results: Seven studies with a total of 715 HCV GT1 patients were included. All were non-randomized cohorts. The majority of patients were male (range 57–81%). Many had advanced fibrosis (range 45–64%). Overall rate of SVR4 was 91.6% (CI: 87.5–94.5%) and SVR12 was 83.4% (CI: 79.6–86.7%). Three studies had SVR12 data sub-grouped by severity of fibrosis (n = 296, 147 with mild fibrosis and 149 with advanced fibrosis). Definition of advanced fibrosis was variable and included METAVIR F3–F4 or cirrhotic patients. SVR12 rate was 89.7% (CI 79.0–95.3%) in patients with mild fibrosis and 76.2% (CI 68.6–82.4%) in advanced fibrosis. By direct comparison, a trend was found favoring SVR12 for patients with mild fibrosis over advanced fibrosis (OR 2.66, CI 0.816–8.650; *p*-value = 0.105). Data was insufficient to allow evaluation of adverse events or subanalysis for outcomes of SMV+SOF with and without RBV or treatment naïve and experienced patients.

Table (abstract P0874).

Author, year	Setting	Collaboration	Intention-to-treat analysis	Patients with SVR12 data	Age (years)	Male, N (%)	Advanced fibrosis, N (%)
Dietrich D et al., 2014	Mixed	Multicenter	Yes	276	Mean 59	181 (57)	145 (45)
Modi AA et al., 2014	Community	Multicenter	Yes	32	Median 59	34 (76)	–
Bichoupan K et al., 2014	University	Single center	No	181	Median 62	-	96 (53)
Capraru CI et al., 2014	University	Single center	No	34	Mean 57.7	31 (66)	–
Roytman M et al., 2014	University	Single center	No	52	Mean 61.5	63 (64)	63 (64)
Lin MV et al., 2014	University	Multicenter	No	121	Mean 57.7	103 (70)	84 (57)
Lingala S et al., 2014	University	Single center	No	19	Mean 59	16 (64)	–



Conclusions: Pooled rate of SVR12 was approximately 83% in SIM+SOF±RBV for 12 weeks based on cohort studies from real-world settings which include a large proportion of patients with advanced fibrosis and/or prior treatment failure and slightly lower than reported rated from clinical trial, suggesting the importance of examining treatment effectiveness in diverse real-world patients in addition to treatment efficacy seen in highly selected clinical trial patients.

P0875

PREDICTORS OF SUSTAINED VIRAL RESPONSE TO 4–6 WEEK DURATION THERAPY WITH LEDIPASVIR + SOFOSBUVIR + GS-9451 +/− GS-9669 IN EARLY AND ADVANCED FIBROSIS (NIH/UMD SYNERGY TRIAL)

S. Kattakuzhy[1], S. Sidharthan[1], E. Wilson[2], A. Price[1], R. Silk[1], C. Gross[1], E. Akoth[1], E. Meissner[3], G. Teferi[4], V. Jenkins[5], P. Pang[6], H. Mo[6], A. Osinusi[6], H. Masur[7], S. Kottilil[1], A. Kohli[2]. *[1]Department of Infectious Diseases, University of Maryland/Institute of Human Virology, Baltimore, [2]Clinical Research Directorate/Clinical Monitoring Research Program, Leidos Biomedical Research, Inc. (formerly SAIC – Frederick, Inc.), Frederick National Laboratory for Cancer Research, Frederick, [3]Division of Infectious Diseases, Medical University of South Carolina, Charleston, [4]Infectious Disease, Unity Healthcare, Inc., [5]Department of Medicine, Family Medical Counseling Services, Inc., Washington, DC, [6]Gilead Sciences, Foster City, CA, [7]Critical Care Department, National Institutes of Health, Bethesda, United States*
E-mail: sarah.kattakuzhy@nih.gov

Background and Aims: Directly-acting antivirals (DAA) have simplified the treatment of hepatitis C into a highly efficacious regimen delivered in as little as 6 weeks. However, limited data exists to define minimum duration of therapy or applicability in advanced liver disease. The aim of the current study is to further eluciate treatment length and predictive factors of response in two cohorts: LDV/SOF + GS-9451 +/− GS-9669 for four weeks in treatment naïve, early fibrosis patients; and LDV/SOF + GS-9451 for six weeks in advanced fibrosis patients, both treatment naïve and experienced.
Methods: In this single-center, open label, phase 2a trial, 100 HCV monoinfected participants were sequentially enrolled into three treatment arms. Treatment naive patients with F0–F2 fibrosis received LDV/SOF + GS-9451 (n = 25) or LDV/SOF + GS-9451 + GS-9669 (n = 25) for 4 weeks. Patients with F3–F4 fibrosis received LDV/SOF + GS-9451 for 6 weeks (n = 25 treatment naïve, n = 25 IFN-treatment experienced). HCV RNA was measured using Roche COBAS Taqman v2.0 assay with a LLOQ of 25 IU/ml. Primary endpoint was sustained virologic response defined as HCV RNA BLLOQ 12 weeks post-treatment (SVR12). Pretreatment serum samples were analyzed for resistance-associated variants (RAV) in the early stage group.
Results: In the early fibrosis cohort, 9/25 (36%) patients receiving LDV/SOF + GS-9451 achieved SVR12, and 5/25 (20%) receiving LDV/SOF + GS-9451 + GS-9669 achieved SVR12. One patient in each group was lost to follow up. Male gender ($p = 0.03$) and baseline HCV VL ($p < 0.0001$) were risk factors for viral relapse in univariate analysis. No patient with a pre-treatment HCV viral mutant conferring >5 fold resistance achieved SVR. In the advanced fibrosis cohort, 22/22 (100%) achieved EOT viral suppression. 6/11 (54.5%) treatment naïve and 5/9 (55.6%) treatment experienced patients achieved SVR12. Data collection and sequencing in this cohort is ongoing, and complete data will be presented.
Conclusions: In this small cohort study, DAA-based treatment for four and six weeks in early and advanced fibrosis, respectively, was effective in select patients. Female patients and those with a low baseline HCV VL were more likely to achieve SVR12. Short treatment durations were not effective in early fibrosis patients with baseline high-level resistance mutants. Larger studies are required to further characterize the biologic correlates in this unique group of responders to short duration therapy, with critical implications on both an individual and public health level.

P0876

SAFETY AND EFFICACY OF SIMEPREVIR/SOFOSBUVIR IN HEPATITIS C (HCV) INFECTED PATIENTS WITH VARYING SEVERITY OF CIRRHOSIS: COMPARISON TO MATCHED UNTREATED AND PROTEASE INHIBITOR (PI)-TRIPLE THERAPY TREATED CONTROLS

Terrault[1]. *[1]University of California San Francisco, San Francisco, [2]Kaiser Permanente Southern California, San Diego, [3]Kaiser Permanente Northern California, Oakland, [4]Kaiser Permanente Colorado, Denver, [5]Kaiser Permanente Mid-Atlantic, Rockville, United States*
E-mail: varun.saxena@ucsf.edu

Background and Aims: All-oral therapy offers safety advantages for patients with decompensated cirrhosis. The risks/benefits of simeprevir (SIM) plus sofosbuvir (SOF) in patients with Child–Pugh (CP) B/C cirrhosis are unknown. We aim to assess safety and sustained virologic responses (SVR) of SIM+SOF±ribavirin (RBV) in CP-B/C vs CP-A cirrhosis and to compare results to matched untreated and PI (telaprevir or boceprevir)-triple therapy treated controls.
Methods: Multicenter cohort of adults with HCV genotype 1 cirrhosis treated with SIM+SOF±RBV who have completed ≥4 weeks of therapy (n = 160). Safety and SVR12 outcomes by CP-B/C vs CP-A were examined. Up to 3 untreated and PI-triple therapy

treated controls matched on site, age±5 yrs, CP class (A vs B/C) and model for end-stage liver disease score (MELD) ±2 were randomly selected.

Results: SIM+SOF±RBV (35%/65%) was used for goal duration of 12 weeks; 36% had CP-B/C and 64% CP-A cirrhosis. Cohort median age was 62 yrs (IQR 58–65), with 39% female, 11% Hispanic, 16% Black, 27% diabetes, median platelet count 98K/mm^3 (IQR 73–140), median albumin 3.6 g/dL (IQR 3.1–4), median MELD 9 (IQR 8–11), 25% with ascites, 23% with hepatic encephalopathy, 15% with varices, 56% treatment experienced, 62% genotype 1a (44% Q80K positive [n = 25]). CP-B/C vs CP-A had more early treatment discontinuations (11% vs 1%), adverse events (AEs) requiring hospitalization (22% vs 2%), infections receiving parenteral antibiotics (20% vs 1%) and decompensating events (20% vs 3%) (all $p < 0.01$). There were 2 deaths: 1 CP-B/C (liver-related) and 1 CP-A (not liver-related). Among eligible patients (n = 104), SVR12 was achieved by 66% of CP-B/C vs 93% of CP-A ($p < 0.01$). In multivariate analysis, CP-A independently predicted SVR12 (OR 7.68, 95% CI 2.13–27.7). Compared to PI-triple therapy, SIM+SOF±RBV patients more frequently achieved SVR12 with fewer early discontinuations, AEs requiring hospitalization, infections requiring parenteral antibiotics and decompensation (Figure). Safety outcomes occurred at similar frequency to matched untreated controls (Figure).

Conclusions: CP-B/C treated with SIM+SOF±RBV for 12 weeks have significantly more adverse events and reduced SVR rates compared to CP-A. However, SIM+SOF±RBV are both safer and more efficacious than prior PI-triple therapy. Frequency of AEs, infections and decompensation were similar to matched untreated controls suggesting safety outcomes seen with SIM+SOF±RBV therapy is reflective of the natural history of cirrhosis and are not drug-specific.

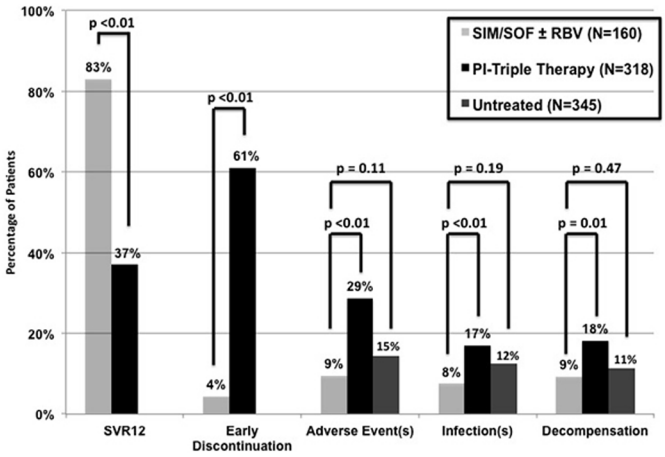


Figure: Virologic and safety outcomes, SIM/SOF±RBV vs. matched PI-triple therapy controls and matched untreated controls.

HCV RNA LEVELS ASSESSED AT EARLY STAGES OF SOFOSBUVIR/RIBAVIRIN DUAL THERAPY IDENTIFY RELAPSE PATIENTS

B. Maasoumy[1], J. Vermehren[2], C. Berkowski[2], B. Bremer[1], G. Cloherty[3], D. Perner[2], M.P. Manns[1], S. Zeuzem[2], M. Cornberg[1], H. Wedemeyer[1], C. Sarrazin[2]. *[1]Department of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, [2]Department of Medicine 1, JW Goethe-University Hospital, Frankfurt, Germany; [3]Abbott Molecular, Des Plaines, United States*
E-mail: maasoumy.benjamin@mh-hannover.de

Background and Aims: Current EASL guidelines recommend HCV RNA measurements at specific time points of sofosbuvir (SOF) therapy to ensure treatment efficacy. However, it is not well studied, how HCV RNA results during SOF-including regimens have to be interpreted.

We here aimed to analyse whether HCV RNA levels during different approved SOF-based therapies predict the final treatment outcome comparing the COBAS TaqMan (CTM) and the Abbott RealTime (ART) assay.

Methods: Samples were collected from consecutive HCV-monoinfected patients (genotype 1–5) at weeks (w) 0, 1, 2, 4, 8, 12, 16, 20 and 24 of SOF-based treatments at two German University clinics (Frankfurt, Hanover) and tested for quantitative HCV RNA by CTM and ART. 171 patients with at least 4w follow up post treatment were included. 87 patients were treated with SOF/ribavirin (RBV), 43 with SOF/RBV and pegylated-interferon alfa (PEG-IFN), 39 with SOF and a second direct acting antiviral (DAA), either simeprevir (n = 35) or daclatasvir +/− RBV (n = 5).

Results: All SOF/DAA, 95% of SOF/PEG-IFN/RBV and 98% of SOF/RBV treated patients were HCV RNA negative with both assays at the end of therapy. Relapse occurred in 10%, 5% and 33%, respectively. HCV RNA levels during the first four weeks of SOF/DAA and SOF/PEG-IFN/RBV treatment did not differ between relapse and SVR patients. In contrast, during SOF/RBV treatment HCV RNA levels were significantly higher in relapse patients according to both CTM and ART at w1 ($p < 0.0001$; and $p = 0.0005$), w2 ($p < 0.0001$ and $p < 0.0001$) and w4 ($p = 0.0002$ and $p = 0.0006$). Patients with an HCV RNA level of >40 IU/ml by CTM or >20 IU/ml by ART at w2 had a significantly lower chance to achieve SVR (28% vs. 92%, $p < 0.0001$ and 43% vs. 96%, $p < 0.0001$, respectively). Sensitivity to detect relapse patients was 85% and 96%, respectively.

By w8 the far majority of SOF/DAA treated patients was HCV RNA undetectable by CTM (97%), while almost half of the patients were detectable by ART (48%). Detectable patients had a lower but still reasonable SVR rate (70% vs. 100%, $p = 0.09$). All three patients with a detectable HCV RNA at w8 of SOF/PEG-IFN/RBV therapy (all by ART) and even one tested positive at the end of SOF/PEG-IFN/RBV therapy achieved SVR.

Conclusions: The predictive value of on-treatment HCV RNA levels seems to be limited for highly potent regimens including SOF and either a second DAA or PEG-IFN. In contrast, early on-treatment HCV RNA levels are closely associated with the outcome of SOF/RBV therapy.

P0878

FIRST RIBAVIRIN-FREE SOFOSBUVIR AND SIMEPREVIR TREATMENT OF HEPATITIS C GENOTYPE 1 PATIENTS WITH SEVERE RENAL IMPAIRMENT (GFR <30 mL/min OR DIALYSIS)

F. Czul[1], E. Schiff[1], A. Peyton[1], C. Levy[1], M. Hernandez[1], L. Jeffers[1], C. O'Brien[1], P. Martin[1], K.R. Bhamidimarri[1]. *[1]Hepatology, University of Miami-Miller School of Medicine, Miami, United States*
E-mail: dr_ram7@yahoo.com

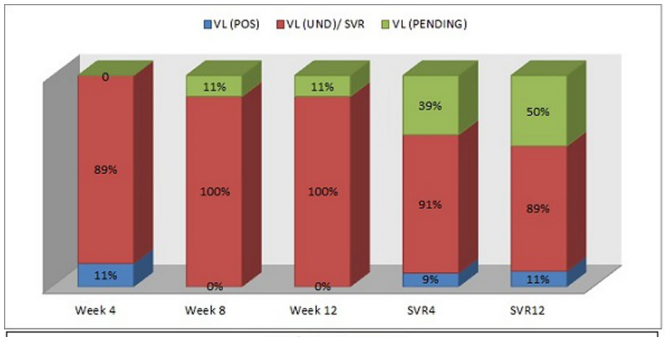
Background and Aims: Hepatitis C (HCV) prevalence in hemodialysis (HD) patients is approximately 13.5% which is significantly higher than the prevalence in general population. However, there is limited data on the use of direct acting antivirals (DAA) or ribavirin-free regimen in this cohort. Our aim is to present the preliminary results of the first ribavirin-free regimen (sofosbuvir and simeprevir) to treat HCV genotype 1 (GT) patients with severe renal impairment (GFR <30 ml/min or HD).

Methods: Eighteen HCV patients (11 GT1a, 7 GT1b) with severe renal impairment (15 on HD, 3 with mean GFR of 16 ml/min) underwent open label treatment with sofosbuvir and simeprevir. Sixteen patients had advanced fibrosis (>F2) and 10 patients had cirrhosis (56%). All patients received full dose simeprevir of 150 mg daily. Sofosbuvir dose was reduced to 200 mg daily in 15 patients and 400 mg every other day in 3 patients. The length of therapy was 12 weeks in 17 patients. Treatment duration was extended to 24 weeks in 1 cirrhotic patient who had low level viremia at week

4. Sixteen patients had completed treatment and 2 others are still undergoing treatment at their 7th and 16th weeks.

Results: All patients had excellent on-treatment response and became aviremic by 8 weeks (2 patients had low level viremia at week 4). One patient developed new onset hepatic encephalopathy and another developed uncontrolled diarrhea, both requiring hospitalizations during treatment. Minor AE's fatigue (28%), anemia (11%), rash/itching (11%) and nausea (5%) were managed medically and there were no treatment discontinuations. Of the 16 patients who completed treatment, only 9 patients reached relevant milestones. As per the current per-protocol analysis, SVR4 was seen in 91% and SVR12 in 89%. One cirrhotic patient (prior PI failure) relapsed within 4 weeks after completion of the treatment. We are still following the response in 9 other patients which will be presented at the time of EASL meeting.

Conclusions: Simeprevir and reduced dose sofosbuvir is safe, well tolerated and efficacious in HCV GT 1 patients with preliminary SVR4 of 91% and SVR12 of 89%. Our data represents the first ribavirin-free DAA regimen in this difficult to treat cohort of HCV with severe renal impairment or HD.



Virologic Response						
	Week 4 N=18	*Week 8 N=17*	*Week 12 N=17*	*Week 24 N=1*	*SVR 4 N=11*	*SVR 12 N=9*

P0879

EXAMINING THE CLINICAL COURSE OF GENOTYPE 1 CHRONIC HEPATITIS C PATIENTS TREATED WITH THE COSMOS REGIMEN: INCLUDING PATIENTS WITH ADVANCED LIVER DISEASE, AND EAST ASIAN ANCESTRY

M. Roytman[1,2], R. Ramkissoon[2], L. Hong[1], R. Trujillo[1], L. Huddleston[1], P. Poerzgen[1], T. Seto[3], N. Tsai[1,2]. *[1]Queen's Liver Center, [2]John A. Burns School of Medicine, [3]Queen's Hospital, Honolulu, United States*
E-mail: resham@hawaii.edu

Background and Aims: The COMSOS phase 2 trial showed high cure rates and a favorable side effect profile of a 12-wk regimen of Sofosbuvir (SOF) and Simeprevir (SIM) in patients with a genotype 1 Hepatitis C infection. However, given the small number of patients in the COSMOS trial, there is uncertainty regarding the efficacy and safety of this combination therapy. We now report our experience with the COSMOS regimen in the multiethnic population of Hawaii, including patients of East Asian ancestry and decompensated cirrhosis.

Methods: Retrospective review of 99 patients treated with a fixed dose regimen of SIM 150 mg and SOF 400 mg daily, beginning January 2014 at a single referral center. We collected data on demographics, side effects, laboratory studies and SVR (sustained virological response). Statistical analysis was performed with Stata v8.2 software.

Results: 99 patients began treatment prior to October 2014. Baseline characteristics: 63.3% cirrhotic (18.2% of those Child–Pugh Class B/C), 38% Asian, 12% Pacific Islander, 64% male, mean age 61.5±8.4, mean BMI 27±5.9, 62% diabetic, 62% genotype 1a, 22/42 IL28B non-CC genotype, 7/32 positive for Q80K mutation.
At interim analysis, 72 patients have reached week 4 and 45 have reached week 12 post-treatment. Overall, the SVR12 rate is 86.5%. 100% decompensated cirrhotic patients achieved SVR12, compared to 85.2% of cirrhotic patients and 82.1% of non-cirrhotic patients. 90% of Asian patients reached SVR12 compared to 84% of non-Asians. Treatment naive patients had higher SVR12 rates than treatment experienced patients (96% vs 82%). Main side effects: headache 16.2%, fatigue 24.2%, pruritis 14.1%; none were >grade 2 in severity. There were no differences in side effect profiles of patients with decompensated cirrhosis. Pruritis was the only statistically significant difference between Asians and non-Asians (24% vs 8%).

Conclusions: The 12 week fixed dose course of SIM+SOF was well tolerated in a multiethnic population of primarily cirrhotic patients, including those with decompensated disease, with the SVR12 rates at interim analysis comparable to COSMOS data. There was a trend toward better SVR12 rates in patients with decompensated cirrhosis and of Asian ancestry possibly due to higher Simeprevir exposures. Higher incidence of adverse side effects was not observed with an exception of higher rate of pruritis in Asians. Complete data on SVR4 and SVR12 will be available on all patients by April 2015.

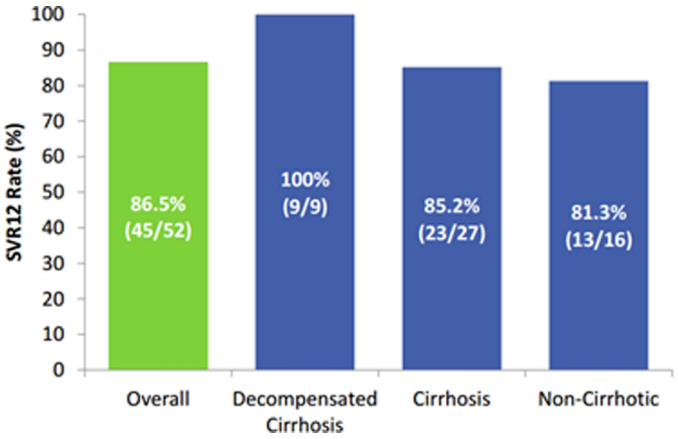

Figure 1. SVR12 rates according to levels of fibrosis.

PHARMACOGENOMIC STUDY TO PREDICT RIBAVIRIN AND PROTEASE-INHIBITOR-RELATED ANEMIA IN HEPATITIS C

J. Ampuero[1], L. Rojas[1], J.A. Del Campo[1], J.L. Calleja[2], J. Crespo[3], X. Forns[4], R. Andrade[5], M. Buti[6], I. Fernández[7], R. Millán[1], M. Romero-Gómez[1]. *[1]Unit for the Clinical Management of Digestive Diseases, Valme University Hospital, Sevilla, [2]Hospital Puerta de Hierro, Madrid, [3]Hospital Marqués de Valdecilla, Santander, [4]Hospital Clinic and IDIBAPS, Barcelona, [5]Hospital Virgen de la Victoria, Málaga, [6]Hospital Vall d'Hebrón, Barcelona, [7]Hospital 12 de Octubre, Madrid, Spain*
E-mail: javi.ampuero@gmail.com

Background and Aims: Anemia is a frequent adverse effect, associated with ribavirin (RBV), in patients with hepatitis C (HCV). It has become the main limitation, in terms of safety, of the addition of first-generation protease inhibitors. We aimed to assess the impact of genes ITPA and SLC28A3 on HCV patients receiving peginterferon (PEG-IFN) + RBV + Boceprevir or Telaprevir.

Methods: Multicenter study including 161 patients with HCV genotype 1. Patients were divided according to treatment: (a) Telaprevir 750 mg/8 h for 12 weeks + PEG-IFN + RBV 48 weeks (n = 95); (b) Boceprevir 800 mg/8 h for 44 weeks + PEG-IFN + RBV 48 weeks (including lead-in phase) (n = 66). We genotyped: (a) ITPA (rs1127354, rs6051702, rs7270101); (b) SLC28A3 (rs56350726, rs10868138, rs11854484). We defined clinically

significant anemia when, at least, one of the following aspects happened: (a) hemoglobin <8.5 g/dL during treatment; (b) blood transfusion requirement; (c) erythropoietin use.
Results: Clinically significant anemia occurred in 43.9% (69/157) of patients, regardless of Boceprevir (37.7%; 20/53) or Telaprevir use (47.1%; 49/104) (p = 0.263). RBV dose was reduced in 62.1% (100/161) of patients, erythropoietin was used in 34.8% (55/158) and 16.4% (26/159) required blood transfusion. SLC28A3 rs11854484 was associated with clinically significant anemia [CC/CT genotypes 33.3% (26/78) *vs.* TT genotype 56.3% (36/64) (p = 0.006)]. Furthermore, it was related to the needed of transfusion [CC 0% (0/18) *vs.* CT 13.1% (8/61) *vs.* TT 26.6% (17/64), p = 0.016]. Similarly, ITPA rs1127354 was linked to clinically significant anemia [AA/AC genotypes 18.8% (3/16) *vs.* CC genotype 45.2% (61/135), p = 0.043]. In multivariate analysis, SLC28A3 rs11854484 TT genotype (OR 2.25, 95% CI 1.03–4.90; p = 0.042), female sex (OR 2.97, 95% CI 1.27–6.94; p = 0.012) and Hb drop at week 4 (OR 1.48, 95% CI 1.19–1.85; p = 0.0001) were independently associated with clinically significant anemia.
Conclusions: In patients receiving first generation protease inhibitors, SLC28A3 rs11854484 predicted clinically significant anemia. Additionally, SLC28A3 rs11854484 genotype CC protected from blood transfusion, identifying a subgroup of patients with better tolerance to triple therapy. The impact of these SNPs on RBV-based IFN-free regimen requires further studies.

P0881
REAL WORLD EFFECTIVENESS AND COST OF SIMEPREVIR- AND/OR SOFOSBUVIR-BASED HCV TREATMENTS: $175,000 PER SVR12

K. Bichoupan[1], N. Tandon[2], D. Del Bello[3], N. Patel[1], R. Yalamanchili[1], S. Chekuri[1], A. Harty[1], S. Chang[1], L. Ku[1], M. Ng[1], D.B. Motamed[1], K.M. Sigel[1], D. Gardenier[1], A. Stivala[1], V. Khaitova[1], M.B. Bansal[1], P. Grewal[1], R. Agarwal[1], C.Y. Chang[1], J. Leong[1], G.Y. Im[1], L.U. Liu[1], J.A. Odin[1], N. Bach[1], S.L. Friedman[1], T.D. Schiano[1], P. Perumalswami[1], D.T. Dieterich[1], A.D. Branch[1]. *[1]Division of Liver Diseases, Icahn School of Medicine, New York, NY, [2]Janssen Scientific Affairs, LLC, Titusville, NJ, [3]Department of Infectious Diseases, Icahn School of Medicine, New York, NY, United States*
E-mail: kian.bichoupan@mssm.edu

Background and Aims: Simeprevir- (SMV) and/or sofosbuvir- (SOF) based regimens were effective in clinical trials, but data on their performance in real world clinical practice are needed.
Methods: Data were collected on the complete cohort of patients with chronic HCV infection who started treatment at the Mount Sinai Medical Center (MSMC) after SMV and SOF received FDA approval (12/2013–6/2014). Patients with HIV infection or liver transplantation were excluded. Data on 223 patients treated with telaprevir (TVR)/boceprevir (BOC) were included for comparison (Bichoupan et al., Hepatology, 2014). Advanced fibrosis/cirrhosis was defined as a FIB-4 score ≥3.25. Sustained virologic response-12 (SVR12) was defined as an undetectable HCV RNA 12 weeks after the end-of-treatment (EOT). Costs of treatment included laboratory tests, physician fees, adverse event management and pharmaceuticals, which were obtained from the Red Book Wholesale Acquisition Cost database.
Results: The SMV/SOF era cohort included 514 patients on regimens that contained SMV and/or SOF. The median age was 60 yr [interquartile range (IQR): 54–64 yr], 54% had a FIB-4 score ≥3.25, 14% were black, and 40% were previously untreated. In comparison to the TVR/BOC cohort, the SMV/SOF cohort was significantly older (59 vs. 55 yr, p < 0.01), had lower albumin (3.90 g/dL vs. 4.15 g/dL, p < 0.01), and had a higher percentage with FIB-4 ≥3.25 (54% vs. 44%, p = 0.02). In the SMV/SOF era cohort, 224 had sufficient follow up to evaluate SVR12: 210 (94%) completed therapy, 50 (22%) relapsed, 10 (5%) never became HCV viral load undetectable, and 2 (1%) died. Relapse after SVR4 was confirmed in 5 (3%). SVR rates for specific regimens are presented in Table 1. Among patients on SMV/SOF +/− RBV, those who failed on a prior protease-inhibitor had a lower SVR12 rate than other patients: 25/35 (71%) vs. 57/62 (92%), p = 0.02. The cost of care for the 224 patients was $28.3 million. Pharmaceuticals accounted for 97% of costs. Patients who failed therapy accounted for 30% of costs. The mean cost per SVR12 was about $175,000, which is lower than $178,000 for TVR-based treatment, but not significantly different (p = 0.62).

Table 1. Cost per SVR by drug regimen and genotype

Regimen (duration)	N (column%)	Total cost	SVR12 rate (%)	Cost per SVR12 (SD)
Total	224	$28,300,000	162/224 (72%)	$175,000 ($51,500)
SOF/RBV (12/24 weeks)	72 (32%)	$8,350,000	40/72 (56%)	$209,000 ($86,000)
Genotype 1 (24 weeks)	22 (30%)	$3,280,000	4/22 (18%)	$821,000 ($260,000)
Genotype 2 (12/16 weeks)	41 (57%)	$3,800,000	34/41 (83%)	$112,000 ($29,000)
Genotype 3 (24 weeks)	7 (10%)	$849,000	1/7 (14%)	$849,000 ($468,000)
Genotype 4 (24 weeks)	2 (3%)	$413,000	1/2 (50%)	$413,000 ($96,000)
SOF/PEG/RBV (12 weeks)	55 (25%)	$5,180,000	40/55 (73%)	$129,000 ($16,000)
Genotype 1 (12 weeks)	44 (80%)	$4,120,000	31/44 (70%)	$133,000 ($18,000)
Genotype 4 (12 weeks)	11 (20%)	$1,060,000	9/11 (82%)	$117,000 ($2,000)
SOF/SMV (12 weeks)	27 (12%)[a]	$4,140,000	22/27 (81%)	$188,000 ($4,450)
SOF/SMV/RBV (12 weeks)	70 (31%)	$10,700,000	60/70 (86%)	$178,000 ($14,000)

[a] One patient who received SOF/SMV was infected with genotype 4 HCV.

Conclusions: Patients treated with SMV and/or SOF regimens were older and had more advanced liver disease than those in the TVR/BOC cohort. Importantly, the overall SVR12 rate increased significantly while cost remained steady. Aging of the HCV population and worsening liver disease may contribute to reduced efficacy compared to clinical trials.

P0882
PILOT STUDY OF EZETIMIBE FOR CHRONIC HEPATITIS C INFECTION: EFFECT OF TREATMENT IN PLASMA, BILE AND STOOL VIRAL LOAD IN HUMANS

H. Monrroy[1], J. Angulo[2], K. Pino[2], J.F. Miquel[1], C. Benitez[1], M. Arrese[1], F. Barrera[1], B. Norero[1], R. Wolff[1], P. Labbe[1], M. Lopez-Lastra[2], A. Soza[1]. *[1]Gastroenterology, [2]Laboratory of Molecular Virology, Pontificia Universidad Católica de Chile, Santiago, Chile*
E-mail: hmonrroy@gmail.com

Background and Aims: Even though direct acting antivirals (DAAs) are showing impressive efficacy and safety in the treatment of hepatitis C virus (HCV) infection, the potential for resistance and high prices may still limit their broad use. Hence, it is of interest to continue exploring alternative host targeted therapies that could be used as complements to current DAAs. A recently report showed that Niemann-Pick C1-Like 1 (NPC1L1) protein acts as a post binding HCV entry factor. Based on this observation in this study we evaluated the impact of ezetimibe treatment, an approved and safe NPC1L1 antagonist, on HCV viral load in plasma, bile and stools.
Methods: Patients with chronic HCV infection were studied after obtaining informed consent. Exclusion criterial included presence of gallstones or history of cholecystectomy, treatment with lipid-lowering therapy and antiviral therapy. Ezetimibe was administered in a dose of 10 mg two times a day for 12 weeks, along with a standardized diet. Patients underwent an upper endoscopy for obtaining bile samples at baseline and at weeks 4 and 12. Stool specimens were collected and preserved in RNALater™. Contamination of stools with occult blood was studied using an immunological human haemoglobin assay. PowerMicrobiome™ RNA Isolation Kit was used for RNA extraction from both bile and stools. HCV RNA level was measured in plasma, bile and stools with Roche COBAS Taqman v2™.
Results: Ten patients, with a mean age 63 years, predominantly genotype 1b and 50% cirrhotic, were recruited. At baseline, HCV RNA was detected in bile in 8 patients, with a median of 58 IU/mL, 4 logs lower than plasma viral load (median 2,044,500 IU/mL). In stools,

HCV RNA was detectable in 8 patients with a median of 125 IU/mL. Despite having a significant decrease in cholesterol level from 143 to 123 mg/dL (p = 0.04) after 12 weeks of treatment, plasma viral load decreased only 0.3 log (p = 0.2) in plasma. Similarly, non-significant decreases in bile and stool viral load were found (see table).

	Baseline	12 weeks	p
Age, years, mean±SD	62.6±7.7	–	–
Male gender, n (%)	5 (50%)	–	–
Cirrhosis, n (%)	5 (50%)	–	–
HCV genotype, n 1a / 1b / 3a	1 / 8 / 1	–	–
Body weight, kg, mean±SD	66.97±15.3	67.26±15.2	0.39
BMI, kg/m^2, mean±SD	24.52±2.69	24.62±2.53	0.41
ALT, U/mL, mean±SD	86±68	86±56	0.99
AST, U/mL, mean±SD	78±67	79±58	0.89
Bilirubin, mg/dL, mean±SD	1.0±0.75	1.1±0.8	0.70
Glucose, mg/dL, mean±SD	99±19	105±49	0.58
Plasma total cholesterol, mg/dL, mean±SD	143±36	123±30	0.04*
Plasma LDL cholesterol, mg/dL, mean±SD	64±25	51±15	0.04*
Plasma HDL cholesterol, mg/dL, mean±SD	54±15	56±22	0.59
Plasma triglycerides, mg/dL, mean±SD	86±44	84±44	0.82
Plasma viral load, mean log IU/mL ±SD	5.93±1.39	5.65±1.31	0.23
Bile viral load, mean log IU/mL ±SD	1.84±1.81	1.16±1.10	0.12
Stool viral load, mean log IU/g ±SD	1.71±1.02	1.65±0.99	0.87

Conclusions: Our results show that HCV RNA can be found and measured in bile and stools of infected patients. No significant changes in plasma, bile or stool viral load were demonstrated after ezetimibe treatment. The lack of response in humans, despite encouraging in vitro data, may be explained by a low expression level of NPC1L1 in the liver compared to the gut or by the lower exposure of liver NPC1L1 to ezetimibe *in vivo*.

P0883

TREATMENT FOR HEPATITIS C VIRUS INFECTION AMONG PEOPLE WHO INJECT DRUGS IN THE OPIOID SUBSTITUTION SETTING: THE ETHOS STUDY

Background and Aims: Assessment and treatment for hepatitis C virus (HCV) among people who inject drugs (PWID) is low and strategies are needed to enhance access to care. This study aims to evaluate the effectiveness of HCV treatment among PWID.
Methods: Enhancing Treatment for Hepatitis C in Opioid Substitution Settings (ETHOS) is a prospective observational cohort, evaluating a model for the provision of HCV assessment and treatment among people with a history of injecting drug use and chronic HCV. Recruitment occurred through six opioid substitution treatment (OST) clinics, two community health centres and one Aboriginal community controlled health organisation in NSW, Australia. Participants initiating pegylated interferon/ribavirin (PEG-IFN/RBV) treatment between February 2009 and December 2012 (genotype 1, G1) or June 2013 (genotypes 2 and 3, G2/3) were included, to allow for adequate post-treatment follow-up. Statistical analyses were performed using Chi-squared or Fisher's exact tests, as appropriate.
Results: Among 415 participants, 27% (n = 111) commenced treatment. Among those treated between 2009 and 2013 (n = 104, mean age 43 years, 77% male), 36% (n = 37) had injected drugs in the past six months and 62% (n = 64) were currently receiving OST. In an intent-to-treat analysis, the sustained virological response (SVR) was 65% overall (68 of 104), 69% in G1 (20 of 29) and 64% in G2/3 (48 of 75). There was no difference in SVR between those never (74%, 23 of 31) and currently (66%, 42 of 64, P = 0.484) receiving OST. SVR was similar among those who had injecting drugs in the past six months (70%, 26/37) compared to those who had not (64%, 43/67, P = 0.665).
Conclusions: Response to treatment in this population was high and active injecting drug use did not compromise treatment response. This data suggests that targeted initiatives to enhance HCV treatment in OST or community health clinics can be successful.

P0884

INTERFERON AND RIBAVIRIN-FREE THERAPY WITH SOFOSBUVIR AND DACLATASVIR IN A REAL-LIFE COHORT OF DIFFICULT-TO-TREAT HIV/HCV-COINFECTED PATIENTS WITH AND WITHOUT PORTAL HYPERTENSION

M. Mandorfer[1], S. Steiner[1], P. Schwabl[1], M.C. Aichelburg[2], K. Grabmeier-Pfistershammer[2], A. Rieger[2], M. Trauner[1], T. Reiberger[1], M. Peck-Radosavljevic[1], on behalf of Vienna HIV & Liver Study Group. *[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine III, [2]Division of Immunology, Allergy and Infectious Diseases, Department of Dermatology, Medical University of Vienna, Vienna, Austria*
E-mail: mattias.mandorfer@meduniwien.ac.at

Background and Aims: Despite promising results for the combination of sofosbuvir and daclatasvir (SOF/DCV) in patients with HCV-monoinfection, there are currently no reports on its use in HIV/HCV-coinfected patients (HIV/HCV). The aim of our study was to investigate the use of SOF/DCV in HIV/HCV, who have an urgent need for effective treatment options.
Methods: All patients were treated with once-daily SOF (400 mg) and DAC. The dose of DAC was adjusted to the cART regimen, as recommended by the European label. The following treatment durations will be applied: HCV-genotype (HCV-GT) 1/4 with previous HCV protease inhibitor (PI) failure or cirrhosis: 24 weeks; HCV-GT3: 24 weeks; all other patients: 12 weeks. HCV-RNA was assessed using the Abbott RealTime HCV assay with a lower limit of quantification (LLOQ) and detection of 12 IU/mL.
Results: All of the 15 patients who have started SOF/DAC were on cART. Six (40%) patients were treatment experienced, including 2 (13%) patients with previous PI failure. The majority of patients had HCV-GT1a (10 [67%]), while HCV-GT3 and 4 were observed in 4 (27%) patients and 1 (7%) patient, respectively. Eleven (73%) patients had high baseline HCV-RNA levels (>600,000 IU/mL) and 14 (93%) patients had the IL28B non-C/C genotype. All patients had either F3 fibrosis (5 [33%]), cirrhosis (7 [47%]), or an extrahepatic manifestation of CHC (3 [20%]). These were cryoglobulinemia with leg ulcers, cryoglobulinemia with glomerulonephritis and end stage renal disease, as well as primary central nervous system lymphoma. The median liver stiffness was 10.2(12.7) kPa and the mean hepatic venous pressure gradient (HVPG) among patients with advanced fibrosis was 9.1±4.5 mmHg. Portal hypertension (HVPG ≥6 mmHg) and clinically significant portal hypertension (CSPH; HVPG ≥10 mmHg) were observed in 9 (60%) and 5 (33%) patients, respectively. At week 4, 1/5 patients had HCV-RNA <LLOQ, while at week 8, 2/5 patients had HCV-RNA <LLOQ and 1/5 patients achieved undetectable HCV-RNA.
The results will be updated prior to the presentation at the meeting to include more than 30 difficult-to-treat HIV/HCV as well as preliminary sustained virologic response rates.
Conclusions: The combination of SOF/DCV allows for the IFN and RBV-free treatment of nearly all HIV/HCV, including patients with cirrhosis and CSPH or extrahepatic manifestations. Results from

our thoroughly documented real-life cohort will provide important evidence for the use of SOF/DCV in this special population.

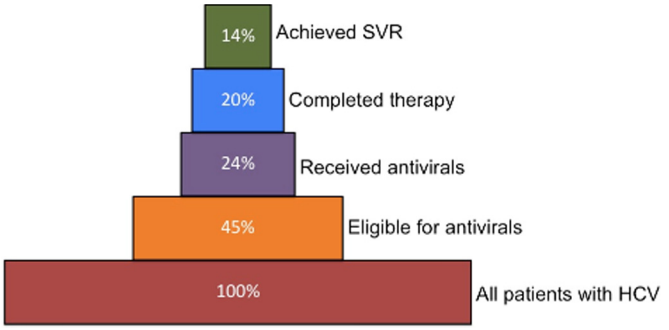
MOST PATIENTS OF HEPATITIS C VIRUS INFECTION IN INDIA PRESENT LATE FOR ANTIVIRAL TREATMENT: AN EPIDEMIOLOGICAL STUDY FROM A NORTH INDIAN CENTER

V. Gupta[1], A. Kumar[1], P. Sharma[1], A. Arora[1]. [1]*Department of gastroenterology and hepatology, Sir Ganga Ram Hospital, New Delhi, India*
E-mail: varun_doc@yahoo.co.in

Background and Aims: Antiviral therapy with Peg-interferon and Ribavirin is offered only to those patients of HCV who are in stage of chronic hepatitis or early cirrhosis. Patients of advanced liver disease do not tolerate this therapy. Since HCV is asymptomatic in early stages and usually presents with advanced disease, the eligibility for antiviral therapy is thus limited. There are no studies from India, which look into clinical spectrum of HCV infection at presentation, with reference to the eligibility and success of antiviral treatment. Our aim is to study the spectrum of presentation of HCV infection, determine their eligibility for antiviral treatment, and follow those treated for treatment response.
Methods: The records of all consecutive patients of HCV, >14 years age, who presented to our department between 2010 and 2014, were analyzed for categorization into chronic hepatitis, cirrhosis and hepatocellular carcinoma; and to assess eligibility for antiviral treatment. Patients with detectable HCV RNA who have chronic hepatitis or Child A cirrhosis were considered eligible for antiviral treatment with Peg-Interferon and Ribavirin. Patients who received treatment were followed for sustained viral response.
Results: A total of 777 patients (median age 49 [range 15–95] years, males 69%) presented during the study period with HCV. Cirrhosis was the most common presentation (56%) followed by chronic hepatitis (37%) and HCC (7%). Of patients who had cirrhosis (including those with HCC) 36% had Child A cirrhosis; 51% had Child B cirrhosis and 14% had Child C cirrhosis. Out of all the 777 HCV patients only 347 (45%) were eligible for antiviral treatment. Among the remaining 430 patients, in 326 (76%) the disease was far too advanced to offer any antiviral treatment. Of patients eligible for antiviral treatment only 54% (189/347) actually received antiviral treatment and 81% (153/189) patients could complete the antiviral course. Of them 70% (107/153) only could achieve the SVR (Figure 1).
Conclusions: Most patients of HCV infection in India present late and only about 45% are eligible for antiviral treatment with Peg-interferon and Ribavirin. At presentation 56% patients already have cirrhosis and 7% have HCC. Since HCV is usually asymptomatic at treatable stage, awareness about screening should be increased so that more patients are diagnosed at treatable stage.



P0886

EFFICACY AND SAFETY OF GRAZOPREVIR/ELBASVIR +/− RBV FOR 12 WEEKS IN PATIENTS WITH HCV G1 OR G4 INFECTION WHO PREVIOUSLY FAILED PEGINTERFERON/RBV: C-EDGE TREATMENT-EXPERIENCED TRIAL

P. Kwo[1], E. Gane[2], C.-Y. Peng[3], B. Pearlman[4], J. Vireling[5], L. Serfaty[6,7,8], M. Buti[9], S. Shafran[10], P. Stryszak[11], L. Lin[11], J. Gress[11], M. Robertson[11], J. Wahl[11], E. Barr[11], B. Haber[11]. Inc., Whitehouse Station, United States*
E-mail: pkwo@iu.edu

Background and Aims: Efficacious, well-tolerated, interferon/ribavirin (RBV)-free, short-duration regimens are desirable for HCV-infected patients who failed prior therapy. In the Phase 2 C-WORTHY study, 12- or 18-weeks' dosing of once daily grazoprevir (GZR) 100 mg + elbasvir (EBR) 50 mg, ± twice-daily RBV, resulted in SVR12 in >90% of cirrhotic HCV genotype (GT) 1-infected patients with prior null response to peginterferon/RBV (PR). The Phase 3 C-EDGE Treatment-Experienced (TE) study is evaluating the efficacy and safety of once-daily, GZR/EBR 100 mg/50 mg fixed-dose combination (FDC) tablet, ± twice-daily RBV, for 12 or 16 weeks in cirrhotic or non-cirrhotic HCV GT1-, 4-, or 6-infected patients who have failed prior PR therapy.
Methods: This trial enrolled cirrhotic and non-cirrhotic HCV GT1-, 4-, or 6-infected patients who failed prior PR therapy. HIV co-infected patients were not excluded. Patients were randomized in a 1:1:1:1 ratio to receive GZR/EBR QD for 12 or 16 weeks, ± twice-daily RBV. Arms were stratified for cirrhosis status and prior PR treatment response. HCV RNA was assessed using COBAS TaqMan v2.0 (LLoQ 15 IU/mL). The primary endpoint was HCV RNA <15 IU/mL 12 weeks after end of treatment (SVR12).

Table: SVR4 by patient characteristics

	GZR/EBR for 12 weeks (N = 105)	GZR/EBR + RBV for 12 weeks (N = 104)
SVR4, n/N (%)		
Overall	100/105 (95%)	102/104 (98%)
GT1a	55/58 (95%)	54/56 (96%)
GT1b (or other than GT1a)	38/38 (100%)	33/33 (100%)
GT4	7 [a]/9 (78%)	15/15 (100%)
Null responder	42/45 (93%)	42/44 (95%)
Partial responder or Relapse	59/60 (98%)	60/60 (100%)
HIV/HCV	6/6 (100%)	5/5 (100%)
Cirrhosis	34/37 (92%)	35/36 (97%)
Virologic failure		
Breakthrough	0	0
Relapse	4	2
Discontinued		
Total	2 [a,b]	0
Of which due to AE	1	0

[a] Death – Cirrhotic, GT4-infected subject died of lymphoma.
[b] Discontinued study med at week 6 due to mood lability: achieved SVR4.

Results: This study is fully enrolled; complete SVR12 data from the 12 week arms will be available at the ILC meeting. Of 209 patients enrolled in the 12-week arms; 66% were male, 34% were cirrhotic, 5% were HIV co-infected, 23% were Black, and 9% were Hispanic. No GT6-infected patient were randomized to 12 weeks treatment. Mean viral load at baseline was 6.3log10 IU/mL. Previous response to PR: relapse in 35%, partial response in 22% or null response in 43%. All patients in 12-week arms have completed 4

weeks of follow-up. Common adverse events during treatment were fatigue (19%), headache (15%), and nausea (9%). The table displays preliminary SVR4 results.

Conclusions: This is an ongoing, Phase III study among subjects with HCV GT1 or 4 infection who failed prior PR therapy, including large numbers of Black/African-American and cirrhotic patients. Preliminary results showed a 12 week regimen of GZR/EBR FDC was highly efficacious with respect to SVR4 among these hard-to-cure patients, and had a favorable safety profile.

C-EDGE CO-INFECTED: PHASE 3 STUDY OF GRAZOPREVIR/ELBASVIR IN PATIENTS WITH HCV/HIV

J.K. Rockstroh[1], M. Nelson[2], C. Katlama[3], J. Lalezari[4], J. Mallolas[5], M. Bloch[6], G. Matthews[7], M. Saag[8], P. Zamor[9], C. Orkin[9], J. Gress[10], S. Klopfer[10], H. Platt[10], M. Robertson[10], M. Sulkowski[11]. *[1]Bonn University Hospital, Bonn, [2]Chelsea and Westminster Hospital, London, United Kingdom; [3]Université Pierre et Marie Curie, Hôpital Pitié-Salpêtrière, Paris, France; [4]Quest Clinical Research, San Francisco, United States; [5]Hospital Clinic-University of Barcelona, Barcelona, Spain; [6]Holdsworth House Medical Practice, Darlinghurst, [7]St Vincent's Hospital, Sydney, Australia; [8]University of Alabama at Birmingham, Birmingham, [9]Carolinas Medical Center, Charlotte, [10]Merck & Co. Inc., Whitehouse Station, [11]Johns Hopkins University School of Medicine, Baltimore, United States*

E-mail: Juergen.Rockstroh@ukb.uni-bonn.de

Background and Aims: The combination of grazoprevir (GZR, MK-5172, a HCV NS3/4 protease inhibitor) and elbasvir (EBR, MK-8742, an HCV NS5A inhibitor), an interferon-free, ribavirin-free, once-daily, fixed-dose combination (FDC) tablet has demonstrated robust efficacy and an excellent safety profile in diverse populations. C-EDGE HIV/HCV is an on-going, phase III study to assess the safety and efficacy of GZR/EBR FDC in HIV co-infected patients with chronic HCV genotype (GT) 1, 4 or 6 infection, with or without cirrhosis.

Methods: Subjects were eligible for enrollment if they met all of the following criteria: chronic HCV GT 1, 4 or 6 infection, cirrhotic or non-cirrhotic, no prior HCV treatment, HIV infection on a stable antiretroviral (ARV) regimen with a CD4 >200 cells/mm^3 and an HIV RNA <20 copies/mL, or HIV-treatment naive with CD4 >500 cells/mm^3 and VL <50,000 copies/mL. ARV therapy included a dual NRTI of tenofovir or abacavir, and lamivudine or emtricitabine; and either raltegravir, dolutegravir or rilpivirine. Presence of cirrhosis was defined by either (1) histology, (2) fibroscan >12.5 kPa, or (3) fibrotest >0.75 and APRI >2.0. All patients received open-label GZR/EBR 100 mg/50 mg FDC QD for 12 weeks. The primary endpoints were sustained virologic response (SVR) at follow-up week 12 (COBAS TaqMan v2.0 [lower limit of quantitation <15 IU/mL]), and assessment of safety and tolerability.

Results: 262 subjects were screened and 218 subjects met criteria for enrollment. Table 1 displays baseline characteristics for the enrolled subjects. In preliminary results among 214 subjects for whom HCV RNA data was available, 212 (97%) achieved SVR4. Virologic failure occurred in 2/218 (0.9%); both categorized as relapses at FW4. Overall adverse events (AEs) were reported in 157/218 subjects (72%); drug-related adverse events occurred in 72/218 subjects (33%); serious AEs occurred in 2/218 subjects (0.9%). The most common AEs reported included fatigue (15%), headache (15%), nausea (10%), diarrhea (10%), and insomnia (9%). Through FW4, no patient has discontinued due to AEs or laboratory abnormalities. Two patients experienced transient HIV viremia (HIV RNA >200 copies/mL); both patients were subsequently undetectable.

Conclusions: This is a large, ongoing, Phase III study among subjects co-infected with HIV and HCV GT1, 4 or 6 including significant numbers of Black/African-American and cirrhotic patients. A 12 week regimen of GZR/EBR FDC was highly efficacious with respect to SVR4 among cirrhotic and non-cirrhotic HIV co-infected subjects with HCV GT 1, 4 or 6 infection, and has a favorable safety profile. SVR12 results will be presented at the ILC meeting.

A SINGLE TABLET REGIMEN OF LEDIPASVIR/SOFOSBUVIR FOR 12 WEEKS IN HCV GENOTYPE 1 OR 4 INFECTED PATIENTS WITH HIV-1 CO-INFECTION: THE PHASE 3 ION-4 STUDY

C. Cooper[1], S. Naggie[2], M. Saag[3], J. Yang[4], L. Stamm[4], P. Pang[4], J. McHutchison[4], D. Dieterich[5], M. Sulkowski[6]. *[1]Ottawa Hospital, Ottawa, Ontario, Canada; [2]Duke University Medical Center, Durham, NC, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Gilead Sciences, Foster City, CA, [5]Mount Sinai Hospital, New York, NY, [6]Johns Hopkins University, Baltimore, MD, United States*

E-mail: luisa.stamm@gilead.com

Background and Aims: Historically HIV co-infection was considered a negative predictor of HCV response to treatment with interferon/ribavirin (IFN/RBV). For sofosbuvir-based regimens, HIV/HCV patients have achieved similar sustained virologic response (SVR) rates as HCV monoinfected patients. We evaluated the safety and efficacy of the IFN-free, RBV-free, single tablet regimen of ledipasvir/sofosbuvir (LDV/SOF) in HCV genotype 1 or 4 patients co-infected with HIV-1 in the Phase 3 ION-4 study.

Methods: HCV treatment naïve and experienced HIV co-infected patients on stable, approved antiretroviral (ARV) regimens were enrolled and received LDV/SOF (90 mg/400 mg) once daily for 12 weeks. Patients with compensated cirrhosis were eligible. Permitted concomitant ARVs included tenofovir/emtricitabine (TDF/FTC) with raltegravir (RAL), efavirenz (EFV) or ripilvirine (RPV). Safety evaluations included adverse event (AE) and standard laboratory parameter monitoring in addition to enhanced renal toxicity monitoring, CD4 count and HIV-1 RNA levels. The primary endpoint was SVR12.

Results: 335 patients with GT1a (75%), GT1b (23%) and GT4 (2%) were enrolled in the study; 83% were male, 61% were white, mean age was 52 years (range 26–72), mean baseline HCV RNA was 6.7 $\log_{10}$ IU/mL (range 4.1–7.8), median baseline CD4 count was 662 cells/uL (Q1, Q3 = 469, 823), 20% had cirrhosis, 24% were *IL28B* CC genotype and 55% had not responded to prior HCV treatment. Most patients were taking EFV (48%) or RAL (44%). The table shows SVR4 by ARV regimen. Overall, SVR4 was 96% (322/335); 2 patients had on-treatment virologic failure due to non-compliance and 8 had virologic relapse after discontinuing treatment. Overall, SVR4 (97%) among non-cirrhotic (F0–F3) patients was similar to SVR4 (94%) among cirrhotic (F4) patients. No patient had confirmed HIV virologic rebound (HIV-1 RNA ≥400 copies/mL). No patients

discontinued study drug due to an AE. AEs occurring in ≥10% of patients were headache (25%), fatigue (22%) and diarrhea (11%). No significant lab abnormalities were observed.

Table: SVR4 by ARV regimen and overall

Virologic response	TDF/FTC+EFV (N = 160)	TDF/FTC+RAL (N = 146)	TDF/FTC+RPV (N = 29)	Overall (N = 335)
SVR4, n (%)	152 (95)	142 (97)	28 (97)	322 (96)
On-treatment failure, n (%)	1 (<1)	0	1 (3)	2 (<1)
Relapse, n (%)	7 (4)	1 (<1)	0	8 (2)
Other, n (%)	0	3 (2)	0	3 (<1)

Conclusions: The IFN-free, RBV-free, single tablet regimen of LDV/SOF administered once daily for 12 weeks is highly effective and well tolerated in treatment-naïve and -experienced, genotype 1 or 4 HCV-infected patients with HIV-1 co-infection, including those with cirrhosis. Complete SVR12 data will be presented.

Viral hepatitis: Hepatitis C – d. Clinical (new compounds, resistance)

E-mail: adrienne.tracey@articulatescience.com

Background and Aims: Patient characteristics can influence efficacy and safety outcomes with HCV therapeutic regimens. A phase 3 study (UNITY-2) of the fixed-dose combination of DCV (NS5A inhibitor), ASV (NS3 inhibitor), and BCV (nonnucleoside NS5B inhibitor), with or without RBV, demonstrated high rates of sustained virologic response (SVR) in treatment-naive and experienced patients with HCV genotype 1 infection and compensated cirrhosis. The influence of baseline disease characteristics and demographic variables on outcomes from this study was investigated.
Methods: The 202 enrolled patients were treatment-naive (N = 112) or treatment-experienced (N = 90) adults with HCV genotype 1 infection and compensated cirrhosis. 74% of patients had GT1a infection; 26% had GT1b. All patients received a twice-daily fixed dose combination of DCV 30 mg, ASV 200 mg, and BCV 75 mg, ± weight-based RBV, for 12 weeks. The primary endpoint was SVR at posttreatment week 12 (SVR12).
Results: Overall, 93% of patients achieved SVR12, with higher response rates in patients treated with DCV/ASV/BCV combined with RBV and in patients with GT1b subtype. Other baseline factors such as age, gender, BMI, IL28B genotype, HCV RNA >800,000 IU/mL, and platelet count $<100\times10^9$/L did not appear to impact SVR12 rates in either cohort (Table). Similarly, race did not appear to influence SVR12 rates; of the 20 black patients enrolled in the study, all 20 achieved SVR12. Prior null response to pegIFN did not significantly impact outcome in the treatment-experienced cohort. Baseline resistance-associated variants (RAVs) in NS5A (28, 30, 31, 93) or NS3 (168) did not impact SVR: 26/28 patients with NS5A RAVs and 2/2 patients with NS3 RAVs achieved SVR12. NS5B-P495 was not detected at baseline. Among patients with virologic failure, RAVs were detected in NS5A (Q30, Y93, L31), NS3 (R155, D168) and NS5B (P495, P421).
Conclusions: The all-oral fixed-dose combination of DCV, ASV, and BCV achieved high rates of SVR12 in patients with HCV genotype 1 infection and compensated cirrhosis. The strongest predictors of SVR12 were GT1b and use of RBV. Factors often associated with reduced responses to less potent regimens, such as advanced age, black race, prior null response to pegIFN, high baseline HCV RNA levels, low platelet counts, non-CC IL28B genotype, and baseline NS5A or NS3 RAVs did not appear to impact SVR12 rates.

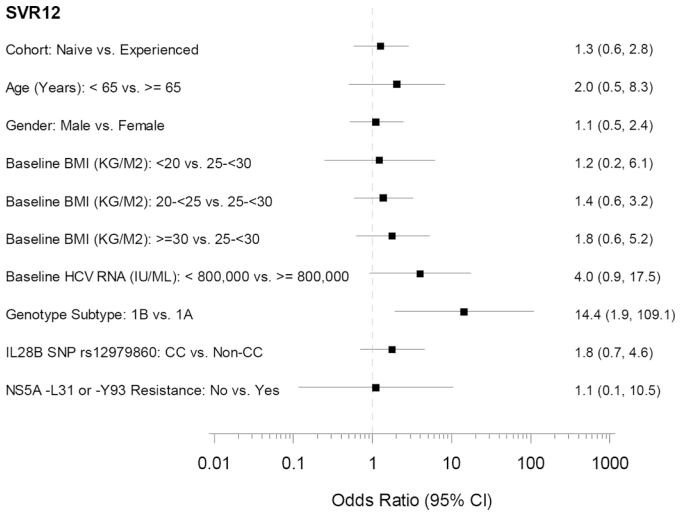
P0889

EFFECT OF BASELINE FACTORS ON RESPONSE TO THE FIXED-DOSE COMBINATION OF DACLATASVIR (DCV), ASUNAPREVIR (ASV) AND BECLABUVIR (BCV) IN NON-CIRRHOTIC PATIENTS WITH HCV GENOTYPE 1 INFECTION

K. Rajender Reddy[1], K.L. Beavers[2], S. Gordon[3], S. Harrison[4], N. Reau[5], J. Yozviak[6], V. DeLedinghen[7], B. Conway[8], E. Tse[9], R. Bhore[10], N. Boparai[10], E. Hughes[10], E.S. Swenson[11], P.D. Yin[11]. *[1]University of Pennsylvania, Philadelphia, [2]Medical University of South Carolina, Charleston, [3]Henry Ford Health System, Detroit, [4]Brooke Army Medical Center, San Antonio, [5]University of Chicago Medical Center, Chicago, [6]Lehigh Valley Health Network, Allentown, United States; [7]Hôpital Du Haut-Leveque, Pessac, France; [8]Vancouver Infectious Diseases Centre, Vancouver, Canada; [9]Royal Adelaide Hospital, Adelaide, Australia; [10]Bristol-Myers Squibb Research and Development, Princeton, [11]Bristol-Myers Squibb Research and Development, Wallingford, United States*
E-mail: adrienne.tracey@articulatescience.com

Background and Aims: The all-oral fixed-dose combination of daclatasvir (DCV; pangenotypic NS5A inhibitor), asunaprevir (ASV; NS3 inhibitor), and beclabuvir (nonnucleoside NS5B inhibitor) was evaluated without ribavirin in non-cirrhotic HCV genotype 1-infected patients in the Phase 3 UNITY-1 study. The influence of baseline disease characteristics and demographic variables on outcomes from this study was investigated.

Methods: This study enrolled 415 adult HCV genotype 1-infected patients without cirrhosis, who were either treatment-naive (N = 312) or treatment-experienced (N = 103). All patients received a twice-daily fixed-dose combination of DCV 30 mg, ASV 200 mg, and BCV 75 mg for 12 weeks. For this analysis, baseline characteristics as predictors of SVR at posttreatment week 12 (SVR12) are assessed using a multivariate logistic regression model.
Results: Overall, SVR12 was achieved by 92% of treatment-naive patients and 89% of treatment-experienced patients. Patients with genotype 1b infection were most likely to achieve SVR12 (Figure; Odds Ratio [OR] 14.4; CI 1.9–109.1). There was a trend toward greater likelihood of SVR12 in patients with baseline HCV RNA <800,000 IU/ml (OR 4.0, CI 0.9–17.5), age <65 years (OR 2.0, CI 0.5–8.3), higher body mass index (BMI; OR 1.8, CI 0.6–5.2) and IL28B genotype CC (OR 1.8, CI 0.7–4.6). Prior treatment experience, gender and NS5A variants L31 or Y93 at baseline were not predictive of SVR. Race did not appear to influence SVR12 rates; of the 41 black patients enrolled in the study, 38 (93%) achieved SVR12.
Conclusions: The all-oral, fixed-dose combination of DCV, ASV, and BCV achieved high rates of SVR12 in non-cirrhotic patients with HCV genotype 1 infection. Genotype 1b was the strongest predictor of SVR12. Baseline factors that have previously been shown to impact response to anti-HCV therapies, such as age, race, prior treatment experience, BMI or high baseline HCV RNA had minimal impact on SVR12 rates in this study.



P0890
NOVEL CYCLOPHILIN INHIBITOR CPI-431-32 SHOWS BROAD SPECTRUM ANTIVIRAL ACTIVITY BY BLOCKING REPLICATION OF HCV, HBV AND HIV-1 VIRUSES

P. Gallay[1], U. Chatterji[1], M. Bobardt[1], D. Ure[2], D. Trepanier[2], R. Foster[2], C. Ordonez[2]. [1]*Department of Immunology & Microbial Science, The Scripps Research Institute, La Jolla,* [2]*Ciclofilin Pharmaceuticals, Del Mar, United States*
E-mail: gallay@scripps.edu

Background and Aims: HCV/HBV-related liver disease is the main cause of morbidity and mortality of HIV-1 patients co-infected with HCV and/or HBV. Despite the recent advent of anti-HCV DAAs, the treatment of HCV/HBV/HIV-1 co-infected patients remains a challenge, as these patients are less responsive to treatment, have higher rates of re-infection, and develop liver fibrosis, cirrhosis and liver cancer more often than mono-infected patients. In this study, we used a novel in vitro co-infection model to demonstrate that CPI-431-32, a novel cyclophilin A (CypA) inhibitor, simultaneously blocks replication of HCV, HBV and HIV-1 in human cells.
Methods: Using a unique and novel *in vitro* co-infection model, we examined whether CPI-431-32 interferes (i) with HCV RNA synthesis of isolated replication complexes using a quantitative replicase assay, (ii) with early steps of viral replication of HIV-1 primary isolates, and (iii) with HBV virus entry (NTCP binding) and viral replication. We also tested by ELISA the CPI-431-32 inhibition of the interaction between CyPA and the viral proteins NS5A and $p24^{gag}$ of HCV and HIV-1 viruses, respectively, to explore the mechanism of action of this drug.
Results: We found that CPI-431-32 blocked viral replication of HCV, HBV and HIV-1. CPI-431-32 was more effective than alisporivir (another CyPA inhibitor) inhibiting replication of each of these three viruses. We also demonstrated that CPI-431-32 blocks nuclear import of HIV-1 virus. CPI-431-32 blocked binding of CYPA to HCV NS5A and HIV-1 $p24^{gag}$ more efficiently than alisporivir, and was more effective than alisporivir against established resistant-variants of HIV-1. No other antiviral agent tested in our assays was able to show such a broad-spectrum of antiviral activity.
Conclusions: The unique broad-spectrum of antiviral activity shown by CPI-431-32 might be related to the role of CyPA in viral infection. CPI-431-32 prevents binding of CyPA, a protein-folding enzyme to viral proteins such as HCV NS5A and HIV $p24^{gag}$, which are critical for HCV and HIV-1 replication. We hypothesize that the inhibition of CyPA by CPI-431-32 is responsible for its broad-spectrum antiviral activity by preventing activation of specific viral proteins required for viral replication. Overall, this study suggests that CPI-431-32, a novel CyPA inhibitor, could potentially become a candidate medicine for the treatment of HIV-1 patients co-infected with HCV and/or HBV.

P0891
RESISTANCE ANALYSIS OF VIROLOGIC FAILURES IN HEPATITIS C GENOTYPE 1 INFECTED PATIENTS TREATED WITH GRAZOPREVIR/ELBASVIR +/− RIBAVIRIN: THE C-WORTHY STUDY

S. Black[1], I. Pak[1], P. Ingravallo[1], P. McMonagle[1], R. Chase[1], M. Shaughnessy[1], P. Hwang[1], B. Haber[1], P.R. Harrigan[2], C. Brumme[2], A.Y.M. Howe[1]. [1]*Infectious Diseases, Merck & Co., Whitehouse Station, United States;* [2]*BC Centre for Excellence in HIV/AIDS, University of British Columbia, Vancouver, Canada*
E-mail: stuart.black@merck.com

Background and Aims: Grazoprevir (GZR) is a potent HCV NS3/4A inhibitor and Elbasvir (EBR) is a potent NS5A inhibitor. The Phase 2 C-WORTHY study evaluated the efficacy and safety of GZR/EBR, given once daily, ± ribavirin (RBV), in 471 HCV genotype (GT) 1 infected subjects (36% cirrhotic). In this population, administration of GZR/EBR for 12 or 18 weeks, +/− RBV resulted in SVR12 in 87–100% of subjects. An 8 week regimen resulted in SVR12 in 80% of subjects. We evaluated the frequency of NS3 and NS5A RAVs at baseline and at the time of failure.
Methods: Plasma samples (>1,000 IU/mL) from all patients at baseline and patients who met the criteria for virologic failure (VF) were evaluated by population sequencing of NS3/4A and NS5A, with selected samples further analyzed by clonal sequencing (≥40 clones) or whole genome Next Generation Sequencing (NGS; Illumina) in duplicate.
Results: Excluding 9 early discontinuations due to reasons other than VF, 22/462 (5%) non-SVR_{12} subjects met the protocol defined criteria for VF including 1 subject who was dually infected with GT1b/2b prior to treatment. Post-baseline resistance-associated variants (RAVs) at NS3, Y56H, A156T/G, D168A/E/N/Y, were noted in 13/22 (59%); 1 NS3 RAVs was detected at baseline in 1 subject by NGS. The prevalence of NS5A at VF was high; 20/22 (91%) samples were detected with M28G/T, Q30H/R, L31M/V, H58D and Y93H/N mutations. NGS analysis of baseline samples showed that 13/22 (59%) non-SVR subjects were infected with NS5A RAVs prior to treatment. Clonal sequencing revealed linked mutations among NS3 RAVs and among NS5A RAVs. RAVs containing dual/multiple

mutations had significantly higher resistance comparing to those with single mutations in HCV replicons.
MK-5172 is active against most of these RAVs and the presence of baseline NS3 RAVs did not affect treatment outcomes. The presence of NS5A baseline RAVs by population sequencing was associated with lower SVR (Table).

Gene	Patients with baseline RAVs, n/N (%)	SVR 12, n/N (%)	
		Patients with baseline RAVs	Patients without baseline RAVs
NS3	151/455 (33%)	141/151 (93%)	293/304 (96%)
NS5A	55/450 (12%)	45/55 (82%)	384/395 (97%)

Conclusions: The combination of GZR/EBR has high SVR rates in a diverse HCV infected population including null responders, cirrhotics and HIV/HCV co-infected patients. Virologic failure is associated with NS3 and NS5A RAVs; many of the RAVs identified at failure also pre-existed at baseline as uncovered by NGS.

P0892
IMPACT OF HCV INFECTION IN A HIV COHORT FOLLOWED OVER 18 YEARS: PAST AND PRESENT

A. Mena[1], I. Rodriguez Osorio[1], H. Meijide[1], Á. Castro Iglesias[1], S. López Calvo[1], P. Vázquez Rodríguez[1], B. Pernas[1], M. Grandal[1], J. Domingo Pedreira[1], E. Poveda[1]. [1]*Division of Clinical Virology, INIBIC-CHUAC, A Coruña, Spain*
E-mail: alvaro.mena.de.cea@sergas.es

Background and Aims: This study evaluates the impact of HCV infection in a cohort of HIV infected patients followed over 16 years and trends in hospitalizations and mortality.
Methods: A cohort of HIV-infected patients was followed at our institution between 1996–2013. Epidemiological, clinical and main data related with hospitalizations and mortality was recorded. Data has been analyzed considering HIV-mono and HIV/HCV populations and two periods of nine years each.
Results: A total of 2257 HIV infected patients (857 HIV/HCV co-infected) were retrospectively examined over 16 years. Overall, 76% were men, median age of 31 (25–37) years and 57% have an AIDS event during the follow-up. Patients under antiretroviral therapy (ART) was similar in HIV/HCV and HIV-mono in both periods (>87%). Main results are depicted in the table.

Variable	1996–2004			2005–2013		
	HIV	HIV/HCV	p	HIV	HIV/HCV	p
N patients (%)	905 (55)	730 (45)		997 (59)	694 (41)	
Follow-up (years)	6.8±4.7	9.4±4.8	0.001	11.6±4.3	16.4±4.8	0.001
Mortality (%)	311 (34)	275 (37)	0.085	178 (18)	189 (27)	<0.001
Infectious (%)	172 (55)	102 (37)	0.040	60 (34)	41 (22)	0.035
Tumoral (%)	62 (20)	27 (10)	0.020	56 (31)	34 (18)	0.020
Cardiovascular (%)	17 (5)	8 (3)	0.045	23 (13)	18 (9)	0.080
Liver-related mortality (%)	7 (2)	74 (27)	<0.001	1 (1)	72 (38)	<0.001
Hospitalizations	1899	1398	0.110	1297	1458	0.050
Infectious (%)	845 (44)	544 (39)	0.060	454 (35)	517 (35)	0.220
Liver-related (%)	59 (3)	119 (8)	0.001	46 (3)	183 (13)	<0.001

Overall, HIV/HCV co-infected population have significant lower CD4 counts (cell/mm3) in both periods (505 vs 312 and 542 vs 322; $p < 0.001$, respectively). A lower rate of patients achieved HIV-RNA <50 cop/mL in the second period compared with HIV-mono (59.2 vs 56.4 and 75.3 vs 67.2; $p = 0.03$, respectively). In this population, a low rate of patients received HCV treatment although was higher in the second period (6.9% vs 11.5%, $p = 0.01$). Consequently, a higher proportion of patients achieved sustained virological response (SVR) in the second period (61% vs 70%, $p = 0.03$). The rate of liver-related mortality was significantly higher in HIV/HCV compared with HIV-monoinfected with an increase in the second period ($p = 0.02$). Moreover, hospitalizations related with liver-disease were higher in HIV/HCV and were higher in the second period ($p = 0.04$). Among patients achieving SVR, only 3.2% and 3.6% in both periods, respectively, had a liver-related hospitalization and none died.
Conclusions: HCV infection has a negative impact on HIV outcome related with lower CD4 recovery and lower rates of virological success in HIV/HCV patients under ART. However, HCV infection does not impact on the mortality related with infectious, tumoral or cardiovascular diseases and only increase the rate of liver-related mortality in HIV/HCV patients compared with HIV-monoinfected. Moreover, HCV infection significantly increased liver-related hospitalizations and mortality on the long-term. Considering the low rate of patients receiving HCV treatment in this cohort, these data confirm the harmful contribution of uncontrolled HCV infection in HIV/HCV infected population.

P0893
RESISTANCE ANALYSIS OF TREATMENT-EXPERIENCED GENOTYPE 1 AND 3 HCV INFECTED PATIENTS TREATED WITH SOFOSBUVIR IN COMBINATION WITH GS-5816 +/− RIBAVIRIN FOR 12 WEEKS

B.P. Doehle[1], E.S. Svarovskaia[1], K. Chodavarapu[1], J. McNally[1], S. Pianko[2], S.K. Roberts[3], D.M. Brainard[1], M.D. Miller[1], H. Mo[1]. [1]*Gilead Sciences, Foster City, United States;* [2]*Monash Medical Center, Clayton,* [3]*The Alfred, Melbourne, Australia*
E-mail: brian.doehle@gilead.com

Background and Aims: The effect of pretreatment NS5A variants on the response to NS5A inhibitors appears to be dependent on the specific variants present, the HCV genotype and the resistance profile of the NS5A inhibitor. In this study we evaluated the impact of preexisting substitutions at resistance associated variant (RAV) positions on treatment outcome and emergence of RAVs at relapse in treatment experienced GT1 or 3 infected patients receiving sofosbuvir (SOF) 400 mg with the investigational NS5A inhibitor GS-5816 (25 mg or 100 mg) ± ribavirin (RBV) for 12 weeks in study GS-US-342-0109.
Methods: NS5A and NS5B deep sequencing analysis was performed for all patients (n = 321; GT 1=111; GT3=210) at pretreatment and for patients who did not achieve SVR12 at failure timepoints. Variants at known NS5A RAV positions as well as the NS5B SOF RAV S282T and treatment-emergent variant (TEV) positions L159 and V321 were analyzed.
Results: Nineteen GT1 infected patients (16%; 12 GT1a, 7 GT1b) had pretreatment NS5A RAVs (Q30H/R, L31M/V, H58D and Y93C/F/H) with 2/19 patients experiencing relapse compared to no relapse in patients without pretreatment RAVs. GT3 NS5A naturally encodes K24S, Q30A, H58P and A92E when compared to GT1a. Forty-five GT3 infected patients (21%; 43 GT3a, 2 GT3b) also had pretreatment NS5A variants at RAV positions (M28T, A30K/M/R/S/T/V, L31M and Y93H). Of these 45 patients, 6/27 (22%) and 1/18 (6%) relapsed following treatment with SOF+GS-5816 25 mg or 100 mg±RBV respectively compared to 14/78 (18%) and 2/87 (2%) without RAVs. All 3 patients (2 GT1; 1 GT3a) with pretreatment NS5B L159F achieved SVR. Twenty-five patients experienced virologic relapse (2 GT1a, 22 GT3a, 1 GT3b) with 20 treated with SOF+GS-5816 25 mg ± RBV, and 5 treated with SOF+GS-5816 100 mg ± RBV. All relapse patients were observed to have NS5A RAVs at posttreatment with Y93H the predominant RAV observed in GT3 subjects, which displays >100 reduction in susceptibility to GS-5816. GT1a patients had Q30H or L31V enrich from low levels at pretreatment to the major quasispecies at relapse. Neither S282T nor other SOF-TEVs in NS5B were detected in any of the patients at relapse.
Conclusions: SOF+100 mg GS-5816 administered for 12 weeks results in high SVR within treatment-experienced GT1 and 3 infected patients irrespective of pretreatment NS5A RAVs. NS5A resistance but not SOF-resistance was detected in relapse patients.

P0894

PREVALENCE OF PRE-TREATMENT NS5A AND NS5B RESISTANCE ASSOCIATED VARIANTS AND GENETIC VARIATION WITHIN HCV SUBTYPES ACROSS DIFFERENT COUNTRIES

E. Svarovskaia[1], C. Hedskog[1], R. Martin[1], D.M. Brainard[1], M.D. Miller[1], H. Mo[1]. [1]*Gilead Sciences, Foster City, United States*
E-mail: jenny.svarovskaia@gilead.com

Background and Aims: Prevalence of resistance associated variants differs by HCV subtype and geographical region. In this study, a comprehensive pooled analysis of HCV sequences was used to investigate genetic variation within HCV subtypes from multiple countries across genotypes 1–6. The prevalence of pre-treatment NS5A and NS5B resistance associated variants was also evaluated across different countries.
Methods: NS5A and NS5B sequencing analyses were performed from >3000 and >7800 patients across 14 and 22 countries, respectively. The presence of NS5A resistance associated variants (K24G/N/R, M28A/G/T, Q30any, L31any, H58D, A92K/T, Y93any in genotype 1a and L31any, A92K, Y93any in genotype 1b) and NS5B NI-associated variants (L159F, S282T, L320F, V321A in genotypes 1–4) were evaluated. Maximum likelihood phylogenetic analyses were performed for a subset of full length NS5A and NS5B sequences from multiple countries.
Results: Prior to treatment, NS5A resistance associated polymorphisms ranged between 6–17% in GT1a and 8–17% in GT1b HCV infected patients from investigated countries (Table). No NS5B S282T or V321A variants were found at baseline. Baseline L320F was only found in 2% of GT1b NZL patients. L159F was mostly found in GT1b, with the highest prevalence in Russia, 34%, followed by Spain, 32%, and the lowest in Japan and Taiwan, 1% and 0%, respectively.
Phylogenetic analyses within subtypes 1a, 1b, 2a, 3a, 4a and 6a revealed a distinct clustering within GT1b suggesting that GT1b is genetically different in several countries. Geographical clustering in other subtypes was less pronounced.

Country	% of GT1a patients with BL NS5A RAVs	% of GT1b patients with BL NS5A RAVs	% of GT1b patients with BL NS5B L159F
Australia	8% (N = 75)	16% (N = 31)	29% (N = 14)
Germany	7% (N = 74)	8% (N = 87)	25% (N = 75)
Spain	6% (N = 33)	14% (N = 22)	32% (N = 34)
France	8% (N = 62)	11% (N = 35)	16% (N = 19)
Italy	17% (N = 41)	13% (N = 67)	20% (N = 51)
Russia	ND	ND	34% (N = 64)
Japan	ND	16% (N = 329)	1% (N = 330)
Korea	ND	16% (N = 85)	5% (N = 86)
Taiwan	ND	12% (N = 68)	0% (N = 67)
USA	8% (N = 2520)	12% (N = 730)	4% (N = 982)
New Zealand	14% (N = 152)	17% (N = 36)	4% (N = 45)

N, number of sequences investigated; ND, no data.

Conclusions: The prevalence of pre-treatment NS5A resistance associated variants varied moderately between different countries and ranged between 6–17%. The major NS5B RAV S282T was not observed in any pre-treatment sample, however L159F showed geographical clustering within GT1b HCV with highest prevalence in Russia and Spain and lowest in Japan and Taiwan.

P0895

COMPARISON OF THREE SEQUENCING METHODS COMMONLY USED IN HEPATITIS C VIRUS RESISTANCE ANALYSIS: POPULATION-BASED VS. CLONAL VS. ULTRA DEEP SEQUENCING

S. Susser[1], B. Beggel[2], D. Perner[1], C. Berkowski[1], S. Zeuzem[1], T. Lengauer[2], C. Sarrazin[1]. [1]*Goethe-University Hospital, Frankfurt/Main,* [2]*Max Planck Institute for Informatics, Saarbrücken, Germany*
E-mail: susser@med.uni-frankfurt.de

Background and Aims: Today, treatment of chronic hepatitis C virus (HCV) infection consists of at least one direct acting antiviral drug, targeting the HCV NS3, NS5A, or NS5B gene. Despite high SVR rates, in some patients selection of resistant variants causes treatment failure. Thus, generation of multi resistant viral variants may become a practical problem. We compared three commonly used sequencing methods (population-based, clonal, and next generation sequencing; NGS) with markedly different sensitivities for variant calling, to find out which method provides the best and most effective resolution of HCV quasispecies.
Methods: From 20 treatment-naïve chronic HCV genotype 1 infected patients, a 6kb-sized PCR product covering NS3-NS5B was analyzed. A population-based and a clonal Sanger sequencing approach were performed, as well as ultra-deep sequencing (454 GS FLX+ system). For clonal investigation a mean of 33 (range 19–45) clones was analyzed. High quality reads were mapped to the HCV-J/HCV-H77 reference genomes. Nucleotide variant distributions were called for each variant position using the SAMtools suite. Sequence data was clipped using the phred-quality scores. Remaining reads were mapped to the subgenotype reference genome using SMALT. The 454 coverage varied between approx. 500 and approx. 3750 reads per position.
Results: The sensitivity of population-based sequencing was clearly shown to be limited. Only 36% of variants with frequencies up to 10% were called. At a 10% cut-off, sensitivity of direct sequencing vs. NGS is 38%, 37%, and 34% for NS3, NS5A, and NS5B, respectively. With the clonal approach sensitivity is 76%, 87%, and 84% for NS3, NS5A, and NS5B, in comparison to NGS, respectively. Specificity is at a high level for both methods and all genes (97% for clonal and 99.9% for direct sequencing).
Conclusions: Clonal sequencing lies qualitatively between population-based and deep sequencing, but it is much more expensive and time-consuming. Population-based sequencing is cheap and fast, but bears the danger of missing important variants associated with DAA resistance. NGS shows the highest sensitivity and becomes more and more affordable, but currently is also a very laborious approach, which might be difficult to integrate in clinical routine.

P0896

LONG-TERM FOLLOW-UP ANALYSIS OF RAVS IN HCV NS3, NS5A, AND NS5B IN DAA THERAPY FAILURE PATIENTS

S. Susser[1], J. Würzburg[1], S. Kofler[1], T.M. Welzel[1], D. Perner[1], S. Zeuzem[1], C. Sarrazin[1]. [1]*Goethe-University Hospital, Frankfurt/Main, Germany*
E-mail: susser@med.uni-frankfurt.de

Background and Aims: Despite high SVR rates to different direct acting antiviral (DAA) drug based regimens for hepatitis C virus (HCV) infection, viral breakthrough or relapse is observed and selection of resistant variants is a major cause for treatment failure. Thus, generation of multi resistant viral variants may become a practical problem. Data on long-term evolution of resistance associated variants (RAVs) especially for NS5A and NS5B inhibitors in patients (pts) with treatment failure are sparse. In the present study, we show first data about long-term persistence and evolution of resistance variants in HCV NS3, NS5A, and NS5B from pts with failure to DAA-based therapies.

Methods: Population-based sequencing was performed from the HCV NS3, NS5A, and NS5B region. For NS3, 12 pts with 2–14 time points up to 2 years after telaprevir triple therapy start were included. For analysis of the NS5A/5B genes, 6/5 pts with 3–6/2–5 time points up to 3 years after daclatasvir/ledispasvir/ombitasvir therapy and until follow-up (FU) week 12 of deleobuvir treatment, respectively, were available.
Results: In 9/12 pts NS3 PI RAVs could be detected by population-based sequencing after stopping treatment. After 1-year FU, in 5/10 pts single RAVs (V36A/L, T54S/A, R155K) were still detectable, while at 2 years FU, in 2/4 pts T54A or R155K could be observed.
Five patients who were treated with an NS5A inhibitor showed variants associated with treatment failure. At 1-year FU in 4/6 pts one or more RAVs were observed (Q30R, L31M, H54A, H58P in genotype 1a and L31M/I, H58S, Y93H in genotype 1b). The Q30R/L31M double variant was still detectable in 1/2 pts after 2 years FU.
No RAVs could be detected in 5 patients who received the non-nucleoside NS5B inhibitor deleobuvir at treatment failure and follow-up so far.
Patterns of evolution, persistence and re-occurrence without any selection pressure present, differed in all groups between the single patients.
Comparison with deep sequencing will be presented at the meeting.
Conclusions: Variable rates of persistence of RAVs in patients with failure to NS3, NS5A and NS5B inhibitors have been observed. While generally RAVs to protease inhibitors tend to decline and RAVs to NS5A inhibitors persist in single patients, highly resistant variants have been observed up to 3 years after treatment failure.

EFFICACY OF SIMEPREVIR AND SOFOSBUVIR FOR TREATMENT OF CIRRHOTIC PATIENTS WITH GENOTYPE 1 CHRONIC HEPATITIS C – A SINGLE CENTER EXPERIENCE

V. Singh[1], T. Frederick[1], E.W. Holt[1], A.E. Wakil[1], J. Guy[1], R.B. Merriman[1], T.J. Davern[1], K.K. Yimam[1], C.K. Ho[1], T.K. Lee[1], S.L. Cooper[1]. *[1]Hepatology, California Pacific Medical Center, San Francisco, United States*
E-mail: singhv@sutterhealth.org

Background and Aims: In the COSMOS study, treatment of genotype (G)1 hepatitis C (HCV)-related cirrhosis (N = 18) for 12 weeks using the HCV protease inhibitor (PI), Simeprevir (SIM), and the polymerase inhibitor, Sofosbuvir (SOF), either with (N = 11) or without (N = 7) ribavirin (RBV), reported a high cure rate (SVR12 in 10/11 [91%] and 6/7 [86%]) and favorable safety profile. Because interpretation is limited by sample size, we evaluated the clinical efficacy and safety of this regimen in 78 cirrhotic patients in real-world use.
Methods: Retrospective analysis of cirrhotic G1 HCV patients treated daily with SIM 150 mg and SOF 400 mg. Post liver transplant cases were excluded. The presence of cirrhosis was based on firm clinical, radiographic or pathological evidence, or FibroSURE test results. Laboratory tests were obtained every 2–4 weeks. HCV RNA was assayed by real-time PCR (COBAS® LLD:15 IU/mL).
Results: Patient demographics and clinical characteristics are shown in table 1. Seventy-eight cirrhotic patients were treated: 73 were treated for 12 weeks, 2 for 4.5 weeks, 1 for 6.5 weeks, 1 for 16 weeks and 1 for 24 weeks. Only 2 received RBV. After starting treatment, viral load (VL) was undetectable at week 2 in 20 of 72 tested patients (28%); data was unavailable for 6 patients. Sixty-three (81%) patients had undetectable VL at week 4. Of 76 patients tested all had undetectable VL at end of treatment (EOT); for 2 patients EOT VL was unavailable. Fifty-two (67%) patients achieved SVR12 while 21 (27%) relapsed. For 5 patients week 12 VL was not obtained due to lost follow-up (N = 2) or a shorter duration of treatment (3). Only 1 patient had on-treatment virologic breakthrough despite reported compliance. Three patients discontinued treatment prematurely due to severe hyperbilirubinemia (N = 2) or hepatic decompensation (N = 1). At start of treatment, mean MELD score was 9.5, bilirubin 1.3, ALT 90, platelets 105. At EOT, mean MELD was 10, bilirubin 1.6, ALT 29, platelets 106.

Table: Demographic and clinical characteristics at baseline and after SIM-SOF: N = 78

	Cohort (N = 78) [a]	Relapsers (N = 21)	SVR12 (N = 52)
Male gender, N (%)	49 (62.8%)	15	N/A
Ethnic origin (N, %)		N/A	N/A
Caucasian	54 (69.2%)		
African American	4 (5.1%)		
Asian	4 (5.1%)		
Hispanic & Latino	2 (2.6%)		
Unknown race	14 (17.9%)		
Age, mean, median (SD)	62.8, 62 (6.6)	59.9, 60 (4.4)	N/A
BMI, mean, median, (SD)	28.5, 26.5 (6.2)	29.7, 27.2 (7.3)	N/A
MELD score, mean	9	11, 2, 3	N/A
Baseline HCV RNA (IU/ml)	N/A	1,485,759	N/A
HCV GT, N (%)			N/A
1a	47 (60.3%)	15	
1b	31 (39.7%)	6	
Treatment history, N (%)			N/A
Treatment naïve	31 (39.7%)	7 (33.3%)	
Prior interferon therapy	47 (60.3%)	14 (42.4%)	
Prior PI therapy	5 (6.4%)	2 (9.5%)	
No response	28 (53.8%)	8 (38.1%)	

N/A, Not yet available: data pending.
[a] 5 patients lost to follow-up.

Conclusions: Twelve weeks of SIM-SOF therapy for G1 HCV cirrhosis cured no more than 67% of patients, indicating a significantly higher relapse rate than previously reported. Overall tolerability and relative safety was acceptable.

P0898

TD-6450, A NEXT GENERATION ONCE-DAILY NS5A INHIBITOR, HAS POTENT ANTIVIRAL ACTIVITY FOLLOWING A 3-DAY MONOTHERAPY STUDY IN GENOTYPE 1 HCV INFECTION

E. Lawitz[1], M. Rodriguez-Torres[2], R. Kohler[3], A. Amrite[3], C. Barnes[3], M.L.C. Pecoraro[3], J. Budman[3], M. McKinnell[3], C.B. Washington[3]. *[1]Texas Liver Institute, University of Texas Health Science Center, San Antonio, TX, United States; [2]Fundacion de Investigacion, San Juan, Puerto Rico; [3]Theravance Biopharma, South San Francisco, CA, United States*
E-mail: cwashington@theravance.com

Background and Aims: TD-6450 is a next generation HCV NS5A inhibitor with superior in vitro potency against resistance-associated variants (RAVs) encountered with first-generation NS5A inhibitors. This study evaluated the safety, pharmacokinetics (PK) and antiviral activity of TD-6450 following multiple oral doses in HCV patients.
Methods: This was a double-blind, randomized, placebo-controlled study in treatment-naïve, non-cirrhotic HCV patients. In the dose ranging portion of the study, patients with GT-1a infection were randomized to receive multiple ascending oral doses of TD-6450 [60 mg to 240 mg daily (QD)] or placebo for 3 days. Additional cohorts of GT-1b, GT-2 and GT-3 HCV patients were administered TD-6450 240 mg QD and one GT-1a cohort was administered 240 mg twice daily (BID) for 3 days. The antiviral activity of TD-6450 was assessed using the COBAS®Ampliprep/COBAS®Taqman® HCV Test, 2.0 (limit of detection, LOD = 15 IU/mL) for up to 28 days after the first dose of TD-6450.
Results: Twenty-four patients with GT-1a infection were evaluated following daily oral doses (60 mg to 240 mg) of TD-6450 (n = 21)

or placebo (n = 3) for 3 days. The mean baseline viral loads ranged from 6.1 to 6.3 log10 IU/mL. All GT-1a patients in these cohorts had a maximum HCV RNA viral load decline of at least 3 log10 IU/mL. The HCV RNA results are presented in Table 1. Seven patients (3 in the 120 mg and 4 in the 240 mg groups) had at least one HCV RNA viral load which fell below the LOD and two of these patients had persistent unmeasurable HCV-RNA at Day 28. All doses of TD-6450 were generally well tolerated after three doses and for the 28-day observation period. There were no serious adverse events and no patient discontinuations. There was no pattern of clinical adverse events or laboratory abnormalities related to treatment. The PK of TD-6450 was similar to that observed in healthy subjects and consistent with QD dosing. The evaluation of TD-6450 in GT-1a (BID), GT-1b, GT-2, and GT-3 HCV patients is currently ongoing but dosing has completed and results will be presented.

Table 1. TD-6450 median maximum decline in log_{10} HCV RNA in GT-1a HCV patients (n = 7)

TD-6450 dose	Median maximum decline in HCV RNA (min, max)
60 mg QD	3.9 (3.49, 4.36)
120 mg QD	4.6 (3.11, 5.91)
240 mg QD	4.9 (3.40, 5.80)

Conclusions: TD-6450 was generally well tolerated at all doses evaluated and demonstrated potent dose-dependent antiviral activity in treatment-naïve HCV GT-1 infected patients.

P0899

PRECLINICAL PROFILE OF THE PAN-GENOTYPIC HCV NS3/4A PROTEASE INHIBITOR GS-9857

J.G. Taylor[1], T. Appleby[1], O. Barauskas[1], X. Chen[1], H. Dvory-Sobol[1], R. Gong[1], J. Lee[1], E. Nejati[1], B. Schultz[1], Y. Wang[1], C. Yang[1], M. Yu[1], S. Zipfel[1], K. Chan[1]. [1]*Gilead Sciences, Foster City, United States*
E-mail: james.taylor@gilead.com

Background and Aims: GS-9857 is a pan-genotypic HCV NS3/4A protease inhibitor (PI) in development for the treatment of chronic HCV infection. During a 3-day monotherapy study in GT1–4 patients, GS-9857 was well-tolerated and resulted in median HCV RNA reductions of >3 log_{10} IU/mL at the 100 mg dose. Here we profile preclinical properties of GS-9857 including in vitro potency, selectivity, activity against resistance associated variants (RAVs) as well as pharmacokinetic properties in preclinical species.
Methods: The binding affinity of GS-9857 was tested against wild-type GT1b and GT3a NS3 proteases in biochemical assays. Antiviral activity was studied in 3-day HCV replicon assays using stable or transient replicons encoding the NS3 protease gene from GTs 1–6. Plasma and liver pharmacokinetics were assessed in Sprague-Dawley rats and beagle dogs after oral and intravenous administration.
Results: GS-9857 has picomolar inhibitory activity against GT1b and GT3a NS3 proteases (Ki values of 38 pM and 63 pM, respectively), potent antiviral activity against representative GT1–6 HCV replicon strains (table), and low cytotoxicity (CC50 18–21μM). GS-9857 has less than a 2.5 fold shift in antiviral activity in vitro against the clinically relevant HCV PI RAVs 1a Q80K, 1a R155K, 1b D168A, 1b D168E, and 1b D168V. Good oral bioavailability was observed with GS-9857 in rats and dogs (27–83%) with plasma half-lives of 1.6 hours and 4.1 hours, respectively. The liver concentrations of GS-9857 are approximately 500-fold (rat) and 55-fold (dog) higher than the corresponding plasma concentrations, demonstrating that GS-9857 preferentially distributes to the liver. GS-9857 is also stable in human microsomes and hepatocytes.
Conclusions: GS-9857 is a potent pan-genotypic HCV NS3/4A PI with antiviral activity against HCV GTs 1–6 and an improved resistance profile compared to previous HCV PIs. Importantly, GS-9857 has similar antiviral activity against replicons of all GTs including GT3 (<2-fold difference in EC50 between GT1 and GT3). GS-9857 has a favorable pharmacokinetic profile in preclinical species and is stable in human hepatocytes. The preclinical profile of GS-9857 supports its development as part of a pan-genotypic regimen to treat chronic HCV infection.

P0900

CONSIDERATION OF VIRAL RESISTANCE FOR OPTIMIZATION OF DIRECT ANTIVIRAL THERAPY OF CHRONIC HEPATITIS C

J. Dietz[1], C. Berkowski[1], D. Perner[1], S. Susser[1], S. Zeuzem[1], C. Sarrazin[1]. [1]*Department of Internal Medicine 1, Goethe University Hospital, Frankfurt, Germany*
E-mail: julia.dietz@em.uni-frankfurt.de

Background and Aims: For chronic hepatitis C virus (HCV) genotype (GT) 1 infected patients, combination therapies of a nucleoside NS5B inhibitor [Sofosbuvir (SOF)] with a NS3 protease inhibitor (Simeprevir, SMV) or a NS5A inhibitor (Daclatasvir, DCV and Ledipasvir, LDV) are available. Alternative options are DCV plus the NS3 inhibitor Asunaprevir (ASV) for GT1b or a triple DAA therapy (NS3, NS5A and non-nucleoside NS5B inhibitor) for GT1 (Paritaprevir, PTV, Ombitasvir, OBV and Dasabuvir, DSV). In the underlying studies, sustained virologic response rates (SVR) were high (up to 99%), but pre-existent resistance-associated variants (RAVs) let to a reduction of SVR rates of a range between 5 and 50%.
Methods: Serum samples of consecutive 312 European patients with a chronic GT 1 HCV infection who were treatment- and DAA-naïve were used for the parallel amplification and population-based sequencing of NS3, NS5A and NS5B genes. NS3 RAVs with relevance for SMV, PTV and ASV were investigated at positions F43, Y56, Q80, R155, A156 and D168. Analysis of NS5A RAVs with relevance for DCV, LDV and OBV occurred at positions M28, Q/R30, L31, P32L, Q54H, H/P58 and Y93. For the non-nucleoside NS5B inhibitor DSV relevant positions C316, S368, Y448, S556 and D559 within NS5B were also examined. Sequencing of SOF RAVs (L159, S282, V321) was not performed as these variants were not detected at baseline and / or were not associated with reduced SOF susceptibility.
Results: Major resistant variants with important differences for HCV subtypes were detected within NS3 in 20.5% of patients and within NS5A and NS5B in 11.5% and 21.5% individuals respectively. For NS3, Q80K was observed in 34.5% and 2.1% of subtype 1a and 1b patients, respectively while other RAVs to second generation protease inhibitors were detected rarely (0.7%). Within NS5A RAVs were observed in 7.0% of subtype 1a and 17.0% of subtype 1b infected patients and Y93H was most prevalent (14.2%, GT1b). NS5B RAVs were found in 2.3% and 44.7% of subtype 1a and 1b patients, while C316N, S556G and combinations of both were most frequently detected (22.7%, 7.1%, 12.8%; GT1b). Considering all three DAA targets all subtype 1a and 98.6% of subtype 1b were wildtype for at least one interferon free DAA regimen currently available.
Conclusions: Baseline resistance testing allows the selection of at least one RAVs-free treatment option for nearly all patients enabling a potentially cost-optimized treatment of chronic hepatitis C.

Table (abstract P0901): Maximal reductions in HCV RNA (log_{10} IU/mL)

	GT1a			GT1b	GT2	GT 3			GT 4

THE PAN-GENOTYPIC NS3/4A PROTEASE INHIBITOR GS-9857 DEMONSTRATES POTENT ANTIVIRAL ACTIVITY IN PATIENTS INFECTED WITH HCV GENOTYPE 1, 2, 3 OR 4 IN A 3-DAY MONOTHERAPY STUDY

M. Rodriguez-Torres[1], S. Glass[2], J. Hill[3], B. Freilich[4], D. Hassman[5], A. Di Bisceglie[6], J.G. Taylor[7], B. Kirby[7], J.C. Yang[7], L.M. Stamm[7], D.M. Brainard[7], S. Kim[8], D. Krefetz[9], W. Smith[10], T. Marbury[11], E. Lawitz[12]. *[1]Fundacion De Investigacion De Diego, San Juan, Puerto Rico; [2]PRA Health Sciences, Philadelphia, PA, [3]Avail Clinical Research, DeLand, FL, [4]Kansas City Research Institute, Kansas City, MO, [5]Comprehensive Clinical Research, Berlin, NJ, [6]St. Louis University Medical Center, St Louis, MO, [7]Gilead Sciences, Foster City, CA, [8]West Coast Clinical Trials LLC, Costa Mesa, CA, [9]PRA International, Marlton, NJ, [10]New Orleans Center for Clinical Research, Knoxville, TN, [11]Orlando Clinical Research Center, Orlando, FL, [12]Alamo Medical Research, San Antonio, TX, United States*
E-mail: luisa.stamm@gilead.com

Background and Aims: GS-9857 is a pan-genotypic HCV NS3/4A protease inhibitor (PI) in development for the treatment of chronic HCV infection with potent antiviral activity against HCV genotypes (GT) 1–6 and an improved resistance profile compared to previous HCV PIs. Herein, we describe the safety, pharmacokinetic (PK) and antiviral activity from a 3-day monotherapy study in patients infected with HCV GT 1a, 1b, 2, 3 and 4.

Methods: HCV NS3/4A PI-naive patients without cirrhosis were randomized to receive placebo or GS-9857 once daily for 3 days at doses ranging from 50 mg to 300 mg. Safety was assessed by physical examination, ECG and laboratory tests during treatment and for 1 week post-dosing. GS-9857 PK was assessed on Day 1 and 3. Antiviral activity was evaluated by measuring HCV RNA using the COBAS Taqman HCV Test, v2.0 for use with Ampliprep (LLOQ = 15 IU/mL).

Results: Sixty-nine (69) patients with GT 1a (n = 28, 41%), 1b (n = 6, 9%), 2 (n = 8, 12%), 3 (n = 23, 33%), and 4 (n = 4, 6%) were enrolled in the study. The population was 71% male with a mean age of 50 (range 30–64) and BMI 27.7 kg/m^2 (range 19.4–52.5) and mean HCV RNA of 6.2 log_{10} IU/mL (range 5.8–6.7). The median reductions (log_{10} IU/mL) in HCV RNA are presented in the table. GS-9857 exhibited comparable half-life, linearity and accumulation as observed in healthy volunteers with approximately 4-fold higher plasma exposures at the same dose. No patients discontinued treatment due to an adverse event (AE). All AEs were mild or moderate in severity. The only AE occurring in >5% of patients was diarrhea (n = 2, 6%). There were no clinically significant changes in ECG or vital signs. One patient had a Grade 4 creatine kinase on Day 3 which increased from screening to baseline prior to dosing and resolved without intervention.

Conclusions: During a 3-day monotherapy study in patients infected with HCV GT 1a, 1b, 2, 3 or 4, GS-9857 was well-tolerated and resulted in median HCV RNA reductions of >3 log_{10} IU/mL at the 100 mg dose.

P0902

EXPOSURE-RESPONSE ANALYSES FOR EFFICACY (SVR12) FOR THE DIRECT ACTING ANTIVIRAL REGIMEN OF ABT-450/R, OMBITASVIR WITH DASABUVIR +/− RIBAVIRIN IN SUBJECTS WITH HCV GENOTYPE 1 INFECTION

A. Khatri[1], S. Mensing[2], T. Podsadecki[3], W. Awni[1], R. Menon[1], S. Dutta[1]. *[1]Clinical Pharmacology and Pharmacometrics, AbbVie, North Chicago, United States; [2]Clinical Pharmacology and Pharmacometrics, AbbVie, Ludwigshafen, Germany; [3]Infectious Disease, GPRD, AbbVie, North CHicago, United States*
E-mail: amit.khatri@abbvie.com

Background and Aims: The 3 direct acting antiviral (DAA) regimen (3D) of coformulated ABT-450/r [protease inhibitor identified by AbbVie and Enanta dosed with ritonavir (RTV)] with ombitasvir (NS5A inhibitor) plus dasabuvir (polymerase inhibitor) ± ribavirin (RBV) has completed Phase 3 clinical trials in HCV genotype (GT) 1 infected subjects. The objective of this analysis was to examine the relationships between the steady-state exposure (AUC and C_{trough}) of DAAs and RBV with SVR_{12} following administration of the 3D regimen in five Phase 3 and one Phase 2 clinical trials.

Methods: Graphical and quantitative multivariate logistic regression (LR) analyses were performed using steady state AUC and C_{trough} of DAAs and RBV based on the population-pharmacokinetic models. Graphical analysis was performed using quartiles plots. Since >99% of GT1b-infected subjects [N = 996] achieved SVR_{12}, only data for GT1a-infected non-cirrhotic subjects (N = 615) who received the 3D + RBV for 12 weeks were included in the multivariate LR analyses performed using SAS (version 9.3). Subject-specific covariates, such as age, body mass index, sex, ethnicity (Hispanic/Latino vs. others) and race (Black vs. others), baseline HCV viral load (VL), IL28B genotype, and prior pegIFN/RBV treatment, were included in the analyses.

Results: No trend was observed between the tested DAA or RBV AUCs and % SVR_{12} among GT1b-infected subjects with graphical analyses. Among GT1a-infected subjects, there was no apparent relationship between the tested dasabuvir AUC and % SVR_{12}, but shallow trends were observed for the tested ABT-450, ombitasvir and RBV AUCs. Multivariate LR analyses did not reveal a significant association between the tested ABT-450, dasabuvir or ribavirin AUCs and SVR_{12}, but an increase in the tested ombitasvir AUCs was associated with a slight increase in probability of SVR_{12} ($P < 0.05$); a maximum of ± 25% change in ombitasvir AUC observed in drug interaction studies predicted about ± 1% change in SVR_{12}, which is not clinically significant. A Prior history of non-response to pegIFN/RBV treatment, IL28B genotype, baseline VL, sex, race and Hispanic/Latino ethnicity were not predictive of a change in the probability of SVR_{12}. Similar relationships were observed between the tested DAA or RBV C_{trough} and SVR_{12}.

Conclusions: The results of these analyses indicate that the doses selected for the 3D regimen achieved high SVR_{12} rates across the range of exposures observed in the Phase 3 studies.

E-mail: ceccherini@med.uniroma2.it

Background and Aims: Hepatitis C Virus (HCV) infection is a leading cause of liver transplantation (LT) and is associated with the worst clinical outcome after LT due to fast and frequent severe HCV recurrence. Our aim was to investigate whether early HCV-RNA kinetics during sofosbuvir (SOF) + ribavirin (RBV) treatment are influenced by HCV-genotype and severity of recurrent HCV hepatitis.
Methods: 34 post-LT patients with severe HCV-recurrence (fibrosing cholestatic hepatitis = 7, cirrhosis = 14, advanced fibrosis F3 by Metavir = 13), infected by HCV genotype 1a, 1b, 2, 3a and 4 (7, 11, 5, 6, 5), received SOF 400 mg/day + RBV 400–1000 mg/day (N = 27) or SOF alone (N = 7), for a median (IQR) of 8 (4–16) weeks. HCV-RNA was quantified at baseline (BL) and weekly during treatment. HCV-RNA kinetics was modeled according to Guedj 2014. Presence of NS5B resistance associated variants (RAVs) was evaluated by Sanger-sequencing. Safety and clinical parameters were also analyzed.
Results: Overall, a slow HCV RNA decay was observed: only 6/34 (18%) patients had undetectable (TND) HCV-RNA values at week 4 (rapid virological response, RVR). No patient infected with genotype 1a, 2 and 4 had RVR. Nine out of 21 evaluable patients (43%) had TND at week 8, and 8/10 (80%) at week 12. Non-cirrhotic patients had a significantly higher BL HCV-RNA compared to patients with cirrhosis (median [IQR] 6.5 [6.2–6.8] Log IU/ml vs 5.7 [5.4–5.9] Log IU/ml, p = 0.001), without different kinetics of HCV-RNA decline and RVR frequencies (18% *vs* 27% respectively, p = 0.6). Failure to achieve RVR was not related to BL viremia (p = 0.2), nor RBV-administration (p = 0.4), but it was associated with slower early HCV-RNA kinetics. Indeed, 17/32 patients had HCV-RNA >100 IU/ml at week 2, and none of them reached RVR vs 33% of patients with HCV-RNA<100 IU/ml (p = 0.01). No baseline-biochemical or clinical parameter significantly correlated with early slow viral kinetics, with the exception of cholesterol levels, that were higher in patients with HCV-RNA >100 IU/ml at week 2 (median [IQR] 156 [143–186] vs 115 [88–160] mg/dl, p = 0.024). No baseline RAVS were detected in all 10 patients analyzed, with the exception of L159F in 1 HCV-1b-naive cirrhotic patient that became RVR.
Conclusions: In the context of an heterogeneous population of patients with severe HCV-recurrence post-LT in real-life setting, at this preliminary phase, the combination of SOF +/− RBV shows an overall slow kinetics of HCV-RNA decay, regardless of BL viremia and, notably, regardless of the type and stage of liver disease.

P0904

RG-101, A NOVEL GalNAc-CONJUGATED INHIBITOR OF MICRORNA-122, DEMONSTRATES SIGNIFICANT VIRAL LOAD REDUCTION AND REDUCES LIVER STEATOSIS IN HUMAN HEPATOCYTE CHIMERIC MICE INFECTED WITH GENOTYPE 1A OR HARD-TO-TREAT GENOTYPE 3A HEPATITIS C VIRUS (HCV)

S. Neben[1], K. Liu[1], J. Tay[1], N. Chau[1], Y. Morikawa[2], B. Bhat[1], N.W. Gibson[1]. *[1]Regulus Therapeutics, San Diego, United States; [2]PhoenixBio Co., Higashihiroshima, Japan*
E-mail: sneben@regulusrx.com

Background and Aims: RG-101 is a novel phosphorothiate oligonucleotide that binds and efficiently inhibits microRNA (miR)-122, which is abundantly and specifically expressed in hepatocytes and plays a key role in the replication of the hepatitis C virus (HCV). Preferential targeting to hepatocytes was achieved through conjugation of the oligo to GalNAc through a phosphodiester linker, which results in a pro-drug that is metabolized in the liver to an active unconjugated oligo. A number of studies have been performed demonstrating significantly enhanced pharmacodynamic activity of RG-101 compared to its unconjugated parent oligo in both normal mice and non-human primates at significantly lower concentrations in the liver (Bhat et al., Hepatology 58; 2013).
Methods: Effects of RG-101 on HCV infection were examined using human hepatocyte chimeric mice (PXB-mice) infected with genotype (GT) 1a and hard-to-treat genotype 3a HCV isolates.
Results: Expression levels of ASGPR, receptors on human hepatocytes that bind GalNAc and facilitate cellular uptake of RG-101, were 2–3 fold lower in stably engrafted human hepatocytes compared to fresh hepatocytes prior to transplantation. Pharmacodynamic activity of RG-101, measured by de-repression of endogenous miR-122 target genes, was 3–5 fold lower in PXB-mice compared to wild-type mice after a single subcutaneous (SC) injection, correlating with a 3 fold reduced level of oligo uptake in the liver of PXB-mice at all doses tested. A single SC administration of RG-101 in HCV GT1a-infected PXB-mice produced statistically significant 1 and 1.5 $\log_{10}$ viral titer reductions at 10 and 30 mg/kg with maximum reduction between 10 and 14 days post-dose. Consensus sequencing of virus in the serum at day 42 post-dose showed no mutations in the miR-122 binding sites. In GT3a-infected PXB-mice, a single SC administration of RG-101 produced about 1.5–2 $\log_{10}$ viral load reduction with maximum reduction at 14–17 days. A further 0.5 $\log_{10}$ reduction was observed following a second SC dose given at day 28. Liver steatosis observed in PXB-Mouse livers was dramatically reduced following RG-101 treatment in line with the known role of miR-122 in hepatic lipid metabolism.
Conclusions: Taken together, these studies in PXB-mice provide in vivo proof that RG-101 is effective against multiple HCV genotypes and may have additional benefits beyond viral titer reduction.

P0905

NO SIGNIFICANT INTERACTION AMONG OMBITASVIR/ PARITAPREVIR/RITONAVIR +/− DASABUVIR AND SOFOSBUVIR

J. King[1], S. Dutta[1], D. Cohen[1], T. Podsadecki[1], B. Ding[1], W. Awni[1], R. Menon[1]. *[1]AbbVie, North Chicago, United States*
E-mail: jennifer.king@abbvie.com

Background and Aims: Paritaprevir [NS3/4A inhibitor identified as a lead compound by AbbVie and Enanta, dosed with ritonavir (r)], ombitasvir (NS5A inhibitor) and dasabuvir (NS5B non-nucleoside polymerase inhibitor) are being developed as an interferon-free direct-acting antiviral agent (DAA)-combination therapy for HCV infection. The 3-DAA (3D) regimen of coformulated ombitasvir/paritaprevir/r + dasabuvir +/− ribavirin (RBV) has completed Phase 3 clinical trials in HCV genotype (GT) 1-infected subjects. The 2-DAA (2D) regimen of ombitasvir/paritaprevir/r +/− RBV has been evaluated in HCV GT1b- and GT4-infected subjects.

The 3D and 2D regimens have the potential for co-administration with sofosbuvir (SOF, nucleoside NS5B inhibitor) in the treatment of HCV. A drug–drug interaction study was conducted to assess the potential for interactions.

Methods: This Phase 1, open-label, multiple-dose, sequential, non-fasting study enrolled 32 healthy subjects into 2 arms; each arm comprised 2 cohorts (Figure 1). Doses of study drugs were: ombitasvir/paritaprevir/r 25/150/100 mg QD, dasabuvir 250 mg BID, and SOF 400 mg QD. Intensive pharmacokinetic assessment was performed on Study Days 7, 14, 15 and 21. The effect of the DAAs on SOF pharmacokinetics and vice versa for each arm was assessed by a repeated-measures analysis using SAS. Safety was evaluated through assessment of adverse events (AEs), vital signs, ECGs and clinical laboratory tests.

Results: Ombitasvir, paritaprevir and dasabuvir C_{max}, AUC and C_{24} during co-administration with sofosbuvir as either the 3D or 2D regimen were similar (≤20% change) to 3D or 2D alone. Sofosbuvir C_{max} and AUC were 61% and 112% higher, respectively, while GS-331007 AUC was 27% higher during co-administration with 3D compared to sofosbuvir alone. Sofosbuvir C_{max} and AUC were 64% and 94% higher, respectively, whereas GS-331007 AUC was 32% higher during co-administration with 2D compared to sofosbuvir alone. The increases in SOF and GS-331007 exposures are not considered clinically significant. No subjects discontinued the study due to study drug-related adverse events.

Conclusions: Ombitasvir/paritaprevir/r +/− dasabuvir increased sofosbuvir plasma concentrations with limited effects (particularly AUC) on GS-331007 plasma concentrations. No dose adjustment is needed for sofosbuvir during co-administration with the 3D or 2D regimen. No dose adjustment is needed for ombitasvir, paritaprevir or dasabuvir when administered as the 3D or 2D regimen with sofosbuvir.

INHIBITION OF HCV REPLICATION BY CCR5 BLOCKADE WITH CENICRIVIROC AND MARAVIROC

K.E. Sherman[1], L. Kong[1], J.T. Blackard[1]. [1]*Digestive Diseases, University of Cincinnati College of Medicine, Cincinnati, United States*
E-mail: kenneth.sherman@uc.edu

Background and Aims: CCR5 is a chemokine co-receptor best known for its central role in HIV binding to T-cells. However, CCR5 is expressed in hepatocytes, stellate cells and Kupffer cells within the liver, and may mediate liver fibrosis. Interaction between HIV (or gp120) and CCR5 has been shown to upregulate HCV replication as well. We hypothesized that CCR5 blockade might modulate HCV replication. We examined the effect of CCR5 blockade using two potent receptor antagonists, cenicriviroc (dual CCR2/5 antagonist) and maraviroc (CCR5 antagonist) on HCV replication.

Methods: Briefly, 100,000 HUH7.5-JFH1 human hepatocyte cells, which constitutively produce a cell-line adapted strain of HCV genotype 2 and express CCR5 were seeded in wells. The next day, cells were incubated with 25 ug/ml, 0.25 ug/ml or 0.0025 ug/ml of the antiviral drugs under investigation. These included maraviroc or cenicriviroc, sofosbuvir (an HCV polymerase inhibitor positive control) or raltegravir (an HIV integrase inhibitor negative control). The culture supernatants were collected after 24 hours of incubation with the drug. Cell number was evaluated to determine if cell viability affected HCV viral load production. HCV replication was monitored using a commercial HCV Core Antigen ELISA assay (Cell BioLabs, San Diego, CA).

Results: A statistically significant and dose-dependent response was observed for maraviroc, cenicriviroc, and sofosbuvir at the 0.25 ug/ml and 25 ug/ml concentrations but not at 0.0025 ug/ml. Raltegravir had no effect on HCV Core Antigen production, nor did DMSO buffer controls. Cell viability was not affected by any drug or by the DMSO buffer solution.

Conclusions: As a result of CCR5 blockade – maraviroc and cenicriviroc – significantly reduced HCV Core Antigen production in an *in vitro* HUH7.5 JFH1 human hepatocyte cell line at levels of inhibition similar to that observed for sofosbuvir, a direct acting HCV RNA polymerase inhibitor. This potent inhibition suggests that CCR5 may represent a new target for multidrug HCV therapy.

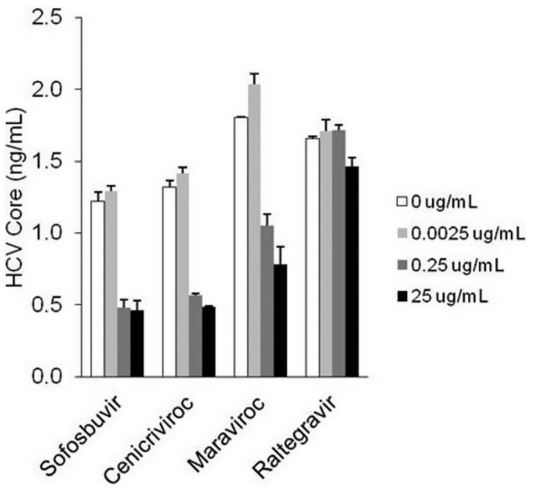

Figure: HCV Core ELISA.

P0907

PHARMACOKINETICS, PHARMACODYNAMICS, AND TOXICITY PROFILE OF RG-101, A NOVEL GalNAc-CONJUGATED HEPATOCYTE-TARGETNG INHIBITOR OF MICRORNA-122, IN RODENTS AND CYNOMOLGUS MONKEYS

S. Neben[1], K. Liu[1], C. Berman[2], J. Tay[1], C. Esau[1], R. Kaiser[3], B. Wahle[4], N. Chau[1], B. Bhat[1], N.W. Gibson[1]. [1]*Regulus Therapeutics, San Diego,* [2]*Berman Consulting, Wayland,* [3]*Charles River Laboratories, Reno,* [4]*Xenometrics, Stillwell, United States*
E-mail: sneben@regulusrx.com

Background and Aims: RG-101 is a novel phosphorothiate (PS) oligonucleotide (oligo) that binds and efficiently inhibits microRNA (miR)-122, which is abundantly and specifically expressed in hepatocytes and plays a key role in the replication of the hepatitis C virus (HCV). Preferential targeting to hepatocytes was achieved by conjugation of the oligo to GalNAc through a phosphodiester linker, which results in a pro-drug that is metabolized in the liver to an active unconjugated oligo. Previous studies using an unconjugated miR-122 anti-miR demonstrated sustained PD activity and no adverse effects in normal mice treated weekly for up to 50 weeks.

Methods: To support first-in-human trials, pharmacokinetics (PK), pharmacodynamics (PD), and toxicity (Tox) of RG-101 administered subcutaneously in mice and cynomolgus monkeys were studied at doses from 0.1 to 450 mg/kg in mice and 1.5 to 150 mg/kg in monkeys.

Results: After injection, rapid absorption into plasma was observed with T_{max} of 0.5–4 hours. RG-101 is stable in plasma and no unconjugated oligo was detected. Uptake in liver and kidney

was rapid, and RG-101 was rapidly and efficiently cleaved to unconjugated oligo in the liver. Half-life of the unconjugated oligo in the liver was 8–14 days in mouse and monkey. Measurement of an endogenous miR-122 target mRNA, *aldoa*, in the liver revealed rapid onset of action with 80% maximal activity within 24 h and greater than 60 days duration of action. Pro-inflammatory effects in mouse and rat were minimal at high doses. In single and repeat dose studies, typical PS oligo class effects, including complement activation and prolonged APTT, were observed in monkeys, but were not considered adverse. No renal toxicity occurred, which reflects the biased distribution of GalNAc-conjugated oligo to the liver. Delayed dose-related increases in liver enzymes, including alanine aminotransferase (ALT), were observed after the first dose with no further increases seen after subsequent doses. None of these findings were associated with adverse clinical signs and complete-to-partial recovery occurred 3 months after last dose. No Observed Adverse Effect Levels (NOAELs) of 450 mg/kg and 45 mg/kg in mouse and monkey, respectively, were declared for RG-101, producing a 30–100 fold therapeutic index.

Conclusions: Taken together, the PK/PD/Tox profile of RG-101 suggests that conjugation of oligos to GalNAc produces significant advantages that are likely to translate to more effective and safer clinical outcomes.

P0908

ADHERENCE TO OMBITASVIR/PARITAPREVIR/R, DASABUVIR, AND RIBAVIRIN IS >98% IN THE SAPPHIRE-I AND SAPPHIRE-II TRIALS

T. Hassanein[1], S. Roberts[2], S.D. Shafran[3], M. Makara[4], M. Bennett[5], B. Müllhaupt[6], F. Poordad[7], S. Ryder[8], A.M. Di Bisceglie[9], B. Fu[10], E. Coakley[10], B.H. McGovern[10], G.R. Foster[11]. *[1]Southern California Liver Centers and Southern California Research Center, Coronado, United States; [2]The Alfred Hospital, Melbourne, Australia; [3]University of Alberta Hospital, Edmonton, Canada; [4]Saint Laszlo Hospital, Budapest, Hungary; [5]San Diego Digestive Diseases, San Diego, United States; [6]University Hospital, Zurich, Switzerland; [7]The Texas Liver Institute/University of Texas Health Science Center, San Antonio, United States; [8]Nottingham Digestive Diseases Centre and Biomedical Research Unit, Nottingham, United Kingdom; [9]Saint Louis University Liver Center, Saint Louis University, Saint Louis, [10]AbbVie Inc., North Chicago, United States; [11]Queen Marys University of London, Barts Health, London, United Kingdom*
E-mail: laurinda.cooker@abbvie.com

Background and Aims: Scant data are available on adherence with direct-acting antiviral (DAA) regimens or the impact of poor adherence on virologic outcomes. Ombitasvir is a NS5A inhibitor and dasabuvir is an NS5B RNA polymerase inhibitor. Paritaprevir (formerly ABT-450) is a HCV NS3/4A protease inhibitor identified by AbbVie and Enanta and co-dosed with the pharmacokinetic enhancer ritonavir (r), to improve peak, trough and overall drug concentrations. We report adherence rates in the 3DAA + ribavirin (3D+RBV) and placebo arms in the phase 3 double-blind, placebo-controlled SAPPHIRE trials among 1025 HCV genotype (GT) 1-infected patients in 20 countries.

Methods: Treatment-naïve (n = 631; SAPPHIRE-I) and treatment-experienced patients (n = 394; SAPPHIRE-II) were randomized to 12 weeks of active treatment (3D+RBV: co-formulated ombitasvir/paritaprevir/r [25 mg/150 mg/100 mg QD] and dasabuvir [250 mg BID] with weight-based RBV [1000 or 1200 mg]), or placebo. For all patients with pill count data available during double-blind treatment, adherence was calculated as: (pills dispensed minus pills returned)/(total pills expected to be taken for days on study drug).

Results: Of 1025 patients, 56% were male, 90% were white, mean (SD) age was 50.9 (10.6) years, and mean (SD) BMI was 26.0 (4.2) kg/m^2. Intent-to-treat SVR12 rates were 96.4% (SAPPHIRE-I) and 96.3% (SAPPHIRE-II). Mean adherence to each study drug in both trials was >98.8% for patients on 3D+RBV or placebo (Table). In the 3D+RBV arms, 5 patients had adherence <80% to one or more study drug; none of the 5 experienced virologic failure. In SAPPHIRE-I, patients with on-treatment virologic breakthrough (n = 1; 0.2%) or post-treatment relapse (n = 7; 1.5%) had ≥95% adherence to all 3 study drugs. In SAPPHIRE-II, all patients with post-treatment relapse (n = 7; 2.4%) had >98% adherence to 3D; 5 of 7 had >98% adherence to RBV, and 2 had missing RBV pill count data. In both trials, most adverse events were mild, and those leading to treatment discontinuation were infrequent: 0.8% (6/770.)

Table: Summary of adherence to study drugs during double-blind treatment

	Adherence [a], Mean % (SD), n [b]			
	SAPPHIRE-I HCV GT1 (treatment-naïve)		SAPPHIRE-II HCV GT1 (treatment-experienced [c])	
	3D+RBV	Placebo	3D+RBV	Placebo
Ombitasvir/Paritaprevir/r	99.71 (1.75) n = 444	99.79 (1.81) n = 152	99.81 (1.00) n = 289	99.62 (0.84) n = 92
Dasabuvir	99.22 (3.07) n = 444	99.34 (2.13) n = 152	99.49 (1.10) n = 289	99.25 (0.84) n = 92
RBV	98.85 (3.96) n = 427	98.93 (2.18) n = 152	99.46 (5.66) n = 272	99.25 (2.42) n = 92

[a] Adherence reflects days on study drug for all patients with pill count data available, including patients who discontinued or interrupted study drug for adverse events or other reasons.
[b] Adherence data for each type of pill not available for all patients.
[c] Treatment-experienced patients had a prior relapse, partial, or null response to pegIFN/ribavirin therapy.

Conclusions: In this analysis, the multi-targeted IFN-free regimen of ombitasvir/paritaprevir/r and dasabuvir with RBV was well tolerated, with high rates of adherence (>98%) to all study drugs, including RBV at 1000 or 1200 mg. Low adherence rates were infrequent and did not lead to virologic failure.

P0909

ANALYSIS OF NATURAL RESISTANCE PROFILE TO NS5A REPLICATION COMPLEX INHIBITORS IN DIFFERENT HEPATITIS C GENOTYPES

S. Bagaglio[1,2], E. Messina[1], M. Merli[1], H. Hasson[1], A. Lazzarin[1,2], C. Uberti-Foppa[1], G. Morsica[1]. *[1]Infectious Diseases Department, Ospedale San Raffaele Scientific Institute, [2]Vita Salute University, Milan, Italy*
E-mail: bagaglio.sabrina@hsr.it

Background and Aims: Recent progress in the understanding of hepatitis C virus (HCV) biology has facilitated the development of direct-acting antiviral agents (DAAs) that target specific steps in the viral replication cycle. Several compounds thought to bind directly with NS5A are now in various clinical trial phases, including the most advanced, daclatasvir, ledipasvir and ABT-267. Resistance mutations have been mapped to the N-terminal region of NS5A (the first 100 amino acids within domain 1). Analysis from daclatasvir clinical trials showed that treatment failure was related to pre-existing variants exhibiting resistance to NS5A inhibitors (NS5A-I) in patients infected by genotype (G) 1a and 1b. We aimed to evaluate the frequency of natural resistant variants to NS5A-I in different HCV genotypes.

Methods: Changes reported to be associated with NS5A-I resistance (positions 28, 30, 31, 54, 58, 93) were examined. A total of 2831 (domain 1: aa 1–100) NS5A sequences deposited at Los Alamos HCV database were analysed: 1209 sequences belonged to G1a, 1552 to G1b, 48 to G3a and 22 to G4 (17 subtype 4a and 5 subtype 4d).

Results: Overall, resistance associated mutations (RAM) were detected in 641 of 2831 (22.5%) isolates. In G1a sequences, 117 (10%) RAM has been detected: 37 sequences showed aa change

at position M28, 16 at Q30, 6 at L31, 37 at H58, 7 at Y93 and 14 sequences harboured 2 aa changes at least. In G1b sequences, 519 (33%) RAM has been detected: 78 isolates showed mutation at aa L31, 364 at Q54, 12 at Y93 and 65 strains harboured 2 aa changes at least. None of 48 G3a sequences showed RAM, 2 of 22 (9%) G4 sequences harboured P58T resistance mutation; both these isolates belonged to subtype 4d. The presence of natural RAM was more frequently reported in G1b than in G1a isolates (33% vs 10%; $p < 0.0001$). The frequency of variants harbouring more than one RAM was significantly different between G1a and G1b (1% vs 4%; $p < 0.0001$). Comparison among different genotype showed a significant difference ($p < 0.0001$).

Conclusions: Natural polymorphisms in NS5A at positions that may influence susceptibility to NS5A-I were less frequently observed in genotypes 3a and 4. Surprisingly, G1a isolates showed a lower prevalence of natural RAM respect to G1b, both considering single RAM or variants with more than one resistance mutation. This information may provide further insights in evaluate the right interferon free regimen including DAAs combination.

P0910

NO EVIDENCE OF PHARMACOKINETIC DRUG–DRUG INTERACTION IN HEALTHY SUBJECTS BETWEEN COADMINISTERED GRAZOPREVIR (MK-5172)/ELBASVIR (MK-8742) AND SOFOSBUVIR

W.L. Marshall[1], W.W. Yeh[1], D. Stypinski[2], P. Auger[2], C. Bethel-Brown[2], L. Caro[1,2], P. Jumes[1], X. Huang[1], Z. Guo[1], M. Martinho[1], H-P Feng[1], D. Armas[2], J. Brejda[2], M. Iwamoto[1], J.R. Butterton[1].
[1]Merck and Co., Inc., Whitehouse Station, NJ, [2]Celerion, Tempe, AZ, United States
E-mail: william.marshall@merck.com

Background and Aims: Grazoprevir (MK-5172) is a potent, once-daily inhibitor of the hepatitis C virus (HCV) NS3/4A protease, and elbasvir (MK-8742) is a potent, once-daily inhibitor of the HCV NS5A replication complex that are being developed as a fixed-dose combination therapy for the treatment of chronic HCV infection. This study evaluated the effect of grazoprevir and elbasvir on the pharmacokinetics of sofosbuvir (SOF), an HCV NS5B inhibitor, when coadministered in healthy subjects.

Methods: This was an open-label, 2-period, fixed-sequence study to assess the effect of multiple oral doses of grazoprevir and elbasvir on the pharmacokinetics of a single oral dose of SOF. Sixteen healthy adult male and female subjects were enrolled. In Period 1, subjects received a single oral 400 mg dose of SOF. Following an 8 day washout period, in Period 2 multiple oral doses of 200 mg grazoprevir and 50 mg elbasvir were co-administered once daily from Days 1 to 15, inclusive. On Day 11, a single oral dose of SOF was co-administered with the dose of grazoprevir and elbasvir. Plasma pharmacokinetic parameters of SOF and its principal nucleoside metabolite (GS-331007) were measured in Period 1 and following Day 11 in Period 2.

Results: SOF + grazoprevir + elbasvir/SOF alone geometric mean ratios (GMRs) [90% confidence intervals (90%CIs)] for plasma SOF $AUC_{0-\infty}$ and C_{max} were 2.43 [2.12, 2.79] and 2.27 [1.72, 2.99], respectively. These changes in SOF are not considered to be clinically meaningful based on the safety margins of SOF. The GMRs [90% CIs] for plasma GS-331007 $AUC_{0-infty;}$ and C_{max} for the same comparison were 1.13 [1.05, 1.21] and 0.87 [0.78, 0.96], respectively. These changes in GS-331007 are not considered to be clinically meaningful. Coadministration of SOF, grazoprevir, and elbasvir was generally well tolerated.

Conclusions: Multiple dose administration of 200 mg grazoprevir and 50 mg elbasvir daily with a single dose of SOF was generally well tolerated by healthy subjects in this study. Co-administration of elbasvir and grazoprevir with SOF had no clinically meaningful effect on the PK of SOF and its metabolite GS-331007. Taken together with the lack of potential for SOF to perpetrate a drug–drug interaction on grazoprevir or elbasvir, these results suggest that SOF, grazoprevir, and elbasvir may be coadministered without dose adjustment.

P0911

CHARACTERIZATION OF CLINICAL PREDICTORS OF NATURALLY OCCURRING NS3/NS4A PROTEASE POLYMORPHISM IN GENOTYPE 1 HEPATITIS C VIRUS INFECTED PATIENTS

G. Lisboa Neto[1], C. Noble[2], J.R.R. Pinho[2], F.M. Malta[2], M.S. Gomes-Gouvêa[2], M.V. Alvarado-Mora[2], M.H. Silva[3], A.G. Leite[4], L.Z. Piccoli[4], F.J. Carrilho[2], M.C. Mendes-Correa[1]. *[1]Department of Infectious Diseases, [2]LIM-07, Institute of Tropical Medicine, Department of Gastroenterology, University of São Paulo School of Medicine, [3]Centro de Referência e Treinamento em DST/AIDS, São Paulo, [4]Centro Especializado em Saúde, Caxias do Sul, Brazil*
E-mail: glneto@gmail.com

Background and Aims: Chronic hepatitis C is a major cause of liver disease worldwide. Its high replication rate and lack of proofreading activity lead to a great diversity in viral population (polymorphisms) that may emerge as dominant strains in a DAA's therapy set. Spontaneously occurring resistance may impair the rate of success in some macrocyclic NS3 protease inhibitors (PI) based regimens. This study aimed to evaluate potential associations between the frequency of amino acid variations in NS3/NS4A protease of hepatitis C virus (HCV) and demographic/clinical features in chronic HCV infected patients.

Methods: Clinical and epidemiological data were retrieved from medical records of 247 HCV chronically infected patients consecutively evaluated in 5 tertiary centers in Brazil. HCV NS3 analysis was performed by direct sequencing with Sanger-based technology.

Results: 156 subjects (63.1%) were male and the mean age was 44.9(±9.6) years. Sixty-seven individuals (27.1%) had history of ethanol use. One hundred and twelve patients (45.3%) were coinfected with HIV. Overall, 21.9% of analyzed subjects had at least one amino acid substitution in HCV NS3 region [95% CI: 15.0–53.9]. Fourteen HCV samples (5.6%) harbored at least one NS3 PI resistance mutation (T54S, V55A or Q80R) [95% CI: 3.1–9.3]. Variables independently associated with NS3 amino acids substitutions were HCV subtype 1b (OR: 5.68, 95% CI: 2.61–12.35), total bilirubin level >1.5 ULN (OR: 5.25, 95% CI: 1.19–23.16) and albumin level <3.5 g/dL (OR: 3.88, 95% CI: 1.19–23.16).

Conclusions: The frequency of HCV NS3 polymorphism in patients with laboratory markers of advanced liver disease was high, indicating a possible relation between length of hepatopathy and accumulation of such amino acid substitutions. HCV protease in subtype 1b appears to be highly variable in our country.

P0912

EARLY-PHASE HCV KINETICS AND ROLE OF PRE-EXISTING RESISTANCE IN CIRRHOTIC OR INTERFERON-INSENSITIVE PATIENTS ON DACLATASVIR PLUS ASUNAPREVIR

V. Cento[1], V. Calvaruso[2], S. Marenco[3], R. Alfieri[4], M. Aragri[1], F.P. Antonucci[1], V.C. Di Maio[1], S. Petta[2], A. Mazzola[2], L. Milanesi[4], A. Picciotto[3], F. Ceccherini-Silberstein[1], A. Craxì[2], C.F. Perno[1].
[1]Experimental Medicine and Surgery, University of Rome "Tor Vergata", Rome, [2]Gastroenterology, "P. Giaccone" University Hospital, Palermo, [3]Gastroenterology, "S. Martino" Hospital, Genova, [4]Institute for Biomedical Technologies, National Research Council, Segrate (Mi), Italy
E-mail: valeriacento@gmail.com

Background and Aims: The combination of daclatasvir (DCV) and asunaprevir (ASV) obtains HCV clearance in up to 90% of patients infected with HCV Gt-1, but treatment response is slower in subjects with a previous non-response to pegIFN+ribavirin (P/R).

No data are available on early HCV-RNA kinetics during DCV+ASV treatment, nor on pre-existing resistance associated variants (RAVs), for Gt-1 patients with previous P/R failure and/or cirrhosis, in whom treatment failure would have major clinical relevance.

Methods: Nine patients with HCV-1b (8 Child A cirrhosis; 8 previous non responders to P/R: 6 null, 2 relapse) receiving DCV 60 mg qd and ASV 100 mg bid were studied. Baseline (BL) presence of NS3-NS5A RAVs was assessed by population sequencing. HCV-RNA was quantified at BL, early time-points (2 h-6 h-24 h-30 h-48 h-72 h-96 h-1w-2w) and per protocol (4w-8w-12w-20w-24w-28w-32w), and its kinetics modeled (Guedj, PNAS 2012). Sustained viral response (SVR) at w4 are presented.

Results: 6/9 patients had a rapid viral response (RVR), and 8/9 patients achieved SVR_4, with 1 RVR-patient relapsing at w4 of follow-up. In all patients, HCV-RNA decay was biphasic, starting 6 h after initial dosing (median [IQR] HCV-RNA decay = −1.0 [−1.7; −0.8] log IU/ml) with the steepest decline at 24 h (median [IQR] HCV-RNA decay = −2.8 [−2.9; −2.2] log IU/ml) then slowing down. Since onset, non-RVR patients tended to have slower BL-24 h HCV-RNA decay as compared to RVRs (median [IQR] = −2.4 [−2.8; −1.4] *vs* −2.9 [−3.0; −2.9] log IU/ml), resulting in lower mean virion clearance rates (c) (15.8 day-1 *vs* 26.0 day-1, respectively). This trend was observed also during phase II, where non-RVRs had lower mean cell clearance rates (δ) (0.09 day-1 *vs* 0.26 day-1 in RVRs), resulting in suboptimal BL-2w HCV-RNA decay (median [IQR] = −4.3 [−4.7; −3.4] *vs* −5.1 [−6.1; −4.4] in RVRs) and always quantifiable HCV-RNA values at w2. Notably, the NS5A-RAV Q54H was detected at BL in all 3 non-RVR patients, in the only DCV+ASV relapser and in 1 RVR/SVR patient. No BL NS3-RAVs were detected.

Conclusions: In HCV-1b cirrhotic and/or IFN-insensitive subjects, a suboptimal virological response can be already visualized in the first days of DCV+ASV. The presence of NS5A-RAV Q54H was associated with a slower response (or treatment failure) in real-life setting, and would suggest a cautious management of high risk patients treated with NS5A inhibitors, considering the potential need for a third drug (NS5B inhibitor?).

P0913

INTERACTIONS STUDY OF HCV NSB5 POLYMERASE INHIBITORS WITH NSB5 NON-STRUCTURED PROTEINS TOWARD BETTER DESIGN OF NEW INHIBITORS BASED ON MOLECULAR DOCKING AND PHARMACOPHORE METHODS

M. Shahmohammadi Aghbolagh[1], E. Pourbasheer[2], R. Aalizadeh[3].
[1]*Department of Chemistry, Umea University, Umea, Sweden;*
[2]*Department of Chemistry, Payame Noor University (PNU), P.O. Box 19395–3697, Tehran, Iran;* [3]*Laboratory of Analytical Chemistry, Department of Chemistry, University of Athens, Panepistimiopolis Zografou, 157 71 Athens, Greece*
E-mail: shahmohammadi80@gmail.com

Background and Aims: Since targeting the NSB5, which is an RNA dependent RNA polymerase and play a crucial role in synthesis of negative and positive strand copy of RNA genome, showed to be an effective therapy, new inhibitors can be designed if the key residuals affecting the bonds formation between the inhibitors and NSB5 non-structured proteins are being identified. In this work, the first attempt is to derive these key residuals that are in close contact with a potent inhibitor based on idole moiety, and then designing some new inhibitors based on molecular docking and QSAR analyses.

Methods: The inhibition activities and inhibitors were taken from literature (J. Med. Chem. 2012, 55, 754–765), and then, the most inhibitor (shown in Figure 1) was studied in AutoDock 4.2 program to understand its existing interactions with NSB5 polymerase. The protein complexes were selected from protein databank (http://www.rcsb.org) with the PDB ID of 3GOL. The results of docking were then analyzed with LigandScout 3.03 program (Figure 1). After deriving the key features for increasing the inhibition activities, new compounds were designed and their activities were predicted using the derived robust and validated QSAR model.

Results: From docking analyses, it was observed that the taken potent inhibitor displayed several hydrophobic interactions with Met414, Leu384, Tyr415, Tyr448 and Phe193 residuals, and several hydrogen bond interactions with Gly449, Gln446, Thr448, Tyr415 and Ser368. Based on the derived results, some new compounds were designed considering the increasing the hydrophobic functional groups in detected substituents, and then the inhibition activities of newly designed drugs were calculated by GA-MLR model as below:

pIC_{50} = 11.65(±0.8449) − 0.4173(±0.04646)PCR
− 1.392(±0.4287)GATS2e − 0.1281(±0.01746)RDF090m
+ 6.991(±0.5781)H7u.

This model was built based on 38 compounds as training set with high reliability (R^2 = 0.866, Q^2_{LOO} = 0.817, F = 53.46) and then its external prediction ability was validated using 10 compounds as test set. The results for test set (R^2 = 0.802, RMSE = 0.322, CCC = 0.894) indicated that the derived model is reliable and can be used for predicting the pIC_{50} values for NSB5 polymerase inhibitors.

Conclusions: The predictive ability of the proposed model was found to be useful for predicting the inhibitory activity of taken inhibitors. Some compounds as HCV NSB5 polymerase inhibitor were designed and their inhibition activities were predicted by QSAR derived model (Figure 1).

E-mail: di.maio@med.uniroma2.it

Background and Aims: This study aims to evaluate the clinical utility of ultra-deep pyrosequencing (UDPS) on the detection of minority resistance associated variants (RAVs) in chronic HCV-1 infected patients treated with telaprevir (TVR)/boceprevir (BOC)/simeprevir (SMV) + pegIFN/ribavirin (RBV) at different time points: before, during and after treatment.

Methods: NS3 protease sequences of 55 selected patients (33 virological failures and 22 responders) treated with TVR (N = 43), BOC (N = 10) or SMV (n = 2) + pegIFN/RBV were analyzed. Presence of NS3-RAVs was evaluated by both Sanger-sequencing and UDPS (cutoff = 0.1%;>3000 sequences/patient) at baseline (BL), early time points (8 h–48 h), failure, and after therapy-interruption.

Results: At BL, 13/55 patients (24%) presented NS3-RAVs by both Sanger and UDPS (Q80K = 8; T54S = 3; R155K = 1; V36L+Q80K = 1). Of them, 9 patients experienced virological failure and 4 achieved a sustained virological response (SVR). Additional BL minority RAVs were found only by UDPS, in 6 TVR-treated patients, all with a prevalence <1%. However, their presence was not directly associated with virological failure. Indeed, 2 previous-null-responders with BL minority RAVs (F43S/Q80K) failed TVR triple-therapy with different RAVs (V36M + R155K; V36AM + R155K + T156ST, respectively). Other 4 patients, none previous-null-responders, having BL minority RAVs (D168A/V170A/T54A/Q80K) achieved SVR.

At early time points, additional minority RAVs (no present at BL) were detected in 3/18 (17%) patients, only by UDPS. Among them, 2 previous null-responders failed TVR triple-therapy showing similar mutations at 48 h and at failure (1 HCV1a showed $V36A_{48\,h}$ = 3% + $R155K_{48\,h}$ = 4% and failed with V36M+$R155K_{week8}$ = 100%; 1 HCV1b showed $V36A_{48\,h}$ = 9% +$V36G_{48\,h}$ = 25% +$T54A_{48\,h}$ = 36% and failed with T54AS+$V36A_{week22}$ = 87-1%).

UDPS was also used to characterize RAV persistence in 5 failing patients after at least 48 weeks of therapy interruption: 3/5 still showed persistence. In particular, 2 HCV-1a patients, both failing with V36M+R155K, still showed $R155K_{week100}$ (at 35% and 4%, with a mutational load of 594,022 and 77,966 IU/ml, respectively). Another HCV-1b patient, failing with T54S+A156T, still showed $T54S_{week60}$ (at 3%, with a mutational load of 15,571 IU/ml).

Conclusions: Although UDPS clinical relevance is still poorly understood, it could provide an added value on resistance detection in selected populations: it can help in the identification of patients to high-risk of failure and on monitoring RAVs persistence after PI-discontinuation.

EMERGENCE OF HEPATITIS C VIRUS GENOTYPE RECOMBINANT FORMS 2K/1B IN GEORGIA

M. Zakalashvili[1], M. Weizenegger[2], S. Kavsadze[1], K. Kvatadze[1], G. Basheleishvili[1], T. Phirtskhalaishvili[1], T. Dzagania[1], J. Zarqua[1], L. Zangurashvili[1], N. Kankia[1], N. Jashiashvili[1], M. Lomidze[1], V. Kerashvili[1], M. Zhamutashvili[1], N. Abramishvili[1], D. Metr.
[1]Medical Center "Mrcheveli", Tbilisi, Georgia; [2]Laboratory Group Limbach, Heidelberg, Germany
E-mail: mamukazakalashvili@gmail.com

Background and Aims: Hepatitis C virus (HCV) today is classified into 11 genotypes and many closely related subtypes. Kalinina et al. identified in the early 1990s HCV strains with genetic divergence, which was not due to mutations but to fusions of parts of different HCV genomes. The authors suggested the extension of the current classification with the term "recombinant form (RF)". In 2001, 2k/1b HCV RF was found in St. Petersburg, Russia. Only few cases are identified worldwide. Patients were mainly from Eastern Europe.

The aim of the study was to evaluate the distribution of HCV genotype 2k/1b – recombinant form (St. Petersburg variant) in Georgia.

Methods: We retrospectively analyzed data of HCV genotypes from Medical Center Mrcheveli, Tbilisi, Georgia, 2012–2014 (24 months), in 491 patients with chronic HCV. All samples were sent to laboratory Limbach (Heidelberg, Germany).

Initially all studies were performed with the VERSANT HCV Genotype 2.0, a second generation line probe assay, containing probes targeting the 5′ non coding region (NCR) and for higher resolution of genotype 1 the core regions of the viral genome. All HCV genotypes 2a/2c were further specified by partially gene equencing the NS5A region.

Results: Distribution of genotypes:

Genotype 1 – 198 (40%): Subtypes 1b 189 (95%); 1a 7 (4%); subtype not identified 2 (1%);
Genotype 3a – 155 (31.5%);
Genotype 2 – 136 (28%);
Genotype 4 (non Georgians) – 2 (0.5%).

All HCV genotypes 2 (136) were further specified. 91 (67%) appeared to be recombinant genotypes 2k/1b.

Distribution of RF 2k/1b genotypes by sex: M 81 (89%), F 10 (11%); distribution of RF 2k/1b genotypes by age: mean 44 (18–66); <20 years – 1 (1%), 20–40 years – 35 (38%), 40–60 years – 54 (59%), >60 years – 2 (2%).

Table (abstract P0916).

Authors	Percentage of HCV RF	Country	Journal
Samokhvalov et al.	0.8%	Russia	Voprosy Virusologii 2013 Jan Feb; 58(1): 36–40.
Viazov S et al.	1.2%	Germany	Journal of Medical Virology 2010 Feb; 82(2): 232–238.
Demetriou et al.	1.6%	Cyprus	Journal of Medical Virology 2009 Feb; 81(2): 238–248.
Kurbanov F et al.	2% Russia; 1 (1%) in Uzbekistan	7 countries	The Journal of Infectious Diseases 2008; 198(10): 1448–1456.
Kurbanov F et al.	1.8%	Uzbekistan	Hepatology Research 2008 May; 38(5): 457–464.
Tallo T et al.	0.5%	Estonia	Journal of Medical Virology 2007 Apr; 79(4): 374–382.

Conclusions: We can conclude that the HCV genotype RF 2k/1b is common in Georgia. About 18.5% of all genotypes and 67% of genotype 2 belonged to a recombinant HCV form: 5′ NCR genotype 2 and NS5 region genotype 1b.
Based on the present literature the prevalence of recombinant forms in different countries do not exceed 2% among of all HCV genotypes.
Because HCV genotypes are predictors of outcome of interferon based therapy (until now most important in Georgia), the widespread of these genotypes in our country can change the HCV treatment options.
New anti-HCV drugs will replaced interferon therapy and will not be dependent on the genotypes. Therefore, identification of resistance to new generation anti-HCV drugs may be a diagnostic challenge.

P1352

PHARMACOKINETICS AND PHARMACOLOGY OF RG-101, A NOVEL GalNAc-CONJUGATED OLIGONUCLEOTIDE TARGETING MICRORNA-122, IN HEALTHY VOLUNTEERS

K. Liu[1], S. Neben[1], N.W. Gibson[1], P. Grint[1], A. van Vliet[2], S. Hadi[2], M. de Vree[3], M. van der Ree[4], H. Reesink[4]. *[1]Regulus Therapeutics, San Diego, United States; [2]PRA Healthsciences, Zuidlaren, Netherlands; [3]Gastroenterology and Hepatology, University Medical Center Groningen, Groningen, Netherlands; [4]Gastroenterology and Hepatology, Academic Medical Center, Amsterdam, Netherlands*
E-mail: sneben@regulusrx.com

Background and Aims: RG-101 is a GalNAc-conjugated chemically modified oligonucleotide designed to inhibit microRNA-122 (the most prevalent microRNA in hepatocytes) and inhibit the replication of HCV. Prior studies showed enhanced delivery to hepatocytes and increased potency of RG-101 relative to a non-conjugated oligonucleotide.
Methods: RG-101 is being evaluated in a four part Phase I clinical study: part A was a single subcutaneous (SC) ascending dose study in healthy volunteers (HV) with doses of 0.5, 1, 2, 4, and 8 mg/kg; part B was a repeat dose study in HV (4 doses of 2 mg/kg given once every 28 days); part C was a drug–drug interaction (DDI) study with single dose RG-101 (2 mg/kg) added on to simeprevir in HV; and part D included a single dose study of 2 and 4 mg/kg RG-101 in HCV genotype 1, 3, and 4 chronic hepatitis C (CHC) patients (data not shown).
Results: RG-101 was well tolerated in HV at all doses with no significant adverse events identified to date. The C_{max} of RG-101 ranged from 0.03 μg/ml (at 0.5 mg/kg) to 8.8 μg/ml (at 8 mg/kg) and the AUC_{0-24hr} ranged from 0.1 μg·hr/ml (at 0.5 mg/kg) to 85.9 μg·hr/ml (at 8 mg/kg). RG-101 increased serum alkaline phosphatase (ALP) (a direct miR-122 target) and decreased serum cholesterol (CHOL) (an indirect miR-122 target). Maximum changes in ALP and CHOL after a single dose of RG-101 were observed at 2 mg/kg when the C_{max} was 1.4 μg/ml and the AUC_{0-24hr} was 6.2 μg·hr/ml. In HV the time to max increase in ALP was ~14 days and time to max reduction in CHOL was ~21 days. Neither ALP nor CHOL returned to baseline by Day 57. RG-101 was also evaluated in combination with simeprevir. HV were administered 150 mg simeprevir on day 1, then daily on days 5 through 14. A single dose of RG-101 (2 mg/kg) was co-administered on day 5. The C_{max} (1.5 μg/ml) and AUC_{0-24hr} (8.4 μg·hr/ml) of RG-101 was not changed by addition of simeprevir. RG-101 had no effect on simeprevir PK parameters with the C_{max} being 1.5 μg/ml and 1.4 μg/ml and AUC_{0-24hr} being 15.5 μg·hr/ml and 14.8 μg·hr/ml in the absence or presence of RG-101 respectively. The combination of RG-101 and simeprevir was well tolerated and no significant adverse events were observed.
Conclusions: RG-101 alone or in combination with simeprevir was well tolerated in HV. No DDI between RG-101 and simeprevir was observed. Maximum pharmacological activity, as measured by increased ALP and decreased CHOL, was observed with RG-101 in HV at 2–4 μg·mg/kg.

ROLE OF FXR CONTROLLED Chop IN MEDIATING BILE ACID EFFECTS IN NAFLD

C.D. Fuchs[1], T. Claudel[1], E. Halilbasic[1], P. Jha[1], W. Spindelboeck[2], T. Stojakovic[3], M. Trauner[1]. *[1]Internal Medicine III, Medical University of Vienna, Vienna, [2]Internal Medicine, [3]Institute of Medical and Chemical Laboratory Diagnostics, Medical University of Graz, Graz, Austria*
E-mail: claudia.fuchs@meduniwien.ac.at

Background and Aims: Farnesoid-X-receptor (FXR) has an important regulatory function in hepatic bile acid (BA) and lipid homeostasis. We aimed to explore the role of FXR and BAs in the control of Chop (recently suggested to impact on lipid homeostasis via regulation of C/ebpa) as potential regulators of hepatic lipid metabolism and inflammation.
Methods: Wild type (WT) and FXR knock-out (KO) mice were fed a MCD diet to induce NASH. Hepatic gene-expression was profiled by RT-QPCR for markers of hepatic lipid metabolism and inflammation. Moreover, serum biochemistry, liver histology and hepatic TG content were assessed. HepG2 cells were treated with glucose, with/without FXR and RXR agonists. Gene-expression was analysed by RT-QPCR and chromatin-immuno-precipitation was performed.
Results: MCD feeding resulted in increased serum BA levels and liver enzymes in both WT and FXR KO mice. However, Chop mRNA was up-regulated only in MCD fed WT but not in FXR KO mice. Moreover, mRNA levels of C/ebpa were down-regulated in MCD challenged WT, but not FXR KO mice. WT MCD mice display markedly increased VLDL-receptor mRNA levels consistent with elevated hepatic TG content. Hepatic inflammation in response to MCD (reflected by F4/80, TNFa mRNA expression) was aggravated by absence of FXR. High BA and low glucose levels increased Chop and subsequently repressed C/ebpa expression in a FXR/RXR dependent fashion in HepG2 cells. Finally, a FXR/RXR binding site was identified in the human promoter of Chop demonstrating a highly conserved regulated pathway.
Conclusions: These findings demonstrate that glucose and BAs control Chop expression via FXR/RXR therefore providing novel insights into pathogenesis and treatment of NAFLD.

IMPAIRED PPARα SIGNALLING INFLUENCES BILE ACID HOMEOSTASIS AND INFLAMMATION IN ATGL LIVER KO MICE

C.D. Fuchs[1], C. Kienbacher[1], E.E. Kershaw[2], M. Trauner[1]. *[1]Internal Medicine III, Medical University of Vienna, Vienna, Austria; [2]Division of Endocrinology & Metabolism, University of Pittsburgh, Pennsylvania, United States*
E-mail: claudia.fuchs@meduniwien.ac.at

Background and Aims: Adipose triglyceride lipase (ATGL) is the main enzyme in intracellular lipolysis and generates PPARα ligands, such as linoleic acid. PPARα activation represses the rate limiting enzyme in bile acid (BA) synthesis Cyp7a1, indicating a key role of PPARα in biliary homeostasis. Therefore, we aimed to determine

the effects of hepatic ATGL deficiency (and subsequently impaired fatty acid signalling via PPARα) on BA homeostasis.
Methods: Bile flow was analyzed in liver specific ATGL knock out (ATGL LKO) and wild type (WT) littermates. Furthermore these mice were subjected to bile duct ligation (BDL) for 7days (acute cholestasis model). RT-QPCR was used to assess BA synthesis, inflammation and fibrosis gene expression markers. Serum biochemistry and histology were also assessed.
Results: ATGL LKO mice show increased bile flow ($p < 0.05$) compared to WT mice. In line, mRNA levels of Cyp7a1 were 4fold induced ($p < 0.05$). Inflammatory markers F4/80 and iNOs were increased 2.2-fold ($p < 0.05$) and 7fold ($p < 0.05$), in line with impaired PPARα signalling. Importantly, acute cholestasis in ATGL LKO mice increased F4/80 expression about 10-fold vs. WT BDL mice ($p < 0.05$). Additionally, mRNA expression of fibrotic marker TGF-β ($p = 0.087$) and elevated proliferation of cholangiocytes reflected by induced CK19 levels ($p = 0.057$) tended to be increased. Of note, mRNA levels of key hepatobiliary (basolateral and apical) BA transporters and levels of serum liver enzymes, cholesterol, TG and BA levels did not differ between groups.
Conclusions: Loss of PPARα activity due to impaired hepatic fatty acid signalling influences BA homeostasis and predisposes to cholestasis-induced inflammation and fibrosis, therefore ATGL and/or PPARα represent potential therapeutic targets.

P0919
DEFECTIVE THERMOGENIC ADAPTATION TO HIGH CALORIE INTAKE: A CONTENDER IN NASH PATHOGENESIS IN FOZ/FOZ MICE

L. Poekes[1], V. Legry[1], O. Schakman[1], A. Bol[1], G. Farrell[2], I.A. Leclercq[1]. [1]*Université catholique de Louvain, Brussels, Belgium;* [2]*Autralian National University at Garan Hospital, Canberra, Australia*
E-mail: isabelle.leclercq@uclouvain.be

Background and Aims: Foz/foz mice fed a High Fat Diet (HFD) represent an appropriate model to study NASH in the context of metabolic syndrome. Foz/foz mice carry a spontaneous mutation in Alms1 encoding for a protein of the primary cilium of yet unknown function. The aim of the study is to understand mechanism contributing to their obese, metabolic and liver phenotype.
Methods: Foz/foz mice are hyperphagic. Pair feeding experiment in which foz/foz mice have restricted access to HFD to the exact equal amount of their WT littermate was set up. Activity level, oxygen consumption, thermogenic adaptation was evaluated.
Results: Compared to WT, 4 weeks of HFD induced more severe obesity, insulin resistance, steatosis and liver and adipose inflammation in foz/foz mice. Caloric restriction to foz/foz mice improved but did not restore metabolic disturbances. Physical activity, circadian rhythm, basal metabolism and body temperature were unaffected in foz/foz mice. By contrast, thermogenic adaptation of their brown adipose tissue (BAT) was impaired. In Wt mice, HFD reduced BAT fat load, increased mtDNA content and up-regulated UCP-1, PGC1α and DIO2 consistent with adaptive fat burning. By contrast in foz/foz mice HFD markedly increased BAT lipid accumulation, up regulation of mtDNA content and thermogenic genes was lower or blunted compared to HFD-fed WT mice. Upon exposure to 4°C for 6 hours, body temperature fell by 2.1°C in WT mice and by 3.9°C in foz/foz mice ($p < 0.05$) and up-regulation of thermogenic genes was 40 to 60% lower in HFD-fed foz/foz compared WT mice. Thermogenic failure was further confirmed by a significant lower up-take of ^{18}FDG (PET-Scan) by foz/foz BAT than by WT BAT upon cold exposure.
Conclusions: Overall, these results suggest that in this model reduced adaptive thermogenesis contributes to obesity and insulin resistance, eventually driving NASH and call upon evaluating targeting of BAT for therapeutic intervention.

SPECIFIC MODULATION OF HEPATIC ESTROGEN RECEPTOR ALPHA PREVENTS FATTY LIVER BUT ALSO OBESITY AND INSULIN RESISTANCE INDUCED BY A HIGH FAT DIET IN MICE

M. Guillaume[1,2], S. Handgraaf[2], I. Raymond-Letron[3], A. Fabre[2], E. Riant[2], A. Montagner[4], H. Guillou[4], C. Bureau[1], J.-F. Arnal[2,5], P. Gourdy[2,6]. [1]*Service de Gastroentérogie et Hépatologie, Centre Hospitalier Universitaire de Toulouse,* [2]*INSERM U1048, Institut des Maladies Métaboliques et Cardiovasculaires (I2MC), Université Toulouse III,* [3]*Histologie – Anatomie pathologique, INP – Ecole Nationale Vétérinaire de Toulouse, Université de Toulouse,* [4]*INRA, ToxAlim, UMR1331, INP, Université de Toulouse,* [5]*Centre Hospitalier Universitaire de Toulouse, Toulouse, France;* [6]*Service de Diabétologie, Maladies Métaboliques et Nutrition, Centre Hospitalier Universitaire de Toulouse, Toulouse, France*
E-mail: guillaume.m@chu-toulouse.fr

Background and Aims: Recent experimental data suggest that hepatic Estrogen Receptor alpha (ERα) activation can prevent fatty liver diseases. Estrogens modulate gene expression through the stimulation of the two distinct transactivation functions AF1 and AF2 harbored by ERα. To further characterize the therapeutic potential of ERα modulation, we questioned here the respective roles of (i) hepatic ERα and (ii) ERαAF1 in the protective effects against the liver and systemic metabolic disorders induced by a high-fat diet (HFD).
Methods: Female mice deleted for the entire ERα (ERα°), only for ERαAF1 (ERα-AF1°) or selectively for the hepatic ERα (ERαLiv°), and their respective wild-type littermates (WT) were used. Four-week-old mice were ovariectomized then fed with a HFD (45% fat) and treated or not with pellets delivering Tamoxifen [1.2 mg/kg/d; subcutaneous, a Selective Estrogen Receptor Modulator (SERM) used as a pharmacological tool, known to specifically activate ERαAF1] for 12 weeks.
Results: In WT mice, TMX strongly prevents HFD-induced body weight gain, adipose tissue accumulation, insulin resistance and fatty liver (histological analyses and triglycerides concentration) ($p < 0.01$ for all parameters). Beneficial effects of TMX are totally abrogated in ERα° and ERα-AF1° confirming that ERα-AF1 activation is absolutely required. In addition, the protective effects on fatty liver are abrogated in ERαLiver° mice. More surprisingly, beneficial effects of TMX on HFD-induced obesity and insulin resistance are also totally abrogated in ERαLiver° mice.
Conclusions: Beyond the protective effects on fatty liver diseases, selective modulation (AF1) of hepatic ERα appears sufficient to prevent obesity and impaired glucose homeostasis induced by a HFD, and should be considered as a promising therapeutic target for the prevention of metabolic syndrome and NAFLD.

P0921
MALE PREVALENCE AND FEATURES OF ADVANCED NASH WITH CIRRHOSIS IN THE LIVER KNOCKOUT OF CYP51 FROM CHOLESTEROL SYNTHESIS

. Urlep[1], G. Lorbek[1], P. Juvan[1], M. Perše[2], J. Jeruc[2], I. Björkhem[3], R. Gebhardt[4], D. Rozman[1]. [1]*Centre for Functional Genomics and Bio-Chips, Institute of Biochemistry,* [2]*Medical Experimental Centre, Institute of Pathology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia;* [3]*Department of Laboratory Medicine, Divison of Clinical Chemistry, Karolinska Institute, Karolinska University Hospital, Huddinge, Sweden;* [4]*Institute of Biochemistry, Medical Faculty, University of Leipzig, Leipzig, Germany*
E-mail: ziga.urlep@mf.uni-lj.si

Background and Aims: Accumulation of free cholesterol in the liver promotes hepatocyte apoptosis and fibrosis, and is associated with NASH pathogenesis. Lanosterol 14α-demethylase (CYP51) presents a rate-limiting step in the latter part of cholesterol synthesis. Applying the liver conditional knockout of *Cyp51* (LKO),

we show that blocking hepatic cholesterol synthesis in adult mice causes NASH-like liver changes (Lorbek et al., in review). Herein we describe the male predominant most severe phenotypes of the *Cyp51* LKO mice that stopped their development prior to adulthood.
Methods: From 376 mice (WT and LKO) that survived to the weaning period, 19 (4 female, 15 male) were underdeveloped, with jaundice and hepatomegaly (runts) and were euthanized at 5–10 weeks of age. All runts were of the LKO genotype. After initial histochemical evaluation and analysis of sterol metabolites we applied expression profiling by Affymetrix microarrays to search for molecular signatures that would differentiate runts from the rest of *Cyp51* LKOs.
Results: The runt livers were severely damaged, resembling NASH with cirrhosis, with frequent apoptoses and mitoses, though without the accumulation of lipids. Sirius red staining showed bridging fibrosis of the portal areas. This was accompanied by moderate to severe oval cell response and immune cell infiltration. Microarray analysis of runts compared to age-matched non-cachectic LKOs gave 5983 differentially expressed genes. Among significantly elevated genes in runts are *Spp1* (osteopontin), *Cxcl10* and c-*Jun*, all linked to NASH pathogenesis. Gene set enrichment analysis of KEGG pathways showed enrichment of TGFβ signalling (involved in apoptotic and fibrotic processes), apoptosis, signalling with growth factors (VEGF, PDGF, ErbB) and cancer related pathways. Gene ontology term enrichment listed the unfolded protein response (integrated stress response) as significantly deregulated, which is in line with our in-house hypothesis that changes in cholesterol balance result in ER stress. On the metabolite level, runts compared to non-cahectic LKOs exhibit further elevation in hepatic lanosterol and 24,25-dihydrolanosterol, both substrates of CYP51, and significantly elevated free cholesterol.
Conclusions: We present a novel model where disrupted cholesterol synthesis results in NASH-like symptoms without the presence of steatosis. The severity of liver damage depends on the cholesterol balance. The male-predominance in the most severe *Cyp51* LKO phenotype is under investigation.

P0922
THE COMBINATION OF PROBIOTICS AND PREBIOTICS SUPPLEMENTATION IMPROVES LIPID METABOLISM, NAFLD AND OBESITY IN OB/OB MICE

J.T. Stefano[1], M.M. Torres[1], I.V.A. Pereira[1], D. Jimenez[1], B. Muntanelli[1], F.M. Malta[1], B. Cogliati[2], J.R.R. Pinho[1], F.J. Carrilho[1], C.P. Oliveira[1]. *[1]Gastroenterology LIM 07, University of São Paulo School of Medicine, [2]Veterinary Medicine, University of São Paulo, São Paulo, Brazil*
E-mail: cpm@usp.br

Background and Aims: Recent evidence suggests that changes in gut microbiota could modulate the intestinal flora and improve metabolic-related disorders, including nonalcoholic fatty liver disease (NAFLD). The reduction of pro-inflammatory cytokines, the improvement of the immune system, reduction of intestinal infections, could increase lean mass and decrease fat mass. The aim of this study was to examine supplementation with the combination of probiotics and prebiotics in NAFLD and obesity in ob/ob mice.
Methods: Ob/ob male mice, weighing 40 g, received in drinking water a combination of probiotics and prebiotics (*L. acidophilus, L. rhamnosus, L. paracasei, B. lactis* and fructooligosaccharide) for 8 weeks [PRO/PRE (treated group; n = 8). Control group (n = 6) received only drinking water. All animals received standard diet. After 8 weeks, the difference between the initial and final body weight was calculated in all animals and liver tissues were collected for mRNA and miRNA isolation, and histological analysis. Genes related to lipids metabolism (SREBP1C, miR-33a, MTP, PPAR-g) and mitochondrial oxidation (CPT, PPAR-α) were evaluated by RT-qPCR.
Results: The combination of probiotics and prebiotics supplementation improved liver histology, decreased visceral fat mass and weight gain, reducing obesity in comparison to control group. Our study showed a statistically significant decrease in MTP ($p = 0.001$), PPAR-g ($p = 0.023$), PPAR-α ($p = 0.016$) and CPT ($p = 0.010$) mRNA expression and increased expression of miR-33a (0.5 fold change) in treated group compared to control. However, there were no relevant modifications in SREBP1C.
Conclusions: The combination of probiotics and prebiotics supplementation improves liver histology, decreased visceral fat mass and reduced obesity. Besides, this combination of probiotics and prebiotics modulated genes involved in the synthesis, exportation and oxidation of hepatic lipids. However, we can not rule out that other mechanisms such as inflammatory pathways could contribute to improvement of NAFLD.

P0924
CYCLOOXYGENASE-2 REGULATES MIRNA EXPRESSION IN LIVER CELLS THROUGH DEAD BOX HELICASE P68 (DDX5). ROLE IN INSULIN SIGNALING

O. Motiño[1], D.E. Francés[2], R. Mayoral[3], L. Castro-Sánchez[1], M. Fernández-Velasco[4], L. Boscá[1,5], C. García-Monzón[6], M. Casado[5,7], N. Agra[1], P. Martín-Sanz[1,5]. *[1]Instituto de Investigaciones Biomédicas Alberto Sols CSIC-UAM, Madrid, Spain; [2]Insituto de Fisiologia Experimental (IFISE-CONICET), Rosario, Argentina; [3]Division of Endocrinology and Metabolism; Department of Medicine, University of California, San Diego, United States; [4]Instituto de Investigación Hospital Universitario La Paz, IDIPAZ, [5]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), [6]Liver Research Unit, Hospital Universitario Santa Cristina, Instituto de Investigación Sanitaria Princesa, Madrid, [7]Instituto de Biomedicina de Valencia (IBV-CSIC), Valencia, Spain*
E-mail: mcasado@ibv.csic.es

Background and Aims: Our previous results revealed that Cyclooxygenase 2 (COX-2) expression is regulated by miRNAs. However, the role of COX-2 in miRNA regulation remains unknown. In the present work, we have studied whether COX-2 regulates the expression profile of miRNAs in liver, and examined the targets of these miRNAs together with their physiopathological properties.
Methods: An RT^{2}miRNA PCR array was performed with microRNA isolated from liver extracts of Wt and transgenic mice overexpressed human COX-2 in hepatocytes. We attempted to confirm the array data in different cell models: in isolated hepatocytes from mice models and in human liver cells stably transfected with a COX-2 expression vector. Western blot analyses were carried out to analyze proteins involved in the biosynthesis of miRNAs with or without treatment with pharmacological inhibitors of different signaling pathways. To evaluate the role of COX-2 in insulin signaling, cells were treated with palmitate to induce insulin resistance. To confirm the results the cells were transfected with DDX5 or COX-2 siRNAs or vector expressing specific miRNAs. Finally, the relationship between COX-2 and miRNA regulation was also studied in human biopsy samples of non-alcoholic steatosis (NAS).
Results: COX-2 represses the expression of miR-23b, miR-146b and miR-183 in liver cells by upregulating the DEAD-box helicase p68 (DDX5) expression through phosphatidylinositol (PI) 3-kinase (PI3K) signaling pathway. Furthermore, COX-2 was shown to inhibit miRNA maturation by associating with the Drosha complex through DDX5 and preventing the conversion of primiRNAs into pre-miRNAs. Analysis of pathways and networks for these miRNAs using the DAVID platform identified the insulin signaling pathway as target. Our results showed that the down-regulation of miRNAs by

COX-2 enhances insulin signaling. Finally, the relationship between COX-2 and the miRNAs was confirmed in NAS.
Conclusions: COX-2 represses the expression of miRNAs implicated in the insulin signaling pathway via a PI3K/p300-dependent upregulation of DDX5, and by modulating the activity of the Drosha complex. Our study proposes a novel miRNA-dependent mechanism through which COX-2 promotes insulin signaling in liver cells.

PHARMACOLOGICAL EVALUATION OF PIOGLITAZONE AND CANDESARTAN CILEXETIL IN A NOVEL MOUSE MODEL OF NONALCOHOLIC STEATOHEPATITIS, MODIFIED CHOLINE-DEFICIENT, AMINO ACID-DEFINED DIET FED LDL RECEPTOR KNOCKOUT MICE

S. Tsuchiya[1], Y. Amano[1], O. Isono[1], M. Imai[1], F. Shimizu[1], M. Asada[1], S. Imai[1], A. Harada[1], Y. Yasuhara[1], R. Tozawa[1], H. Nagabukuro[1].
[1]Pharmaceutical Research Division, Takeda Pharmaceutical Company Ltd., Kanagawa, Japan
E-mail: shuntarou.tsuchiya@takeda.com

Background and Aims: Low-density lipoprotein receptor knockout (LDLR-KO) mouse fed with modified choline-deficient and amino acid-defined (mCDAA) diet exhibits non-alcoholic steatohepatitis (NASH)-like pathophysiology. In order to pharmacologically benchmark this model, effects of pioglitazone, a thiazolidinedione and candesartan cilexetil, an angiotensin II type 1 receptor blocker (ARB) on steatosis and liver fibrosis were examined.
Methods: Pioglitazone (10 mg/kg) and candesartan cilexetil (3 mg/kg) were orally administered once daily to LDLR-KO mice under mCDAA diet for 1 week. After 7 weeks of treatment, blood biochemistry and hepatic histology were assessed, and hepatic expression levels of mRNA, and hepatic triglyceride content were measured.
Results: Pioglitazone suppressed hepatic gene expression of collagen-1 by 43% and attenuated hepatic fibrosis areas by 49%. Pioglitazone also decreased plasma alanine aminotransferase (ALT) levels, liver weight, hepatic triglyceride content and hepatic expression of other fibrosis-related genes such as transforming growth factor β, osteopontin, and tissue inhibitor of metalloproteinase 1, and interleukin-6. Candesartan cilexetil suppressed hepatic collagen-1 gene expression by 33%, while hepatic fibrosis was not affected histomorphometrically. In addition, candesartan cilexetil had no effect on plasma ALT levels, liver weight, hepatic triglyceride content or the hepatic expression of other fibrosis-related genes.
Conclusions: Pioglitazone exhibited anti-fibrotic effects accompanied by anti-steatotic and anti-inflammatory effects, but the effect of candesartan cilexetil was only limited unlike previous reports on ARBs. Since the pharmacological effects of pioglitazone in the current animal model are similar to those reported in patients with NASH, this model may represent some aspects of the pathophysiology of NASH. The partial efficacy of candesartan cilexetil might be attributed to the lesser contribution of the local renin-angiotensin system associated with obesity in this model. Further profiling using other agents or mechanisms that have been tested in the clinic will better clarify the utility of the animal model.

P0926
REPRESENTATION OF HUMAN NON-ALCOHOLIC FATTY LIVER DISEASE IN MURINE MODELS

Hampe[3]. *[1]Internal Medicine I, University of Regensburg, Regensburg, [2]Internal Medicine I, University of Kiel, Kiel, [3]Internal Medicine I, University of Dresden, Dresden, [4]Institute of Translational Immunology and Research Center for Immunotherapy, University of Mainz, Mainz, [5]Department Visceral and Thoracic Surgery, University of Kiel, Kiel, Germany; [6]Department of Clinical Research, University of Berne, Berne, Switzerland; [7]Department of Pathobiochemistry, University of Dresden, Dresden, Germany*
E-mail: andreas.teufel@ukr.de

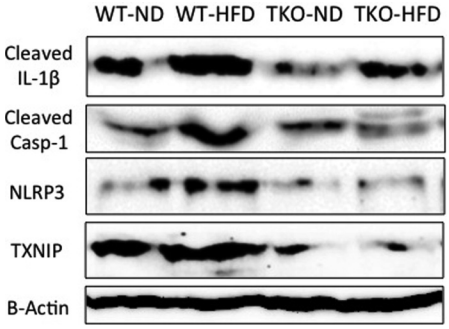
Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is the most common chronic liver disorder in industrialized countries. Murine models are a central mechanistic platform to study the disease.
Methods: We systematically evaluated genome-wide mRNA expression data from five common murine models of NAFLD [high fat diet (HFD) w/wt fructose, methionine-choline deficient diet, streptozotocin and HFD, PTEN (Fox) KO] in comparison to human data from 77 NAFLD patients and 39 healthy controls spanning the range of disease severity.
Results: We found profound differences between the human and murine transcriptome that override any disease or phenotype signature. Thus of the significantly regulated human genes in NAFLD only between 1 and 16are significantly and concordantly regulated in mice. The dataset, depending on mouse model and human phenotype, shows correct reflection of key pathways, lack of regulation, or reverse effects thereby providing a guide for murine model selection in future experiments to improve applicability to human NAFLD.
Conclusions: In a global cross-species analysis we found profound differences between human and murine expression patterns in fatty liver disease that override any disease or phenotype signature.

P0928
DELETION OF TXNIP PROTECTS AGAINST HFD--INDUCED STEATOHEPATITIS AND LIVER INJURY

M. El-Sherbiny[1,2], M.A. Eladl[1,3], I.N. Mohamed[4], N.M.M. Reda[5], A.B. El-Remessy[6]. *[1]Anatomy & Embryology, Mansoura University, Mansoura, Egypt; [2]Basic Medical Science, AL-Maarefa College, Riyadh, Saudi Arabia; [3]Basic Medical Science, Sharjah College of Medicine, Sharjah, United Arab Emirates; [4]Program in Clinical and Experimental Therapeutics, University of Georgia, College of Pharmacy, Augusta, United States; [5]Histology, Mansoura University, Mansoura, Egypt; [6]Program in Clinical and Experimental Therapeutics, University of Georgia, College of Pharmacy, Augusta, United States*
E-mail: meladl@sharjah.ac.ae

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is a hepatic manifestation of the metabolic syndrome. Oxidative stress and inflammation play a pivotal role in the pathogenesis of NAFLD. Inflammasomes are shown to be implicated in liver damage, steatosis, inflammation and fibrosis. Nevertheless, TXNIP-mediated activation of NLRP3 inflammasome and its involvement in the pathogenesis of HFD-induced NAFLD and NASH remains unknown. In the current study we investigated the role of Thioredoxin-interacting protein TXNIP in steatohepatitis and fibrosis.
Methods: All metabolic parameters including glucose intolerance and plasma levels of total cholesterol and triglycerides were performed after 8-weeks. Using western blotting we examined the changes in the protein levels of TXNIP, NLRP3, caspase-1, IL1β and TNF-α in liver samples from WTND, WTHFD, TKOND and TKOHFD

groups. Furthermore, we tested the impact of TXINB deletion in the developing of steatohepatitis and fibrosis by different histological and immnohistopathological methods including anti-interleukin1 beta (anti-IL1β antibody) and anti-alpha smooth muscle actin (Anti-αSMA) antibody immunostain.
Results: Our results show, massive hepatic steatosis prominent lobular and portal inflammation were more in WTHFD group. Furthermore, significant increase in area and area % of fibrosis by approximately 27 and 40 folds respectively was observed in specimen isolated from WT groups with HFD in comparison to the normal control group (WTND and TKOND) ($n = 5–8$; $p < 0.05$). On the other hand, retraction of fibrosis and little amount fibrous tissue around central vein and portal tract with no fibrous tissue in sinusoidal wall was detected in liver specimen from TKOHFD for 8 weeks ($n = 5–8$; $p < 0.05$). Such observed reduction in area and area% of fibrosis and fibrosis retraction with reduction of accumulation of fibrous tissue in the liver with TKOHFD is consistent with the previous observed reduction in the expression of IL1b, NLRP3, Caspase-1and TXNIP WT liver samples which supporting the important effect of deletion of TXNIP on accumulation of ECM and inhibition of progression of liver fibrosis.
Conclusions: Our results showed that TXNIP deletion can protect against HFD-induced steatohepatitis, and its associated pro-inflammatory and fibrotic response through the activation of the NLRP3 inflammasome and its downstream proinflammatory cytokine IL-1β. Therefore, TXNIP signaling system is a potential therapeutic target to treat NAFLD.



P0929

A DIET-INDUCED MOUSE MODEL OF NASH THAT PRODUCES ROBUST INFLAMMATION AND FIBROSIS

Y.O. Kim[1], R. Surabattula[1], K.-S. Park[1], R. Heck[1], S.-Y. Weng[1], D. Schuppan[1,2]. *[1]Institute of Translational Immunology and Research Center for Immunotherapy, University Medical Center Mainz, Mainz, Germany; [2]Division of Gastroenterology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States*
E-mail: kimy@uni-mainz.de

Background and Aims: Better mouse models that reflect all features of human NASH are needed. We developed a NASH model using a diet which rich in transfats, carbohydrates, and cholesterol (nutritional stress diet, NSD) that mimicks major features of human fibrotic NASH.
Methods: Female 6 wk old C57BL/6 mice ($n = 10$ per group) were fed a control diet (13% kcal fat; 65% kcal carbohydrates), or a high saturated fat diet enhanced in fructose and cholesterol (nutritional stress diet, NSD: 59kJ% kcal lipid, hydrogenated coconut oil; 26kJ% kcal carbohydrates, fructose and glucose; 15kJ% kcal protein, casein; 2% cholesterol), plus fructose-sucrose in drinking water (12.6%: 55:45) for 30 weeks. At sacrifice, liver function, lipid accumulation, IR, inflammation, fibrosis, oxidative stress, and mRNA levels related to fat metabolism, inflammation, fibrogenesis, fibrolysis, and macrophage polarization were analyzed by IHC and qRT-PCR.
Results: Compared to the control mice, mice on the NSD developed a significant increase in body and liver weight, fat deposition, insulin resistance, steatosis, hepatocyte ballooning, and inflammation (NAS score 4), serum parameters of liver injury, and fibrosis (Ishak score 3). Their livers showed significantly increased transcript levels related to fat metabolism, inflammation, M1/M2 polarization, fibrogenesis, and fibrolysis (PPARG, LPL, TNFA, CCL5, MCP1, COL1A1, ACTA2, TGFB1, ITGB6, PDGFRB, PAI1, SPP1, TIMP1, MMP2, MMP8, MMP13). The mRNA levels of IL6 and TNFA were also significantly upregulated in visceral fat tissue. As assessed by IHC, the oxidative stress markers 4-hydroxynonenal and 8-hydroxyguanosine were highly overexpressed in livers of mice fed the NSD.
Conclusions: We describe an optimized diet-induced mouse model that produces all features of human NASH, with robust inflammation and fibrosis. This model will permit to test novel agents that address the major pathologies of human NASH.

P0930

LESSONS FROM HEPATOCYTE-SPECIFIC CYP51 KNOCKOUT MICE: IMPAIRED CHOLESTEROL SYNTHESIS LEADS TO NASH-LIKE OVAL CELL DRIVEN LIVER INJURY

G. Lorbek[1], M. Perse[2], J. Jeruc[3], P. Juvan[4], R. Gebhardt[5], I. Bjorkhem[6], D. Rozman[4]. *[1]Institute of Biochemistry, Centre for Functional Genomics and Bio-Chips, University of Ljubljana, Faculty of Medicine, CFGBC, [2]Medical Experimental Centre, Institute of Pathology, [3]Institute of Pathology, [4]Institute of Biochemistry, Centre for Functional Genomics and Bio-Chips, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia; [5]Institute of Biochemistry, Faculty of Medicine, University of Leipzig, Leipzig, Germany; [6]7Department of Laboratory Medicine, Division of Clinical Chemistry, Karolinska Institute, Karolinska University Hospital, Stockholm, Sweden*
E-mail: damjana.rozman@mf.uni-lj.si

Background and Aims: Steatosis and NASH might represent separate conditions with potentially different molecular causes. While hepatic triglycerides are a hallmark of steatosis, the role of cholesterol remains controversial. We addressed the role of hepatic cholesterol in liver disease aethiology by applying the liver conditional knockout (LKO) mice of *Cyp51* from cholesterol synthesis.
Methods: 3-week mice were assigned to either standard diet (low-fat no-cholesterol, LFnC) or high-fat diet without (HFnC) or with cholesterol (HFC) for 16 weeks. Blood, bile and organs were collected. Hematoxylin and eosin, Sirius red, pan-cytokeratin stainings, Sudan III and CYP51 stainings were performed on liver sections. Lipids, ALT, AST, corticosterone and TNF-α were measured in plasma. Liver gene expression was performed by qPCR and Affymetrix microarrays and proteins evaluated by western blots. Liver sterols and gallbladder bile acids s were analyzed by GC-MS. Linear regression modeling and empirical Bayes smoothing were applied with the genotype, sex and diet as predictor variables.
Results: LKO mice developed hepatomegaly with oval cell proliferation, fibrosis and inflammation, but without steatosis. The key trigger were reduced cholesterol esters that provoked cell cycle arrest, senescence-associated secretory phenotype and ultimately the oval cell response, while elevated CYP51 substrates promoted the integrated stress response. In spite of the oval cell-driven fibrosis being histologically similar in both sexes, microarray data indicated a female-biased down-regulation of primary metabolism pathways and a stronger immune response in males. Liver injury was ameliorated by dietary fats predominantly in females, whereas dietary cholesterol rectified fibrosis in both sexes. Steatosis provoked by HFC diet did not worsen the liver injury in male LKOs and had beneficial effects in the female LKOs. This is in line with the recent observation that people with hepatic

triglyceride accumulation ("good fat storers") are protected from NASH.
Conclusions: The diminished hepatic cholesterol synthesis through sterol imbalance and ISR led to NASH-features, while dietary fats (in the absence of dietary cholesterol and hepatic cholesterol synthesis) led to steatosis. Only when cholesterol was added to the diet, the NASH-like features of LKOs were ameliorated, placing defective cholesterol synthesis in the focus of NASH.

P0931
OSTEOPONTIN PLAYS A KEY ROLE IN ALCOHOL AND HIGH FAT DIET INDUCED LIVER INJURY

D. Seth[1], E. Huang[2], A. Duly[2], S. McLennan[3]. [1]*Royal Prince Alfred Hospital and Centenary Institute,* [2]*Centenary Institttue,* [3]*University of Sydney, Sydney, Australia*
E-mail: d.seth@sydney.edu.au

Background and Aims: Alcoholic Liver Disease (ALD) and Non-Alcoholic Fatty Liver Disease (NAFLD) are highly prevalent liver diseases that may coexist and contribute significantly to liver disease related mortality. Recent literature suggests both disorders share some common pathogenic pathways, including Osteopontin (OPN). There has been little research investigating the combined effects of high fat diet (HFD) and alcohol in liver injury. The current study aimed to investigate role of OPN in a mouse model of alcohol+HFD induced steatohepatitis.
Methods: C57BL6 wt male mice were fed chow or 45% kCal HFD for 12 weeks. Half the mice received a physiologically relevant dose of alcohol (2 g/kg body weight) twice a week. Control mice were given an equal volume of saline. A subset of mice in each treatment group was also given ip injections weekly either with OPN-R3 or control aptamer. Animal weight gain was recorded over time. Blood and livers were harvested at the end of the experiment. The extent of liver injury was examined by histopathology, quantitative analysis of hepatic inflammatory cells, liver and serum biochemistry. Changes in expression of lipid metabolism, inflammation and fibrogenesis related molecules were tested using Q-PCR and immunofluorescence staining.
Results: Superimposing alcohol on the HFD exacerbated the extent of liver damage caused by either agent alone, including increased liver weight, TG, HDL, CHL, serum insulin, lipogenesis (H&E, ORO, SREBP1, SCD1, ACOX1, PPARa), inflammation (leukocytes, Kupffer cells, monocyte) and fibrogenesis (Col1, hepatic stellate cell activation, TGFb). OPN-R3 aptamer intervention significantly reduced myeloid, neutrophil and monocyte cell populations induced by alcohol and HFD in the liver but increased KCs, and lipid deposits, compared to control intervention, suggesting OPN may be required for migration of monocytes and granulocytes from the general circulation to liver tissue, reducing the inflammatory component in steatohepatitis. These observations were confirmed in OPN knockout animals.
Conclusions: OPN is a key mediator of liver injury and has a therapeutic potential for ALD and NAFLD.

P0932
TREATMENT WITH NGM282 SIGNIFICANTLY IMPROVES LIVER HISTOPATHOLOGY IN A MOUSE MODEL OF NON-ALCOHOLIC STEATOHEPATITIS (NASH)

J. Luo[1], B. Ko[1], C. To[1], L. Ling[1], S. Rossi[1], A. DePaoli[1], H. Tian[1]. [1]*NGM Biopharmaceuticals, Inc, South San Francisco, United States*
E-mail: srossi@ngmbio.com

Background and Aims: Human fibroblast growth factor 19 (FGF19) has been shown to regulate glucose homeostasis, body weight, triglycerides synthesis and bile acid (BA) synthesis, factors closely associated with NASH pathogenesis. NGM282 is a novel non-tumorigenic recombinant variant of FGF19 with potent metabolic and BA regulatory activity. The therapeutic potential of NGM282 in NASH was evaluated in a mouse model of steatohepatitis (STAM™ mice).
Methods: STAM™ mice were induced with a single subcutaneous injection of streptozotocin to 2-day old C57BL/6J male mice and a high fat diet [32% (w/w)] feeding beginning at 4 weeks of age. The model is characterized by steatosis, lobular inflammation and hepatocyte ballooning consistent with NASH. Adeno-associated virus encoding green fluorescent protein (GFP) as control or NGM282 were injected intravenously into mice *via* tail vein at 6 weeks of age. Mice were euthanized at 9 weeks of age after the 3 week treatment period. Blood and liver tissue were collected for serum chemistry and histologic analyses.
Results: NGM282 treated mice had significant decreases in total body weight, liver weight and liver-to-body weight ratio reflective of a decrease in total liver fat content (Figure 1a,1b). NGM282 significantly improved all components of the NAFLD activity score (steatosis, lobular inflammation, hepatocyte ballooning) as well as the total score compared to GFP treated controls (Figure 1c). Decreases in ALT, glucose and triglycerides were seen in NGM282 treated mice compared to controls.
Conclusions: NGM282 significantly improved liver histopathology associated with NASH, further supporting the therapeutic potential of this novel compound in NASH.

NGM282 EXHIBITS POTENT ANTI-INFLAMMATORY AND ANTI-FIBROTIC ACTIVITY IN FXR-NULL MICE WITH NON-ALCOHOLIC STEATOHEPATITIS (NASH) HISTOPATHOLOGY

L. Ling[1], M. Zhou[1], H. Yang[1], M. Humphrey[1], M. Learned[1], S. Rossi[1], A. DePaoli[1], H. Tian[1]. [1]*NGM Biopharmaceuticals, Inc, South San Francisco, United States*
E-mail: srossi@ngmbio.com

Background and Aims: NASH is an increasingly common cause of chronic liver disease worldwide and is associated with increased liver-related morbidity and mortality. There is an increased understanding of the role of bile acids (BA) and FGF19 in the pathogenesis of NASH and related fibrosis. NGM282 is a novel non-tumorigenic recombinant variant of FGF19 with potent inhibition of CYP7A1 and BA synthesis. We evaluated the effects of NGM282 in aged FXR-null mice that exhibit hepatic steatosis, degeneration and fibrosis consistent with NASH.
Methods: Sustained exposure of NGM282 was achieved by adeno-associated virus (AAV)-mediated gene delivery following a single tail vein injection into 6-month old FXR null mice. Hepatic expression of pro-inflammatory and pro-fibrotic genes was assessed by quantitative RT-PCR at 24 weeks after AAV administration in FXR null mice. Serum levels of ALT and alkaline phosphatase were determined as markers of hepatocellular and biliary damage. Liver sections were evaluated following H&E staining

Results: NGM282 significantly reduced hepatic expression of pro-inflammatory cytokines (*TNFa, IL-1b;* Figure 1A) and chemokines (*Ccl2, Cxcl2*) as well as key pro-fibrotic genes including *TGFb1* and *Galectin-3* (Figure 1B). mRNA levels of collagen (*Col1a1, Col1a2, Col3a1, Col14a1*, Figure 1C), matrix metallopeptidases (*Mmp2, Mmp12*) and tissue inhibitors of matrix metallopeptidases (*Timp1, Timp2*) were normalized by NGM282 treatment. Histological analysis demonstrated that NGM282 reduced hepatic steatosis, immune cell infiltration, and bile duct proliferation in FXR-null mice.
Conclusions: NGM282 protects aged FXR-null mice from developing steatosis, hepatic inflammation and fibrosis. These activities, in addition to the metabolic and BA synthetic actions, are supportive of the clinical development of NGM282 in NASH.

P0934

LYSOPHOSPHATIDYLCHOLINE (LPC) AS CENTRAL PLAYER FOR HEPATIC FAT ACCUMULATION AND INFLAMMATION: IMPLICATION FOR PATHOGENESIS OF NASH

W. Stremmel[1], S. Staffer[1], A. Wannhoff[1], A. Pathil-Warth[1], W. Chamulitrat[1]. *[1]Internal Medicine, University Clinics of Heidelberg Prof. Dr. W. Stremmel, Heidelberg, Germany*
E-mail: wolfgang_stremmel@med.uni-heidelberg.de

Background and Aims: In NASH the intracellular ratio of phosphatidylcholine (PC): lysophosphatidylcholine (LPC) is decreased due to activation of the membrane localized phospholipase A2 (iPLA2β). Here we aim the evaluation of LPC levels in development and reversal of fat accumulation and inflammation.
Methods: In HepG2 cells the bile acid-phospholipid conjugate ursodeoxycholate-lysophosphatidylethanolamide (UDCA-LPE) as $iPLA_2\beta$ inhibitor was used to modify intracellular LPC levels. We examined the impact of LPC on JNK1-p and transcription of the heterotetrameric fatty acid transport complex constituted of CD36, $FABP_{PM}$, caveolin1 and $iPLA_2\beta$. A NASH phenotype was generated by exposure of HepG2 cells with high concentrations of oleate bound to albumin (4:1) for 3 h.
Results: Addition of 1–10 μM LPC to delipidated cytosolic extracts revealed a dose dependent increase of JNK1-p a central promoter of fatty acid metabolism and lipoapoptosis. In vitro transcription with native HepG2 nuclear extracts exposed to these LPC conditioned cytosolic samples resulted in synthesis stimulation of all members of the fatty acid uptake complex. In contrast, the NASH phenotype was reversed or prevented by incubation with the $iPLA_2\beta$ inhibitor UDCA-LPE (1 h, 100 μM) suppressing cytosolic LPC levels. Accordingly JNK1-p and transcription of fatty acid transporter biosynthesis were reduced, concomitantly with disappearance of lipid droplets, triglyceride accumulation and LDH release in the medium.
Conclusions: $iPLA_2\beta$ mediated generation of LPC represents a central regulator for hepatic steatosis and inflammation via JNK1-p. Inhibition of iPLA2β by nontoxic UDCA-LPE could be an ideal therapeutic strategy against NASH.

P0935

NON-ALCOHOLIC STEATOHEPATITIS (NASH): 2 COMPLEMENTARY DIETARY MOUSE MODELS

M.V. Machado[1,2], G.A. Michelotti[2], G. Xie[2], J. Boursier[2,3], T. Pereira de Almeida[2], L. Kruger[2], G. Karaca[2], C. Guy[4], A.M. Diehl[2]. *[1]Gastrenterologia, Hospital de Santa Maria, Lisboa, Portugal; [2]Gastroenterology, Duke University, Durham, United States; [3]HIFIH Laboratory, LUNAM University, Angers, France; [4]Pathology, Duke University, Durham, United States*
E-mail: mverdelhomachado@gmail.com

Background and Aims: Non-alcoholic steatohepatitis (NASH), the potentially progressive form of nonalcoholic fatty liver disease (NAFLD), is the pandemic liver disease of our times. However, its ideal treatment has yet to be found. To better understand the physiology of NASH and develop therapeutic strategies, a good animal model is needed that is reproducible, easy to implement, and that causes not only hepatic steatosis, but also the characteristics of NASH (cellular injury/death, inflammation), as well as fibrosis (the pathology that confers bad prognosis in humans). We compared features of NASH in 2 mouse models most widely used to study the disease: methionine-choline deficient (MCD) diet and Western diet.
Methods: 36 C57Bl6 mice were fed either chow diet, MCD diet for 8 weeks or Western diet (45% energy from fat, predominantly saturated fat, with 0.2% cholesterol, plus drinking water supplemented with fructose and glucose) for 16 weeks. All animals were sacrificed at 20 weeks of age. Liver pathology and metabolic profile were compared.
Results: The metabolic profile associated with human NASH was best mimicked by Western diet, which induced weight gain, hyperleptinemia, insulin resistance and dyslipidemia. Hepatic steatosis (i.e., triglyceride accumulation) was also more severe in Western diet than MCD diet. However, liver non-esterified fatty acids content was higher in the MCD diet group. Hepatic steatosis associated with increased *de novo* lipogenesis in Western diet and decreased VLDL secretion in MCD diet. NASH was much more severe and reproducible in the MCD model, as evidenced by greater liver cell death/apoptosis and inflammation. Compared to mice fed Western diets, MCD diet-fed mice developed an enhanced ductular response, and significantly more fibrosis. Various mechanisms implicated in human NASH pathogenesis/progression were also significantly more robust in the MCD diet model, including oxidative stress, ER stress, autophagy deregulation, and hedgehog pathway activation.
Conclusions: MCD and Western diet are two complementary models to study NASH. Only Western diet reproduces the metabolic disturbances seen in human NASH. Western diet induces severe hepatic steatosis but after 4 months of diet exposure, liver injury is limited and minimal fibrosis is evident. MCD diet more efficiently reproduces the pathophysiologic mechanisms that drive human NASH pathogenesis/progression and causes substantial liver injury and fibrosis in 2 months.

P0936

THE IMPORTANCE OF THE INTERPLAY BETWEEN HEPATOCYTES AND HEPATIC STELLATE CELLS DURING FIBROGENESIS IN A NASH IN VITRO MODEL

P.J. Giraudi[1], V.J. Barbero Becerra[2], V. Marin[1], N.C. Chavez-Tapia[2], C. Tiribelli[1], N. Rosso[1]. *[1]Centro Studi Fegato, Fondazione Italiana Fegato, Trieste, Italy; [2]Liver Research Unit, Medica Sur Clinic & Foundation, Mexico City, Mexico*
E-mail: natalia.rosso@csf.units.it

Background and Aims: Activation of hepatic stellate cells (HSC) and dysregulation of several mediators such as matrix metalloproteinases (MMPs) and their inhibitors (TIMPs) play a determinant role in the fibrogenesis during the progression of NAFLD to NASH. This study was aimed to establish the interplay between hepatocytes and HSC in an *in vitro* cell model of NASH.
Methods: The effect of free fatty acids (FFA) (Oleic:Palmitic, 2:1) was analyzed at short (24 h) and long (96 h) exposure times in different experimental set-ups: (1) Monoculture of each cell type; (2) Transwell system (soluble mediators effects) and (3) simultaneous co-culture (SCC) by seeding both cell types together (cell-to-cell interaction). In each system was assessed the amount of steatosis; expression of HSC activation marker (α-SMA), ECM turnover regulators (MMP-2 and TIMP-2) as well as collagen biosynthesis in comparison to untreated cells (ctrl).
Results: The amount of steatosis was comparable among all the experimental set-ups. However, HSC activation in terms of α-SMA gene (2.20±0.25-folds; $p < 0.01$) and protein (1.70±0.20-folds; $p < 0.01$) expression was only increased in the SCC and was maximal after 24 h of FFA exposure. Similarly, the close contact of the two cell types induced an up-regulation of TIMP2 protein (1.42±0.27-folds; $p < 0.05$) which was inversely correlated both with MMP-2 protein (0.58±0.10-folds; $p < 0.01$) and activity (0.70±0.13-folds; $p < 0.05$). This dysregulation was accompanied by an increase of collagen biosynthesis at longer FFA exposure times (1.5±0.10-folds, $p < 0.01$). Any of these effects was directly induced by FFA (monoculture) nor by the soluble mediators (transwell).
Conclusions: Our data suggest that hepatocytes-to-HSC proximity/interaction is essential for fibrosis initiation in NASH.

LIVER STEATOSIS IS ASSOCIATED WITH INCREASED PORTAL PRESSURES AND IMPAIRED LIVER REGENERATION FOLLOWING PARTIAL HEPATECTOMY IN MICE

R. Fahrner[1], E. Patsenker[1], F. Stickel[1], F. Rauchfuss[2], U. Settmacher[2], D. Candinas[1], D. Stroka[1], G. Beldi[1]. *[1]Division of Visceral Surgery and Medicine, University Hospital Bern, Bern, Switzerland; [2]Division of General, Visceral and Vascular Surgery, University Hospital Jena, Jena, Germany*
E-mail: r.fahrner@web.de

Background and Aims: Liver steatosis negatively impacts outcome after major liver resection in humans. The aim of this study was to analyze liver injury, cellular stress and impact on liver regeneration in a murine model of liver steatosis compared to lean controls.
Methods: Male C57Bl/6 mice were fed with either normal chow (4.5% fat content) or high fat diet (HFD, 16.6% fat content) for 6 weeks to induce liver stetosis and then subjected to minor (30%) or standard (60%) partial hepatectomy (PH). Serum transaminases (ALT, AST) and tissue analysis (mRNA) were measured before surgery. Survival and liver regeneration was assessed 48 hours post surgery. Portal pressure was measured by direct cannulation of an ileocolic vein before and after liver resection, and liver regeneration was assessed by BrdU and Ki-67 immunohistochemistry.
Results: After six weeks of HFD, liver weight was significantly increased compared to control mice. By histology, significantly more fat content, cellular ballooning and inflammatory infiltrations were observed in steatotic, compared to lean mice. Serum transaminases were significantly increased in the HFD group. In liver tissue, mRNA of TNF alpha, GADD45 and p21 were significantly increased in steatotic livers compared to control livers. The 2 groups did not differ significantly in terms of baseline portal pressures and hepatic hydroxyproline content. Following both, minor and standard PH portal venous pressure was increased in steatotic compared to lean mice during the early phase of regeneration (minor PH 11 vs 10 mmHg, $p = 0.001$; standard PH 12 vs. 11 mmHg, $p < 0.0001$). Liver regeneration measured by BrdU and Ki-67 positivity was significantly reduced after minor PH in steatotic than in control mice [BrdU positive hepatocytes per high power field (HPF): 3.8 vs. 11, $p < 0.0001$; Ki-67 positive hepatocytes per HPF: 6.4 vs. 19.4, $p < 0.0001$]. Survival after standard PH was significantly reduced in steatotic than in lean mice, whereas there were no deaths after minor PH in both groups.
Conclusions: Liver steatosis is associated with an increased portal venous pressure after partial hepatectomy and reduced liver regeneration leading to decreased survival. Furthermore, liver steatosis has impact liver function and is associated with increased cellular stress and tissue inflammation.

OLIVE OIL COMSUMPTION AMELIORATES NON-ALCOHOLIC STEATOHEPATITIS INDUCED BY HYPERCALORIC AND HYPERLIPIDIC WESTERN DIETS

F. Martín[1], E. Jurado[1], R. Gallego-Durán[2], G. Berná[1], A. Robles-Frías[3], M.J. Pareja[3], J.A. del Campo[2], M. Romero-Gómez[2]. *[1]CIBER de Diabetes y Enfermedades Metabólicas Asociadas, CABIMER-UPO, [2]UCM Digestive Diseases and CIBERehd, [3]Pathology Unit, Valme University Hospital, Sevilla, Spain*
E-mail: rociogallegoduran@gmail.com

Background and Aims: To evaluate the protective role of extra virgin olive oil consumption in NAFLD, analysing signalling and molecular mechanisms.
Methods: 5-week-old male C57BL6J (n = 150) were fed 9 months with: (i) standard diet [3.4% fats; 0.6% saturated fats (SFA); 0.7% MUFA] (Ct; n = 30); (ii) saturated fats HFD (43% fats; 18% SFA; 20% MUFA) (HFD-SFA; n = 30); (iii) extra virgin olive oil HFD (43% fats; 4% SFA; 34% MUFA) (HFD-EVOO; n = 30); (iv) HFD-EVOO rich in phenolic compounds (five times higher) (HFD-O; n = 30) and (v) 3 months with HFD-SAF, followed by another 6 months with standard diet (R; n = 30). Standard diet energy density was 2.9 kcal/g and HFD was 5.9 kcal/g. It was evaluated: (i) food and fluid intake; (ii) body weight gain; (iii) glycaemia, insulinaemia, HOMA-IR and lipid profile; (iv) inflammatory plasmatic markers (IL-6, TNF-α, IFN-γ); (v) liver weight; (vi) total lipids liver content; (vii) liver fatty acids and triglycerides profile; (viii) histology (hematoxylin–eosin, Sirius Red and Oil-Red) and (ix) liver proteomic analysis. Statistical analysis was performed using SPSS v22, by ANOVA and Tukey–Kramer.
Results: Comparing HFD-EVOO and HFD-O with HFD-SFA mice, it was observed: (i) Significant reduction of body weight, glycaemia and HOMA index; (ii) Significant reduction of total cholesterol, LDL and triglycerides plasmatic values; (iii) Significant increase of plasmatic HDL concentrations; (iv) Significant reduction of IFN-γ plasmatic levels; (v) Significant reduction of total hepatic lipids; (vi) Significant increase of MUFAs and trioleins hepatic content; (vii) Significant reduction of NAS score and Sirius Red positive cells and (viii) Significant reduction of proteins involved in insulin resistance, hepatic steatosis, inflammation and NAFLD.
Comparing HFD-EVOO with HFD-O mice, it was observed: (i) Significant reduction of LDL and IFN-γ plasmatic levels and significant increase of HDL; (ii) Significant reduction of liver lipids content and (iii) Significant reduction of NAS score and Sirius Red positive cells. All parameters analysed returned to normality in R group.

Table (abstract P0938).

	Control	HFD-SAF	HFD-EVOO	HFD-O	R	Statistics
Weight (g)	42±1.3	52±1.6	47±1.4	44±2.6	43±1.8	N = 30/group; *$p < 0.05$; NS

Hepatic trioleins (g/100 g liver tissue)	3.2±0.5	6.7±0.2	12.5±0.2	12.8±1	ND	N = 5/group; *$p < 0.01$; NS
NAS score	0±0	4.6±0.3	3.6±0.5	2±0	0±0	N = 3/group; *$p < 0.05$; *$p < 0.05$
Positive Sirius Red cells (%)	0.2±0.03	2.6±0.5	1.2±0.6	0.4±0.02	0.3±0.02	N = 3/group; *$p < 0.05$; *$p < 0.01$

First statistics are referred to HFD-SAF vs HFD-EVOO and HFD-O; second statistics corresponds to HFD-EVOO vs HFD-O.

Conclusions: Enriched olive oil with HFD decreased NAFLD-induced liver manifestations. Compounds with antioxidant activity partially explains the improvement of some parameters. Insulin resistance decrease and changes in liver lipids content profile, together with the modification of the expression of proteins related with hepatic steatosis and inflammation have a relevant impact in the improvement observed in NAFLD.

P0939
FATTY LIVER VS. FIBROTIC LIVER: COMPARISON OF INFECTION-ASSOCIATED PORTAL HYPERTENSION

J. Schewe[1], M.-C. Makeschin[2], I. Liss[1], A.L. Gerbes[1], C.J. Steib[1].
[1]Department of Medicine II, [2]Department of Pathology, LMU Munich, Klinikum Grosshadern, Munich, Germany
E-mail: Julia.Schewe@med.uni-muenchen.de

Background and Aims: Portal hypertension and alterations of liver structure are of major relevance for chronic liver diseases. We have identified TXA_2 as important vasoconstrictor upon infection following TLR 2/6 activation in the liver (e.g. Steib CJ et al., Hepatology 2010). The aim of this study was therefore to investigate, whether the cause of liver disease influences the extent of TXA_2 induced portal hypertension.
Methods: Bile duct ligation (BDL) in male Sprague-Dawley rats caused fibrosis after 4 weeks (BDL4) and fatty liver was induced by high fat diet. Isolated liver perfusion was performed for 80min. In all three liver models three groups (each n = 5) were investigated: **A**: control perfusion; **B**: + Zymosan A (150 μg/ml, 40.–46.min.); **C**: + U46619 (TXA_2 analogue, 0.1μM/ml, 40.–46.min.). Portal perfusion pressure (p) and Thromboxane B_2 (TXB_2, stable degradation product) in the perfusate (+ Zym) were measured (mean ± SEM; *$p < 0.05$). Immunhistochemical evaluation of the livers using CD163 (to determine Kupffer cell density) and α-SMA (to estimate number of activated hepatic stellate cells) is in process.
Results: HE staining showed, in comparison to healthy livers, a mild inflammation and moderate to severe fat deposition in fatty livers and a moderate to severe fibrosis with moderate inflammation in BDL4. Portal perfusion pressure and TXB_2 production after Zymosan A (group B) and portal perfusion pressure after TXA_2 analogue U46619 (group C) are shown in Table 1. Interestingly, p_{max} was significantly lower after Zymosan A in fatty livers compared to healthy livers and following U46619 p_{max} was lower in fatty livers compared to fibrotic livers.
Conclusions: Fatty livers were less sensitive to TLR 2/6 activation and TXA_2 analogue administration than healthy and fibrotic livers. The correlation between portal perfusion pressure and TXB_2 decreases from healthy to fatty on fibrotic liver, which might be depend on the increasing damage and alteration of liver architecture because of the liver disease. In summary, this leads to the assumption that fatty livers have a protective effect on infection-associated portal hypertension. Hereby, it offers future clinical situations the possibility to stratify the risk for patients with fatty livers and prompts further research.
This study is supported by DFG STE 1022/2-3 and DFG STE 1022/4-1.

CHRONIC PARTICULATE MATTER EXPOSITION REPRESENTS A SECOND HIT IN THE PROGRESSION FROM STEATOSIS TO STEATOHEPATITIS

M. Tarocchi[1], G. Marroncini[1], S. Polvani[1], S. Tempesti[1], E. Ceni[1], T. Mello[1], M. Peluso[2], A. Galli[1]. *[1]Department of Experimental and Clinical Biomedical Sciences, University of Florence, [2]Cancer Risk Factor Branch, Cancer Prevention and Research Institute, Florence, Italy*
E-mail: mirko.tarocchi@unifi.it

Background and Aims: Nonalcoholic fatty liver disease (NAFLD), a hepatic manifestation of metabolic syndrome, is the most common chronic liver disease, and the prevalence is rapidly increasing in developed countries. Nonalcoholic steatohepatitis (NASH), the severe form of NAFLD, can also progress to liver cirrhosis and hepatocellular carcinoma. Recent evidences suggest that environmental factors can trigger hepatic inflammation and progression of steatosis to NASH. We evaluate if a western style diet in association with chronic urban particulate matter exposition can modifies the pathogenesis and progression of NASH.
Methods: The experimental model was created to reproduce urban lifestyle: C57Bl/6 mice were fed with normal chow (ND) or a western style diet (HFD) rich in fat, cholesterol and sugar, and treated with or without particular matter (PM) collected from the urban area of Florence (Italy). After 4 and 8 weeks were performed the morphologic analysis of liver tissues, the evaluation of inflammatory cell infiltrate and the collagen deposition; we evaluate also the effects of PM on cytokine production and oxidative stress related cellular damage.

Results: Already after 4 week of treatment were present differences among the HFD group and the HFD-PM group; as expected the HFD groups developed fat accumulation in the liver but, interestingly at 8 weeks, the NASH score was significantly increased in the second group ($p < 0.01$) based on the histological analysis of the liver, the tissue fat content, the inflammatory cell infiltrate and the collagen deposition. The cytokine profiles indicate an increased production of pro-inflammatory molecules in presence of PM. The levels of DNA adducts were significantly increased in the HFD groups compared to standard chow. Many adducts were identified in liver tissues: one of them was benzo(a)pyrene, that is a well known polycyclic aromatic hydrocarbon with strong mutagenic properties. Interestingly the effects of HFD and PM were synergic in the sense that the levels of DNA adducts were about thirty fold greater in HFD mice in respect to controls treated with the same amounts of air particulate matter extracts mainly due to benzo(a)pyrene increment.
Conclusions: Our data suggest that in subject with steatosis due to a western style of life, the association with a chronic exposition to urban particulate matter plays an important role in the pathogenesis of NASH and its evolution to cirrhosis and also to cancer.

CD44 IS AN IMPORTANT ACTOR IN NON ALCOHOLIC STEATOHEPATITIS

D. Rousseau[1,2], R. Anty[1,2,3], S. Bonnafous[1,2,3], S. Patouraux[1,2,3], A.-S. Schneck[1,2,3], A. Iannelli[1,2,3], M.-C. Saint-Paul[1,2,3], J. Gugenheim[1,2,3], B. Bailly-Maitre[1,2], A. Tran[1,2,3], P. Gual[1,2].
[1]INSERM U1065, Team 8 hepatic complications in obesity, INSERM, [2]University of Nice-Sophia-Antipolis, [3]Centre Hospitalier Universitaire of Nice, Nice, France
E-mail: gual@unice.fr

Background and Aims: CD44 is expressed on many cell types that contribute to inflammation. CD44 plays an important role in the recruitment of macrophages into adipose tissue with obesity and of leukocyte into liver in response to lithogenic diet. However, its role in hepatic inflammation in obese patients and in mouse models of steatohepatitis has not yet been investigated.
Methods: CD44 rs187116 and rs13347 genotypes were determined by allelic discrimination using TaqMan reagents in a cohort of 274 morbidly obese patients with liver biopsy-proven NAFLD. Gene expression of CD44, IL1β, TNFα was evaluated in 30 obese patients (8 without NAFLD, 13 with hepatic steatosis and 9 with NASH). The role of CD44 was evaluated in *cd44*$^{-/-}$ mice with steatohepatitis induced by methionine- and choline-deficient diet (MCD) (Wt Ctr Diet=8, MCD=14; *cd44*$^{-/-}$ Ctr Diet=12, MCD=19) by histological, biological, gene expression and flow cytometry analysis.
Results: Carriage of CD44 rs187116 minor A allele was associated with presence of hepatic inflammation independently of age, gender, body mass index and the presence of type 2 diabetes in morbidly obese patients ($p = 0.0312$). Further, CD44 hepatic gene expression was strongly upregulated in NASH patients and correlated with NASH grading ($r_s=0.668$, $p < 0.001$), NAS ($r_s=0.562$, $p = 0.001$), ballooning ($r_s=0.531$, $p = 0.003$) and ALT ($r_s=0.496$, $p = 0.005$). Experiments in mouse model of steatohepatitis (MCD) further showed the hepatic upregulation of CD44 at the mRNA and protein level. AST and ALT levels were strongly decreased in *cd44*$^{-/-}$ mice compared with wild-type mice after MCD challenge (−28% and −39%, respectively). Histological analysis of the liver of *cd44*$^{-/-}$ mice revealed a significantly lower incidence of hepatic steatosis (10±4% vs 48±8%, $p < 0.001$) and inflammation (2±1 vs 7±2 inflammatory foci/10 fields, $p < 0.001$). In addition, the hepatic expression level of markers of inflammation (MCP1, TNFα and IL1β) and macrophages (F4/80) was strongly decreased in *cd44*$^{-/-}$ mice versus wild-type mice after MCD. Flow cytometry analysis also revealed a prevention of F4/80 macrophage infiltration into the liver of *cd44*$^{-/-}$ mice in response to MCD.
Conclusions: Human and experimental data suggest an important role for CD44 in the pathogenesis of NAFLD (steatosis and NASH).

P0942
IMMUNE REACTIONS IN STEATOHEPATITIS INITIATION AND PROGRESSION TO FIBROSIS: CRITICAL ROLE OF TH17 AND TH22 LYMPHOCYTES

E. Alchera[1], S. Rolla[2], C. Imarisio[1], V. Bardi[2], G. Valente[3], A. Follenzi[1], B. Revanna Chandrashekar[1], F. Novelli[2], R. Carini[1].
[1]Health Sciences, University, University of Piemonte Orientale, Novara, [2]Biotechnology and Healthy Sciences, University of Turin, Turin, Italy, Torino, [3]Translational medicine, University of Piemonte Orientale, Novara, Italy
E-mail: elisa.alchera@med.unipmn.it

Background and Aims: The mechanisms responsible for steatosis progression to NASH and for NASH evolution to fibrosis are incompletely understood. Recent evidences, indicate that hepatic immune response may also play critical role in NASH. In particular, IL-17 and IL-22 produced by CD4+ T cells can modulate the inflammatory reactions and survival processes. This study investigated Th17 ($CD4^+IL\text{-}17^+$) and Th22 ($CD4^+IL\text{-}22^+$) lymphocytes infiltration in mice liver during NASH development and explored the role of IL-17/ IL-22 production in this process.
Methods: C57BL/6 WT and IL-17KO mice were fed either a normal diet (ND) or a methionine/choline deficient diet (MCD) diet. Liver T lymphocytes were analyzed by flow cytometry. Primary mouse hepatocyte were exposed to palmitic acid (PA)
Results: MCD diet induced progressive hepatic damage as evidenced by ALT increase, progressive micro and macro steatosis, necrosis, lobular inflammation and finally fibrosis. In the liver, Th17 cells significantly increased already at 1 week of MCD diet compared to ND mice, decreased at 2 and 4 weeks, and further increased at 8 weeks. By contrast, Th22 displayed an opposite kinetic.
We investigated the role of IL-17 and IL-22 in steatotic liver damage and protection, by employing primary mice hepatocyte exposed to PA. PA alone induced hepatocytes damage and increased JNK phosphorylation, a known marker of hepatocyte lipotoxicity. IL17 treatment further increased these parameters, whereas IL-22 protected them and activated a central mediator of cellular survival processes: Akt. Consistently inhibition of Akt, reversed IL-22-induced prevention of JNK phosphorylation and abolished cytoprotection.
To clarify the importance of IL-17 in initiate and sustain liver damage, NASH was induced in IL-17 KO mice. Lower ALT levels and lower NASH and fibrosis markers and an higher percentage of Th22 cells in the liver were observed in IL-17KO mice compared to WT mice. The reduced liver injury and fibrosis in IL-17 KO mice was related to an increased Akt activation and decreased JNK phosphorylation, according to *in vitro* results.
Conclusions: a biphasic increase of Th17 over Th22 is associated to NASH initiation and evolution to fibrosis in mice. Such effects are mediated by a prevalence of the lipotoxic JNK-dependent activity of IL-17 on the Akt-related cytoprotective action of IL-22.

P0943

BENEFICIAL EFFECTS OF IL-1 CYTOKINE INACTIVATION AND THE ROLE OF THE SERINE/THREONINE KINASE MK-2 IN HEPATIC STEATOSIS IN A MURINE OBESITY MODEL

J. Wohlfahrt[1], A. Fettelschoss[2], T. Kündig[2], H. Hermanns[3], B. Müllhaupt[4], J. Schmitt[1], A. Geier[1]. *[1]Division of Hepatology, University Hospital Würzburg (UKW), Würzburg, Germany; [2]Department of Dermatology, University Hospital Zürich (USZ), Zürich, Switzerland; [3]Rudolf-Virchow-Zentrum for experimental Biomedicine, University Würzburg, Würzburg, Germany; [4]Department of Gastroenterology and Hepatology, University Hospital Zürich (USZ), Zürich, Switzerland*
E-mail: wohlfahrt_j@ukw.de

Background and Aims: Although non-alcoholic fatty liver disease (NAFLD) is among the most common causes of chronic liver disease worldwide, its pathogenesis is yet poorly understood. Recent studies show that IL-1α/β play a crucial role in disease development. Their recognition by cells does not only result in transcriptional regulation of many IL-1 target genes, but also negatively affects cell surface expression of the IL-6 signal transducer in an MK-2 (mitogen-activated protein kinase-activated protein kinase 2)-dependent mechanism. Therefore the cells might become less susceptible for IL-6 signalling, which is suspected to be beneficial in steatosis. We aim to investigate the role of IL-1 in early steatosis in IL-1-immunized and MK-2 deficient mice.
Methods: C57BL/6J wild-type and MK-2 deficient mice were fed a Surwit High Fat Diet (HFD) for 8 weeks; for inactivation of IL-1 mice were subcutaneously vaccinated against IL-1α/β using virus-like particles presenting antigens of IL-1α/β (Cytos-Biotechnology). Liver and fat tissue was analysed and RNA was isolated to assess gene expression via qPCR.
Results: Our recent findings show that inactivation of IL-1 by virus-like particles drastically reduces steatosis in mice fed a HFD for 6 weeks on a macroscopic and molecular level. Lipid accumulation is drastically reduced and lipogenic enzyme as well as proinflammatory molecule expression is significantly downregulated. Although no cytokine expression is detectable in the liver at such an early timepoint expression levels are elevated in adipose tissue of animals fed a HDF. IL-1β serum levels show no differences between chow- or HFD-fed mice, pointing towards an indirect effect of fatty tissue inflammation on the liver. MK-2 deficient mice show no significant differences in liver weight or expression of any inflammatory markers in qPCR after 8 weeks of feeding.
Conclusions: Our results strongly support future studies on IL-1 for clinical applications since its inactivation prevents liver steatosis in HFD-fed mice. The present study indicates that the main initial target site for IL-1 is the adipose tissue rather than the liver itself. Therefore, the effect on the liver appears to be indirect as IL-1β serum levels do not increase upon feeding mice a HFD. Furthermore, MK-2 deficient mice fed a HFD for 8 weeks show no difference in liver inflammation in comparison to WT mice, indicating that the IL-1/IL-6 cross-talk does not affect the early phase of steatosis.

MODULATION OF MUSCLE MICRORNA EXPRESSION PROFILES IN PATIENTS WITH NAFLD AND IN C2C12 CELLS INCUBATED WITH PALMITIC ACID

A.L. Simão[1], M.B. Afonso[1], P.M. Rodrigues[1], A.J. Amaral[2], M. Gama-Carvalho[2], P.M. Borralho[1], M.V. Machado[3,4], H. Cortez-Pinto[3,4], C.M.P. Rodrigues[1], R.E. Castro[1]. *[1]Research Institute for Medicines (iMed.ULisboa), [2]BioFIG – Center for Functional and Integrative Genomics, [3]Gastrenterology, Hospital Santa Maria, [4]IMM, Faculty of Medicine, Universidade de Lisboa, Lisbon, Portugal*
E-mail: adlsimao@ff.ul.pt

Background and Aims: In the skeletal muscle, non-alcoholic fatty liver disease (NAFLD) associates with intramyocellular lipid deposition, mitochondrial dysfunction and insulin resistance (IR), particularly in obese patients. Further, recent evidences support a functional role for microRNAs (miRNA/miRs) in regulating muscle mitochondrial impairment and IR. Finally, tauroursodeoxycholic acid (TUDCA) is cytoprotective in both liver and muscle cells, in part, by stabilizing mitochondria. Our aims were to profile global muscle miRNA expression profiles from patients at different NAFLD stages and validate their role, as well as of TUDCA, in insulin-resistant muscle cells.
Methods: Muscle and matching liver biopsies were obtained from morbid obese NAFLD patients undergoing bariatric surgery. Muscle RNA was run in TaqMan MicroRNA arrays. qPCR array data was analyzed using the HTqPCR package in Bioconductor. Differential expression analysis was performed with interquantile range values >1.5 using the lmfit function of the Limma package and the Benjamini-Hochberg conditional hypergeometric test algorithm. C2C12 cells were incubated with or without palmitic acid (PA), in the presence or absence of TUDCA, for characterization of the insulin signaling pathway, as well as mitochondrial and overall cellular toxicity.
Results: Our results show a progressive and significant increase in the expression of 6 muscle miRNAs from steatosis to more severe NASH (at least $p < 0.05$). These included miR-339-3p, which has been described to regulate glucose synthesis, and miR-361, found increased in type II diabetes (T2D) patients serum. Inversely, 8 miRNAs were decreased (at least $p < 0.05$), including miR-20b, reported as down-regulated in T2D patients plasma. Incubation of C2C12 cells with PA inhibited the insulin-signaling pathway, while increasing mitochondrial dysfunction and apoptosis (at least $p < 0.05$), all of which were prevented by co-incubation of cells with TUDCA ($p < 0.05$). Of note, miR-339-3p was also increased by PA ($p < 0.05$), targeting MAPK phosphatase-7 (MKP-7), a negative regulator of JNK, thus likely contributing for IR.
Conclusions: In conclusion, our results indicate that miRNAs associated with T2D and mitochondrial dysfunction are differently modulated with NAFLD severity in the muscle, with miR-339-3p arising as a novel mechanistic player. In addition, TUDCA attenuates muscle cells IR and lipoapoptosis and, as such, may ameliorate NAFLD-associated muscle dysfunction.

SURGICAL REMOVAL OF INFLAMED EPIDIDYMAL WHITE ADIPOSE TISSUE OF OBESE C57BL6/J MICE ATTENUATES THE DEVELOPMENT OF NON-ALCOHOLIC STEATOHEPATITIS

P.C. Mulder[1], M. Morrison[1], T. Kooistra[1], H. van Bockel[2], P. Wielinga[1], R. Kleemann[1]. *[1]Metabolic Health Research, TNO, [2]Vascular surgery, LUMC, Leiden, Netherlands*
E-mail: petra.mulder@tno.nl

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) and the development of its severe form non-alcoholic steatohepatitis (NASH) is strongly associated with abdominal obesity. It has been postulated that obesity-associated inflammation in abdominal white adipose tissue (WAT) contributes to this relationship. To investigate whether inflamed WAT plays a causal role in the pathogenesis of NAFLD, we surgically removed the inflamed abdominal (epididymal) WAT of obese mice (with established steatosis) and investigated further progression of NAFLD towards NASH.
Methods: Male C57BL/6J mice were fed a high-fat diet (HFD) for 12 weeks to develop obesity with inflammation in epididymal WAT (eWAT) and liver steatosis. Subsequently, surgical removal of inflamed eWAT (WATx) or a SHAM procedure was performed and mice continued on HFD for another 12 weeks. NAFLD development was analyzed histologically and by RT-PCR.

Results: Body weight and total fat mass were comparable between the groups at the end of the experiment, but eWAT mass remained low after surgery in WATx. Liver histology scores demonstrate that WATx mice showed a similar degree of steatosis compared to SHAM, but NASH development was significantly reduced as revealed by a reduction in inflammatory aggregates (−40%) and inflammatory factors (TNF-alpha: −37% and MCP-1: −31%). Attenuation of NASH development was accompanied by reduced circulating levels of inflammatory mediators, such as leptin and free fatty acids.
Conclusions: Surgical removal of inflamed eWAT attenuated the progression of NAFLD towards NASH, indicating a causal role of eWAT in NAFLD development. The crosstalk between WAT and liver may be mediated by WAT-derived pro-inflammatory factors such as leptin and free fatty acids.

CX3CR1-EXPRESSING INFLAMMATORY DENDRITIC CELLS CONTRIBUTE TO THE PROGRESSION OF NONALCOHOLIC STEATOHEPATITIS (NASH) IN MICE

S. Bruzzì[1], S. Sutti[1], A. Jindal[1], I. Locatelli[1], M. Vacchiano[1], C. Bozzola[1], E. Albano[1]. [1]*Health Sciences, University of Eastern Piedmont, Novara, Italy*
E-mail: stefania.bruzzi@med.unipmn.it

Background and Aims: Liver dendritic cells (DCs) are a heterogeneous population of specialized bone marrow-derived cells mainly involved in antigen presentation to lymphocytes. In healthy livers DCs have a predominant tolerogenic phenotype, but recent evidence suggests their possible contribution in the evolution of chronic liver diseases. In this study, we have investigated the role of monocyte-derived inflammatory dendritic cells (moDCs) in experimental NASH.
Methods: NASH was induced in C57BL/6 mice by feeding a methionine-choline deficient (MCD) diet for up to 8 weeks.
Results: In MCD-fed mice the progression of NASH to fibrosis was associated with a ten fold expansion of myeloid-derived F4–80$^+$ cells featuring the combination of inflammatory monocyte markers (CD11b, Ly6C) and the fractalkine receptor (CX_3CR1). These CX_3CR1^+ cells were also characterized by the expression of dendritic cell markers (CD11c, MHCII) and by a sustained TNF-α production, suggesting monocyte differentiation to inflammatory moDCs. The accumulation of CX_3CR1^+ moDC in advanced NASH paralleled with the lowering in phasmocytoid and lymphocytoid DC and a decline in macrophage M1 activation markers. Conversely, the expansion of TNF-α-producing CX_3CR1^+ moDCs was associated with an elevation in hepatic and circulating TNF-α levels and the worsening of parenchymal injury. Hydrogen sulfide (H_2S) has been shown to interfere with CX_3CR1 up-regulation in monocyte-derived cells exposed to pro-inflammatory stimuli. Treating 4 weeks MCD-fed mice with the H_2S donor NaHS while continuing on the same diet prevented the accumulation of TNF-α-producing CX_3CR1^+-moDCs without interfering with hepatic macrophage functions. Furthermore, NaHS reduced hepatic and circulating TNF-α levels and ameliorated transaminase release and parenchymal injury.
Conclusions: Altogether, these results indicate that inflammatory CX_3CR1^+-moDCs contribute in sustaining lobular inflammation and liver injury during NASH progression.
This work has been supported by a grant from the Fondazione Cariplo, Milan Italy.

A COMPUTATIONAL MODEL OF ZONATION IN HEPATIC METABOLISM: UNDERSTANDING ZONATED STEATOSIS IN NAFLD AND IDENTIFICATION OF POTENTIAL DRUG TARGETS

W.B. Ashworth[1,2,3], I.D.L. Bogle[1,3], N.A. Davies[2]. [1]*CoMPLEX,* [2]*Institute of Liver and Digestive Health,* [3]*Department of Chemical Engineering, University College London, London, United Kingdom*
E-mail: w.ashworth@ucl.ac.uk

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is strongly associated with insulin resistance (IR). In adult NAFLD, steatosis (STT) originates in perivenous (PV) cells before spreading across the sinusoid. Since PV cells are lipogenic, whilst periportal (PP) cells preferentially uptake fatty acids (FA), this pattern of lipid build-up is often considered counter-intuitive given the context of reduced insulin stimulation of lipogenesis but raised plasma lipid levels. We aim to develop an *in silico* model to understand the causes of PV-STT and the implications of hepatic heterogeneity on drug development.
Methods: Fully characterizing the metabolic changes occurring in each region of the sinusoid in NAFLD experimentally would be complex, time-consuming and animal intensive. To reduce *in vivo* experimentation, a computational model of the sinusoid was rigorously built based on compartments of hepatocytes interacting with blood as it passes from PP to PV ends of the sinusoid.

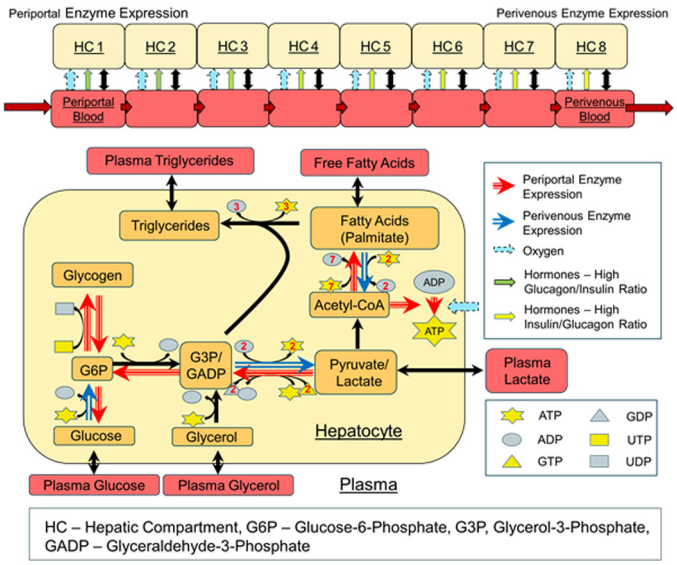

Figure: A simplified schematic of metabolism across the sinusoid as represented in the model.

Results: PV-STT was predicted to occur when the short term effects of IR were simulated alone. This was due to the build-up of carbohydrate metabolic intermediates in PV cells causing the rapid storage of FAs as triglycerides (TGs). PV-STT was also seen when simulating a high fat diet in metabolically normal individuals as a result of increased lipogenesis and lipid uptake.
The effects of targeting each pathway in the model in turn were analysed to assess potential drug targets for reducing STT. Only suppressing FA synthesis from acetyl-CoA was predicted to reduce hepatic and plasma lipid concentrations without disturbing energy metabolism. Suppression of lipid uptake or stimulation of TG release as VLDL were predicted clear hepatic STT, but also raised plasma lipid levels redirecting fats to other tissues. Blocking TG synthesis led to a vast increase in the FA concentration of PV cells likely to expedite cell damage. All relevant alterations to carbohydrate metabolism were predicted to disturb ATP synthesis, particularly in PV cells.

Conclusions: Firstly, we hypothesize that the build-up of carbohydrate metabolic intermediates as a result of defective glycogen storage, particularly in PV cells, contributes to the development of PV-STT in IR. Secondly, we propose that blocking the synthesis of FAs from acetyl-CoA is a promising target pathway to reduce STT without disturbing ATP production. Interventions in other metabolic processes are predicted to redirect lipids to other tissues or cause complications in energy metabolism.

UPREGULATED EXPRESSION OF SENP3 PLAYS AN IMPORTANT ROLE IN THE PROGRESSION OF NON-ALCOHOLIC FATTY LIVER DISEASE

Y. Liu[1], Q. Xie[1], Y. Han[1], Q. Li[1], Z. Cao[1], R. Lai[1], G. Zhao[1], S. Jiang[1], X. Xiang[1]. [1]*Department of Infectious Diseases, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China*
E-mail: liuyuhan0621@126.com

Background and Aims: Non-alcoholic fatty liver disease (NAFLD), ranging from nonalcoholic fatty Liver (NAFL) to progressive non-alcoholic steatohepatitis (NASH) and fibrosis, has become an increasingly common healthy problem. SENP3, a sentrin/de-SUMO specific protease, plays an important role in spectrum of cellular process. Reports have demonstrated that SENP3 was sensitive to a variety of stresses. However stresses such as oxidative stress, lipid accumulation, cytokines, et al, have been known as major factors involved in the development of NAFLD. Thus, the aim of this study was to investigate if and how SENP3 was involved in NAFLD.
Methods: Liver biopsy samples of 20 NAFLD patients and 3 normal controls, obtained from Shanghai Ruijin Hospital from 2012 to 2014, were subject to immunohistochemical staining (IHC) of SENP3 expression. Meanwhile, Sprague Dawley (SD) rats fed with high-fat diet were utilized as NAFLD animal model to further validate the results found in human. Finally, we treated normal liver cell line (L02) with medium containing oleate and palmitate (oleate/palmitate, 2:1 ratio) as the cell model of NAFLD to explore the potential mechanistic link between SENP3 and NAFLD. SENP3 was ectopically overexpressed or silenced in L02, and determined the cellular lipid content by Oil Red O staining.

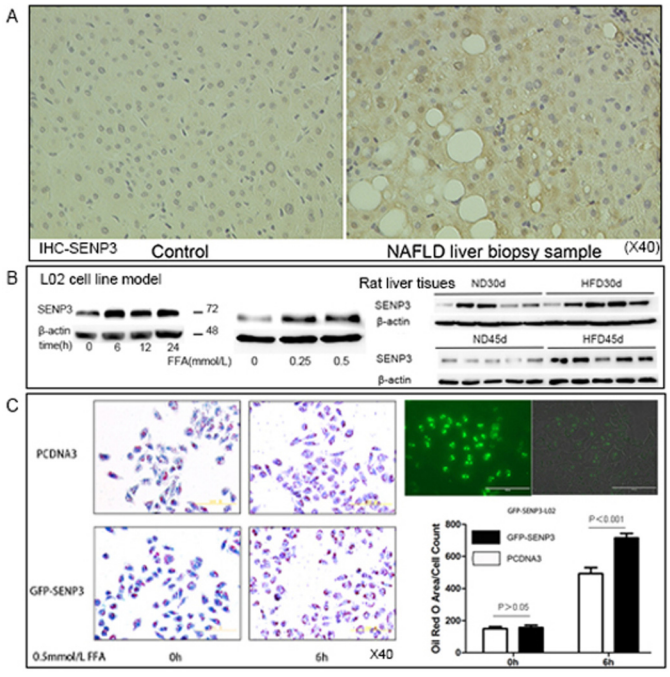

Figure: (A) Typical pictures of IHC with SENP3 antibody in human liver biopsy samples. (B) Western Blot showing SENP3 expression in L02 cells and rats. (C) Overexpression of SENP3 promoting lipid accumulation.

Results: IHC results showed that intrahepatic levels of SENP3 were higher in NAFLD patients than normal controls, and interestingly, SENP3 was found located around fat vacuole (typical pictures shown in Figure A). Moreover, elevated expression of SENP3 was also observed in the NAFLD rat model and cell model by Western Blot, PT-PCR and IHC, which is in consistency with the IHC results in human liver tissues (results of Western Blot shown in Figure B). Furthermore, SENP3 overexpression by transfected with GFP-SENP3 promoted lipid accumulation, while the ablation of it by transfected with SENP3 si-RNA inhibited lipid accumulation (results of SENP3 overexpression shown in Figure C).
Conclusions: Taken these findings together, we report for the first time that upregulated expression of SENP3 in the liver tissue may play an important role in the progression of NAFLD, especially in regulating hepatic lipid accumulation. The potential underline mechanism of SENP3 in NAFLD is still under investigation.

P0949

PIOGLITAZONE HYDROCHLORIDE PREVENTS NK CELL INSULIN RESISTANCE AND ENHANCES THEIR ACTIVITY IN NONALCOHOLIC FATTY LIVER DISEASE PATIENTS VIA mTOR PATHWAY

J. Amer[1], A. Salhab[1], R. Safadi[1]. [1]*Liver & Gastroenterology Units, Hadassah Hebrew University Medical Center, Jerusalem, Israel*
E-mail: johnnyamer@hotmail.com

Background and Aims: Obesity and insulin resistance are considered to play a role in Nonalcoholic Fatty Liver Disease (NAFLD) progression. Impairment of NK cells was explored as a mechanism for fibrosis progression into cirrhosis, suggesting that attenuating NK function is a prerequisite for the progression of the disease. We investigated a potential role of pioglitazone hydrochloride (insulin sensitizer) in NK cell modulation of "Insulin Resistance" in NAFLD patients.
Methods: Fifteen histology documented NAFLD patients lacking metabolic syndrome with advanced fibrosis score (F3–4) analyzed and correlated to fresh peripheral blood NK characterizations by flow-cytometry. Healthy volunteers used as a control. NK cells were investigated for insulin receptors and activity by CD107a. NK cells were in vitro pre-incubated with 10 mg/ml pioglitazone hydrochloride prior to modulations with physiological concentrations of insulin (20 IU) and 10 mg/ml rapamycin (mTOR inhibitor).
Results: Insulin receptors were expressed on 68.6±8% of healthy NK population, but significantly reduced to 48.4±3.3% in NAFLD NK cells ($P < 0.05$). This was correlated with increased insulin resistance (HOMA-score) suggesting NK cell insulin resistance. CD107a expressions although were unchanged (19.6±2.1%) within advanced fibrosis of NAFLD patients as compared to healthy donors, their NK cells had reduced secretions of γINF suggesting NK impairment. These changes in NAFLD NK cells were accompanied with a significant lower mTOR activity ($p = 0.001$). Using *in vitro* cultures, NAFLD NK cells had higher apoptosis rate and fail to reduce hepatic stellate cells (HSCs) activations as compared to normal donors. Pioglitazone hydrochloride inhibited decrease in NK insulin receptor on NAFLD NK cells an effects that were accompanied by elevations of NK CD107 and mTOR activity ($P < 0.04$). Rapamycin additions to the cultures reversed these effects while prevented by exposure of NK cells to insulin concentrations. NK exposure with physiologic insulin levels enhanced the killing of HSCs, while NK insulin resistance and impairment (induced by rapamycin) blocked the insulin effects to kill HSCs.
Conclusions: Pioglitazone hydrochloride enhanced NK functionality through modulations of mTOR activity and increase expressions of insulin receptor and consequently responded to physiological levels of insulin. Our data suggest a protective role of pioglitazone hydrochloride to increase potentials of NK cells to kill HSCs and limit NAFLD progression.

P0950

IMPACT OF KUPFFER CELLS ON HIGH FAT INDUCED INSULIN RESISTANCE AND LIVER FETUIN-A EXPRESSION

N. Lanthier[1], V. Lebrun[1], M.-P. Berghmans[1], O. Molendi-Coste[1], I.A. Leclercq[1]. *[1]Laboratory of Hepato-Gastroenterology, Institut de Recherche Expérimentale et Clinique, Université catholique de Louvain, Brussels, Belgium*
E-mail: Nicolas.Lanthier@uclouvain.be

Background and Aims: Hepatokines (liver secreted proteins with possible distant action) are emerging potential players in insulin resistance in type 2 diabetic patients. Here, we explore the effect of a high fat diet on the expression of fetuin-A, one of those candidate liver proteins, and its relation with liver macrophage (Kupffer cell) activation.
Methods: Male mice of 5 weeks of age were fed a normal diet (ND) or a high fat diet (HFD) for 3 days, known to initiate steatosis and insulin resistance. A preventive Kupffer cell (KC) depletion was obtained by intravenous injection of clodronate loaded liposomes and compared with PBS liposomes. The mRNA and protein expression of fetuin-A was evaluated by RT-PCR, Western-blot and immunofluorescence (IF) on different insulin-sensitive tissues (liver, adipose tissue and muscle).
Results: Short term HFD induced steatosis, KC activation and insulin resistance together with a significant increased expression of liver fetuin-A mRNA (1.5 fold, $p < 0.01$). However, liver fetuin-A protein expression remained unchanged under short term HFD. This increase in fetuin-A under high fat diet was not evidenced in the peripheral insulin sensitive tissues (skeletal muscle and adipose tissue) whether at the mRNA or at the protein level. Kupffer cell depletion in this setting did not reduce hepatic steatosis but significantly ameliorated insulin sensitivity proved by clamp studies. This amelioration in insulin sensitivity in KC-depleted mice was associated with a significant decrease in fetuin-A mRNA expression (0.7 fold, $p < 0.01$) compared to animals with KC. On immunofluorescence, fetuin-A was mostly expressed in centrilobular hepatocytes. Interestingly, while selectively depleting liver macrophages without affecting adipose tissue macrophage infiltration, intravenous clodronate injection was associated with a significant reduction in epididymal adipose tissue expansion compared to PBS injection (1.1% of body weight versus 1.6% of body weight, $p < 0.001$).
Conclusions: This study demonstrates liver fetuin-A overexpression at the initiation of HFD feeding, concurrent with hepatic steatosis and insulin resistance. Targeting KC in this setting improved insulin sensitivity and was associated with a decreased adiposity and a reduced liver fetuin-A expression suggesting that fetuin-A acts as an hepatokine with pro-adiposity and pro-insulin resistance effects.

MIR-21 INHIBITION AND FXR ACTIVATION SYNERGISTICALLY AMELIORATE DISEASE PATHOGENESIS IN A MOUSE MODEL OF NAFLD

P.M. Rodrigues[1], M.B. Afonso[1], A.L. Simão[1], M. Caridade[1], C.C. Carvalho[2], A. Trindade[2,3], A. Duarte[2,3], P.M. Borralho[1], M.V. Machado[4,5], H. Cortez-Pinto[4,5], C.M.P. Rodrigues[1], R.E. Castro[1]. *[1]Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Universidade de Lisboa, [2]Reproduction and Development, Interdisciplinary Centre of Research in Animal Health (CIISA), Faculty of Veterinary Medicine, Universidade de Lisboa, Lisbon, [3]Gulbenkian Institute of Science, Oeiras, [4]Gastrenterology, Hospital Santa Maria, [5]IMM, Faculty of Medicine, Universidade de Lisboa, Lisbon, Portugal*
E-mail: pmvrsrodrigues@ff.ulisboa.pt

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) comprises a spectrum of liver lesions, from simple steatosis to non-alcoholic steatohepatitis (NASH). Intrahepatic accumulation of fat represents a major triggering factor; still, disease pathogenesis remains incomplete. Recently, microRNAs (miRNA/miRs) have been linked to NAFLD. In particular, mir-21 may contribute to disease progression by targeting peroxisome proliferator-activated receptor α (PPARα). Indeed, PPARα and farnesoid X receptor (FXR) constitute promising NAFLD therapeutic targets. We aimed to elucidate the role of miR-21 during NAFLD pathogenesis in mice, further evaluating the synergistic effect of miR-21 inhibition and FXR activation, using obeticholic acid (OCA).
Methods: Wild type (WT; n = 24) and miR-21 knockout (KO; n = 24) mice were fed either a standard diet (SD; n = 12) or a fast food diet (FF; n = 12) for 25 weeks. 6 animals from each group had their diets supplemented with 60 mg/kg OCA (kindly provided by Intercept). Mice were weighed weekly while blood was collected and liver extracted and weighed at sacrifice. In parallel, human liver biopsies were obtained from morbid obese NAFLD patients at different disease stages (n = 28). Liver samples were processed for histological analysis and determination of miR-21 and PPARα expressions by qRT-PCR and immunoblotting, respectively. Serum was used for biochemical parameters analysis.
Results: Our results show that, after 25 weeks, WT FF-fed mice develop NASH in parallel with an increase in both body weight and liver/body weight ratio, comparing with WT SD-fed mice ($p < 0.05$). Further, they exhibited increased miR-21 ($p < 0.05$) and decreased PPARα expressions ($p < 0.05$). Strikingly, miR-21 and PPARα also displayed an inverse and significant correlation in human patients, increasing from steatosis to less and more-severe NASH ($p < 0.05$). WT FF+OCA-fed animals displayed lower levels of miR-21, compared with WT FF-fed mice. KO FF-fed mice body weights and liver/body weight ratios were below WT FF-fed mice, as were serum levels of triglycerides and free fatty acids. Importantly, most of these beneficial effects were augmented in KO FF+OCA-fed mice ($p < 0.05$).
Conclusions: In conclusion, our results indicate that miR-21 downregulation, likely leading to increased PPARα, together with FXR activation by OCA, ameliorate NAFLD pathogenesis, highlighting the therapeutic potential of novel synergistic therapies in NAFLD. (PTDC/BIM-MEC/0873/2012, SFRH/BD/88212/2012 and SFRH/BD/91119/2012, FCT, Portugal).

TRANSIENT HEPATIC OVEREXPRESSION OF THE INSULINE-LIKE GROWTH FACTOR 2 (IGF2) INDUCES LIPID DROPLET FORMATION

S.M. Kessler[1], S. Laggai[1], E. Van Wonterghem[2], R.E. Vandenbroucke[2], M. Ogris[3], C. Libert[2], A.K. Kiemer[1]. *[1]Pharmaceutical Biology, Saarland University, Saarbruecken, Germany; [2]Department for Molecular Biomedical Research, VIB, Ghent, Belgium; [3]Department of Pharmaceutical Chemistry, University of Vienna, Vienna, Austria*
E-mail: s.kessler@mx.uni-saarland.de

Background and Aims: Although insulin-like growth factor 2 (IGF2) has been reported to be overexpressed in steatosis and steatohepatitis, a causal role of IGF2 in steatosis development remains elusive.
Aim of our study was to decipher the role of IGF2 in steatosis development.
Methods: Hydrodynamic gene delivery was used for transient *IGF2* overexpression employing codon-optimized plasmid DNA. Lipids were quantified by vanilloid-sulfuric assay and stained by Scharlach Red. Lipid classes were determined by thin layer chromatography and free cholesterol by filipin staining. Lipid droplets (LD) were evaluated by fluorescence staining with LD540. mRNA and protein levels were quantified by real-time RT-PCR and Western blot, respectively.
Results: Hydrodynamic gene delivery of the IGF2 plasmid resulted in a strong induction of hepatic *IGF2* expression. The exogenously delivered IGF2 had no influence on endogenic *IGF2* expression. The downstream kinase AKT was activated in IGF2 expressing

animals. Analysis of serum parameters revealed decreased ALT levels mirroring the cytoprotective effect of IGF2. Serum cholesterol was increased in IGF2 expressing mice. Histology and a colorimetric assay confirmed lipid accumulation in the IGF2-livers without signs of inflammation. Interestingly, hepatic cholesterol and phospholipids were specifically increased. Phospholipids are mainly incorporated into LD coats and cell membranes. LD size was not changed, but their number was significantly elevated. Furthermore, free cholesterol, which can be stored in LD and has been reported to be critical for steatosis progression, was elevated in IGF2 overexpressing mice. Accordingly, the key enzyme involved in cholesterol biosynthesis, *HmgCoAR* was upregulated. To have a closer look at *de novo* lipid synthesis we investigated expression of the lipogenic transcription factor Srebp1 and its target genes. SREBP1 was induced on both mRNA and protein level. Also Srebp1 target genes were slightly upregulated. Interestingly, the expression of Cpt1a, which is responsible for mitochondrial fatty acid oxidation, was induced.

Conclusions: Hepatic IGF2 expression induces a fatty liver, characterized by increased cholesterol and phospholipids leading to a higher amount of lipid droplets. Therefore, IGF2 might play an important role in the development of steatosis.

P0953

FXR RESISTANCE CHARACTERIZES HUMAN AND MOUSE MODEL OF NASH

S. Cazanave[1], R. Vincent[1,2], J. Srivastava[2,3], A. Asgharpour[1,2], M. Sheneshaw[1,2], F. Mirshahi[2], D. Prasanna Kumar[1,2], P. Puri[1,2], D. Sarkar[2,3], A. Sanyal[1,2]. *[1]Gastroenterology, Hepatology and Nutrition, [2]Virginia Commonwealth University, Richmond, United States; [3]Human and Molecular Genetics, Virginia Commonwealth University, Richmond, United States*
E-mail: AAsgharpour@mcvh-vcu.edu

Background and Aims: Non-alcoholic steatohepatitis (NASH) is the most common cause of chronic liver disease in North America and it is commonly associated with type 2 diabetes mellitus (T2DM) and the metabolic syndrome. T2DM is associated with increased bile salts in circulation. Bile salts bind to and activate farnesoid X receptors (FXR) which decrease endogenous bile acids synthesis, decrease gluconeogenesis, enhance triglyceride clearance, inhibit of inflammation and fibrosis. However, these parameters move in the opposite direction in subjects with NASH. To explain this discrepancy, we hypothesized that there is an FXR resistance state in NASH. *Aims:* (1) confirm an increase in plasmatic bile salts in human NASH, (2) test the effects of a diet-induced obesity (DIO) mouse model of NASH that progress to steatosis to steatohepatitis to fibrosis with HCC and fully mimics the human disease.

Methods: Plasma samples were obtained from 7 obese normal, 14 NAFLD and 31 NASH patients and secondary bile salt profiles were measured by GC-MS chromatography. A DIO-mouse model of NASH was also used: male C57BL6/S129 were fed either (1) chow diet with normal tap water or (2) high-fat western diet (WD) with high fructose-glucose solution (HFS) for 8 and 52 weeks. Insulin tolerance tests were performed to evaluate insulin resistance. mRNA expression was assessed using real-time PCR.

Results: As compared to control patients, several circulating secondary bile acids (BA) were increased in NAFLD and NASH patients indicative of a decrease in FXR activation. The mice fed a WD + HFS develop hyperinsulinemia, insulin resistance and hypercholesterolemia and macro- and small droplet steatosis in a centrilobular distribution by week 8, with accompanying inflammation and pericellular fibrosis by week 52. As compared to mice fed a chow diet, mice fed a WD + HFS had a 40% and 80% decrease in mRNA expression for the FXR-target gene small heterodimer partner (SHP) at 8 and 52 weeks respectively. As a direct consequence of decrease expression in the transcription factor SHP, the mRNA expression of the rate-limiting enzyme in BA synthesis cholesterol 7 alpha-hydroxylase (CYP7A1) was increased by 4-fold in mice fed a WD + HFS for 52 weeks. Also, phospholipid transfer protein (PLTP) mRNA was increased by 2-fold and organic anion transporting polypeptides (Oatp-1) mRNA was reduced by 80% in mice fed a WD + HFS for 8 and 52 weeks, both indicative of decreased FXR signalling.

Conclusions: NASH is an FXR resistance syndrome.

P0954

PU-ERH TEA EXTRACT AMELIORATES HIGH-FAT DIET-INDUCED NONALCOHOLIC STEATOHEPATITIS AND INSULIN RESISTANCE BY ENHANCING HEPATIC STAT3 PHOSPHORYLATION IN MICE

X.B. Cai[1], C.Y. Fang[2,3], S. Hayashi[2,4], M.M. Zhao[5], S. Nishiguchi[1], H. Tsutsui[2,4], J. Sheng[3]. *[1]Departments of Internal Medicine, [2]Pu-erh Tea and Medical Science, Hyogo College of Medicine, Nishinomiya, Japan; [3]Key laboratory of Pu-erh tea science, Yunnan Agricultural University, Kunming, China; [4]Department of Microbiology, Hyogo College of Medicine, Nishinomiya, [5]Center for iPS Cell Research and Application, Kyoto University, Kyoto, Japan*
E-mail: cxbin1@qq.com

Background and Aims: Pu-erh tea, made from the leaves of *Camellia sinensis*, possess potential health benefits for human, such as anti-inflammatory, anti-oxidant, and anti-obesity properties. Here, we investigated the effect of a Pu-erh tea extract (PTE) on nonalcoholic steatohepatitis (NASH) and its molecular mechanism.

Methods: Eight-week-old male C57BL/6J mice were fed with normal chow diet (ND) or high-fat diet (HFD) for 17 weeks. PTE was simultaneously administered via drinking water for 17 weeks. Body weight and plasma glucose levels were monitored during the treatment. Hepatic inflammation, steatosis, insulin sensitivity, and STAT3 phosphorylation were evaluated. HepG2 cells (human hepatocellular carcinoma cell line) were co-treated with PTE for 48 hours, followed by treatment with IL-6 and oleic acid. The phosphorylation of STAT3, the lipid accumulation, and the expression of lipid metabolism related genes were analyzed.

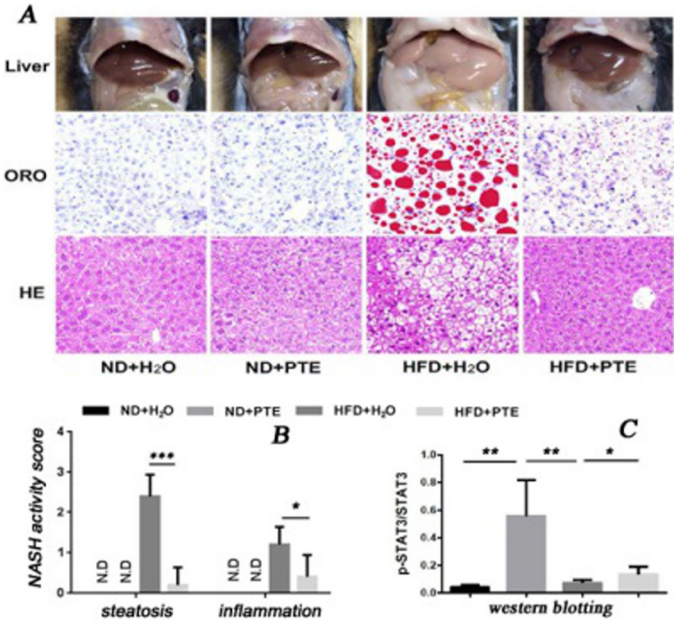

Figure: PTE improves HFD-induced steatohepatitis with enhanced nucleic translocation of STAT3 in hepatocytes. (A) macropathology (upper panels) and Oil Red O staining (middle panels) and HE (lower panels) staining (original magnification ×200). NAS score (B) were calculated. (C) Western blotting analysis were performed to detect the phosphorylated STAT3. ND, normal diet; HFD, high fat diet; H2O, water; PTE, 5% pu-crh tea extract. Data is expressed as the mean ± SEM (n–5). *P < 0.05, **P < 0.01, ***P < 0.001.

Results: PTE inhibited HFD-induced obesity. PTE also significantly attenuated HFD-induced hepatosteatosis and liver inflammation (Fig. A-B). The mRNA expression levels of sterol regulatory element-binding protein-1c (SREBP-1c), fatty acid synthase (FAS), and pro-inflammatory cytokines were markedly down-regulated in the livers of PTE-treated, HFD-fed mice. Amounts of their lipid droplets were reduced as well. As is expected, glucose and insulin tolerance tests revealed that PTE improved both glucose tolerance and insulin sensitivity. Moreover, insulin receptor substrate 2 (IRS2) expression levels were significantly increased, and the gluconeogenesis related genes such as Forkhead box protein O1 (FOXO1), glucose-6-hosphatasecould (G6Pase), and phosphoenolpyruvate carboxykinasereduce (PCK-1) were significantly dampened in the livers. Strikingly, the PTE treatment enhanced STAT3 phosphorylation in the liver (Fig. C). Consistent with those in vivo study, pre-treatment of HepG2 cells with PTE enhanced IL6-induced STAT3 phosphorylation and attenuated oleic acid-induced lipid accumulation in a manner dependent on STAT3.
Conclusions: These findings indicate that PTE ameliorates the hepatic lipid accumulation, inflammation, and insulin resistance in HFD-fed mice presumably through enhancing hepatic STAT3 phosphorylation in mice.

P0955
COMBINATION THERAPY WITH LOSARTAN AND YC-1 PRODUCES BROWNING PHENOMENON OF WHITE ADIPOSE MASS IN OB/OB MICE

H.M. Liu[1], T.-Y. Lee[2], J.-F. Liao[1], H.-C. Lin[3]. *[1]National Yang-Ming University, Taipei, [2]Chang Gung Univervsity, Tao-Yuan, [3]Taipei Veterans General Hospital, Taipei, Taiwan*
E-mail: miaowhale@gmail.com

Background and Aims: Browning process is characterized by promoting activity of mitochondrial uncoupling protein 1 (UCP1) as well an unique functionally thermogenesis in white adipose tissue (WAT), as well as can resist weight gain, obesity and improve metabolic syndrome from obese individuals. Losartan is an angiotensin II receptor antagonist and YC-1, a hypoxia-inducible factor 1 (HIF1) inhibitor, the effect of combine losartan and YC-1 in WAT have never been studied before, therefore we hypothesis that combine therapy with losartan and YC-1 produces browning process in abdomen WAT in *ob/ob* mice.
Methods: Male $Lep^{ob/ob}$ obese mice were administrated with losartan (100 mg/L) for 30 days and YC-1 (25 mg/kg) at last 10 days or vehicle control. Analysis of thermogenic genes (Ucp1 and Prdm16, Cox7a1) expression by real-time PCR from adipose tissue. Hematoxylin/eosin and immunohistochemistry stain of numerous lipid vacuoles, thermogenic factors (UCP1, Tmem26) and inflammatory monocytes (F4/80) were evaluated for histological analysis.
Results: Combination therapy with losartan and YC-1 were markedly ameliorates body weight and abdominal white adipocytes size in ob/ob mice. Treatment of the *ob/ob* mice with losartan only moderately increased Tmem26, Cox7a1 and Prdm16 mRNA expression; however combined treatment with YC-1 enhanced the thermogenic genes and protein expression, subsequently suppressed the induction of inflammation response in neutrophil and marcrophage (F4/80) infiltration expression in WAT.
Conclusions: Combine therapy with losartan and YC-1 show protective role through increased white adipose tissue browning process adaptive the development of metabolic dysfunction, therefore it may illustrate the therapeutic for metabolic syndrome.

MIR-22 DEFICIENCY EXACERBATES SYSTEMIC AND HEPATIC METABOLIC DISORDERS ASSOCIATED WITH DIET-INDUCED OBESITY IN MICE

A.-S. Berthomieu[1], D. Portius[1], D. Abegg[2], P. Rantakari[3], F.-P. Zhang[4], M. Poutanen[4], D. Picard[5], S. Nef[6], A. Adibekian[2], M. Foti[7]. *[1]Departement Physiologie et Métabolisme, Université de Genève, [2]Departement of organic Chemistry, University of geneva, Genève, Switzerland; [3]Departement of Phsiology, [4]Departement of Physiology, Turku Center for Disease Modeling, Turku, Finland; [5]Departement of Cell Biology, [6]Departement of Genetic Medecine, [7]Departement Physiologie et Métabolisme, University of geneva, Genève, Switzerland*
E-mail: anne-sophie.berthomieu@unige.ch

Background and Aims: With obesity and diabetes, miR-22 is drastically downregulated in the liver suggesting an important role for this microRNA in hepatic metabolic disorders. However, direct *in vivo* data examining the role and function of miR-22 in metabolic diseases are lacking. The aim of this study was to investigate *in vivo* the role of miR-22 deficiency in diet-induced obesity, insulin resistance and non-alcoholic fatty liver diseases.
Methods: *MiR-22* knockout (miR22KO) mice were generated and fed an obesogen diet for 4 weeks or 4 months. Mice were metabolically phenotyped and histological and molecular analyses were performed on primary hepatocytes and explanted tissues. High throughput proteomic analysis was performed with liver tissues of CTL and miR22KO mice.
Results: *MiR-22* constitutive deletion in mice breed in normal conditions was completely asymptomatic with no phenotypical changes. However, when mice were fed a high fat-containing diet for a short or long period (4 weeks/months), miR-22 deficiency dramatically exacerbated fat mass gain, glucose intolerance, hepatomegaly and liver steatosis as compared to control mice. Analyses of the liver proteome by mass spectrometry, of *ex-vivo* liver tissues and of *in vitro* primary/cultured hepatocytes indicated that miR-22 inhibition alters the expression of numerous important regulators of the hepatic glucose and lipid metabolism.
Conclusions: miR-22 deficiency in peripheral organs, including the liver, is an important pathological mechanism fostering the development of systemic and hepatic metabolic disorders associated with diet-induced obesity.

P0957
VITAMIN D3 ACTS ON THE GUT–LIVER–ADIPOSE TISSUE AXIS TO MODULATE OBESITY AND ASSOCIATED METABOLIC AND INFLAMMATORY CHANGES IN DIET-INDUCED OBESE MICE

D. Jahn[1], L. Gildein[1], J.C. Fleet[2], J. Schmitt[1], H.M. Hermanns[1], A. Geier[1]. *[1]Division of Hepatology, University Hospital Würzburg, Würzburg, Germany; [2]Department of Nutrition Science, Purdue University, West Lafayette, United States*
E-mail: jahn_d@ukw.de

Background and Aims: Obesity and associated metabolic disorders are increasing problems in industrialized countries. Serum 25-OH Vitamin D3 (VD3) levels negatively correlate with BMI, insulin resistance and NAFLD. The causal relation between VD3 status and NAFLD as well as the potential underlying mechanisms are, however, not fully understood.
Methods: The impact of VD3 on obesity and NAFLD was explored in two animal models. In a first set of experiments, obesity and early NAFLD were induced in wild-type C57BL/6 mice by high-fat diet (HFD)-feeding. HFDs contained predominantly long-chain fatty acids (LCFA) and different levels of VD3 (500 vs. 10,000 IU/kg diet). Liver histology and hepatic fat content were analysed. Expression of metabolic and inflammatory target genes in liver and adipose tissue (AT) was measured by qPCR. Serum parameters were determined by ELISA. To address tissue-specific effects of VD3, a

second set of experiments was performed with Vitamin D Receptor (VDR)-deficient mice (VDR-KO) and VDR-KO mice with an intestine-specific human VDR transgene (VDR-KO hTg) on a similar HFD.
Results: In wild-type mice, high dietary VD3 enhanced the HFD-induced gain of body weight and fat mass. This was associated with unfavourable effects in AT including increased pro-inflammatory M1 macrophage markers and signs of increased adipocyte apoptosis and reduced insulin signalling. These AT-specific changes coincided with trends towards increased immune activation and ER stress in the liver. In the second set of experiments, VDR-KO mice were resistant to HFD-induced obesity when compared to heterozygous controls that is in accordance with previous observations. Interestingly, however, this was partially reversed in VDR-KO hTg mice which gained more weight and fat mass compared to VDR-KOs. Similarly, VDR-KO animals were protected from fatty liver (assessed by histology and mRNA expression) and this effect was partially reversed in the VDR-KO hTg group.
Conclusions: These data reveal a potential pro-adipogenic effect of VD3 in the applied HFD-model based on LCFAs at least during early NAFLD. Comparison of VDR-KO and VDR-KO hTg mice suggests that this could possibly be driven by an unanticipated role of VDR in the regulation of intestinal lipid metabolism. This pro-adipogenic effect of the VD3–VDR axis in the gut could, in turn, promote certain unfavourable metabolic and inflammatory effects in AT and liver highlighting the importance of the gut–liver–adipose tissue axis for the pathophysiology of obesity and NAFLD.

ANIMAL MODELS OF NON-ALCOHOLIC STEATOHEPATITIS: AN EXTENSIVE SYSTEMATIC REVIEW

J.P. Mann[1], O. Brewster[2], P. Harries[2], C. Wall[2], L. Bell[3], M.J. Armstrong[4]. *[1]Paediatrics, [2]University of Cambridge, Cambridge, [3]University of Birmingham, Birmingham, United Kingdom; [4]NIHR Centre for Liver Research, University of Birmingham, Birmingham, United Kingdom*
E-mail: jakemann@doctors.org.uk

Background and Aims: Animal models are widely used in the study of non-alcoholic fatty liver disease (NAFLD). A range of models have been produced to reflect the spectrum of disease, including non-alcoholic steatohepatitis (NASH) and fibrosis. We performed a comprehensive systematic review to identify which animal models demonstrate: NAFLD, type 1 NASH, type 2 NASH, and HCC.
Methods: MEDLINE search for all articles (in English) including "animal model" and "non-alcoholic steatohepatitis" or "non-alcoholic fatty liver disease". Only primary research papers with animal models were included. Models were described by animal, genetic modifications, diet, and if toxic insults were used. Models were assessed for concordance with features of NAFLD: obesity, insulin resistance, steatosis, portal steatohepatitis, centrolobular steatohepatitis, and development of hepatocellular carcinoma (HCC).
Results: MEDLINE search identified 951 articles, 472 were excluded (230 not relevant, 132 reviews or comments, 70 papers could not be obtained, and 39 had no animal model).
Data was extracted from 479 studies, which used 208 different animal models of NAFLD: 72 dietary, 35 genetic, 11 toxic, 4 offspring, and 86 combination models. The most frequently used models were: high fat diet (HFD) in mice (83/479), HFD in rats (64/479), and methionine-, choline-deficient (MCD) diet in mice (64/479).
129/208 models had evidence of Type 1 ("adult") NASH, with predominance of zone 3 inflammation or panacinar steatohepatitis. An *ad libitum* 'Atherogenic diet' (≈ 1% cholesterol + 0.5% cholate, with or without high fat supplementation) for 6–24 weeks in mice (used by 9/479) most accurately recapitulated the NASH phenotype without use of a genetically modified animal.
Only 1/208 models demonstrated a predominance of portal inflammation. Mice fed an *ad libitum* high-fat, high-fructose diet (~4800 kcal/kg diet) for 16 weeks (used by 4/479 studies) most closely reflects paediatric type 2 NASH, with portal fat infiltration, zone 1 steatohepatitis, and portal fibrosis.
19/208 models demonstrated development of hepatocellular carcinoma.
Conclusions: A 6–24 week atherogenic diet is the most accurate model for type 1 NASH without use of genetic modification. A 16-week high-fat, high-fructose diet in mice most closely reflects paediatric type 2 NASH.

P0959
DIETARY INTERVENTION COMPLETELY REVERSES NON-ALCOHOLIC STEATOHEPATITIS IN OBESE AND INSULIN RESISTANT MICE

J. Verbeek[1], I. Vanhorebeek[2], P. Spincemaille[3], G. Van den Berghe[2], I. Vander Elst[1], P. Windmolders[1], J. van Pelt[1], P. Bedossa[4], F. Nevens[1], B. Cammue[3,5], K. Thevissen[3], D. Cassiman[1]. *[1]Department of Hepatology, University Hospitals KU Leuven, [2]Clinical Department and Laboratory of Intensive Care Medicine, Division Cellular and Molecular Medicine, [3]Centre of Microbial and Plant Genetics (CMPG), KU Leuven, Leuven, Belgium; [4]Department of Pathology, Hôpital Beaujon, Clichy, France; [5]Department of Plant Systems Biology, VIB, Ghent, Belgium*
E-mail: jef.verbeek@uzleuven.be

Background and Aims: Life style intervention including dietary intervention is the cornerstone of non-alcoholic steatohepatitis (NASH) treatment, although histological evidence for this approach in humans is rather limited and its impact on hepatic pathways involved in NASH is underreported. This can be explained by the limited duration of human trials, the difficulty of obtaining human liver tissue repetitively and the varying patients' adherence to life style measures, even in the context of clinical trials. The therapeutic potential of the angiotensin receptor type 1 blocker Losartan remains controversial because of varying results in a few animal and human pilot studies. We evaluated the effect of dietary intervention versus Losartan on NASH and associated systemic metabolic features in a representative mouse model.
Methods: Mice with pre-existent NASH, obesity, insulin resistance and hypercholesterolemia (Verbeek *et al.*, *Gut*, 2014) were subjected to dietary intervention (based on a switch from a high fat-high sucrose diet to a normal chow diet) or Losartan administration (30 mg/kg/day). A detailed metabolic profiling was performed.
Results: Dietary intervention normalized obesity, insulin resistance and hypercholesterolemia and remarkably, completely reversed all histological features of pre-existent NASH, including fibrosis. At the hepatic molecular level, dietary intervention targeted fibrogenesis (normalization collagen type I alpha 1, transforming growth factor b1, tissue inhibitor of metalloproteinase 1 mRNA levels), lipid metabolism (normalization fatty acid translocase/CD36, fatty acid transport protein 5, fatty acid synthase mRNA levels) and markers related to mitochondrial function (normalization hepatic ATP content and sirtuin1, tumor necrosis factor-a, uncoupling protein 2 mRNA levels). Dietary intervention abolished p62 accumulation, suggesting a restoration of autophagic flux. On the contrary, Losartan did not affect obesity, insulin resistance, hypercholesterolemia or any histological NASH feature.
Conclusions: Dietary intervention is able to completely reverse NASH in our high fat-high sucrose diet induced mouse model. In order to exploit the maximal therapeutic potential of dietary intervention, improving patient adherence should be a main goal in the care of NASH patients in the coming years. The lack of effective pharmacological alternatives and the additional beneficial effect of dietary intervention on other components of the metabolic syndrome further underpin this strategy.

P0960

A DIET ENRICHED IN PALMITIC AND MYRISTIC ACID CAUSES STEATOHEPATITIS BY INCREASING DE NOVO CERAMIDE SYNTHESIS AND ENDOPLASMIC RETICULUM STRESS

L. Martinez[1,2], M. Elena[3], J.C. Fernandez-Checa[1,2], C. Garcia-Ruiz[1,2]. *[1]Cell Death and Proliferation, Institute of Biomedical Research of Barcelona (IIBB), CSIC, [2]Liver Unit, Hospital Clinic i Provincial de Barcelona, IDIBAPS and CIBERehd, [3]Biomedic Diagnosis Center, Hospital Clinic i Provincial de Barcelona, IDIBAPS, Barcelona, Spain*
E-mail: lau.mg86@gmail.com

Background and Aims: Non-alcoholic steatohepatitis (NASH) is characterized by lipid overload and progressive liver injury with inflammation and fibrosis. Palmitic acid (PA) is a saturated fatty acid that induces lipoapoptosis by different mechanisms and fuels ceramide synthesis in the endoplasmic reticulum (ER). Conversion of dihydroceramide into ceramide is done by dihydroceramide desaturase, whose activity increases upon myristoylation at the N-terminus with myristic acid (MA). Since the role of *de novo* ceramide synthesis in PA-mediated lipotoxicity and ER stress in the liver is controversial, our aim was to investigate whether the combination of PA and MA potentiates ceramide synthesis and ER stress and their impact in steatohepatitis *in vivo*.
Methods: C57BL/6 male mice were fed custom-made high fat diets based on PA (30% of Kcal), MA (30% of Kcal) or their combination (PM) (30% of Kcal each) as the only lipid source, complemented with essential fatty acids. Animals weight and ingestion were measured weekly until 6 months, when animals fed PM combination began to die. Animals were euthanized and blood and different tissues collected for serum, histology, qPCR, ceramide and ER stress analysis.
Results: Animals fed PA, MA or their combination did not gain body weight. Interestingly, PM diet induced hepatosplenomegaly and a dramatic adipose tissue reduction. Both PA and especially PM-fed mice had elevated blood serum transaminases and serious liver histological alterations, with necrosis and macrophages infiltration. Moreover, liver cytokines expression increased in mice fed PA and PM diets. Interestingly, neither hyperlipidemia nor steatosis was detected in any of the diets, but a significant increase in liver ceramide was observed, especially in PM-fed animals, which triplicated control levels. Lipid metabolism genes expression showed a preference for ceramide lipogenic genes in PA and PM-fed mice, accompanied by an increase in the fatty acid transporter expression CD36 and a reduction of free fatty acids and triglycerides lipogenic genes. Importantly, ER stress markers such as CHOP, P-PERK, ATF6α, Grp78 or XBP1 were increased in PA and particularly in PM-fed animals, which exhibited 2–4 fold augment.
Conclusions: These results indicate that MA potentiates the lipotoxic effects of PA and their combination increased ceramide synthesis and ER stress leading to steatohepatitis.

P0961

MICROVESICLES AS NOVEL MARKERS IN NON-ALCOHOLIC FATTY LIVER DISEASE PROGRESSION

L.A. Ban[1,2], N.A. Shackel[2], S.V. McLennan[1]. *[1]Department of Endocrinology, Sydney Medical School and the Royal Prince Alfred Hospital, [2]Liver Injury and Cancer, Centenary Institute of Cancer Medicine and Cell Biology, Sydney, Australia*
E-mail: lban4851@uni.sydney.edu.au

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is the most prevalent liver pathology and is the most complex to diagnose due to the lack of a clinically useful circulating biomarker. Microvesicles are a potential novel candidate. These submicron vesicles are shed from cells in both physiological and disease conditions, but their secretion profile in NAFLD progression have not been well documented. We therefore investigated the effect of high-fat diet as a model of NAFLD on circulating and liver secreted microvesicles. Additionally we examined their expression of CD147, a proinflammatory molecule known to be secreted in microvesicles and linked to dysregulated tissue remodelling and hepatic fibrogenesis.
Methods: Six week old male C57Bl/6 mice were fed a high-fat diet (45%kcal fat) or chow *ad libidum* for 12 or 50 weeks. At termination, blood and livers were harvested for circulating and secreted microvesicles respectively. These were isolated by ultracentrifugation of platelet-poor plasma or serum-free media collected from 18 hr culture of liver sections. Microvesicle concentration and size were quantified using NanoSight™ while CD147 protein expression was determined by immunoblotting.
Results: Circulating microvesicle numbers were elevated in steatotic animals versus controls for both timepoints (by 2.2 and 12.6-fold, $P < 0.01$). In contrast, we observed a significant decline in the corresponding liver secretome per gram tissue (by 2.5 and 25.9-fold, $P < 0.02$). The microvesicle size distribution was unchanged. Immunoblotting revealed distinct changes in the liver microvesicle protein signature between the timepoints which also translated to CD147 expression; the high glycan form of the molecule was significantly reduced with high-fat feeding at 12 weeks (63% decrease, $P < 0.02$) and was almost completely diminished by 50 weeks.
Conclusions: These results show dysregulation between circulating and tissue microvesicle numbers which was more prominent at 50 weeks, the more physiologically advanced stage of NAFLD. The proportional reduction in microvesicular CD147 secreted from the liver is an interesting phenomenon that could be explained by either the retention of the molecule within the liver during steatosis, or an alternate pathway for its translocation. Together these findings suggest that circulating microvesicles have potential utility as biomarkers of NAFLD.

P0962

MANIFESTATION OF DIET-ASSOCIATED NAFLD/AFLD IN DIFFERENT MOUSE STRAINS

V.H.I. Fengler[1], J. Haybäck[2], C. Lackner[2], K. Sargsyan[1]. *[1]Biobank Graz, [2]Institute of Pathology, Medical University Graz, Graz, Austria*
E-mail: vera.fengler@medunigraz.at

Background and Aims: Animal models are essential for the investigation of non-alcoholic and alcoholic fatty liver disease (NAFLD and AFLD, respectively). Still the complex pathophysiological mechanisms contributing to NAFLD/AFLD pathogenesis are incompletely understood. The aim of our study was to compare the manifestation of liver damage caused by different feeding regimens in commonly used wild type (wt) mouse strains in order to identify those best suited for modelling human NAFLD/AFLD.
Methods: Accordingly, 3 different wt mouse strains (C57BL/6, CD-1 and 129Sv) were fed with liquid Lieber DeCarli high fat diet (HFD), liquid Lieber DeCarli diet supplemented with alcohol and liquid Lieber DeCarli HFD supplemented with alcohol for different periods of time. The effects on liver histology as well as serum markers of liver function (aspartate-aminotransferase, AST and alanine-aminotransferase, ALT) were assessed.
Results: C57BL/6 mice responded very variable to the feeding regimens. Some of these mice featured pronounced steatosis, liver inflammation as well as elevated AST and ALT serum levels, whereas other animals showed no liver damage. No statistical difference between treated mice and controls with respect to histological or biochemical features was observed. CD-1 mice did not develop significant steatosis or inflammation and their AST/ALT serum levels were not different to controls. Most consistent results were achieved with 129Sv mice, which consistently developed moderate steatosis in combination with inflammation. Histological features of steatosis and inflammation and AST serum levels were

significantly higher in HFD and alcohol feeding groups compared to controls (Kruskal–Wallis followed by Dunn's test of selected pairs of columns, $P < 0.05$), while no significant differences in ALT levels could be detected.

Conclusions: As a conclusion, our data suggest the use of 129Sv mice for NAFLD/AFLD studies, in which a homogeneous response to feeding regimens is needed. If more pronounced liver injuries are required, C57BL/6 mice should be preferred. But a higher number of animals will be needed, since not all mice will develop liver damage. The use of CD-1 mice is discouraged because of the lack of histological and biochemical response to standard dietary regimens, used to induce NAFLD/AFLD-associated liver damage.

P0963

PROGRESSION FROM NAFLD TO NASH: GENDER DOES REALLY MATTER?

V. Marin[1], S. Gazzin[1], M. Dal Ben[1], A. Raseni[2], C. Degrassi[3], C. Tiribelli[1,4], N. Rosso[1]. *[1]Centro Studi Fegato, Fondazione Italiana Fegato, [2]S.C Laboratorio analisi Cliniche, IRCCS Burlo Garofalo, [3]Medical Research Institute, [4]Department of Medical Sciences, University of Trieste, Trieste, Italy*
E-mail: natalia.rosso@csf.units.it

Background and Aims: NAFLD is most prevalent among males, bur NASH has been reported more prevalent among middle-aged women. The aim of this study is to assess the events involved in the progression of the disease in both genders.

Methods: Male and female C57BL/6J mice, immediately after weaning were randomly assigned to either control diet (CTRL) or high-fat high-carbohydrate (HFHCD). Animals had ad-libitum access to these diets for 16 weeks, thereafter blood and liver samples were collected for further analysis (histology, gene expression and products of lipoperoxidation). Data was compared *vs* animals of each gender fed with CTRL diet.

Table 1. Summary of the obtained data

	Folds vs animals fed control diet, mean±SD	
	HFHCD males	HFHCD females
Body weight	1.43±0.15***	1.46±0.13***
Liver weight	1.70±0.20***	1.50±0.12***
Adipose tissue weight (epididymal fat pads)	3.12±0.40***	3.20±0.34***
Serum parameters		
Glucose	1.65±0.29***	1.64±0.19***
Insulin	7.30±4.30**	1.75±0.30
Cholesterol	1.50±0.17***	7.3±4.3***
HDL	1.52±0.14***	1.52±0.24***
LDL	1.70±0.20***	2.40±0.50***
ALT	3.15±0.88**	1.88±0.65*
AST	2.30±0.33**	1.75±0.27
Gene expression		
Lipid metabolism		
DGAT2	1.64±0.31*	2.25±0.06***
LDLR	2.09±0.51*	1.72±0.08*
SREBP-1c	1.35±0.16*	1.65±0.31*
Inflammatory response		
TNF-α	2.16±0.94*	1.13±0.25
Fibrosis		
α-SMA	2.03±0.48*	2.28±0.37*
Lipoperoxidation		
MDA	0.87±0.29	3.82±0.40***

*p < 0.05; **p < 0.01; ***p < 0.001.

Results: HFHCD induced weight gain, hyperplasia of adipose tissue, hepatomegaly, alterations in glycaemia, lipid profile and ALT both in males and females; hyperinsulinaemia was present exclusively in males (Table 1). Histological analysis showed mixed macro-micro vesicular steatosis in both genders, in line with the increased expression of DGAT2 (important in the final step of triglycerides synthesis), LDLR, receptor and SREBP-1c, both involved in the lipogenesis. Likewise, both groups developed sinusoidal/periportal fibrosis with increased activation of hepatic stellate cells (α-SMA). Surprisingly, only males showed inflammatory cells foci with some ballooning and increased expression of TNF-α, whereas females presented only an increased lipid peroxidation (absent in males) with no signs of inflammation.

Conclusions: Altogether these data suggest that even if the onset of fibrosis is similar between genders, the mechanism of liver injury is different. Whereas in males is associated to insulin resistance and inflammation, in females is related with an increase of the oxidative process.

DIRECT GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONISM AMELIORATES STEATOHEPATITIS AND FIBROSIS IN MODELS OF NASH AND BILIARY FIBROSIS VIA REGULATION OF LIVER MACROPHAGE INFILTRATION AND ACTIVATION

X.-Y. Wang[1], S.-Y. Weng[1], T. Klein[2], Y.O. Kim[1], D. Schuppan[1,3]. *[1]Institute of Translational Immunology and Research Center for Immunotherapy, University Medical Center, Mainz, Germany, Mainz, [2]Boehringer Ingelheim Pharma, Biberach an der Riss, Germany; [3]Division of Gastroenterology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States*
E-mail: wang@uni-mainz.de

Background and Aims: Glucagon-like peptide-1 (GLP-1) improves insulin sensitivity via enhanced glucose-dependent insulin secretion, inhibition of glucagon release, and delayed gastric emptying following its release into the circulation from the gut. We aimed to explore the utility of the long-acting GLP-1 receptor agonist BYDUREON (BY) to address both inflammation and fibrosis in models of NASH and biliary fibrosis.

Methods: BY was administered twice weekly by subcutaneous injection at 0.4 or 2 mg/kg to Mdr2KO mice, and to C57BL/6 mice fed a methionine and choline deficient (MCD) diet for 4 weeks. Hepatic fibrosis was assessed by morphometric analysis of Sirius red stained collagen and measurement of hydroxyproline content. Hepatic inflammation was measured by semiquantitative immunohistochemistry. Fibrosis and inflammation related transcript levels were quantified by quantitative real-time polymerase chain reaction (qPCR). Ex vivo analysis ofhepatic inflammatory cells was performed by FACS

Results: In the MCD and Mdr2$^{-/-}$ model, BY significantly decreased collagen content, fibrosis and inflammation related transcripts and protein levels including αSMA, CD68, CCL3, and TNFα, while it increased the (anti-inflammatory) macrophage markers Arg1and Ym1. BY treatment also reduced the IHC expression of procollagen type III, CD68, F4/80 and caspase 3. With BY treatment the number of liver infiltrating CD45$^+$CD11b$^+$ (myeloid, innate) immune cells and of F4/80$^+$ Kupffer cells was reduced. With By treatment there was a significant decrease of hepatic CD11b$^+$Ly6C$^+$ high cells, indicating less proinflammatory monocyte/macrophage infiltration as compared to mice that received the MCD diet without BY. Differences were even more pronounced for the ratio of CD11b$^+$Ly6C$^+$low or CD11b$^+$Ly6C$^+$ high vs CD45$^+$ cells. BY treatment also significantly lowered elevated serum liver enzymes.

Conclusions: Treatment of MCD diet treated and of Mdr2KO mice with BY reduced parameters of hepatic steatosis, inflammation, fibrosis and apoptosis, without negative effects on weight gain, liver or plasma indices. These results demonstrate that treatment with BY attenuated liver injury through inhibition of inflammatory and apoptosis pathways that govern NASH and fibrosis and support further clinical evaluation of the utility of GLP-1R agonists for treatment of NASH and liver fibrosis.

P0965

HIGH FAT DIET TREATMENT OF CONDITIONAL c-met KO-MICE DEVELOP AN INFLAMMATORY PHENOTYPE AND PROGRESS TO FIBROSIS INDEPENDENTLY FROM STEATOSIS

F. Schumacher[1], P. Ramadori[1], M. Hatting[1], N. Gassler[2], C. Trautwein[1], K.L. Streetz[1], D.C. Kroy[1]. [1]*Department of Medicine III,* [2]*Department of Pathology, RWTH Aachen University, Aachen, Germany*
E-mail: fabschumacher@gmail.com

Background and Aims: The metabolic syndrome including non-alcoholic-fatty liver disease (NAFLD) turns out to be one of the fastest growing medical problems in industrial countries. NAFLD progressing to NASH (non-alcoholic steatohepatitis), can ultimately result in liver cirrhosis and hepatocellular carcinoma. Previously we could show that HGF/c-Met signalling protects against the development of NASH in a Methionine-Choline Deficient Diet mouse model. Now we aimed to characterize the role of HGF/c-met in a more clinically relevant model of the metabolic syndrome
Methods: Hepatocyte specific c-met knockout mice (c-met$^{\Delta hepa}$) using the cre-loxP system and wildtype control mice (c-met^{loxPloxP}) were fed with a High Fat Diet (HFD) at least for 16 weeks.
Results: After 16 weeks of HFD feeding c-met^{loxPloxP} mice show a significant higher liver weight and more epididymal fat compared to c-met$^{\Delta hepa}$ animals. Mice lacking c-Met display a significantly decreased liver body weight ratio, while both groups presented microvesicular steatosis in hepatic HE- and Oil Red O Stainings and a similar increase of hepatic triglyceride content. Furthermore both groups showed increased blood glucose level under diet conditions, but c-Met$^{\Delta hepa}$ littermates presented significantly lower levels of hepatic Glucose-6-Phosphatase-RNA, a key-enzyme of hepatic gluconeogenesis after a 16 week HFD treatment. Moreover, c-Met knockout mice displayed a significant increase of hepatic PPAR-y RNA levels as compared to c-met^{loxPloxP} mice after 16 weeks of HFD treatment. Most interestingly we could detect a significant increase of infiltrating immune cells in c-Met$^{\Delta hepa}$ mice compared to wildtype animals (in particular neutrophils, macrophages and CD4 positive T cells). Further analyses provide evidence for a beginning liver remodelling in c-Met$^{\Delta hepa}$ littermates as indicated by an upregulation of hepatic Col1a1 and TGF-beta-RNA. Those data were corroborated by higher collagen deposition and alpha-SMA staining.
Conclusions: Hepatocyte specific deletion of c-Met causes the development of a distinctive hepatic inflammation and matrix deposition process under the condition of HFD-treatment. Those changes were largely independent from the development of liver steatosis.

ADIPOSE TISSUE INFLAMMATION OCCURS PRIOR TO LIVER INFLAMMATION IN MICE FED A HIGH-FAT DIET

F. Sheedfar[1], R.A. Van Der Heijden[2], M.C. Morrison[3], P.H. Hommelberg[1], S. Youssef[4], N. Gruben[1], A. De Bruin[4], M.H. Hofker[1], R. Kleemann[5], D.P. Koonen[1], P. Heeringa[2]. [1]*Department of Pediatrics, Section Molecular Genetics,* [2]*Department of Pathology and Medical Biology, Section Medical Biology, University Medical Center Groningen, Groningen,* [3]*Department of Metabolic Health Research, Netherlands Organisation for Applied Scientific Research (TNO), Leiden,* [4]*Dutch Molecular Pathology Center, Department of Pathobiology, Faculty of Veterinary Medicine, Utrecht University, Utrecht,* [5]*Department of Metabolic Health Research, Netherlands Organisation for Applied Scientific Research (TNO), Leiden, Netherlands*
E-mail: f.sheedfar@umcg.nl

Background and Aims: Chronic metabolic inflammation is considered to be important in the etiology of obesity-induced insulin resistance. However, the extent to which inflammation in the adipose tissue and the liver contributes to insulin resistance remains unknown. Here we examine the sequence of inflammatory events between adipose tissue and the liver and their relevant contribution to the development of insulin resistance.
Methods: C56BL/6J male mice fed a low-fat diet (LFD; 10% kcal fat) or high-fat diet (HFD; 45% kcal fat) for either 24, 40 or 52 weeks. Glucose tolerance and plasma levels of glucose, insulin, leptin and adiponectin were measured throughout the study. Adipose and hepatic tissues dissected to assess lipid accumulation and inflammation.
Results: With HFD, mice developed a progressive obesity, evidenced by increased body weight and increased lipid accumulation in adipose and liver tissues. This phenotype was accompanied by the development of insulin resistance after 24 and 40 weeks of HFD, but insulin resistance was attenuated after 52 weeks of HFD. We observed inflammation of the adipose tissue, as measured by an increase in crown-like structures and upregulation of pro-inflammatory genes *Tnf, Il1*b, *Mcp1 and F4/80* after 24 weeks of HFD and made similar observations in the liver only after 40 weeks of HFD.
Conclusions: Our data show that adipose tissue inflammation precedes liver inflammation. Moreover, insulin resistance is present both in the absence (24 weeks of HFD) and in the presence (40 weeks of HFD) of hepatic inflammation. We conclude that obesity-related insulin resistance is more likely to be caused by adipose tissue inflammation than by liver inflammation.

P0967

ROLE OF FATTY ACIDS FOR CHOLANGIOCYTE LIPID METABOLISM AND LIPOTOXICITY

I. Pierantonelli[1,2], T. Claudel[1], C. Pinto[2], G. Svegliati Baroni[2], M. Trauner[1]. [1]*Division of Gastroenterology and Hepatology, Medical University of Vienna, Vienna, Austria;* [2]*Department of Gastroenterology, Università Politecnica delle Marche, Ancona, Italy*
E-mail: pierantonelli_irene@libero.it

Background and Aims: Impaired free fatty acid (FA) handling results in hepatic lipotoxicity. Saturated FAs including palmitate (PA) are poorly incorporated into triglycerides resulting in endoplasmic reticulum (ER) stress and lipoapoptosis. Conversely, monounsaturated FAs such as oleate (OA) reduce lipotoxicity. Excess of FAs has been linked to hepatocellular injury; but little is known about their impact on cholangiocytes with potential relevance for cholangiopathies and progression of fatty liver disease.
Aims: To determine the capacity of cholangiocytes to handle FA-mediated stress and decipher the underlying molecular mechanisms.
Methods: Mouse cholangiocytes were incubated with OA and PA (200–800 μM 24 hrs). Lipid droplets were measured using Oil Red O staining (ORO). Cell death, apoptotic markers and reactive oxygen species (ROS) were quantified. Expression of key genes involved on lipid metabolism was analyzed by QPCR.
Results: Cholangiocytes expressed enzymes involved in FA synthesis (FASn), oxidation (CPT1A) and transport (CD36). PA but not OA induced cell death, as shown by viability assay ($p < 0.005$); whereas OA supplementation rescued PA toxicity ($p < 0.05$). Lipotoxicity induced by PA was associated with ER stress markers such as GRP78, sXBP-1, ERDJ4 mRNA ($p < 0.05$; $p < 0.005$ and $p < 0.005$ respectively), while OA co-incubation normalized the ER stress response. This resulted in pro-apoptotic signaling as shown by CHOP mRNA induction and caspase 3 cleavage ($p < 0.05$ and $p < 0.005$). OA addition reduced apoptosis ($p < 0.05$). OA increased lipid storage (ORO) and reduced free FAs in cholangiocytes ($p < 0.05$), as well as PPARγ2 and DGAT gene expression (both $p < 0.05$). FA oxidation was significantly increased by PA compared to control and OA, as shown by elevated CPT1A gene expression ($p < 0.05$). Remarkably, PA+OA incubation increased the expression of antioxidative genes such as catalase and SOD

(both $p < 0.005$) resulting in ROS elevation only in PA treated cells, as revealed by dihydroethidium staining and i-NOS expression. Notably, the anti-oxidant N-acetylcysteine counteracted PA induced lipoapotosis as shown by viability assays ($p < 0.005$).
Conclusions: Saturated FAs induced ER stress, oxidative stress and apoptosis in cholangiocytes. Importantly, lipotoxicity can be counteracted by stimulating ROS detoxification and FA storage.

Background and Aims: Today probiotics have been suggested as a treatment for the prevention of chronic liver damage, because they prevent bacterial translocation and epithelial invasion, inhibit bacterial mucosal adherence, production of antimicrobial peptides, that results in decrease of inflammation and stimulation of host immunity. However the question about the comparison of efficacy of different probiotic strains, their combination and form (alive or lyophilized) in management of nonalcoholic fatty liver disease (NAFLD) is still open.
Methods: We included 70 rats divided into 7 groups 10 animals in each. Rats of group I were intact. Newborn rats of groups II–VII were injected with monosodium glutamate (MSG) (4 mg/g). The groups III–V received lyophilized monoprobiotics *B. animalis VKL*, *B. animalis VKB*, *L. casei IMVB-7280* respectively. The group VI received the mix of these three probiotic strains. The group VII was treated with multiprobiotic "Symbiter" containing concentrated biomass of 14 alive probiotic bacteria (*Bifidobacterium, Lactobacillus, Lactococcus, Propionibacterium).* Administration was started at 4 weeks after birth and continued intermittently two-week course in 2 weeks intervals. To assess morphological changes in liver we used NAS (NAFLD activity score). Lipid extraction from liver was performed according to Folch.
Results: For steatosis stage there was no significant difference between MSG-obesity group and lyophilized groups III–VI strains. But we found significantly lower degree of steatosis (2.3 ± 0.21 vs 0.7 ± 0.15, $p < 0.001$) for alive probiotic group (VII) as compared to MSG-obesity. For both alive and lyophilized probiotic mixtures reduction of lobular inflammation was observed. These histological data were confirmed by the significant decrease of total lipids and triglycerides content in liver approximately by 22–25% in groups treated with probiotic mixtures (VI, VII) compared to MSG-obesity.
Conclusions: Thus, the obtained data suggest failure of NAFLD prevention with lyophilized monoprobiotic strains. Opposite we established the efficacy of probiotic mixture with the preference of alive probiotic strains. It may be related to more pronounced viability of alive strains, their prevention of bacterial translocation, formation of mutualistic interactions in mixtures and therefore synergistic enhancement of single effect.

E-mail: rociogallegoduran@gmail.com

Background and Aims: To evaluate micro-RNAs influence in non-alcoholic steatohepatitis (NASH) development.
Methods: Total RNA was isolated from frozen hepatic tissue (miRvana miRNA isolation kit, Life Technologies, USA) in 10 NASH and 10 simple steatosis patients. RNA Integrity Number (RIN) was measured by electrophoresis as quality control. Subjects presenting a RIN <5 were not suitable for analysis. miRNA profile was assessed using the 84-miRNA miScript PCR Array (Qiagen, USA). Independent validation was performed in liver biopsy ($n = 20$) and plasma samples ($n = 40$, 20 NASH and 20 simple steatosis) by RT-PCR. Two SNPs were genotyped: PNPLA3 rs738409 and TM6SF2 rs58542926 by Taqman assay (Applied Byosistems, Spain). Liver histology was evaluated by Kleiner score. Statistical analysis was performed by SSPSv22.
Results: In screening, two miRNAs were found over-expressed in NASH vs simple steatosis: (a) miR-200b (fold induction 2.80); (b) miR-224 (fold induction 3.08).
In liver tissue ($n = 16$), 100% (8/8) of patients with *miR-200b* upregulated presented NASH (5.91 ± 8.70) vs 0% (0/8) with miR-200b inhibited (-2.53 ± 0.61; $p = 0.0001$). miR-200b induction was associated with ballooning [62.5% (5/8) vs. 0% (0/8); $p = 0.026$]. 100% (5/5) of patients with *miR-224* upregulated presented NASH (3.95 ± 2.05) vs 9% (1/11) with miR-224 inhibited (-3.46 ± 1.87; $p < 0.0001$). Over-expression of miR-224 was associated with NAS Score >4 [60% (3/5) vs 0% (0/11); $p = 0.018$], steatosis presence [100% (5/5) vs 27% (3/11); $p = 0.026$] and portal inflammation [60% (3/5) vs 0% (0/11); $p = 0.018$].
In plasma ($n = 22$), *miR-200b* induction was associated with NASH [91.7% (11/12) *vs.* 50% (5/10); $p = 0.05$] and ballooning [66.7% (8/12) vs. 10% (1/10); $p = 0.011$] in patients with miR-200b inhibited. *miR-224* was found upregulated in 100% (9/9) of NASH patients. In patients protected from NASH development, such as non-GG PNPLA3 carriers, miR-224 induction was detected in 6/9 NASH vs 0/7 with simple steatosis; $p < 0.01$; also in patients bearing TM6SF2 CC genotype, miR-224 induction was observed in 7/9 of NASH vs 0/6 with simple steatosis; $p = 0.007$.
Conclusions: miRNA profile analysis associated to hepatic dysfunction has identified two candidates, miR-200b and miR-224, overexpressed in NASH at intrahepatic level and circulating in plasma. miR-224 expression seems to regulate NASH progression in patients bearing protective genotypes, as non-GG PNPLA3 and CC TM6SF2. These miRNAs could constitute potential biomarkers or novel therapeutic targets based on its marked epigenetic effect.

P0970
FAT-LADEN MACROPHAGES MODULATE LOBULAR INFLAMMATION IN NONALCOHOLIC STEATOHEPATITIS (NASH)

S. Sutti[1], S. Bruzzì[1], A. Jindal[1], I. Locatelli[1], M. Vacchiano[1], C. Bozzola[1], E. Albano[1]. *[1]Dept. Health Sciences, University of East Piedmont, Novara, Italy*
E-mail: salvatore.sutti@med.unipmn.it

Background and Aims: NASH is characterized by extensive hepatic monocyte infiltration and macrophages have an important role in regulating the disease evolution. However, little is known about the functional changes occurring in liver macrophages during NASH progression. In this study we have investigated phenotypic and

functional modifications of hepatic macrophages in experimental NASH.
Methods: NASH was induced in C57BL/6 mice by feeding a methionine-choline deficient (MCD) diet up to 8 weeks.
Results: In mice receiving the MCD diet hepatic F4/80-positive macrophages increased in parallel with the disease progression. Histology revealed that the macrophages accumulating in advanced NASH were enlarged, vacuolized and formed small aggregates. At immunofluorescence these cells contained lipid vesicles positive for the apoptotic cell markers Annexin V suggesting the phagocytosis of apoptotic bodies derived from dyeing fat-laden hepatocytes. Similar vacuolized macrophages were also evident in liver biopsies of NASH patients. Flow cytometry revealed that these enlarged macrophages expressed the inflammatory monocyte markers (CD11b, Ly6C). However, as compared to regular size macrophages the enlarged sub-set was characterized by a lower IL-12 production and by an enhanced expression of the anti-inflammatory mediators IL-10 and annexin A1. Consistently, the accumulation of enlarged macrophages in NASH paralleled with a lowering in the expression of the macrophage M1 activation markers iNOS and IL-12, while the levels of M2 polarization markers arginase-1 and MGL-1 were unchanged.
Conclusions: Altogether, these data indicate that during the progression of NASH the phagocytosis of hepatocyte-derived apoptotic bodies promotes functional changes in macrophages that influence hepatic inflammatory responses.
This work has been supported by a grant from the Fondazione Cariplo, Milan, Italy.

A DIET-INDUCED MOUSE MODEL OF NONALCOHOLIC FATTY LIVER DISEASE WITH PROGRESSION TO ADVANCED FIBROSIS AND HEPATOCELLULAR CARCINOMA WITH A GENE EXPRESSION SIGNATURE MIMICKING HUMAN DISEASE
A. Asgharpour[1], P. Bedossa[2], Y. Hoshida[3], S. Cazanave[1,3,4], R. Vincent[1], T. Pacana[1], F. Mirshahi[1], M. Sheneshaw[1], K. Daita[1], P. Puri[1], A. Sanyal[1]. *[1]Gastroenterology, Hepatology and Nutrition, Virginia Commonwealth University, Richmond, United States; [2]Pathology, Hôpital Beaujon, Paris, France; [3]Gastroenterology, Hepatology and Nutrition, Mount Sinai School of Medicine, New York, United States; [4]Pathology, Hôpital Beaujon, Paris, France*
E-mail: AAsgharpour@mcvh-vcu.edu

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) has become the most common form of chronic liver disease and has the propensity to progress to cirrhosis and hepatocellular cancer (HCC). Currently no validated animal model of NASH exists. We have recently described a diet induced obesity (DIO) model of NAFLD in mice devoid of genetic or chemical manipulation that progressively develops steatosis, inflammation, hepatocyte ballooning, fibrosis and HCC. To compare the gene expression profile of this mouse model to human NASH and HCC and to compare histologic scoring of this model over time.
Methods: A unique isogenic mouse strain derived from a C57Bl/6J and 129Sl/SvlmJ background was created. Mice were fed one of two diets: (1) chow diet with normal tap water, (2) high-fat diet (HFD) + high fructose–glucose solution (HFS). Histology was assessed from hematoxylin+eosin and sirius red. Histologic scoring using the NASH Activity Score (NAS) and Fibrosis scoring was done at early and late time points. Liver tissue was snap-frozen for analyses. Liver tissue was compared between diets at early and late time points using genome wide expression profiles and this data was compared to human disease. Furthermore, mouse HCC found at 52 weeks on the HFD+HFS, was compared to human HCC using Gene Set Enrichment Analysis (GSEA). Normalized enrichment scores (NES) were used to compare mouse gene expression to human disease.
Results: Compared to chow diet, HFD+HFS fed mice had larger, pale livers with the addition of numerous tumors in the livers at 52 weeks. Macro- and small droplet steatosis in a centrilobular distribution developed universally in HFD+HFS mice by 8 weeks with accompanying inflammation and some hepatocyte ballooning. By week 36–52, there was increasing fibrosis with some bridging fibrosis, hepatocyte ballooning and Mallory bodies. 0/15 mice fed CD developed HCC by wk 52 compared to 8/9 mice fed HFD+HFS ($p < 0.01$). The HFD+HFS fed mice showed a gene signature similar to that expressed in humans with a NES of 1.81, $p < 0.01$, and a False discovery rate (FDR) <0.01. Furthermore, the signature of the HCC tumors in HFD+HFS fed mice were similar to aggressive human HCC of the S1 (NES = 1.46, $p < 0.01$, FDR = 0.013) and S2 (NES = 1.42, $p < 0.01$, FDR = 0.014) molecular classifications. Wnt signaling pathways were also increased in in the mouse HCC as in human S1 HCC.
Conclusions: This DIO model of NASH and HCC in mice has a gene expression signature similar to that seen in humans with advanced NASH and HCC.

EXPRESSIONS OF BILE ACID TRANSPORTERS ARE INVERSELY CORRELATED WITH NAFLD ACTIVITY SCORE IN THE LIVER OF PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE
K. Okushin[1], T. Tsutsumi[1], K. Enooku[1], A. Kado[1], H. Fujinaga[1], K. Moriya[1], H. Yotsuyanagi[1], K. Koike[1]. *[1]Department of Gastroenterology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan*
E-mail: koxin-tky@umin.org

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is increasing in the world including Asian countries. NAFLD includes a disease spectrum ranging from simple steatosis to nonalcoholic steatohepatitis (NASH). The latter is considered as a progressive disease and its pathogenesis remains largely unclear. Recently, bile acid (BA) metabolism is focused as a therapeutic target of NASH. The aim of this study was to identify changes of bile acid metabolism in NAFLD patients in terms of disease progression.
Methods: Fifty male and thirty-three female patients histologically diagnosed as NAFLD by Matteoni classification were analyzed. Patients taking UDCA were excluded in this study. Disease progression was estimated by NAFLD activity score (NAS). Intrahepatic expression levels of genes related to BA metabolism were determined by quantitative PCR.
Results: FXR, the nuclear receptor for BA, and its downstream transcriptional repressor SHP mRNA levels were not significantly changed in both genders. CYP7A1, a key enzyme of BA synthesis, was also similarly expressed. However, expressions of an export transporter, bile salt export pump (BSEP), and an uptake transporter, NTCP, were significantly down-regulated with the elevation of NAS in male. In female, interestingly MRP2, another BA export transporter and NTCP were significantly down-regulated with the elevation of NAS.
Conclusions: Expressions of BA uptake and export transporters are significantly down-regulated in patients with high NAS in both genders. The BA content of hepatocyte is thought to be increased in NASH. The down-regulation of NTCP is reasonable for the protection from BA cytotoxcicity. But, the down-regulation of BSEP and MRP2 may cause the excess of BA content in hepatocyte and excessive BA may induce hepatocellular injuries. Although the mechanism of the down-regulation and the difference between genders remain to be elucidated, our findings might lead to the development of new therapeutic options for NASH.

E-mail: spisv@unileon.es

Background and Aims: Flavonoids seem to display beneficial effects on non-alcoholic fatty liver disease (NAFLD). In this study, we aimed to investigate the effect of the flanovol quercetin on gene expression deregulation involved in NAFLD development, as well as the possible implication of phosphatidylinositol 3-kinase (PI3K)/AKT pathway modulation.
Methods: C57BL/6J male mice were fed with methionine and choline deficient (MCD) diet supplemented or not with quercetin (0.05%) for 4 weeks (1W-4W). Huh7 cells were incubated for 24 hours with MCD medium supplemented with or without quercetin (10 μM) and/or the PI3K inhibitor LY294002 (50 μM). ROS and RNS production, lipoperoxidation and lipid accumulation were assessed by flow cytometry. Fatty acid uptake and FAT/CD36 localization were analysed by fluorescence microscopy. Lipid metabolism, pro-inflammatory and oxidative/nitrosative-related gene expression was measured by RT-qPCR. PI3K/AKT pathway activation was assessed by western blot.
Results: MCD-fed mice showed classical pathophysiological characteristics of non-alcoholic steatohepatitis (NASH), with increased lipoperoxidation, inflammation and lipid accumulation, associated with gene expression deregulation (TNFα, 3W: +412%; SOCS3, 3W: +61%; OPN, 4W: +152%; iNOS, 3W: +308%; FAT/CD36, 4W: +5800%; FABP1, 3W: −72%; FATP5, 3W: −74%; FOXA1, 4W: −70%; PPARα, 3W: −39%; C/EBPα, 4W: −48%; SHP, 3W: −79%; C/EBPβ, 4W: +238%, *vs* control mice). MCD-incubated Huh7 cells showed similar gene expression deregulation. PI3K/AKT pathway was activated by MCD (MCD-fed mice, 4W: +169%; MCD-treated Huh7 cells: +208%, *vs* respective controls) and triggered gene deregulation causing either activation or inhibition of studied genes as demonstrated through cell incubation with LY294002 (FAT/CD36: −76%; FABP1: −17%; SOCS3: −61%; TNFα: −95%; FOXA1: −29%; SHP: −71%; C/EBPβ: −67%; iNOS: +132%; FATP5: +168%; PPARα: +430%; C/EBPα: +63%, *vs* MCD-treated cells). Treatment with quercetin reduced AKT phosphorylation and oxidative/nitrosative stress, inflammation and lipid metabolism-related genes displayed a tendency to normalize in both *in vivo* and *in vitro* models.
Conclusions: These results place quercetin as a potential therapeutic strategy for preventing NAFLD progression by attenuating gene expression deregulation, at least in part through PI3K/AKT pathway inactivation.

EFFECTS OF RESVERATROL ON EXPERIMENTAL NON-ALCOHOLIC STEATOHEPATITIS

S. Heebøll[1], K.L. Thomsen[1], A. Clouston[2], N. Jessen[3], E.I. Sundelin[3], S.B. Pedersen[4], Y. Radko[5], L.P. Christensen[5], L. Hebbard[6], H. Grønbæk[1], J. George[6]. *[1]Department of Hepatology and Gastroenterology, Aarhus University Hospital, Aarhus, Denmark; [2]Centre for Liver Disease Research, University of Queensland, Brisbane, Australia; [3]Research Laboratory for Biochemical Pathology, [4]Department of Endocrinology, Aarhus University Hospital, Aarhus, [5]Department of Chemical Engineering, Biotechnology and Environmental Technology, University of Southern Denmark, Odense, Denmark; [6]Storr Liver Centre, Westmead Millennium Institute, University of Sydney and Westmead Hospital, Sydney, Australia*
E-mail: saraheeb@rm.dk

Background and Aims: Non-alcoholic steatohepatitis is an increasing clinical problem for which effective treatments are required. The polyphenol resveratrol prevents the development of experimental non-alcoholic steatosis in numerous *in vivo* studies due to anti-inflammatory, anti-oxidant and AMPK/SIRT1 activating effects. We hypothesized that resveratrol would reverse steatohepatitis, including hepatic inflammation and fibrosis, in a well-characterised rodent model.
Methods: To induce steatohepatitis, a 65% fat, 2% cholesterol (HFC) diet was fed to rats for 1 or 16 weeks, prior to treatment. Subsequently, the diet was supplemented with resveratrol (100 mg/rat/day) to 3 intervention groups, week 2–5, 2–8, and 17–23. Treated animals were sacrificed at the end of each intervention period with appropriate control and HFC diet controls. Blood and liver were harvested for analysis.
Results: Resveratrol treatment partially mitigated hepatic enlargement and transaminase elevations when commenced early, but not plasma bilirubin or α2-MG elevations. Resveratrol treatment did not modidy the elevated hepatic triglyceride levels or histological steatohepatitis. We observed a minor reduction in Coll1α1 mRNA in intervention group 17–23 ($p = 0.03$) and generally no significant alterations in the mRNA expression of TGFβ, TNFα, α2-MG, PGC-1α, SREBP-1c. Protein expression of TNFα induced protein-3 was lowered by *trans*-resveratrol ($p = 0.03$).
Ten resveratrol metabolites, including *trans*-resveratrol-3-*O*-sulphate and *trans*-resveratrol-4′-*O*-sulphate, were quantified in plasma by LC-MS/MS at a total mean concentration of 24.7 μg/ml.
Conclusions: Contrary to the findings in experimental steatosis, resveratrol treatment had only limited therapeutic efficacy in alleviating experimental steatohepatitis.

Gazzin[1]. *[1]Centro Studi Fegato, Fondazione Italiana Fegato, [2]S.C Laboratorio analisi Cliniche, IRCCS Burlo Garofalo, [3]Medical Research Institute, [4]Department of Medical Sciences, University of Trieste, Trieste, Italy*
E-mail: natalia.rosso@csf.units.it

Background and Aims: The booming increase worldwide prevalence of pediatric Non-Alcoholic Fatty Liver Disease (NAFLD) is worrisome and draws attention.
Methods: Male (M) and female (F) C57BL/6J mice were randomly assigned immediately after weaning to control or high-fat high-carbohydrate diet (HFHCD). Animals had access ad-libitum to food for 16weeks. Body-weight, glycaemia, insulinemia, triglycerides, total cholesterol, HDL-C, ALT, AST, liver histology were screened every 4 weeks and compared to control animals (CTRL).
Results: Soon after the first week, HFHCD induced in both genders a significant gain of bodyweight. Males, after 4 weeks presented

also hyperplasia of epididymal fat-pads and only after week 12th, a significant hepatomegaly. As shown in Table 1, males showed earlier alteration of glycemia, insulinemia as well as lipid profile and ALT. Interestingly, comparable body/blood alterations were observed in females only at the 16th week. Liver histology showed in both genders a mixed macro-microvesicular steatosis steadily increasing after the 8th week. Inflammatory cells foci were observed in males from the very beginning and sustained over the time with presence of ballooning cells towards the 16th week. On the contrary this inflammatory pattern was absent in females. Surprisingly, both genders developed progressive fibrosis starting from the 8th week and rising steadily over the time

Conclusions: This juvenile model of diet-induced NAFLD progresses faster than those reported in adults. A clear gender difference was found in the onset of the liver injury. Even though the final outcome (fibrosis) was comparable between genders, males presented early signs of liver injury, while females do not.

E-mail: totoali1@hotmail.com

Background and Aims: The prevalence of non-alcoholic fatty liver disease (NAFLD) has markedly increased, especially with patient exhibit one or more features of the metabolic syndrome. This study investigates the effect of rosuvastatin (RSV) or/and b-carotene (bC) in NAFLD-induced rats.

Methods: Rats were classified into nine groups; normal (I), NAFLD-induced with high-fat diet (HFD; II), NAFLD switched to regular diet (RD; III), NAFLD-HFD or NAFLD-RD treated with RSV (IV, V), bC (VI, VII) or both RSV+bC (VIII, IX) respectively for four weeks then killed to obtain serum samples and liver tissues. Liver histology, lipid profile, liver oxidative stress markers, and adipocytokines were measured.

Results: Liver sections of NAFLD-HFD rats revealed steatosis, loss of hepatic architecture, inflammation and hepatocyte vacuolation with high percentage of cell fibrosis. Serum levels of ALT, AST, ALP, GGT and lipid profile (triglycerides, cholesterol, LDL and VLDL) were significantly increased ($P < 0.05$) compared with normal. Also, hepatic MDA level and serum leptin, TNF-a and TGF-b1 were increased. Meanwhile, SOD activity, GSH content and serum HDL and adiponectin were decreased ($P < 0.05$) *vs* normal. These changes were to a less extent in NAFLD-RD group. Administration of RSV or/and bC almost improves all previously mentioned parameters. Moreover, hepatic steatosis was decreased and inflammation markedly ameliorated with reduction of TNF-a and TGF-b. These results were more pronounced in the groups VIII and IX *vs* each drug alone.

Conclusions: RSV and βC could be beneficial for the treatment and prevention of NAFLD. Combined RSV+bC is better than RSV alone.

P0977

ASSOCIATION OF LONG-CHAIN FATTY ACID OXIDATION WITH OXIDATIVE STRESS AND INFLAMMATION IN DIFFERENT PREECLAMPSIA-LIKE MOUSE MODELS

Z. Yang[1], X. Ding[1], Y. Han[1], H. Yu[1]. *[1]Department of Obstetrics and Gynecology, Peking University Third Hospital, Beijing, China*
E-mail: zi_yang@email.com

Background and Aims: The pregnancy complication of preeclampsia as a syndrome has been further recognized. The long-chain fatty acid oxidation (FAO) disorders may be associated with some preeclampsia, but the mechanism of FAO in the pathogenesis of subset of preeclampsia syndrome remains unclear. This study aimed to explore the role of FAO and its relationship with oxidative stress and inflammatory in preeclampsia syndrome by establishing four different preeclampsia-like models.

Methods: PE-like groups were ApoC3 transgenic mice with abnormal fatty acid metabolism, classical PE-like models with injection of Nw-nitro-L-arginine-methyl ester (L-NA) or lipopolysaccharide (LPS) and the antiphospholipid syndrome (APS) mouse model with beta2GPI injection (ApoC3+NS, ApoC3+L-NA, L-NA, LPS and beta2GPI groups). The control group was wild-type mice with normal saline injection. Serum FFA concentration and the mRNA and protein expression of long-chain 3-hydroxyacyl-CoA dehydrogenase (LCHAD), p47phox and NF-kB in placental and hepatic cell were detected. The correlation was analyzed statistically.

Results: Compared with controls, FFA levels were significantly increased in all groups except in the LPS group ($P < 0.05$). LCHAD mRNA and protein expression in the liver and placenta significantly increased in ApoC3+NS, ApoC3+L-NA and beta 2GPI group, decreased in L-NA group ($P < 0.05$) and had no significant difference in the LPS group compared to the control group. P47phox and NF-kB mRNA and protein expression in the liver and placenta displayed variations according to different preeclampsia-like models. Serum FFA levels positively correlated with P47phox and NF-kB mRNA and protein expression in liver of all groups ($P < 0.05$) except in LPS group and in placenta of L-NA and beta2GPI groups ($P < 0.05$).

Conclusions: The liver and placenta may be more crucial sites of production of toxic intermediates of long-chain free fatty acid metabolism, which accumulate to cause liver damage in subset preeclampsia syndrome. There is different interaction of long-chain

FAO disorders with oxidative stress and inflammation in subset pre-eclampsia syndrome.

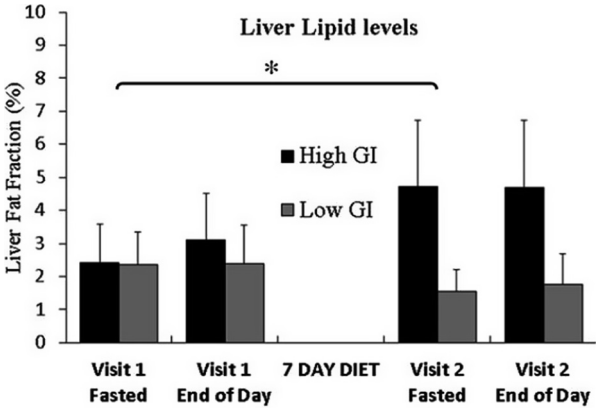
A 7 DAY LOW VS HIGH GLYCAEMIC INDEX DIET REDUCES LIVER FAT CONTENT IN HEALTHY SUBJECTS: A ^{1}H MRS STUDY

S. Bawden[1,2], M. Stephenson[3], K. Hunter[4], M. Taylor[5], P. Morris[2], L. Marciani[1], I. Macdonald[6], G. Aithal[1], P. Gowland[2]. *[1]NIHR Nottingham Digestive Diseases Biomedical Research Unit, Nottingham University Hospitals NHS Trust, [2]SPMIC, University of Nottingham, Nottingham, United Kingdom; [3]Agency for Science, Technology and Research, Singapore, Singapore; [4]Unilever Discover, Colworth, [5]Faculty of Human Nutrition, [6]School of Life Sciences, University of Nottingham, Nottingham, United Kingdom*
E-mail: stephen.bawden@nottingham.ac.uk

Background and Aims: Glycaemic index (GI) is a way of ranking carbohydrates according to the postprandial effect on blood glucose levels and has received increasing interest in recent years. Low glycaemic index diets have been considered potentially beneficial in a range of metabolic conditions and cohort studies have shown correlations between dietary glycaemic index and non-alcoholic fatty liver disease (NAFLD). The aim of this study was to investigate the effects of a low (LGI) v high (HGI) glycaemic index diet on hepatic lipid stores.
Methods: ^{1}H Magnetic resonance spectroscopy (MRS) was used to assess liver lipid levels before and after a 7 day HGI v LGI dietary intervention in a two-way randomized cross over study with >4 week washout between test visits. 8 healthy males (age 20.1±0.4 years, BMI 23.0±0.9 kg/m^2) attended the test centre and blood glucose measurements were taken at baseline and regularly following a HGI v LGI test breakfast. MRS was acquired at baseline and end-of-day (t = 360 min) on a Philips 3T scanner using a respiratory triggered PRESS localisation sequence with varying TE for T_2 correction (BW = 2 kHz, samples = 1024, TR = 5000 ms, NSA = 40, TE = 40 ms, 50 ms, 60 ms, 80 ms). Areas under the CH_2 (1.3 ppm) and water (4.7 ppm) peaks were used to calculate tissue weight fat fraction.



Results: Blood samples confirmed a high and low glycaemic response for respective test meals. On the pre diet test day, fasted liver fat fractions were consistent for both HGI and LGI arms (HGI 2.4±1.2%; LGI 2.4±1.0%; P = 0.82) and end of day lipid levels were within error of fasted levels. Following the 7 day diet, fasted liver fat fractions increased for HGI (4.7±2.0%) compared with LGI (1.6±0.7%) reaching statistical significance (two way F-test, P < 0.05) and this effect was consistent across the test day.
Conclusions: This study used a simple MRS protocol to show the beneficial impact on liver lipid levels of a LGI compared with HGI diet after only 7 days. This has important applications in the design of dietary interventions to prevent and treat NAFLD as well as its metabolic consequences. Further studies should explore longer term interventions and patient groups.

P0979
PILOT STUDY OF A NEW TREATMENT IN NAFLD/NASH, INTERFERING INTESTINAL MICROBIOTA AND BILE ACIDS RESORPTION AND METABOLISM

A.M. Popescu[1]. *[1]Internal Medicine, Fundeni Clinical Institute, Bucharest, Romania*
E-mail: adrianadorupop@yahoo.com

Background and Aims: Intestinal microbiota plays an important role, modulating inflammation and absorption of bile acids, thus its dysfunction might trigger the NAFLD/NASH. Rifaximine (RFX) is known to eradicate intestinal bacterial overgrowth, followed by a symbiotic (SYN) that increases colonization with Bifidobacteria, exert an immunomodulatory effect, induction of tall-like receptors, increase of IL10 production and inhibition of Th1 lymphocyte generation. Ursodeoxycholic acid (UDCA) also, has been used in previous studies in NASH. *Aim:* Assess the efficacy of a new combined therapy consisting in RFX, followed by SYN formula and associated to UDCA in a discontinued regimen for improving NASH.
Methods: 40 patients diagnosed with NASH on transaminases elevation, serological tests for NASH/fibrosis, associated diseases and liver histology, were prospectively randomized between January 2012 and September 2014 into 2 similar groups: 20 patients were treated with RFX 1200 mg/day 10 days, followed by SYN 1 bag/day, 10 days, in association with UDCA 15 mg/kg/day; 20 patients received only UDCA 15 mg/kg/day. This regimen was repeated for 3 consecutive months, 3 times/year, with final evaluation after 1 year.
Results: Both groups were comparable: mean age 45–47 years; more men, 12/20 and 14/20; 16/20 in group 1 and 15/20 in group 2 were overweight, 90% with abdominal obesity; 40% group 1 and 50% group 2 had diabetes mellitus, 50% with insulin resistance; 80%, respectively 70% had hyperlipidemia; 30% vs. 50% had HTA. 90% over 80% of patients had AST/ALT ratio >1, with an increased level by 1.5×. NASH test was positive in all patients, on liver biopsies steatosis was over 60%, inflammation grade 2 to 3 and fibrosis grade 2, no liver cirrhosis. In patients treated with the combined regimen, no side effects were reported, with an improvement in bloating, abdominal pain, and diarrhea/constipation symptoms. Associated diet, change in life style, medication to correct the co-morbidities had a compliance of about 60%. After 1 year of follow-up improvements were found with regard to: weight loss of 4–10% in 70% of cases in both groups, normalization of ALT, AST and insulin sensitivity in 90% of patients from group 1, vs. 40% in group 2, decrease in steatosis infiltration by 40% and in fibrosis by 1 stage only in group 1 with combined treatment.
Conclusions: Several cycles of an associated regimen with RFX+SYN+UDCA, improved significantly liver histology, steatosis and inflammation in about 60% of patients with NASH.

DIET, ENDOTOXAEMIA AND FATTY LIVER: A POPULATION STUDY USING MAGNETIC RESONANCE SPECTROSCOPY AND TRANSIENT ELASTOGRAPHY IN 920 CHINESE SUBJECTS

V.W.-S. Wong[1], G.L.-H. Wong[1], H.-Y. Chan[1], W.C.-W. Chu[2], H.L.-Y. Chan[1]. [1]*Department of Medicine and Therapeutics,* [2]*Department of Imaging and Interventional Radiology, The Chinese University of Hong Kong, Hong Kong, China*
E-mail: wongv@cuhk.edu.hk

Background and Aims: Patients with non-alcoholic steatohepatitis (NASH) have increased intestinal permeability and small intestine bacterial overgrowth. We aimed to test the hypothesis that endotoxaemia is associated with fatty liver in the general population and to study dietary factors associated with endotoxaemia.
Methods: Community adult subjects were randomly selected from the Hong Kong Government's census database and underwent proton-magnetic resonance spectroscopy and transient elastography to assess hepatic steatosis and fibrosis, respectively. Intrahepatic triglyceride content (IHTG) of 5% was the cutoff to define fatty liver. Endotoxaemia was assessed using the Limulus Amebocyte Lysate, lipopolysaccharide-binding protein (LBP) and EndoCab immunoglobulin G (IgG) assays. Dietary pattern was recorded by a 7-day food-frequency questionnaire.
Results: 920 subjects were included (42% male, age 48±11, 23% body mass index ≥25 kg/m^2 and 5% diabetes). 263 (29%) had fatty liver; 60 (7%) had raised serum cytokeratin-18 fragment level (CK-18) suggestive of NASH; 27 of 887 (3%) subjects with reliable liver stiffness measurement had advanced fibrosis or cirrhosis. Compared with those without fatty liver, subjects with fatty liver had higher LBP (13.4±3.2 μg/ml vs 11.4±2.7 μg/ml; $P < 0.001$) and EndoCab IgG (228±247 GMU/ml vs 188±137 GMU/ml; $P = 0.013$) levels. Endotoxin markers also correlated positively with aminotransferases, IHTG, CK-18, insulin resistance and dyslipidaemia. Endotoxaemia was not associated with increased liver stiffness. Fetuin-A, the ligand linking fatty acid and Toll-like receptor 4, correlated with IHTG, insulin resistance and dyslipidaemia but did not have consistent association with endotoxaemia markers. Although total energy consumption and individual macronutrients were not associated with endotoxaemia, current drinkers (median alcohol consumption 20 g/week [interquartile range 10–70 g]) had lower endotoxin, EndoCab IgG and fetuin-A levels than non-drinkers.
Conclusions: Endotoxaemia is associated with fatty liver and possibly NASH in the general population. People with modest alcohol consumption have lower serum endotoxin. This may partly explain the lower risk of fatty liver and NASH in modest drinkers in previous observational studies.
This study was supported by a grant from the Health and Medical Research Fund sponsored by the Hong Kong SAR Government [Ref CUHK-11120621].

E-mail: ckoliaki@yahoo.com

Background and Aims: Lower muscle mitochondrial activity relates to insulin resistance and non-alcoholic fatty liver (NAFL). However, hepatic mitochondrial function in insulin resistant humans with NAFL or steatohepatitis (NASH) remains unclear. Here we applied high-resolution respirometry (HRR) to quantify mitochondrial respiration in liver biopsies of obese insulin resistant humans with histologically-proven NAFL and NASH.
Methods: We performed HRR in liver tissue and isolated mitochondria to assess *ex vivo* maximal coupled and uncoupled respiration in obese humans with NAFL ($n = 16$, age 41±3 years, body mass index, BMI 53.7±2.1 kg/m^2) and obese humans with NASH ($n = 7$, age 51±3 years, BMI 47.3±0.7 kg/m^2) undergoing bariatric surgery, as well as in lean humans undergoing elective abdominal surgery (CON; $n = 12$, age 41±3 years, BMI 25.5±0.7 kg/m^2). Whole-body and hepatic insulin-sensitivity measured with euglycemic-hyperinsulinemic clamps and [6,6-$^2H_2$]glucose. Citrate synthase activity served as a marker of hepatic mitochondrial mass. Hepatic oxidative stress and oxidative damage were assessed from thiobarbituric acid reactive substances and hepatic 8-OH-deoxyguanosine (8-OH-dOG), respectively.
Results: Both NAFL and NASH displayed markedly lower whole-body insulin sensitivity than CON (M-value in mg/kg·min; NAFL 2.5±0.3, NASH 1.4±0.9, CON 7.7±0.8, $p < 0.05$), whereas only NASH had lower hepatic insulin sensitivity. In the face of similar mitochondrial content, NAFL presented with 84% higher maximal uncoupled respiration in isolated mitochondria than CON, whereas NASH had 40% lower respiration rates than NAFL despite compensational increase of mitochondrial mass. Both NAFL and NASH showed evidence of mitochondrial uncoupling, but only NASH exhibited increased proton leakage. Hepatic oxidative stress was elevated in both NAFL and NASH, while oxidative DNA damage was noted only in NASH (8-OH-dOG in nM; NAFL 18.5±4.5 vs. CON 11.3±0.9, $p < 0.05$) due to reduced anti-oxidant defense capacity (hepatic catalase activity in arbitrary units; NAFL 0.67±0.09, NASH 0.36±0.20, CON 0.86±0.08, $p < 0.05$).
Conclusions: These data provide direct evidence for adaptation of liver mitochondria in obese insulin resistant humans with NAFL. In livers of NASH patients, this adaptation is lost, which associates with hepatic insulin resistance, leaking mitochondria and hepatocellular oxidative damage along with impaired anti-oxidant defense.

P0982

NONALCOHOLIC FATTY LIVER DISEASE AND THE RISK OF PROGRESSED CORONARY ARTERY CALCIFICATION: A LONGITUDINAL STUDY

D. Kim[1], M.-S. Kwak[1], H.E. Park[1], M.-K. Kim[1], S.-Y. Choi[1].
[1]*Department of Internal Medicine, Seoul National University Hospital Gangnam Center, Seoul, Korea, South*
E-mail: messmd@chol.com

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is associated with coronary artery calcification and increased prevalence of cardiovascular disease in many cross-sectional studies. However, whether NAFLD *per se* affect the progression of coronary artery calcification still remains to be elucidated. The aim of this study was to investigate the prospective association between NAFLD and the incidence and progression of coronary artery calcification (CAC) in a longitudinal cohort study.
Methods: Among 1732 subjects who underwent serial CAC score evaluation, we evaluated 847 subjects with NAFLD and 885 subjects without NAFLD. Only those without viral hepatitis, significant alcohol consumption and known coronary artery disease were enrolled. NAFLD was diagnosed by ultrasonography in subjects without significant alcohol consumption. CAC score was evaluated by the Agatston method with multi-detector computed tomography.
Results: The baseline CAC score was higher in those with NAFLD, and greater number of these subjects showed progression (48.8% vs. 38.4%, $p < 0.001$ in subjects with vs. without NAFLD). NAFLD was prospectively associated with progression of CAC score (odds ratio [OR] 1.53, 95% confidence interval [CI] 1.26–1.85, $p < 0.001$). Noticeably, the impact of NAFLD significantly varied with the severity of baseline coronary atherosclerosis. In those without calcification at baseline, NAFLD significantly affected progression of atherosclerosis (adjusted OR 1.54, 95% CI 1.05–2.27, $p = 0.028$), after adjustment for age, hypertension diabetes mellitus, dyslipidemia, smoking, gender and body mass index. Analysis according to the severity of NAFLD showed that NAFLD in its more severe form promotes progression of CAC (adjusted OR 1.77, 95% CI 1.08–2.88, $p = 0.022$). However, in subjects with baseline CAC, NAFLD did not affect progression of CAC ($p = 0.482$).
Conclusions: NAFLD plays a role in early stage of coronary atherosclerosis, and it also seems that greater degree of NAFLD affects the progression independent of traditional risk factors. Thus NAFLD does not solely show a simple association, but also plays a role in the development and progression of coronary artery disease.

P0983

ASSOCIATION BETWEEN MACRO-NUTRIENT INTAKE AND PRESENCE OF NONALCOHOLIC FATTY LIVER DISEASE IN THE ROTTERDAM STUDY: A POPULATION-BASED STUDY

B J. Veldt[1], J.C. Kiefte-de Jong[2], B.E. Hansen[1], H.L. Janssen[3], E.P. Plompen[1], B.H. Stricker[2], A. Hofman[2], O.H. Franco[2], R.J. de Knegt[1], H.J. Metselaar[1], S. Darwish Murad[1]. [1]*Department of Gastroenterology and Hepatology,* [2]*Department of Epidemiology, Erasmus MC, Rotterdam, Netherlands;* [3]*Toronto Centre for Liver Disease, Toronto Western & General Hospital, University Health Network, Toronto, Canada*
E-mail: b.veldt@erasmusmc.nl

Background and Aims: Specific macronutrient intake may be associated with presence of nonalcoholic fatty liver disease (NAFLD).
Methods: Macronutrient intake was assessed by the validated Food Frequency Questionaire in participants of the Rotterdam study, a large population-based cohort study of Caucasian subjects aged ≥55 years. In this cohort, liver steatosis was assessed by ultrasound and liver fibrosis was assessed by transient elastography. All participants with reliable liver stiffness measurements (LSM) between January 2010 and March 2014 were included in the analyses. Subjects were excluded in case of viral hepatitis, excessive alcohol intake or hepatotoxic medication or if the LSM suggested significant fibrosis (LSM >8.0 kPa), in the absence of steatosis on ultrasound. Three separate univariate logistic regression analyses were performed to assess the effect of different macronutrients on the odds of having NAFLD. All analyses were corrected for total energy intake.
Results: 1357 subjects were included. In 903 subjects there were no signs of either steatosis or fibrosis and 454 subjects (33%) had non-alcoholic fatty liver disease i.e. steatosis with or without fibrosis.
Total carbohydrate intake (OR 0.997, 95% CI 0.994–0.999, p = 0.010), total protein intake (OR 1.010, 95% CI 1.002–1.018, p = 0.010) and total fat intake (OR 1.006, 95% CI 1.001–1.011, p = 0.023) were all associated with presence of NAFLD, whereas total fiber intake was not (OR 1.000, 95% CI 0.985–1.015, p = 0.954).
Conclusions: Our study suggests that higher intake of protein and fat are associated with increased odds of NAFLD.

P0984

DEVELOPMENT AND VALIDATION OF A SIMPLE CLINICAL PREDICTION MODEL TO IDENTIFY PATIENTS WITH NONALCOHOLIC STEATOHEPATITIS RESOLUTION AFTER 52 WEEKS OF LIFESTYLE MODIFICATION

E. Vilar-Gomez[1,2], A. Yasells Garcia[1], L. Calzadilla Bertot[1], Y. Martínez Perez[1], M. Romero-Gomez[2], M. Diago[3]. [1]*Hepatology, National Institute of Gastroenterology, Havana, Cuba;* [2]*Unit for the Clinical Management of Digestive Diseases, Valme University Hospital, University of Seville, Sevilla, Spain, Sevilla,* [3]*Liver Unit, Valencia University Hospital, Valencia, Spain*
E-mail: eduardovilar2000@yahoo.com

Background and Aims: The identification of predictors of nonalcoholic steatohepatitis (NASH) resolution after therapeutic intervention are need to avoid unnecessary liver biopsies. Thus, we developed and validated a simple scoring system including clinical, laboratory and histological variables to predict NASH resolution after 52 weeks of lifestyle intervention.
Methods: A total of 293 patients with histological diagnosis of definite NASH were treated in the clinical practice with low-fat hypocaloric diet and increased physical activity for 52 weeks. At baseline, patients were randomly stratified into two cohorts to develop (199) and validate (94) a predictive model. Subjects with NASH borderline and cirrhosis were excluded. A second liver biopsy was performed at 52 weeks to detect NASH resolution with no fibrosis impairment. Liver biopsies were reviewed by two pathologist who were unaware of patient's identity and clinical condition. Clinical, histological and laboratory data were recorded at baseline and at the end of the intervention.
Results: NASH resolution occurred in 31% (derivation group) and 34% (validation group). In the derivation cohort, weight loss percentage (OR, 2.03; 95% CI, 1.5–2.7; P < 0.0001), type 2 diabetes mellitus (OR, 0.05; 95% CI, 0.009–0.26; P < 0.001), ballooning (OR, 0.15; 95% CI, 0.04–0.59; P = 0.001), ASAT (OR, 0.96; 95% CI, 0.93–0.99; P = 0.002), and body mass index (OR, 0.83; 95% CI, 0.72–0.93; P = 0.01) were independently associated to NASH resolution. The area under the ROC curve (AUC) of the selected model was 0.9297 (95% CI, 0.896–0.962) and 0.883 (95% CI, 0.817–0.950) in the derivation and validation cohorts, respectively. Using a score threshold of <−0.705 corresponding with a low probability of NASH resolution, negative predictive values were 93% and 91% in the derivation and validation groups, respectively. By applying a high cutoff >1.418 which corresponds with high probability of NASH resolution, positive predictive values were 97% and 85% in the derivation and validation groups, respectively. Using both cutoffs, a liver biopsy would have been avoided in 223 (76%) of 293 patients with a correct prediction in 203 (91%).

Conclusions: A simple prediction model may help to identify patients with low and high probabilities of NASH resolution after 52 weeks of lifestyle modification. Unnecessary liver biopsies could be avoided using our proposed score.

P0985

METABOLOMICS PROFILING IDENTIFIES POTENTIAL PATHWAYS INVOLVED IN THE INTERACTION OF IRON HOMEOSTASIS WITH INSULIN RESISTANCE

L. Stechemesser[1], A. Stadlmayr[2], D. Niederseer[2], T. Felder[3], M. Strasser[1], S. Eder[1], C. Datz[2], E. Aigner[1]. *[1]First Department of Medicine, Paracelsus Medical University, Salzburg, [2]Department of Internal Medicine, Oberndorf Hospital, Oberndorf, [3]Department of Laboratory Medicine and Medicinal Chemistry, Paracelsus Medical University, Salzburg, Austria*
E-mail: e.aigner@salk.at

Background and Aims: Elevated serum ferritin has been linked to type 2 diabetes and adverse outcomes in subjects with the Metabolic Syndrome (MetS). In NAFLD subjects mild iron overload is frequently found and has been named dysmetabolic iron overload. As the mechanisms underlying the negative impact of excess iron have so far remained elusive, we aimed to identify potential pathways using a metabolomics analysis.
Methods: In all subjects, a detailed clinical and biochemical characterization was obtained. Metabolomics profiling was performed in patients with NAFLD with (n = 56) and without iron overload (n = 54) and a lean, healthy control group (n = 53) utilizing the AbsoluteIDQ™ p180 kit (BIOCRATES Life Sciences AG). Significant differences between groups were calculated using the false discovery rate (FDR) approach. NAFLD was diagnosed as steatosis on ultrasound examination after biochemical exclusion of other causes of liver disease.
Results: Clinically, subjects with NAFLD and high ferritin had higher indices of impaired glucose homeostasis as assessed by fasting glucose, HOMA-IR and oral glucose tolerance test ($P < 0.01$, Man-Withney-U test) compared to NAFLD subjects matched for components of the MetS without iron overload. Comparison of the metabolome between NAFLD subjects and healthy controls confirmed results from previous studies, i.e. differences in concentrations of branched-chain amino acids, kynurenin, and multiple long-chain lyso-phosphatidylcholines (FDR <0.001 for all analytes). In addition, the comparison between NAFLD with high and low ferritin demonstrated highly significant differences in the serum concentrations of sarcosine, methionine, and citrulline as well as multiple long-chain phosphatidylcholines (FDR <0.001 for all analytes).
Conclusions: Our data confirm that in NAFLD high serum ferritin concentrations are clinically linked to impaired glucose homeostasis as indicated by oral glucose tolerance test and fasting glucose concentrations. Furthermore, our study identifies novel associations of iron excess in NAFLD subjects with distinct subsets of phosphatidylcholines as well as a pathway involving methionine, sarcosine and citrulline. These metabolic pathways may be involved in iron-induced augmentation of IR.

P0986

EFFECTS OF SHORT TERM VERY LOW ENERGY DIETS PRIOR TO BARIATRIC SURGERY ON LIVER HISTOLOGY AND CIRCULATING BIOMARKERS: RESULTS OF A RANDOMISED CONTROLLED TRIAL (RCT)

E. Baldry[1,2], G.P. Aithal[3], P. Kaye[3], I. Idris[4], P. Leeder[5], A. Bennett[6], I. Macdonald[6]. *[1]Schools of Life Sciences and Medicine, University of Nottingham, Nottingham, [2]Leicester Diabetes Centre, University Hospitals of Leicester NHS Trust, Leicester, [3]NIHR Nottingham Digestive Diseases Biomedical Research Unit, Nottingham University Hospitals NHS Trust, [4]School of Medicine, University of Nottingham, Nottingham, [5]Royal Derby Hospital, Derby Hospitals NHS Foundation Trust, Derby, [6]School of Life Sciences, University of Nottingham, Nottingham, United Kingdom*
E-mail: emma.baldry@uhl-tr.nhs.uk

Background and Aims: Short term very low energy dietary regimens are used prior to bariatric surgery with the aim of reducing liver volume and improving liver flexibility to enable the laparoscopic approach to surgery. We examined the effects of very low energy dietary regimes on non-alcoholic fatty liver disease (NAFLD) and circulating biomarkers in severely obese adults.
Methods: The effects of two energy restrictive regimens, a food-based diet or meal replacement plan (LighterLife Ltd., Harlow, U.K.) over a two week period, were investigated in a prospective RCT. Clinical and anthropometric information and fasting blood were collected pre and post diet, and a liver biopsy obtained during surgery.
Results: Of 60 participants recruited 54 completed the study. Diet groups did not differ demographically, 81.5% female, median age 45 years, median body mass index (BMI) pre-diet 50.7 kg/m^2, 30% with Type 2 diabetes. Reported daily energy intake and body weight loss were similar in both groups (median 715kcal/d and median 3.4% respectively). Liver histology was not significantly different between groups; 86% had steatosis grade ≤1, 71% had no ballooning and 61% were without lobular inflammation. Serum leptin, IL6 and CRP fell in both groups. Changes in other biomarkers are in Table 1. A fall in Enhanced Liver Fibrosis (ELF) panel markers (pre to post diet) were associated with increased body weight loss (%) ($p = 0.05$). ELF levels post-diet were positively associated with steatosis (%) ($p = 0.01$). Also ELF levels post-diet above the median were associated with higher frequency and values of NAFLD activity scores ($p = 0.001$).

Table 1

Biomarker	Pre–post diet change			
	Food based diet		Meal plan	
	Change, median (range)	P value	Change, median (range)	P value
Aspartate transaminase	7.0 (−3.0, 22.6)	<0.001	5.5 (−7.6, 40.3)	<0.001
Cytokeratin-18 M30	15.9 (−119, 209)	0.019	20.2 (−94.1, 228)	0.011
Enhanced liver fibrosis (ELF) panel	−0.6 (−2.3, 0.6)	0.001	−0.6 (−1.6, 0.7)	0.002

Conclusions: Two weeks of energy restrictive diet prior to bariatric surgery were associated with a reduction in serum leptin, IL6 and CRP and an increase in AST and CK18 M30. On liver biopsy low prevalence of advanced liver histological changes were found, contemporaneous to a fall in circulating ELF panel markers. No statistically significant difference in histological outcomes was found between diet groups. Overall, short-term very low energy dietary regimes positively affect NAFLD.

P0987

A METABOLIC DEFINITION OF NASH AND ITS RESOLUTION BY S-ADENOSYLMETHIONINE IN Mat1a KO MICE

J.M. Mato[1], D. Fernandez-Ramos[1], I. Martínez-Arranz[2], R. Mayo[2], S.C. van Liempd[1], H. Sann[3], J. Platon[4], M. Noureddin[5], P. Aspichueta[6], C. Alonso[2], M.L. Martínez-Chantar[1], S.C. Lu[7]. *[1]CIC bioGUNE, [2]OWL Metabolomics, Derio, Spain; [3]Abbott Laboratories GmbH, Hannover, Germany; [4]Abbott Products Operations, Allschwil, Switzerland; [5]Keck School of Medicine, Los Angeles, United States; [6]University of the Basque Country UPV/EHU, Leioa, Spain; [7]Cedars-Sinai Medical Center, Los Angeles, United States*
E-mail: director@cicbiogune.es

Background and Aims: *Mat1a* KO mice spontaneously develop nonalcoholic steatohepatitis (NASH), which highlights the role of this gene in hepatic energy stores. *MAT1A* encodes the enzyme that catalyzes the conversion of methionine into S-adenosylmethionine (SAMe), the main biological methyl donor. NASH patients often have reduced expression of *MAT1A*, indicating that the *Mat1a* KO mouse model not only recapitulates the histological and metabolic features of NASH but it is also a relevant model to study human NASH.
Methods: Here we used NASH *Mat1a* KO mice (showing ultrasound fatty liver and elevated ALT) to: (1) evaluate if oral SAMe treatment for two months reverts NASH; (2) study the hepatic metabolic phenotype of NASH in *Mat1a* KO mice treated with placebo or SAMe (over 500 metabolites were analyzed); and (3) obtain a lipid signature of NASH through the serum lipidomic phenotype in *Mat1a* KO mice. To translate these findings to humans, we examined the presence of this identified lipid signature of NASH in *Mat1a* KO mouse in the serum of patients with biopsy proven NASH diagnosis.
Results: (1) The histological exam of liver samples revealed a marked reduction of steatosis, inflammation, necrosis and fibrosis as well as a normalization of serum ALT after SAMe treatment in *Mat1a* KO mice. (2) Lipidomic studies show that the main effect of SAMe in NASH treatment is to improve mitochondrial function, which leads to the reestablishment of a normal response to the accumulation of hepatic fatty acids (FA) (increased FA β-oxidation and decreased lipogenesis) and to the reduction of FA and triglyceride content. In addition to this, SAMe reestablished normal bile acid metabolism. (3) We compare the serum lipidomic profile in WT and *Mat1a* KO mice to generate a serum signature of NASH comprised of 50 metabolites (M-type signature). To translate these findings to humans, we carried out a hierarchical clustering of the serum lipidomic data of 134 patients with biopsy-confirmed NASH. Patients were classified into two well-defined clusters based on optimum average silhouette width: one cluster with an M-type signature that included 78 patients (58.2%) and a second cluster that contained 56 patients (41.8%), which suggests that the target for NASH patients with an M-type signature may be considered when assessing the efficacy of SAMe treatment.
Conclusions: These results show that SAMe treatment halted progression of NASH and reverted toward normal histology in *Mat1a* KO mice.

P0988

NONALCOHOLIC FATTY LIVER DISEASE: SERUM BILE ACID LEVELS IN CHILDREN AND ADOLESCENTS AS MARKER FOR PROGRESSION?

E. Zöhrer[1], J. Jahnel[1], G. Fauler[2], H. Scharnagl[2], T. Stojakovic[2], M. Trauner[3], V. Nobili[4]. *[1]Department of Pediatrics, [2]Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University Graz, Graz, [3]Deparmtent of Internal Medicine II, Medical University Vienna, Vienna, Austria; [4]Hepato-Metabolic Disease Unit, Bambino Gesù Children's Hospital – IRCCS, Rome, Italy*
E-mail: e.zoehrer@medunigraz.at

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is frequent in obese children. A reliable non-invasive biomarker for monitoring of progression to liver fibrosis would be useful. Serum bile acid (BA) levels are elevated in cirrhosis, probably for mechanical reasons. Interestingly, BA can influence glucose and lipid metabolism by stimulating insulin release via the TGR5/GLP1 pathway; and, reciprocally, insulin can downregulate BA synthesis from cholesterol via the FXR/SHP and/or the PI3K/AKT pathways. We hypothesized that changes in BA levels in NAFLD vary depending on grade of fibrosis.
Methods: In this multicenter study adolescents with NAFLD (n = 92) were classified between stages of fibrosis (non-fibrosis n = 27; fibrosis ≥1 n = 65) based on liver-biopsy findings. Metabolic and cholestatic status was assessed by blood tests (glucose, insulin, cholesterol, LDL, HDL, AST, bilirubin, ALT, GGT). The full BA pool, including 15 BA species, was measured by HPLC-MS/MS and compared to healthy controls (n = 105).
Results: Both groups showed hyperglycemia (non-fibrosis 126±44; fibrosis 119±18 mg/dl), hyperinsulinism (83±33 vs 88±41 μE/ml), and elevated ALT levels (63±20 vs 87±58 U/l). Non-fibrotic adolescents had significantly ($p < 0.001$) decreased median BA levels (1.28; range 1.18–2.34 μmol/l) compared to controls (3.36; range 2.16–4.69 μmol/l). In fibrosis BA values increased (1.86; 1.05–3.22 μmol/l; $p < 0.001$). Non-fibrotic patients lacked glycine-conjugated BA with a significant ($p < 0.05$) predominance of unconjugated BA. In fibrosis, glycine-conjugated BA values rose and the BA pool resembled that in healthy controls. Other values did not differ significantly between the groups.
Conclusions: BA levels decrease in early NAFLD and seem to increase continuously during progression to fibrosis and cirrhosis. BA may serve as a non-invasive biomarker for progression of disease.

P0989

A COMBINATION OF ELASTOMETRY AND BLOOD MARKERS IMPROVES THE NON-INVASIVE STAGING OF LIVER FIBROSIS IN NAFLD

J. Boursier[1], J. Vergniol[2], A. Guillet[1], J.-B. Hiriart[2], B. Le Bail[2], S. Michalak[1], S. Bertrais[3], F. Chermak[2], F. Oberti[1], J. Foucher[2], I. Fouchard-Hubert[1], M. Charbonnier[2], M.-C. Rousselet[1], P. Cales[1], V. de Ledinghen[2]. *[1]University Hospital, Angers, [2]University Hospital, Bordeaux, [3]University, Angers, France*
E-mail: JeBoursier@chu-angers.fr

Background and Aims: Accurate evaluation of liver fibrosis is required in NAFLD as patients with advanced (F3/4) fibrosis have an impaired liver-related prognosis. Combining liver stiffness measurement (LSM) by Fibroscan with blood fibrosis tests significantly improves their diagnostic accuracy in chronic hepatitis C, but this combinative tactic remains poorly evaluated in NAFLD. We directly compared LSM and 8 blood fibrosis tests in NAFLD, and developed a new test combination to improve the diagnostic accuracy.
Methods: 646 NAFLD patients with liver biopsy (NASH-CRN F fibrosis stage), LSM, and 8 blood fibrosis tests designed either for NAFLD (BARD, NAFLD Fibrosis Score, FibroMeter[S]) or chronic

viral hepatitis (APRI, FIB4, Fibrotest, Hepascore, FibroMeter^{V2G}) were included.

Results: LSM (0.834±0.014) and FibroMeter^{V2G} (0.798±0.016, p = 0.063 vs LSM) had higher Obuchowski indexes than the 7 other blood tests (p ≤ 0.036). The rate of patients with a reliable diagnosis (≥90% predictive values) of advanced fibrosis was the highest with LSM and FibroMeter^{V2G} (respectively, 50.7% and 46.7%, p < 0.001 vs other fibrosis tests). Independent predictors of advanced fibrosis (LSM median, alpha2-macroglobulin, hyaluronate, prothrombin time, diabetes, AST) were combined in a new BLEN-test. In a validation set, the BLEN-test had a significantly higher Obuchowski index (0.854±0.020) than FibroMeter^{V2G} or LSM (p ≤ 0.015). The rate of patients with a reliable diagnosis (≥90% predictive values) of advanced fibrosis was 74.3% with the BLEN-test (p < 0.001 vs FibroMeterV^{2G} or LSM). Fibrosis classifications derived from LSM or BLEN-test provided 7 fibrosis classes and avoided any biopsy requirement. In the validation set, 85.5% of F3/4 patients were well-classified with the BLEN-test classification vs 69.7% with the LSM classification (p = 0.004). Calculating the BLEN-test with the M or XL probe LSM results did not lead to significant change in the accuracy of the BLEN-test classification.

Conclusions: By comparing 9 non-invasive fibrosis tests in a large population, we identified FibroMeter^{V2G} and Fibroscan as the best tools for liver fibrosis evaluation in NAFLD patients. A combination of Fibroscan result with blood markers significantly improved diagnostic accuracy compared to single fibrosis tests. This combination accurately identified the subset of F3/4 NAFLD patients without any liver biopsy requirement.

P0990

NON-ALCOHOLIC STEATOHEPATITIS IS AN INDEPENDENT PREDICTOR OF MORTALITY IN A COHORT OF 493 MORBIDLY OBESE PATIENTS UNDERGOING BARIATRIC SURGERY

N. Goossens[1,2], Y. Hoshida[3], S. Friedman[1], P. Morel[4], J.-L. Frossard[2], L. Spahr[2], F. Negro[2,5], L. Rubbia-Brandt[5], E. Giostra[2]. *[1]Division of Liver Diseases, Icahn School of Medicine at Mount Sinai, New York, United States; [2]Division of Gastroenterology and Hepatology, University Hospital, Geneva, Switzerland; [3]Liver Cancer Program, Tisch Cancer Institute, Division of Liver Diseases, Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, United States; [4]Department of Surgery, [5]Department of Pathology, University Hospital, Geneva, Switzerland*

E-mail: nicolas.goossens@hcuge.ch

Background and Aims: The role of liver biopsy in the context of bariatric surgery remains unknown. We aimed to study the prognostic relevance of clinical parameters, including liver histology, on overall survival in a single centre cohort of obese patients undergoing bariatric surgery.

Methods: We included all patients undergoing bariatric surgery in our institution between January 1997 to December 2004 who had routine perioperative liver biopsy to assess for evidence of NAFLD or other liver disease. All had Roux-en-Y gastric bypass. Baseline clinical data were obtained and patient files and public records were checked to assess for mortality. All liver histology specimens were reviewed by an experienced pathologist (LRB) using the NASH Clinical Research Network Scoring System.

Continuous values are described as mean (±SD) and categorical values as n (%). Survival analysis was performed using the log-rank test and Cox-proportional hazards.

Results: 500 patients underwent gastric bypass surgery of whom 493 (99%) had a histological sample for analysis. Baseline characteristics were: male gender 91 (18%), age 41 y (±10), BMI 45 kg/m^2 (±6.7), AST 23 IU/ml (±14), ALT 34 IU/ml (±26), total cholesterol 5.3 mmol/L (±1.2), triglycerides 1.7 mmol/L (±1.2), HOMA-IR score 7.5 (±7.6), diabetes 82 (16%), arterial hypertension 156 (32%). Baseline histology demonstrated 436 (88%) patients with steatosis >5%, 57 (12%) patients with NASH of which 45 (79%) had fibrosis.

NASH patients were older (46 vs 40 y, p < 0.001), had higher ALT (52 vs 32 IU/ml, p < 0.001), triglycerides (2.2 vs 1.6 mmol/L, p = 0.01) and HOMA-IR (12 vs 7, p = 0.004), were more likely to be diabetic (46 vs 13%, p < 0.001) and to have arterial hypertension (51 vs 29%, p = 0.001) than non-NASH individuals. However, baseline BMI was not statistically different (46 vs 45, p = 0.49) between the 2 groups.

Twenty-one patients (4.2%) died during a mean follow-up of 9.4 y (±3.9). Univariate and multivariate survival analyses are shown in Table 1. Baseline factors independently associated with mortality were arterial hypertension and presence of NASH. Fibrosis was not included in the multivariate analysis due to multi-collinearity with NASH.

Table 1. Baseline factors associated with overall mortality in survival analysis

Characteristic	Survival group		Univariate analysis		Multivariate analysis	
	Alive	Dead	HR	p-value	Adjusted HR	p-value
Age	41 y	47 y	2.06 [a]	**0.0025**	1.27	0.41
Male gender	17%	43%	3.94	**0.0019**	1.93	0.16
Hypertension	29%	76%	7.98	**<0.0001**	4.65	**0.0098**
Diabetes	16%	38%	3.47	**0.0058**	0.955	0.93
OSA	13%	19%	1.56	0.42		
BMI	45	46	1.06 [b]	0.67		
NASH	10%	38%	5.28	**0.0002**	2.95	**0.027**
NASH with fibrosis	8%	33%	6.02	**0.0002**		

BMI, body mass index; HR, hazard ratio; OSA, obstructive sleep apnoea.
[a] HR for 10 year increase.
[b] HR for 5 kg/m^2 increase.

Conclusions: In a well characterised cohort of 493 morbidly obese patients undergoing bariatric surgery with a mean follow-up of more than 9 years, presence of NASH at liver biopsy and arterial hypertension were independently associated with overall mortality.

Note: LRB and EG contributed equally to this work.

P0991

RECIPIENT AND DONOR ADIPONECTIN POLYMORPHISMS ARE NOT ASSOCIATED WITH NEW ONSET DIABETES AFTER LIVER TRANSPLANTATION

B. John[1], A. Garber[2], T. Aiken[3], D. Thomas[4], D. Chen[5], R. Konjeti[6], R. Lopez[4,7], J.J. Fung[8], M. Askar[4,5]. *[1]Gastroenterology and Hepatology, [2]Medicine, Cleveland Clinic, [3]Cleveland Clinic Lerner College of Medicine, [4]Cleveland Clinic, Cleveland, United States; [5]Pathology and Laboratory Institute, Cleveland Clinic, Cleveland, [6]Medicine, Brown University, Rhode Island, [7]Quantitative Health Sciences, [8]Transplant Surgery, Cleveland Clinic, Cleveland, United States*

E-mail: johnb@ccf.org

Background and Aims: Post-transplant metabolic syndrome is an important cause of morbidity and mortality in liver transplant recipients. Adiponectin is an adipokine with anti-inflammatory and anti-atherogeneic properties and hypoadiponectinemia may be associated with post transplant atherosclerosis, metabolic syndrome and insulin resistance. We have demonstrated that Adiponectin polymorphisms are associated with post-transplant hepatic steatosis but it is unclear if this effect is mediated by post transplant metabolic syndrome. In this study, we explored the association between donors and recipient Adiponectin genetic polymorphisms and New Onset Diabetes After Transplantation (NODAT).

Methods: We identified consecutive patients who underwent liver transplantation (LT) for HCV cirrhosis between 2006–2011 at a tertiary care center in the United States. This was a case-control study with cases and controls defined as subjects with and without NODAT respectively. New onset diabetes was defined as subjects with no evidence of diabetes prior to LT and documented

diabetes post-LT and was defined according to the WHO and American Diabetes Association 2003 criteria based on a fasting blood glucose level of greater than 126 mg/dl or the presence of diabetic symptoms and post prandial sugar of >200 mg/dl.
Donors and recipients were tested for the rs1501299, rs2241766, rs266729 and rs2241766 Adiponectin polymorphisms using the QLAamp DNA Mini Kit assay testing by TaqMan SNP genotyping assay.
Results: Clinical data were collected for a total of 302 patients who were transplanted for HCV during the study period. A total of 112 patients are included in the analysis. Mean age of recipient at time of transplant was 56±7 years and 73% were male. 21% developed NODAT (cases). Cases and controls were well matched in terms of age, gender, donor risk index, cold ischemia time, immunosuppression used, HCV genotypes as well as pre and post transplant metabolic syndrome. There was a trend toward association of NODAT in recipients without CMV (p = 0057), HCV genotype 1 (p = 0.087) and higher donor risk index (p = 0.051) but none were statistically significant. On both univariable and multivariable analysis, donor or recipient rs1501299, rs266729 and rs17300539 polymorphisms were not associated with NODAT.

Table: Association of genotypes and new onset diabetes: logistic regression analysis

Factor	Unadjusted		Adjusted [a]	
	OR (95% CI)	p-value	OR (95% CI)	p-value
Recipient rs1501299: GG vs non-GG	1.4 (0.54, 3.4)	0.51	1.3 (0.52, 3.4)	0.56
Donor rs1501299: GG vs non-GG	1.2 (0.46, 2.9)	0.75	0.96 (0.38, 2.5)	0.94
Recipient rs2241766: TT vs non-TT	1.5 (0.45, 4.8)	0.53	1.3 (0.40, 4.1)	0.67
Donor rs2241766: TT vs non-TT	2.3 (0.64, 8.7)	0.2	2.3 (0.65, 8.0)	0.2
Recipient rs266726: CC vs non-CC	0.84 (0.32, 2.2)	0.73	0.93 (0.34, 2.5)	0.88
Donor rs266726: CC vs non-CC	0.87 (0.34, 2.2)	0.78	1.07 (0.40, 2.8)	0.9
Recipient rs17300539: GG vs non-GG	9.4 (0.49, 180.8)	0.14	7.4 (0.38, 141.0)	0.19
Donor rs17300539: GG vs non-GG	0.56 (0.18, 1.8)	0.32	0.55 (0.17, 1.8)	0.32

CI, confidence interval; OR, odds ratio.
[a] Adjusted for HCV genotype (1 vs. other).

Conclusions: Recipient and donor Adiponectin gene polymorphisms are not associated with NODAT. It appears that the association of Adiponectin polymorphisms and post transplant steatosis is independent of insulin resistance.

P0992
METABOLIC DISTURBANCES AFTER FRUCTOSE OVERCONSUMPTION ARE NOT LINKED TO INTESTINAL PERMEABILITY IN HEALTHY YOUNG VOLUNTEERS

C. Kienbacher[1], W. Dolak[1], S. Traussnigg[1], P. Steindl-Munda[1], K. Oettl[2], V. Stadlbauer[3], S. Knapp[4], H. Vogelsang[1], M. Trauner[1].
[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, [2]Institute of Physiological Chemistry, [3]Division of Gastroenterology and Hepatology, Department of Internal Medicine, Medical University of Graz, Graz, [4]Laboratory of Infection Biology, Department of Internal Medicine I, Medical University of Vienna, Vienna, Austria
E-mail: christian.a.kienbacher@meduniwien.ac.at

Background and Aims: Fructose overconsumption in Western diet is linked to non-alcoholic fatty liver disease (NAFLD). In animal models fructose overconsumption leads to chronic metabolic low-grade inflammation and was also linked to cardiovascular disease (CVD) as well as development of type 2 diabetes (T2DM). Until now, the impact of fructose overconsumption is often studied in overweight, T2DM or NAFLD patients, but is poorly understood in healthy subjects. To test our hypothesis that fructose overconsumption may impact on the gut–liver axis by increasing intestinal permeability, bacterial translocation, and consecutively metabolic inflammation as important mechanisms in the pathogenesis of NAFLD, CVD and T2DM, we examined the impact of a high oral fructose challenge (FC; 150 g/day for 4 weeks) on intestinal permeability and inflammation.
Methods: Ten healthy volunteers were enrolled (m:f = 5:5; median [range] age 24.5 [21–37] years; p = n.s.). Intestinal permeability was assessed by sucrose–lactulose–mannitol (SLM) test using high performance liquid chromatography of urine collected over 5 hours. CRP and fibronectin were assessed using nephelometry. Fetuin-A was measured using a commercial available ELISA Kit.
Results: After FC changes in energy homeostasis reflected by increased BMI (mean±SD 21.11±2.68 vs 21.51±2.77 kg/m^2; p < 0.001), fasting glucose levels (mean±SD 83.2±8.37 vs 88.4±5.48 mg/dL; p = 0.035) and increased fetuin-A levels during an oral glucose tolerance test at 90 min (260.9±30.1 vs 277.2±43.3 μg/ml; p = 0.046) and 120 min (234.8 [224.1–332.2] vs 288.1 [238.4–372.5] μg/mL; p = 0.007) were observed. Gastroduodenal permeability, reflected by recovered sucrose (p = 0.68) as well as small intestinal permeability reflected by lactulose/mannitol ratio (p = 0.622) remained stable. In line, inflammatory parameters CRP (p = 0.066) and fibronectin (p = 1.0) remained unchanged.
Conclusions: Fructose overconsumption (150 g/day for 4 weeks) in healthy young volunteers on top of their normal diet induces metabolic alterations without any increase in intestinal permeability or inflammation. This further supports the hypothesis that fructose overconsumption may act as "hepatotoxin" as a second hit in pre-existing metabolic diseases and/or on top of genetically predisposing factors such as PNPLA3 genotype.

LOBULAR ENRICHMENT OF REGULATORY T CELLS WITHIN LIVERS OF PATIENTS WITH NON-ALCOHOLIC STEATOHEPATITIS

A.K. Baumann[1], R. Taubert[1], J. Schlue[2], M. Blueher[3], H. Bantel[1], M.P. Manns[1], E. Jaeckel[1]. *[1]Department of Gastroenterology, Hepatology and Endocrinology, [2]Department of Pathology, Hannover Medical School, Hannover, [3]Department of Endocrinology and Nephrology, University of Leipzig, Leipzig, Germany*
E-mail: jaeckel.elmar@mh-hannover.de

Background and Aims: NAFLD is a metabolic disease with dramatically increasing relevance for the health care systems all over the world. The transition from steatosis to hepatitis with the subsequent risk of irreversible liver damage and carcinogenesis is incompletely understood. So far the innate and not the adaptive immune system is thought to be the immunological driver of liver inflammation.
Methods: We analyzed the intrahepatic T cell infiltration compartment specific (portal/lobular) employing a multicolor immunofluorescence in 32 liver biopsies of NAFLD patients.
Results: CD4$^+$FOXP3$^+$ regulatory T cells (Treg) significantly accumulated in the lobules, the focus of inflammation, and not in the portal fields with increasing histological disease activity (NAS-score). Thus NASH showed a significantly higher lobular Treg infiltration than NAFL, what was mirrored by increased Treg frequencies in the peripheral blood of NASH patients. Treg infiltration seemed to be more related to steatosis and hepatocyte ballooning than to lobular inflammation. Furthermore lobular CD4$^+$ Teff are significantly higher in NASH than NAFL and are correlated with the AST levels. In this cohort of mostly pre-obese patients we found no correlation of T cell infiltration with adiponectin, leptin and caspase cleaved cytokeratin-18 levels (M30).
Conclusions: In conclusion we found a compartment specific intrahepatic regulation of Treg with an accumulation at the site of inflammation according to the severity of NASH. The significant changes in the intrahepatic and peripheral T cell compartment point to a relevant involvement of the adaptive immune response in the pathogenesis of NASH.

P0994

CONTROLLED ATTENUATION PARAMETER (CAP) FOR DETECTION OF HEPATIC STEATOSIS IN PATIENTS WITH CHRONIC LIVER DISEASES

H. Tang[1], J. Chen[1], E.-Q. Chen[1], D. Wu[1], L. Bai[1]. [1]*Center of Infectious Diseases, West China Hospital of Sichuan University, Chengdu, China*
E-mail: htang6198@hotmail.com

Background and Aims: The objective of this study was to evaluate the performance of controlled attenuation parameter (CAP) to assess liver steatosis in patients with chronic liver diseases, and to analyse the relationships between CAP value and clinical or biological parameters in patients.
Methods: A total of 1152 consecutive patients with suspected chronic liver disease who completed CAP examination were enrolled. Of them, there were 121 patients who had undergone liver biopsy. Histological steatosis was categorized into S0 (<5%), S1 (5–33%), S2 (34–66%) and S3 (>66% of hepatocytes). The performance of CAP for evaluation of hepatic steatosis compared with liver biopsy was calculated by area under receiver operating characteristic curves (AUROC). In addition, the liver function and blood lipid level of the patients over the same period were detected. And the correlations of CAP with these data were analysed.
Results: The median age (875 males and 277 females) was 44 years old. The optimal cut-off value for CAP with steatosis suggested by abdominal ultrasound was 260 dB/m, and this study showed a good agreement of both methods (Kappa = 0.638, P < 0.001). In the 121 patients with liver biopsy, the median CAP values with S0, S1, S2 and S3 were 195 dB/m (range, 100–306), 236 dB/m (range, 146–336), 271 dB/m (range, 229–328) and 297 dB/m (range, 274–319) respectively. The cut-offs for the CAP value with steatosis ≥5%, ≥34% and ≥67% were 222 dB/m, 246 dB/m and 273 dB/m respectively. For the diagnosis of steatosis ≥5%, ≥34% and ≥67%, the areas under the curves were 0.88 (95% CI 0.82–0.95), 0.92 (95% CI 0.87–0.97) and 0.94 (95% CI 0.90–0.99), respectively. By multivariate analysis, factors associated with Controlled Attenuation Parameter (CAP) were BMI (P < 0.001), TG (P < 0.001), ALB (P < 0.001) and fasting glucose (P = 0.018).
Conclusions: CAP is a very good marker for the detection of hepatic steatosis. It was positively correlated with the level of serum lipid markers and impair of liver function.

P0995

THE USE OF THE ATTENUATION COEFFICIENT COMPUTED ON THE ULTRASONIC IMAGE COULD IMPROVE THE SPECIFICITY OF THE CLASSICAL ULTRASONOGRAPHIC EXAMINATION FOR THE ASSESSMENT OF STEATOSIS GRADE IN DIFFUSE LIVER DISEASES PATIENTS

M. Lupsor-Platon[1], C. Vicas[2], S. Nedevschi[2], H. Stefanescu[3], C. Radu[3], D. Crisan[3], Z. Sparchez[3], A. Serban[4], M. Grigorescu[3], R. Badea[1]. [1]*Medical Imaging, Regional Institute of Gastroenterology and Hepatology, Iuliu-Hatieganu University of Medicine and Pharmacy,* [2]*Computer-Science, Technical University,* [3]*Hepatology,* [4]*Pathology, Regional Institute of Gastroenterology and Hepatology, Iuliu-Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania*
E-mail: monica.lupsor@umfcluj.ro

Background and Aims: Usual ultrasonography (US) is a useful diagnosis method in chronic liver disease (CLD) patients, but it cannot formulate an accurate quantification of fat content and cannot differentiate steatosis from fibrosis. We aim to evaluate the performance of a new parameter – attenuation coefficient (AC) computed on the US image in quantifying steatosis in CLD, compared to classical US examination.
Methods: 682 consecutive histological proven CLD patients (46.27±10.33 years, 57.2% females, 508 HCV, 74 HVB, 100 NASH) were prospectively included in this study. Liver fibrosis and necro-inflammatory activity were evaluated according to the Metavir scoring system in HCV and HBV, respectively Brunt in NASH. Steatosis was categorized as S0: <5%, S1: 6–33%, S2: 34–66% and S3: 67–100% of hepatocytes. They were referred to an US exam 1 day prior to liver biopsy (LB), using the same setting of a GE Logiq 7 device. Along a region of interest from easch US image there were stored the average gray level and the depth. Linear regression by least-squares approximation was applied to this dataset. The slope represents the attenuation coefficient (AC). Its diagnostic performance was compared with the performance of classical US examination.
Results: The univariate analysis provides a significant correlation between AC and steatosis (p < 0.001), but no correlation with fibrosis (r = −0.053, p = 0.214) and necroinflamatory activity (r = −0.054, p = 0.220) in HCV and HBV patients. In NASH, AC was significantly correlated with steatosis (r = −0.326, p = 0.001), ballooning (r = −0.234, p = 0.033) and lobular inflammation (r = −0.288, p = 0.009), with no significant correlation with fibrosis (r = −0.013, p = 0.897). In multivariate analysis, only steatosis was significantly correlated with AC (p < 0.001). The AC diagnostic performance in quantifying each steatosis grade was: for S ≥1 AUROC = 0.790 (cutoff = −0.0471, Se = 50.73%, Sp = 92.72%, PPV = 88.8%, NPV = 62.4%); for S ≥2, AUROC = 0.853 (cutoff = −0.0821, Se = 79.66%, Sp = 76.47%, PPV = 43.1%, NPV = 94.4%), respectively for S = 3, AUROC = 0.845 (cutoff = −0.1474, Se = 66.67%, Sp = 91.60%, PPV = 32%, NPV = 97.1%). AC increases the specificity of usual US from 84.84% to 92.72% for S ≥1 (p, 0.0001), from 70.39% to 76.47% for S ≥2 (p = 0.014), respectively from 87.85% to 91.60% for S3 detection (p = 0.03).
Conclusions: The use of the attenuation coefficient computed on the US image could substantially improve the ability of the usual US for the assessment of steatosis grade.

P0996

THE EFFECTS OF SHORT-TERM EXENATIDE ON CIRCULATING ADIPONECTIN LEVELS IN PATIENTS WITH TYPE 2 DIABETES MELLITUS (DMT2) WITH OR WITHOUT NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD): A RANDOMIZED, OPEN-LABEL, CONTROLLED INTERVENTION TRIAL

S. Savvidou[1,2,3], K. Karatzidou[1,2], A. Gagalis[3], K. Tsakiri[1,2], P. Hytiroglou[4], J. Goulis[5]. [1]*1st Department of Internal Medicine,* [2]*Medical Center of Diabetes Mellitus,* [3]*Hepatology Outpatients' Clinic, "Papageorgiou" University Hospital,* [4]*Department of Pathology, Medical School of Aristotle University,* [5]*4rth Department of Internal Medicine, Hippocration University Hospital, Thessaloniki, Greece*
E-mail: ssavidou@med.auth.gr

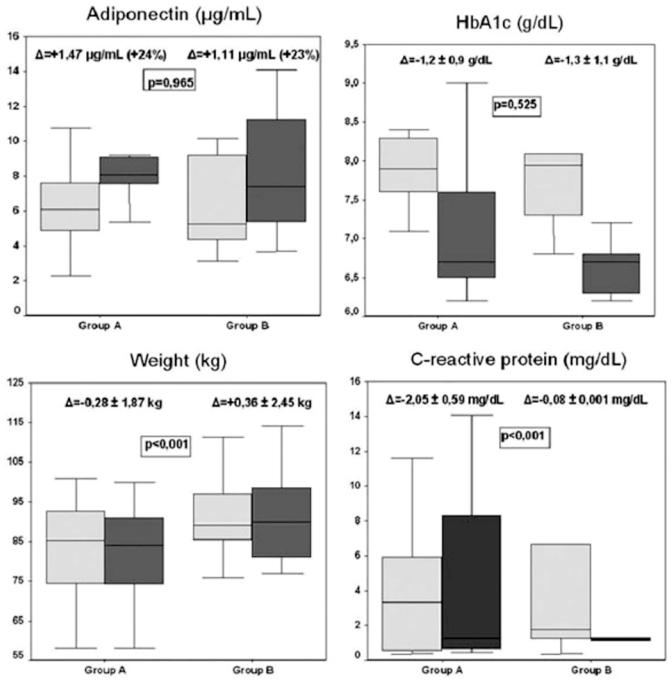
Background and Aims: DMT2 and NAFLD are both characterized by decreased circulating adiponectin levels. Furthermore, replenishment of hypoadiponectinemia is able to restore insulin sensitivity and to reverse weight gain, hyperglycemia and fatty liver. Recently, glucagon lipid peptide-1 receptor agonists like exenatide, have been shown not only to exert their action within liver parenchyma, but also to induce adiponectin expression. However, strong evidence of their interaction is still lacking.
Methods: DMT2 patients with abnormal aminotransferases were screened for NAFLD and subjected to liver biopsy to confirm/stage disease. A subgroup of patients, after assessed for eligibility criteria, was blindly randomized to receive either 6-month exenatide supplementation on glargine insulin (group A) or intense, self-regulated, insulin therapy alone (group B). Serum adiponectin was measured with ELISA before and after intervention, and several determinants like weight, BMI, waist circumference, aminotransferases, high-sensitivity C-reactive protein, HbA1c and lipidemic profile were recorded.
Results: From 470 DMT2 patients who had their aminotransferases for ≥6-month-period accessible in hospital databases, 110 took part

in the intervention trial for a mean duration of 6.7 months (finally analyzed group A n = 55 vs. group B n = 48). Baseline characteristics: 41 (39.8%) males, aged 62.9±7.2 years, weight 87±12.2 kg, BMI 31.2±5.5 kg/m^2, HbA1c 8.29±1.49%, median ALT 23 (5–126), AST 20 (7–72) U/L, 78 (15.6%) patients with abnormal ALT, 17 (3.6%) biopsy-proven NAFLD [median Activity Score 5 (2–7), fibrosis stage 3 (1–4)].

The graph shows the results of intervention. Adiponectin was significantly raised during intervention in both groups (Student's t for paired samples, $p < 0.001$) but this elevation was not attributable to the type of intervention, the degree of glycemic control, level of CRP or alterations in somatometrics.

Presence of NAFLD was accompanied by a significant decline in adiponectin ($p < 0.001$), which was found to negatively correlate with the degree of ALT in all groups (Spearman's correlation, $r_s = -0.544$, $p < 0.001$).

Conclusions: Supplementation of exenatide to glargine insulin compared to standard insulin was: (i) effective in inducing weight loss, (ii) non-inferior in lowering HbA1c and (iii) non-inferior in raising circulating adiponectin. Higher serum adiponectin concentrations were associated with lower ALT levels in all patient groups, confirming the hepatoprotective role of this cytokine.



P0997

WFA$^+$-M2BP IS A PREDICTIVE FACTOR FOR FIBROSIS PROGRESSION IN NAFLD

T. Nakajima[1], I. Ozeki[1], S. Hige[1], Y. Karino[1], J. Toyota[1]. [1]*Hepatology, Sapporo Kosei General Hospital, Sapporo, Japan*
E-mail: nakajimasapporo@gmail.com

Background and Aims: The *Wisteria floribunda* agglutinin-positive Mac-2 binding protein (WFA$^+$-M2BP) using the glycan "sugar chain"-based immunoassay was recently shown to be a liver fibrosis marker. Moreover, the feasibility of WFA$^+$-M2BP for assessing liver fibrosis progression in non-alcoholic fatty liver disease (NAFLD) was proven with clinical samples. On the other hand, cytokeratin-18 (CK-18) fragments levels are regarded as predictor of severity of NAFLD. The aim of this study was to compare the serum WFA$^+$-M2BP and CK-18 levels with clinical assessments of fibrosis and to compare WFA$^+$-M2BP with other fibrosis markers.

Methods: Serum WFA$^+$-M2BP and CK-18 levels were evaluated in 51 patients with NAFLD who had undergone liver biopsy. Histological findings were evaluated by three experienced, liver-specific pathologists. We analyzed predictive factor for fibrosis progression in NAFLD and compared WFA$^+$-M2BP with hyaluronic acid, type 4 collagen 7s, FIB-4 index, and NAFLD fibrosis score.

Results: The median age of the 51 patients (23 men and 28 women) was 59 (29–92) years old. Serum WFA$^+$-M2BP levels in patients with fibrosis stages 0/1/2/3/4 were 0.49±0.08/0.77±0.24/1.38±0.36/1.61±0.73/3.74±2.92 and there was significant difference between fibrosis stages 0–1 and 2–4 ($P < 0.001$). Multivariate analysis showed that FIB-4 index 2.0≤ ($P = 0.010$), WFA$^+$-M2BP 1.0≤ ($P = 0.020$), and albumin 4.0> ($P = 0.043$) were independently associated with the presence of fibrosis (Stage 2–4). CK-18 wasn't associated with the progression of fibrosis. The AUROC curve values for differentiating Stage 2–4 from Stage 0–1 were compatible for the serum WFA$^+$-M2BP (0.964), hyaluronic acid (0.926), type 4 collagen 7s (0.978), FIB-4 index (0.946), and NAFLD fibrosis score (0.917).

Conclusions: WFA$^+$-M2BP is one of the non-invasive predictors of fibrosis progression in NAFLD.

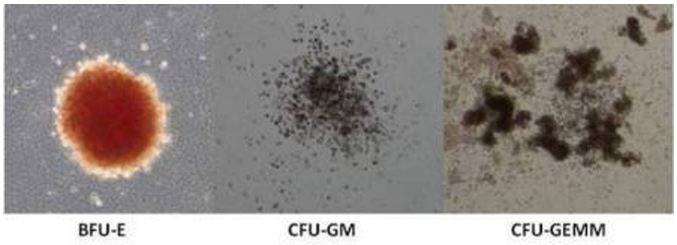
P0998

EVALUATION OF CIRCULATING PROGENITOR CELLS LEVELS AND FUNCTIONAL CAPACITY IN PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE (NAFLD)

E. Elsheikh[1,2], Z. Younoszai[2], M. Otgonsuren[2], T. Jeffers[2], H. Allawi[2], B. Marsiglia[3], D. Chapman[3], S.L. Hunt[1,2], B.P. Lam[1], Z. Younossi[1,2]. [1]*Center for Liver Diseases,* [2]*Betty and Guy Beatty Center for Integrated Research,* [3]*Department of Pathology, Inova Fairfax Hospital, Falls Church, United States*
E-mail: zobair.younossi@inova.org

Background and Aims: The functions and the levels of progenitor cells are closely linked to metabolic syndrome. Thus, in this study we investigated the level and functions of circulating progenitor cells (CPC) in patients with NAFLD.

Methods: The study cohort consisted of 82 patients [37 with NAFLD (mean age 60 years, 75% male, 64% CAD) and 45 matched controls (mean age 64 years, 75% male, 68% CAD). Each patient had fasting serum, clinical data and abdominal ultrasound. NAFLD was defined as radiologic fatty liver in the absence of other causes of liver disease and excessive alcohol use. Circulating progenitor cells (CPC) were quantified by flow cytometry based on the expression of (CD34$^+$, CD133$^+$, CD34$^+$ CD133$^+$) in presence or absence of the hematopoietic marker (CD45). To study the functional capacity of CPC, colony-forming unit (CFU) assay was used. These include erythroid progenitors [burst-forming unit erythroid (BFU-E)]; granulocyte/macrophage progenitors [CFU-granulocyte, macrophage (CFU-GM)]; and multi-potential progenitors [CFU-granulocyte, erythroid, macrophage, megakaryocyte (CFU-GEMM)].



Results: The level of CD45$^+$CD133$^+$ cells was higher in NAFLD patients (Median, 0.19%) than in controls (median, 0.16, $p = 0.003$). NAFLD patients in the lowest quartile (25th) of CD45$^+$CD133$^+$ cells had the lowest risk for NAFLD [OR: 0.29 (95% CI: 0.10–0.84)]. In contrast CFU-GM [OR: 5.92 (95% CI: 1.51–23.24)] and CFU-GEMM [OR: 5.18 (95% CI: 1.31–20.57)] were associated with increased risk

for NAFLD for the same quartile. In multivariate analysis, presence of $CD45^+CD133^+$ cells was independently protective [OR: 0.29 (95% CI: 0.08–0.99)] against NAFLD.
Conclusions: NAFLD patients have an increased level of circulating progenitor cells $CD45^+CD133^+$, possibly due to impaired differentiation capacity of these progenitors to the committed cell line. Furthermore, functional CPS may play a protective role against development of NAFLD.

P0999
SERUM VITAMIN D DEFICIENCY IN NON-ALCOHOLIC FATTY LIVER DISEASE; CHICKEN OR THE EGG?

D.W. Jun[1], W.K. Saeed[1], H.H. Nam[1]. [1]*Internal Medicine, Hanyang University, Seoul, Korea, South*
E-mail: noshin@hanyang.ac.kr

Background and Aims: Serum Vitamin D concentrations are reduced in non-alcoholic fatty liver patients (NAFLD); however, there is no data whether it is caused by reduced dietary intake, reduced sunlight exposure, or liver disease itself [reduced 25(OH)D conversion]. We would like to check the change of serum vitamin D level after calorie intake restriction without changing sunlight exposure in non-alcoholic fatty liver disease (NAFLD) patients.
Methods: Ninety sonographic fatty liver disease subjects were enrolled. All participants received nutritional education for two months. Dietary intakes were assessed using three-day food records. Dietary education program was served to take 25kcal/kg according to ideal body weight to reduce weight. Sunlight exposure and physical activity were also assessed.
Results: Eighty-two participants finished 8 weeks education program. At baseline, the average serum vitamin D concentrations were 13.0 ng /mL. Serum vitamin D level was lower than 20 ng /mL in 74 patients (91.1%), and 29 patients (35.4%) had less than 10 mg/mL. Although vitamin D intake (4.9 μg/day vs. 4.0 μg/day, $p = 0.14$) as well as total calorie uptake were decreased, serum vitamin D concentration increased (13.0 ng/mL vs. 15.9 ng/mL, $p < 0.001$). Increasing of serum vitamin D level was associated with body weight reduction not by vitamin D intake, and sunlight exposure. The participants had the same intensity of physical activities and sunlight exposure during the study period as before. Serum vitamin D level was independent risk factor for normalization of aminotransferase activities and improvement hepatic fat contents as assessed with liver HU and liver spleen HU ratio.
Conclusions: Weight loss induced improved fatty liver increases serum vitamin D concentration independent of vitamin D intake and sunlight exposure.

P1000
PREVALENCE AND PREDICTORS OF TRANSIENT ELASTOGRAPHY-DEFINED NON-ALCOHOLIC FATTY LIVER DISEASE WITH AND WITHOUT SIGNIFICANT LIVER FIBROSIS AMONG ASYMPTOMATIC SUBJECTS UNDERGOING A MEDICAL HEALTH CHECK-UP

H.W. Lee[1], S.U. Kim[1], B.K. Kim[1], J.Y. Park[1], D.Y. Kim[1], S.H. Ahn[1], K.J. Song[2], K.-H. Han[1]. [1]*Department of Internal Medicine,* [2]*Department of Biostatistics, Yonsei University College of Medicine, Seoul, Korea, South*
E-mail: lorry-lee@yuhs.ac

Background and Aims: Transient elastography (TE) can accurately assess the degree of liver fibrosis and steatosis. However, few data have been available regarding the clinical role of TE in screening general population and identifying high-risk sub-population. Thus, we have investigated the prevalence and predictors of non-alcoholic fatty liver disease (NAFLD) and nonalcoholic steatohepatitis (NASH) among asymptomatic subjects undergoing a medical health check-up.
Methods: Between April 2013 and August 2014, a total of 2,944 subjects without alcoholic and chronic viral liver diseases who received a medical health check-up including TE examination were consecutively recruited. NAFLD was defined as Controlled Attenuation Parameter (CAP) >250 dB/m, significant fibrosis as liver stiffness (LS) >7 kPa, and non-alcoholic steatohepatitis (NASH) as both CAP >250 dB/m and LS >7 kPa.
Results: The mean age of the population in this study (men 1,761 and women 1,183) was 54 years. Among them, 121 (4.1%) subjects had significant fibrosis, and 1,290 (43.8%) had NAFLD. Subjects with NAFLD were significantly older and had higher alanine aminotransferase (ALT) level, higher prevalence of parameters related to metabolic syndrome such as high blood pressure, high body mass index (BMI), glucose intolerance, and dyslipidemia than those without NAFLD (all $P < 0.05$). Independent predictors of NAFLD were age, BMI, ultrasonographic fatty liver, the amount of visceral fat, serum albumin, hypertension, diabetes, and high-density lipoprotein (all $P < 0.05$). In addition, NASH was identified in 84 (2.9%) subjects. Its independent predictors were male gender (odds ratio [OR] 3.435, 95% confidence interval [CI] 1.328–8.885, $P = 0.011$), age (OR 1.041, 95% CI 1.003–1.081, $P = 0.032$), high BMI (OR 1.285, 95% CI 1.071–1.542, $P = 0.007$), hypertension (OR 3.004, 95% CI, 1.731–5.213, $P < 0.001$), and diabetes (OR 2.993, 95% CI 1.525–5.873, $P = 0.001$).
Conclusions: Using TE, we identified the prevalence of NAFLD (43.8%) and NASH (2.9%) and their predictors in asymptomatic subjects undergoing a medical healthy check-up. Specifically, subjects with risk factors of NASH such male gender, high BMI, hypertension, and diabetes should be screened using TE for early identification of disease progression in spite of no history of alcoholic or chronic viral hepatitis.

P1001
CAROTID-FEMORAL PULSE WAVE VELOCITY (CF-PWV) AS A SURROGATE MARKER OF ADVANCED LIVER FIBROSIS IN TYPE-2 DIABETIC (T2DM) PATIENTS EVALUATED BY TRANSIENT HEPATIC ELASTOGRAPHY

N.C. Leite[1], M.T. Ferreira[1], G. Salles[2], C.R. Cardoso[2], C.A. Villela-Nogueira[3]. [1]*Internal Medicine Division – Clementino Fraga Filho University Hospital,* [2]*Internal Medicine Department – School of Medicine,* [3]*Internal Medicine Department/Hepatology Division – School of Medicine, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil*
E-mail: crisvillelanog@gmail.com

Background and Aims: So far, it is not known whether there is any association between cf-PWV, the gold standard measure of aortic stiffness, and advanced liver disease. We aimed to evaluate the association between cf-PWV among diabetes and non-diabetes-related factors and advanced fibrosis identified by transient hepatic elastography (THE) (Fibroscan®, Echosens, France) in T2DM patients.
Methods: Baseline and follow-up clinical, laboratory and cf-PWV data from T2DM outpatients were obtained. A second cf-PWV was registered. The cutoff value for considering increased cf-PWV was 10 m/s. Liver fibrosis was evaluated by THE with controlled attenuated parameter (CAP) on a follow up time of 7 years after baseline. At THE, a cutoff value above 7.9 kPa (M probe) and 7.2 kPa (XL probe) were considered as advanced fibrosis. Data was retrospectively analyzed and the independent factors associated to advanced fibrosis were identified by logistic binary regression. A significance level of 0.05 was adopted.
Results: Two hundred and twenty-one T2DM patients [male 74 (34%), mean age 58±8 yrs] with a BMI of 30±5 kg/m^2 and mean weight of 77±13 kg were included. Only 89 (40%) patients had glycated hemoglobin less than 7%. A cf-PWV >10 m/s was observed in 16% and 28% in the first and second measurement,

respectively and 132 patients (60%) increased their initial cf-PWV values. Advanced fibrosis was identified in 69 (31%) patients and liver steatosis above 66% was observed in 42% of patients. Surprisingly, there was no association between advanced fibrosis and T2DM parameters (diabetes duration, macro and microvascular complications prevalence at baseline) neither with diabetes-related drugs. In two different models of multivariate logistic regression, both a second PWV >10 m/s (OR: 2.46, 95% CI: 1.14–5.32; p = 0.021) and an evolutive increase in PWV of at least 2 m/s (OR: 2.65, 95% CI: 1.08–6.49; p = 0.03) were independently associated with greater odds of having advanced liver fibrosis as well as persistently high GGT levels (OR: 5.76, 95% CI: 2.16–15.38; p < 0.01), HDL-cholesterol levels (reduction of 1 mmol/L, OR: 1.03, 95% CI: 1.06–2.0; p = 0.04) and increased steatosis diagnosed by the CAP (increment of 1 dB/m, OR: 1.01; 95% CI: 1.00–1.02; p < 0.01).

Conclusions: Cf-PWV measurement is a non-invasive tool that may be a useful surrogate marker of advanced liver fibrosis in T2DM patients. These findings suggest that it might also be valid in patients with NAFLD, which is the main cause of chronic liver disease in diabetic patients.

P1002

THE HISTOLOGICAL SEVERITY OF NAFLD DETERMINES THE CARDIOVASCULAR RISK AND INSULIN RESISTANCE IN METABOLICALLY HEALTHY AND UNHEALTHY OVERWEIGHT INDIVIDUALS

R. Pais[1], J. Aron Wisniewsky[1], F. Nascimbeni[2], J. Tordjman[1], P. Lebray[1], F. Charlotte[1], P. Bedossa[3], T. Poynard[1], K. Clement[1], V. Ratziu[1], FLIP Consortium. *[1]Université Pierre et Marie Curie, Hôpital Pitié Salpetrière, Assistance Publique Hôpitaux de Paris, Institute for Cardiometabolism and Nutrition (ICAN), Paris, France; [2]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [3]Université Pierre et Marie Curie, Hôpital Beaujon, Assistance Publique Hôpitaux de Paris, Paris, France*
E-mail: ralu_pais@yahoo.com

Background and Aims: Obesity is a heterogeneous condition in terms of metabolic and cardiovascular (CV) risks, which are attributed to the presence of metabolic risk factors (MRF) rather than obesity *per se*. The prevalence and severity of NAFLD in different categories of obese patients (pts) and its impact on insulin resistance (IR) and CV risk could, however, confound this relationship.

Aim: To explore the prevalence, determinants and impact of the histological severity of NAFLD on IR and 10-year CV risk in a heterogeneous population of overweight pts.

Methods: 401 pts with biopsy-proven NAFLD (Hepatology Cohort-HC) and 626 morbidly obese pts (Bariatric Cohort-BC). NAFLD/NASH was defined according to SAF classification; significant fibrosis: ≥F2. Metabolically healthy (MH) individuals were defined as non-diabetic pts with ≤1 of the following MRF: visceral obesity, arterial hypertension, hypoHDL. Pts were classified into 3 categories based on the above MH status and overweight (BMI≥25 kg/m^2): metabolically healthy and unhealthy overweight (MHO, MUHO) and normal weight (NW) pts with/without MRF. The Framingham Score (FRS) was calculated.

Results: HC: 62% of patients were males; mean age 54±12 years; mean BMI 30.7±6.1 kg/m^2; 70% NASH; 49% ≥F2; mean FRS 11±8%. 30% of patients were MHO, 55% MUHO and 15% NW. The prevalence and severity of histological lesions gradually increased across groups (Table).

These results were reproduced in 200 age and sex-matched pts from BC (2:1 random selection).

The distribution of HOMA and FRS across groups (NW, MHO, MHNO) was: 3.9±4.4, 4±4.1, 6.2±6.1, p = 0.001 and 11±8, 8±7, 13±8, p < 0.001, respectively. Pts with advanced NASH (NASHF2) vs. those without, had higher FRS in both MHO (10±8 vs. 7±6 p = 0.015) and MUHO (15±8 vs. 11±8, p = 0.003), but not in NW pts. In the entire cohort, NASHF2 predicted IR (beta=0.145, p = 0.008) and FRS (beta=0.081, p = 0.036) independent of MRF and body weight, in a model adjusted for age and sex.

	NW	MHO	MUHO	P, MHO vs.	
				MUHO	NW
NASH	49	68	75	0.14	0.016
Steatosis grade 3 or 4	15	16	26	0.05	0.76
Activity Score >2	18	36	51	0.006	0.012
≥F2	30	41	58	0.003	0.12

Conclusions: In pts with excessive body weight advanced NAFLD (NASH with fibrosis) independently determines CV risk and IR above and beyond MRF and the degree of overweight. In turn, MRF confers a higher risk of histologically severe NAFLD regardless of body weight. The NAFLD phenotype needs to be assessed in overweight pts to better characterize their overall health risks.

P1003

NONINVASIVE PREDICTION OF EROSIVE ESOPHAGITIS USING A CONTROLLED ATTENUATION PARAMETER (CAP)-BASED RISK ESTIMATION MODEL

Y.E. Chon[1], H. Chung[1], S.U. Kim[1], S.K. Lee[1], K.S. Jung[1], K.-H. Han[1], C.Y. Chon[1]. *[1]Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, South*
E-mail: nachivys@yuhs.ac

Background and Aims: Erosive esophagitis and fatty liver share obesity and visceral fat as common critical pathogenesis. We evaluated the relationship between the amount of hepatic fat measured by controlled attenuation parameter (CAP) using transient elastography and the presence of erosive esophagitis, and then developed a CAP-based risk estimation model for erosive esophagitis.

Methods: We enrolled 1,045 consecutive participants (training cohort, n = 705; validation cohort, n = 340) from a health check-up center who underwent esophagoduodenoscopy and CAP. Independent predictors for erosive esophagitis that have been investigated through logistic regression analyses were used as components for establishing a risk estimation model.

Results: Among the entire population, the prevalence of erosive gastritis was 10.7% (9.4% in the training cohort; 13.5% in the validation cohort). A CAP-based risk estimation model for erosive esophagitis using CAP, Body mass index, and significant alcohol Drinking as constituent variables was established, and was dubbed the CBD score. The CBD score ranged from 0 to 11, with the accuracy showing an area under the receiver operating characteristic curve (AUROC) of 0.819 for predicting erosive esophagitis. The high-risk group (CBD score ≥3) showed significantly higher risk of having erosive esophagitis than the low-risk group (CBD score <3) (24.1% vs. 2.7%, respectively; P < 0.001). The diagnostic accuracy of CBD score was maintained in the validation cohort (AUROC = 0.848).

Conclusions: The CBD score is a simple CAP-based risk model for predicting erosive esophagitis. The CBD score may be the alternative option for EGD in monitoring the occurrence of erosive esophagitis, considering its convenience and non-invasiveness.

P1004
IMPACT OF AEROBIC EXERCISE IN POSTMENOPAUSAL WOMEN WITH NONALCOHOLIC FATTY LIVER DISEASE: A 24 WEEKS RANDOMIZED CLINICAL TRIAL

R.E. Rezende[1], S.M. Duarte[1], J.T. Stefano[1], L.A. Perandini[2], T. Dassouki[2], A.L. Sa-Pinto[2], H. Roschel[2], B. Gualano[2], D.C. Vezozzo[1], F.J. Carrilho[1], C.P. Oliveira[1]. *[1]Gastroenterology LIM 07, [2]Rheumatology, University of São Paulo School of Medicine, São Paulo, Brazil*
E-mail: cpm@usp.br

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is common in postmenopausal women and it is associated with an increased prevalence of cardiovascular disease. The aim of this study was to establish the effectiveness of aerobic exercise and its influence in reducing metabolic and cardiovascular risk in postmenopausal women with NAFLD.
Methods: Forty sedentary postmenopausal women (mean age 55.3±8.0 years), range BMI (24.2–43.3 kg/m^2) biopsy-proven NAFLD were randomly divided into two parallel groups: Exercise Group (19 patients) and Control Group (21 patients). The exercise group performed a supervised aerobic exercise program of 60min/2 days/week at 60–85% of heart rate reserve for 24 weeks. The anthropometric parameters, body composition, hepatic, lipid, and glycemic profiles, HOMA-IR, cytokines (IL8, TNF and VEGF), transient elastographyby FibroScan (FS) – CAP and cardiorespiratory exercise test on the treadmill (Centurion 200, Micromed) were evaluated at baseline (T0) and after 24 weeks of protocol (T1). All patients were advised to use hypocaloric diet, with monthly returns with nutritionist.
Results: At baseline there were no statistically significant differencein the age, blood pressure, anthropometric parameters, percent body fat (PBF), hepatic, lipid, glycemic profiles, HOMA-IR, cytokines and liver histology/FS [liver stiffness (LS)/CAP] among the groups. We observed decrease of abdominal circumference (CA) ($p = 0.05$), BMI, and increase of HDL levels ($p < 0.05$) in the exercise group after 24 weeks. There were no statistically significant differences in the cytokines (IL8, TNF, and VEGF) between the groups. Regarding FS there was a stabilization of LS/CAP in the exercise group and a trend of increase of these parameters in the control group. The CAP analysis showed improvement of hepatic fat content in exercise group.
Conclusions: An aerobic exercise program of 24 weeks in NAFLD postmenopausal women showed improvement in some variables such as CA, BMI, HDL and hepatic fat content that may be beneficial in improving cardiovascular risk factors.

P1005
IS ASPIRIN USE A PROTECTOR FACTOR OF NONALCOHOLIC FATTY LIVER DISEASE?

A. Peltec[1], V. Ivanov[2], G. Curocichin[3], A. Munteanu[4], V. Dumbrava[1]. *[1]Gastroenterology, University of Medicine and Pharmacy "Nicolae Testemitanu", [2]Interventional Cardiology, Institute of Cardiology, [3]Genetic Laboratory, [4]Morphopathology, University of Medicine and Pharmacy "Nicolae Testemitanu", Chishinev, Moldova, Republic of*
E-mail: apeltec@yahoo.com

Background and Aims: Nonalcoholic fatty liver disease is now conceptualised as a 'multiple hit' process, consisting of insulin resistance, which causes a reversible fat accumulation in hepatocytes as the first hit, and a combination of oxidative stress, lipid peroxidation and pro-inflammatory cytokines as the subsequent hits. Aspirin may affect oxidative stress, vascular inflammation and insulin sensitivity.
Aim: To investigate an association between aspirin use and NAFLD prevalence in the patient with arterial hypertension.
Methods: A total of 625 patients (mean age: 48.15±10.5 years, 72% males) who had arterial hypertension and underwent ultrasonography were included in the study; of those, 167 patients (mean age: 49.62±9.97 years, age range: 23–73, 85/167 [50.9%] females) were identified as having NAFLD and 458 as control. Aspirin use during the month prior to interview was categorised as never use (0 times), occasional use (1–14 times) and regular use (≥15 times).
Results: Patient with NAFLD were more likely to be obese, physically inactive, have diabetes. This group were less frequently use aspirin, than patient from control group. In the multivariate unconditional logistic regression analysis, regular relative to no aspirin use was inversely associated with prevalent NAFLD. Odds ratio 0.23, 95% confidence interval (CI) 0.12–0.42; $p < 0.01$.
Conclusions: Regular aspirin use (≥15 times per month) associated with a lower prevalence of NAFLD in case of patient with arterial hypertention and may be had a protective effect in development of nonalcoholic fatty liver disease.

P1006
LIVER IRON CONCENTRATION IN THE METABOLIC SYNDROME WITH HYPERFERRITINEMIA (DYSMETABOLIC HYPERFERRITINEMIA). RESULTS FROM A COHORT OF PATIENTS STUDIED BY MRI

E. Zapata[1], A. Castiella[1], L. Zubiaurre[1], A. Iribarren[1], J.M. Alustiza[2], E. Salvador[2], J.I. Emaparanza[3], P. Otazua[4]. *[1]Gastroenterology, Mendaro Hospital, Mendaro, [2]Radiology, Osatek Donostia, [3]Clinical Epidemiology, Donostia Universitary Hospital, Donostia, [4]Gastroenterology, Mondragon Hospital, Mondragon, Spain*
E-mail: agustincastiella@yahoo.es

Background and Aims: Nearly 25% of adult population in western countries have the metabolic syndrome (MS). Hyperferritinemia (HF) is frequently present in patients with this clinical entity (dysmetabolic hyperferritinemia). There are some publications that support that HF is associated with a raised liver iron concentration (LIC) in these patients, but some doubts persist about this subject.
To study the LIC in patients referred for hyperferritinemia to a secondary hospital in the Basque Country, Spain, and determine if there are differences between patients with or without metabolic syndrome.
Methods: A prospective study of 132 consecutive patients with HF (>200 μg/L women, >300 μg/L men) was conducted from January to December 2010. The Metabolic syndrome was defined by the presence of waist circumference ≥94 cm men/≥80 cm women and two of the following factors: Triglycerides ≥≥150 mg/dL or treatment for this dislipidemia; HDL <40 mg/dL women/<50 mg/dL men or treatment for this dislipidemia; glucose ≥100 mg/dL or Type 2 diabetes; hypertension: blood pressure ≥130 mmHg/≥85 mmHg or treatment for arterial hypertension. LIC was determined by MRI (SIR method).
Results: In 97 of 132 patients we have all the data to determine the MS presence: 44/80 men (55%) and 10/17 women (59%) presented MS. In 54/97 patients MRI for LIC determination (mean±SD) was performed. From the MS group (54 patients), 44 were men (27 had MRI) and 10 women (9 MRI). So that, we have LIC results (μmol/g) from 36 patients. The mean LIC was 27.63±20.18 (men) and 28.44±18.31 (women), with *27.83±20.90* for all the MS group. In 43/97 patients MS was not diagnosed (NMS): 36 were men (13 MRI), and 7 women (5 MRI). In 18 patients from the NMS group LIC by MRI was determined. The mean LIC was 30.84±23.79 in men, and 39.2±23.79 in women, with *33.16±19.61* for all the NMS group. We compare the mean values of LIC from both groups (MS vs NMS) by Pearson's Chi square test. No significant differences were retrieved ($p = 0.067$).
Conclusions: Patients with HF and MS (dysmetabolic hyperferritinemia) present a mean LIC within normal values and their values do not differ from those of patients with HF and without MS.

P1007

H63D/H63D GENOTYPE AND H63D ALLELE PREDISPOSE PATIENTS WITH HYPERFERRITINEMIA TO DEVELOP METABOLIC SYNDROME

E. Zapata[1], A. Castiella[1], M.D. De Juan[2], L. Zubiaurre[1], A. Iribarren[1], P. Otazua[3]. [1]*Gastroenterology, Mendaro Hospital, Mendaro,* [2]*Immunology, Donostia Universitary Hospital, Donostia,* [3]*Gastroenterology, Mondragon Hospital, Mondragon, Spain*
E-mail: agustincastiella@yahoo.es

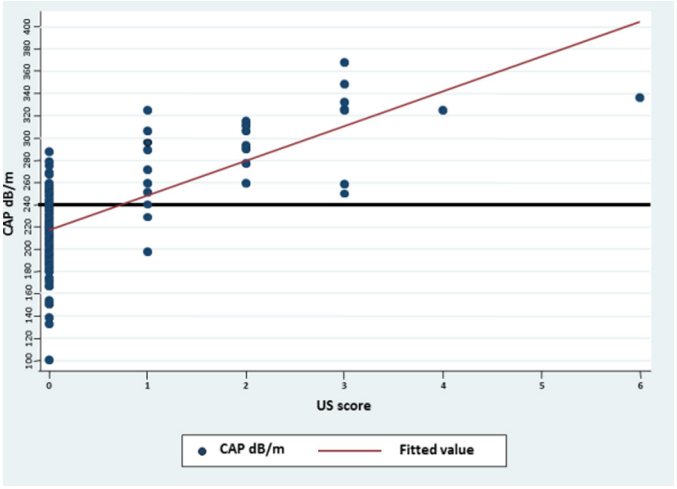
Background and Aims: Nearly 25% of adult population in western countries have the metabolic syndrome (MS). Hyperferritinemia (HF) is frequently present in patients with this clinical entity (dysmetabolic hyperferritinemia). The presence of mutations in the HFE gene, like the H63D/H63D mutation, may induce MS in these patients.
Methods: A prospective study of 132 consecutive patients with HF (>200 μg/L women, >300 μg/L men) was conducted from January to December 2010. The Metabolic syndrome was defined by the presence of waist circumference – ≥94 cm men, ≥80 cm women, and two of the following factors: triglycerides ≥150 mg/dL or treatment for this dislipidemia; HDL <40 mg/dL women, <50 mg/dL men or treatment for this dislipidemia; glucose ≥100 mg/dL or type 2 diabetes; hypertension: blood pressure ≥130 mmHg/≥85 mmHg or treatment for arterial hypertension. DNA was extracted from the blood samples and *HFE* gene analysis was performed by multiplex real-time PCR using LightCycler technology (LC 1.0). Simultaneous detection of the *HFE* C282Y, H63D and S65C mutations was carried out in a single capillary using LC-Red 640, LC-Red 705 and fluorescein-labelled hybridization probes (Tibmolbiol, Berlin, Germany). Melting curve analysis was used to distinguish wild type and mutant alleles in each case. The results were compared with a control group of blood donors from the same geographical area.
Results: In 97 of 132 patients we have all the data to determine the MS presence: 44/80 men (55%) and 10/17 women (59%) presented MS. The HFE mutations from 51/54 patients with MS were: 2 C282Y/wt (3.92%); 11 H63D/H63D (21.56%); 15 H63D/wt (29.41%); 3 C282Y/H63D (5.88%); 19 wt/wt (37.25%); 1 S65C/ wt (1.96%). The genotype frequency of the H63D/H63D mutation in MS cases was significantly higher than in controls (7) – 21.56% vs 7.76% ($p = 0.011$); the H63D allelic frequency was 42.15% in the MS group and 31% in controls ($p = 0.027$).
Conclusions: The H63D/H63D genotype and H63D allele predispose individuals with HF to MS.

P1008

VALUE OF CONTROLLED ATTENUATION PARAMETER (CAP) IN THE CLINICAL PRACTICE: PRELIMINARY RESULTS

G. Ferraioli[1], R. Lissandrin[1], C. Tinelli[2], E. Above[3], C. Dellafiore[3], M. Di Gregorio[1], G. Poma[3], M. Zicchetti[1], R. Maserati[3], C. Filice[1]. [1]*Infectious Diseases Dept, Fondazione IRCCS Policlinico San Matteo, University of Pavia,* [2]*Clinical Epidemiology and Biometric Unit,* [3]*Infectious Diseases Dept, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy*
E-mail: giovanna.ferraioli@unipv.it

Background and Aims: Several studies have shown that controlled attenuation parameter (CAP), a new technique that noninvasively estimates the fat in the liver, is accurate in detecting liver steatosis. The aim of this study was to assess the role of CAP in the clinical practice.
Methods: Consecutive patients referred to the Ultrasound Unit of the Infectious Diseases Dept. of our Institution for abdominal ultrasound (US) examination were enrolled. Liver steatosis was assessed with US by using the Hamagouchi score, which is a 6-point scale. CAP was performed in all subjects by using the M+ probe of the FibroScan device (Echosens, Paris, France). For the detection of liver steatosis, US and CAP score greater than 0 and greater than 240 dB/m, respectively, were considered. A 2×2 contingency table and the Students *t* test were used to compare the group differences. Spearman rank coefficient was used to test correlation between CAP and US. Data were expressed as means and standard deviations.
Results: One hundred and thirty-three subjects [74 males and 59 females; mean age, 51.2 (SD: 13.9) yrs; BMI, 24.4 (6.5) kg/m^2] were studied. CAP measurements were not obtained in 6/133 (4.5%) of subjects due to skin to liver capsule distance >25 mm, thus the data of 127 subjects were analyzed. CAP and US were highly correlated ($r = 0.61$, $p < 0.0001$). US detected liver steatosis in 26/127 (20.5%) subjects; they showed a significantly higher CAP value with respect to subjects without US liver steatosis [291.7 (40.5) vs 214.4 (33.3) dB/m, $p < 0.0001$]. CAP was >240 dB/m in 22/101 (21.8%) subjects in whom liver steatosis was not detected at US. CAP was ≤240 dB/m in three subjects with liver steatosis assessed with US; these subjects showed liver stiffness values of 7.6, 8.7 and 11.5 kPa. In detecting liver steatosis, US had 51.1% sensitivity and 96.3% specificity.
Conclusions: These preliminary results show that CAP is more sensitive than US in the detection of liver steatosis. Liver fibrosis could be a confounding factor in the US detection of liver steatosis.



P1009

INCIDENCE OF MAJOR CARDIOVASCULAR AND CEREBRAL EVENTS IN PATIENTS WITH NAFLD AND IN CONTROLS OF GENERAL POPULATION DURING 10 YEARS OF FOLLOW UP: CORRELATION BETWEEN VASCULAR AND LIVER DAMAGE

G. Pisano[1], S. Tiraboschi[1], R. Lombardi[1], C. Bertelli[1], L. Valenti[1], A. Baragetti[2], L. Grigore[2], M. Porzio[1], A. Catapano[3], S. Fargion[1], A.L. Fracanzani[1]. [1]*Department of Pathophysiology and Transplantation, Maggiore Policlinico Hospital Foundation IRCCS, University of Milan,* [2]*Centro Studi Aterosclerosi Department of Pharmacological and Biomolecular Sciences, Multimedica IRCCS, University of Milano,* [3]*Centro Studi Aterosclerosi Department of Pharmacological and Biomolecular Sciences, Multimedica IRCCS, University of Milano, Milan, Milan, Italy*
E-mail: anna.fracanzani@unimi.it

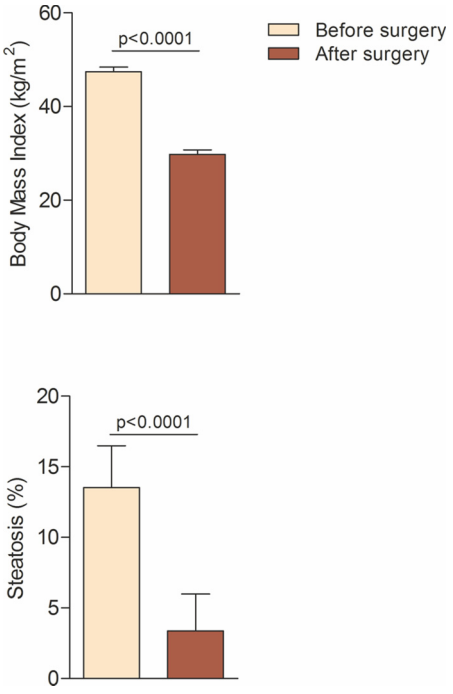
Background and Aims: NAFLD represents a risk factor for vascular damage. Carotid intima-media thickness (cIMT) is a known precursor of cardiovascular disease. Aims: to evaluate (1) risk factors affecting the progression of cIMT and early carotid plaques (CP) in patients with NAFLD and in a control group from general population, (2) incidence of major cardiovascular and cerebral events in ten years of follow up, (3) correlation between vascular and liver damage.

Methods: 125 patients with NAFLD diagnosed by ultrasonography matched 1:2 for sex and age with subjects from general population underwent vascular evaluation in 2003 and were prospectively followed for a period of 10 years. In all subjects cIMT by echo color doppler, clinical and biochemical data were evaluated at enrollment (time 0). After 10 years follow-up (time 1), 90/125 patients with NAFLD and 182/250 controls underwent abdominal ultrasonography to evaluate the presence of liver steatosis and a second cIMT measurements and CP evaluation, the remaining patients were lost at follow up. All clinical, biochemical data were recorded at time 0 and time 1.
Results: At enrollment cIMT was significantly more elevated in NAFLD than in controls (0.87±0.23 vs 0.64±0.14, p = 0.001) and the prevalence of CP significantly higher (21% vs 6%, p = 0.001). After 10 years 54/182 (30%) controls developed steatosis. cIMT remained significantly more elevated in NAFLD than in controls who developed steatosis (0.95±0.21 and 0.8±0.13 mm, p = 0.004), while the higher prevalence of plaques was observed in controls who developed steatosis (50%, 46% and 60%, in NAFLD, controls without and controls with steatosis respectively). Thirty-five subjects developed major cardiovascular and cerebral events, the prevalence was significantly higher in NAFLD and in controls with steatosis (p = 0.02). At logistic regression analysis variables significantly associated with events were age unit (OR 1.01, 95% CI 1.02–1.1, p = 0.004), systolic pressure (OR 1.05, 95% CI 1.01–1.08, p = 0.004), the presence of plaques (OR 3.78, 95% CI 1.5–8.8, p = 0.002) and basal ALT >35 (OR 3.7, 95% CI 1.08–14, p = 0.03).
Conclusions: Subjects of general population are at high risk of developing steatosis throughout their life, major cardiovascular events have the same prevalence in NAFLD and controls with the higher prevalence in controls who developed steatosis and are related with liver damage. All subjects with steatosis have to be considered at high risk for cardiovascular complications.

P1010
INFLAMMATION, OXIDATION AND ECTOPIC FAT ACCUMULATION IN MORBID OBESITY

M. Guirro[1], E. Rodríguez-Gallego[1], A. Hernández-Aguilera[1], R. Mariné-Casadó[1], F. Luciano-Mateo[1], S. Fernández-Arroyo[1], J. Joven[1]. *[1]Unitat de Recerca Biomèdica, Institut d'Investigació Sanitària Pere Virgili, Universitat Rovira i Virgili, Reus, Spain*
E-mail: maria.guirro@gmail.com

Background and Aims: Obesity severely affects human health. Non-alcoholic fatty liver disease (NAFLD) is associated with high morbidity and mortality and is characterized by the presence of increased amounts of fat in the liver (steatosis). The deleterious effects of the excessive energy intake are associated with inflammation and oxidation. Chemokine (C-C motif) ligand 2 (CCL2) is known to play a critical role in the migration of inflammatory cells and paroxonase-1 (PON1) and 4-hydroxynonenal (4-HNE) are related in lipid peroxidation and oxidative stress. The aim of this study was to better understand the pathogenesis of NAFLD in morbid obesity.
Methods: Patients undergoing bariatric surgery following procedures involving laparoscopic sleeve gastrectomy were recruited as a model of obesity-induced NAFLD in an observational, prospective, single-site, and cross-sectional study with a pre-set duration of 1 year. Samples were obtained in these patients immediately before undergoing bariatric surgery and after a 12-month period. Relevant data like BMI and histological features in the liver were obtained prospectively and surrogate markers of inflammation and lipid peroxidation (CCL2, PON1 and 4-HNE) were analysed in the liver by immunochemical staining analysis.
Results: We found a significant decrease in steatosis after surgery and also BMI was considerably reduced. In addition, the presence of CCL2, PON1 and 4-HNE was significantly increase in liver obtained before bariatric surgery compared to samples obtained after a 12-month period.
Conclusions: Bariatric surgery seems to reverse the progression of NAFLD since BMI, steatosis and the presence of inflammation and lipid peroxidation markers decrease in the liver of morbid obese patients after 12-month period of the surgery.



P1011
FIBROSCAN IS A USEFUL CLINICAL TOOL TO EXCLUDE SIGNIFICANT STEATOSIS IN CHRONIC LIVER DISEASE PATIENTS

M. Lupsor-Platon[1], D. Feier[1], H. Stefanescu[2], A. Tamas[1], E. Botan[3], R. Badea[1]. *[1]Medical Imaging, [2]Hepatology, [3]Pathology, Regional Institute of Gastroenterology and Hepatology Prof. Dr. Octavian Fodor, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania*
E-mail: monica.lupsor@umfcluj.ro

Background and Aims: Steatosis is a common histological finding in patient with chronic liver disease (CLD). Its detection is relevant because it may progress to fibrosis, cirrhosis, and hepatocellular carcinoma A novel non-invasive tool for steatosis assessment, called controlled attenuation parameter (CAP), is based on the evaluation of ultrasound attenuation using transient elastography (TE). We aim to establish utility of CAP in predicting each steatosis grade.
Methods: 225 CLD patients (48 with HBV, 130 with HCV, 47 with NASH), mean age 52 years, 63% females, were enrolled. All of them underwent percutaneous liver biopsy (LB) for grading and staging the disease and were referred for CAP measurement, 1 day prior to LB. In all patients, steatosis was categorized by visual assessment as S0: steatosis in less than 10% of hepatocytes, S1: 11%>33%, S2: 34%>66% and S3: 67%>100% of hepatocytes. The median size of the LB specimens was 15 (12–20) mm, with a median of 14 (10–22) portal spaces. The diagnostic performance of CAP for steatosis prediction was assessed using sensitivity (Se), specificity (Sp), positive (PPV) and negative predictive value (NPV), positive (+LR) and negative (−LR) likelihood ratios and area under ROC curves (AUC).
Results: The median (range) CAP values (dB/m) according to the steatosis grades were: 212 (124–359) for S0; 266 (153–353) for S1; 304 (215–359) for S2 and 321 (218–377) for S3. The differences were statistically significant between

all the steatosis grades, except S2 vs S3. The diagnostic performances of CAP in quantifying each steatosis grade was: for S ≥1 AUC = 0.813 (cutoff 260 dB/m, Se = 64.84%, Sp = 87.27%, PPV = 80.8%, NPV = 75%, +LR = 5.09, −LR = 0.40, DA = 76.11%); for S ≥2 AUC = 0.822 (cutoff 285 dB/m, Se = 69.70%, Sp = 85.12%, PPV = 47.9%, NPV = 93.5%, +LR = 4.68, −LR = 0.36, DA = 82.08%); for S ≥3 AUC = 0.838 (cutoff 294 dB/m, Se = 83.33%, Sp = 82.54%, PPV = 23.3%, NPV = 98.7%, +LR = 4.77, −LR = 0.20, DA = 81.59%). AUCs calculated between two steatosis grades only were: 0.772 (for S0 vs S1), 0.874 (S0 vs S2), 0.904 (S0 vs S3), 0.659 (S1 vs S2), 0.777 (S1 vs S3), and 0.665 (S2 vs S3) respectively.
Conclusions: Maximal diagnostic accuracy could be obtained for the prediction of ≥S2 and S3 (82.06% and 81.59% respectively) while, for the prediction of ≥S1, the accuracy reached only 76.11%. CAP has a high negative predictive value (93.5% and 98.7% respectively) for ≥S2 and S3, which suggests that CAP could be an useful clinically tool to exclude these steatosis grades.

P1012
PROSPECTIVE COMPARISON OF NONINVASIVE FIBROSIS ASSESSMENT TO PREDICT ADVANCED FIBROSIS OR CIRRHOSIS IN ASIAN PATIENTS WITH NAFLD

S.K. Joo[1], W. Kim[1], S. Oh[2], H.Y. Kim[1]. *[1]Hepatology, [2]Biostatistics, Seoul National University Hospital Seoul Metropolitan Government Boramae Medical Center, Seoul, Korea, South*
E-mail: joo.sammy@gmail.com

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is one of the major causes of liver disease worldwide. Its prevalence continues to rise, and it threatens to become a serious health problem. This study aimed to evaluate the diagnostic accuracy of noninvasive fibrosis assessment to predict advanced fibrosis or cirrhosis in Asian patients with NAFLD.
Methods: One hundred sixteen patients with a liver biopsy-confirmed diagnosis of NAFLD were prospectively evaluated between March 2013 and September 2014. Liver stiffness measurement (LSM) was performed by acoustic radiation force impulse (ARFI) elastography in all patients. Aspartate aminotransferase to alanine aminotransferase ratio (AAR), Fib-4, aspartate aminotransferase to platelet ratio index (APRI), NAFLD fibrosis score and BARD scores were calculated according to published algorithms. Diagnostic measurements of serum fibrosis indices and ARFI imaging were compared to predict advanced fibrosis or cirrhosis by analyzing the area under the receiver operating characteristic (AUROC) curve.
Results: The median age of the study population was 54.3 years (range, 18–78). Fib-4, NAFLD fibrosis score, BARD score and LSM showed significant, positive correlations with METAVIR stages (P < 0.001). LSM by ARFI had the greatest AUROC for predicting advanced fibrosis (≥F3) (0.883; 95% CI, 0.804–0.961) and cirrhosis (F4) (0.926; 95% CI, 0.848–1.000). And Fib-4 had the good AUROC for predicting cirrhosis (F4) (0.873; 95% CI, 0.803–0.942). A tendency toward increasing liver stiffness existed in a graded fashion across METAVIR stages (P < 0.001).
Conclusions: Liver stiffness by ARFI was useful noninvasive fibrosis assessment for predicting advanced fibrosis and cirrhosis in Asian patients with NAFLD. In addition, A Fib-4 exhibited acceptable diagnostic performance in the assessment of hepatic fibrosis in patients with NAFLD.

CHRONIC INTERMITTENT HYPOXIA IS ASSOCIATED WITH LIVER DAMAGE AND ATHEROSCLEROSIS IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE

S. Petta[1], O. Marrone[2], D. Torres[3], M. Buttacavoli[4], C. Cammà[1], V. Di Marco[1], A. Licata[1], A. Lo Bue[2], G. Parrinello[3], A. Pinto[3], A. Selvaggio[2], A. Tuttolomondo[3], A. Craxì[1], M.R. Bonsignore[4]. *[1]Section of Gastroenterology, Di.Bi.MI.S University of Palermo, Italy; [2]National Research Council, Institute of Biomedicine and Molecular Immunology, Palermo, Italy; [3]Sezione di Medicina Interna, DiBiMIS, University of Palermo, Italy; [4]Sezione di Pneumologia, DiBiMIS, University of Palermo, Italy, Palermo, Italy*
E-mail: petsa@inwind.it

Background and Aims: Obstructive sleep apnea syndrome (OSAS) has been reported as a new risk factor for metabolic disturbances, including clinical and subclinical cardiovascular alterations. Growing data are also available among bariatric nonalcoholic fatty liver disease (NAFLD) patients on the impact of obstructive sleep apnea syndrome OSAS on liver damage in NAFLD. We assessed whether OSAS is associated with severity of liver fibrosis and carotid atherosclerosis in NAFLD patients without morbid obesity.
Methods: 126 consecutive biopsy-proven (Kleiner score) NAFLD patients assessed for anthropometric, biochemical, and metabolic features underwent ultrasonographic carotid assessment and STOP BANG questionnaire for estimate of low or high OSAS risk. A carotid plaque was defined as a focal thickening >1.3 mm at the level of either common and internal carotid arteries or bifurcations. 50 patients accepted to perform nocturnal cardiorespiratory polygraphy, and OSAS was defined as an apnea/hypopnea index (AHI) ≥5.
Results: The prevalence of high OSAS risk was similar in patients without and with polygraphy (76% vs 68%, p = 0.17). Among these last subjects who underwent polygraphy 50% had OSAS. The prevalence of OSAS was significantly higher in patients with, than in those without, F2–F4 fibrosis (72% vs 44%, respectively; p = 0.04). After correction for confounders, significant fibrosis was associated with mean oxyhemoglobin saturation (SaO2) levels <95% (OR 3.21, 95% CI 1.02–7.34; p = 0.04). Similarly, the prevalence of OSAS was slightly higher in patients with, than in those without, carotid plaques (64% vs 40%; p = 0.08). After correction for confounders, the association between carotid plaques and time spent with SaO2 <90% (T90) >1% was maintained (OR 6.30, 95% CI 1.02–12.3; p = 0.01).
Conclusions: In NAFLD patients without morbid obesity OSAS was highly prevalent and indexes of oxygen saturation were independent indicators of the severity of liver fibrosis and of carotid atherosclerosis risk. These data, if further validated, could suggest to look for OSAS in all NAFLD patients, considering OSAS as a potential additional therapeutic target for NAFLD.

ASSESSING BIAS IN A MAGNETIC RESONANCE IMAGING METHOD FOR MEASUREMENT OF LIVER FAT FRACTION

T. St Pierre[1], M. House[1], S. Bangma[2], W. Pang[2], E. Gan[3,4], L. Adams[3,5], O. Ayonrinde[3,4], P. Bhathal[6], J. Olynyk[4,7]. *[1]School of Physics, The University of Western Australia, Crawley, [2]Resonance Health Ltd, Claremont, [3]School of Medicine & Pharmacology, The University of Western Australia, Crawley, [4]Department of Gastroenterology, Fremantle Hospital, Fremantle, [5]Liver Transplant Unit, Sir Charles Gairdner Hospital, Nedlands, [6]Department of Pathology, The University of Melbourne, Melbourne, [7]Institute for Immunology & Infectious Diseases, Murdoch University, Murdoch, Australia*
E-mail: Tim.StPierre@uwa.edu.au

Background and Aims: Most MRI and MRS methods of assessing fatty liver report a ratio of fat protons to water protons. While there can be good correlations between such measures and biopsy observations of liver fat, the two measurements are inherently

measuring different quantities and so bias cannot be assessed directly. The recently cleared (FDA, CE Mark, and TGA) HepaFat-Scan MRI method reports a volumetric fraction of liver tissue that is fat, a measure that can be directly compared with measurements from biopsy histological sections. This study measures the degree of bias of the HepaFat-Scan method against unbiased stereological measurements from biopsies. Stereological analysis (SA) is a method of obtaining unbiased estimates of volume fractions of a phase of material in a 3D matrix from a cross section through the matrix.

Methods: Volumetric fractions of fat in liver tissue of 59 patients (autoimmune hepatitis 3, alcoholic liver disease 2, viral hepatitis 16, NAFLD 10, NASH 17, normal 3, primary sclerosing cholangitis 4, other 4) recruited from the hepatology outpatient clinics at Fremantle and Sir Charles Gairdner Hospitals (Western Australia) were measured by SA of digital images of histological sections of liver biopsies and with non-invasive HepaFat-Scan measurements. Bland–Altman (BA) statistics were used to assess the bias between the two methods of measurement. A steatosis grade for each biopsy was also assessed by an experienced hepatopathologist. ROC curve analysis was used to determine sensitivity and specificity of HepaFat-Scan for predicting steatosis grade.

Results: Figure 1 shows a plot of the volumetric fraction of fat measured by HepaFat-Scan plotted against that measured by SA of biopsy histological sections. The straight line is the line of equivalence (not a fitted regression line). BA analysis indicates a small systematic bias with HepaFat-Scan reporting volumetric liver fat fractions 1.4% higher than SA of biopsy. Sensitivities, specificities and areas under ROC curve for HepaFat-Scan predicting steatosis grade >0 were 97%, 96%, and 0.963; >1 were 100%, 94%, and 0.996; and >2 were 100%, 88%, and 0.971.

Conclusions: The 1.4% bias between HepaFat-Scan and SA of biopsy is not clinically significant since it represents less than 5% of the overall range of fat fractions measured. The observed high sensitivities and specificities indicate that overall accuracy of HepaFat-Scan is sufficient for clinical patient management.

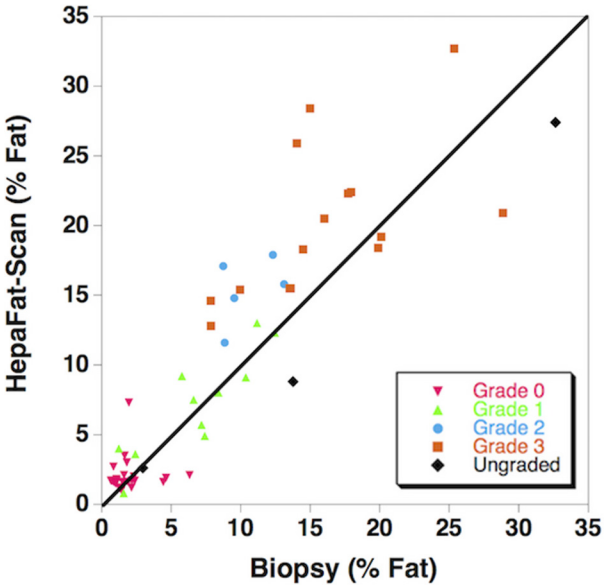

Figure 1.

P1016

FACTORS ASSOCIATED WITH THE DEVELOPMENT OF FATTY LIVER OR GLUCOSE INTOLERANCE

A. Moriya[1], Y. Iwasaki[2], S. Ohguchi[3], E. Kayashima[3], T. Mitsumune[3], H. Taniguchi[4], M. Ando[1]. *[1]Department of Medicine, Mitoyo General Hospital, Kanonji, [2]Health Service Center, Okayama University, [3]Junpukai Health Maintenance Center, Okayama, [4]Department of Medicine, Tottori Municipal Hospital, Tottori, Japan*
E-mail: moriyaakio@gmail.com

Background and Aims: Non-alcoholic fatty liver (NAFLD) is a phenotype of the metabolic syndrome in the liver; insulin resistance is the key mechanism of the metabolic syndrome. On the other hand, insulin resistance is also further exacerbated by the development of NAFLD. NAFLD and insulin resistance are supposed to influence each other. However, some patients have only either fatty liver (FL) or impaired glucose intolerance (IGT), although the other one is likely to develop over time. We hypothesized that there are possibly any differences between cases with FL first followed by IGT and those with IGT first followed by FL.

Methods: We obtained clinical and laboratory data from Japanese subjects (3431 men and 1997 women; median age, 47 years old) who serially underwent annual health checkups with ultrasonography in 2009 and 2010 in Junpukai Health Maintenance Center. IGT was defined as fasting plasma glucose level ≥100 mg/dL or use of medications for diabetes mellitus. We analyzed cases with either FL or IGT to determine the factors associated with the development of the other one using logistic regression analysis. We also made a comparison between cases with FL first followed by IGT and those with IGT first followed by FL using Fisher's exact test or Welch's t test.

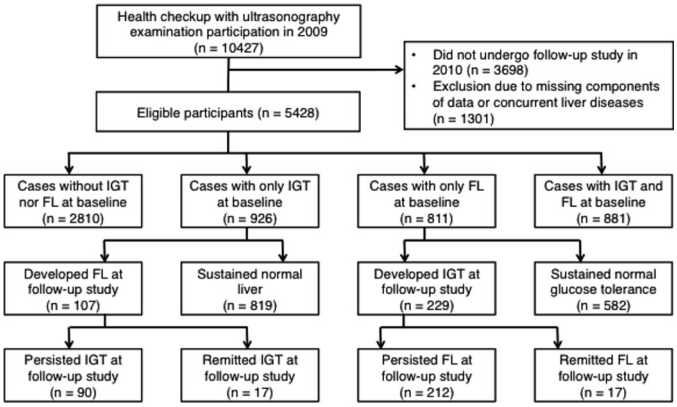

Figure: Inclusion and exclusion flow chart.

Results: In cases with IGT at baseline, 107 out of 926 (12%) newly developed FL; obesity (OR, 2.85; 95% CI, 1.74–4.58) and dyslipidemia (OR, 1.68; 95% CI, 1.07–2.59) were directly, and habitual exercise (OR, 0.61; 95% CI, 0.40–0.91) was inversely associated with the development of FL. Meanwhile, in cases with FL at baseline, 229 out of 811 (28%) newly developed IGT; dyslipidemia (OR, 1.41; 95% CI, 1.03–1.93), male sex (OR, 1.84; 95% CI, 1.22–2.86), and age (1-year increments; OR 1.02; 95% CI, 1.01–1.04) were associated with the development of IGT. In comparison between the cases with IGT first followed by FL and the cases with FL first followed by IGT, the former were significantly elder (51 years old vs. 47 years old, $P = 0.012$) and the latter had significantly higher prevalence of obesity (29% vs. 53%, $P < 0.001$) and dyslipidemia (36% vs. 50%, $P = 0.032$) at baseline.

Conclusions: Obesity and dyslipidemia possibly contribute especially to the development of FL, while aging does to that of IGT.

P1017

CIRCULATING SCLEROSTIN AND DICKKOPF-1 IN PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE

S.A. Polyzos[1], A.D. Anastasilakis[2], E. Terpos[3], P. Makras[4], A. Papatheodorou[5], P. Kokkoris[5], J. Kountouras[1]. *[1]Second Medical Clinic, Aristotle University of Thessaloniki, [2]Endocrinology, 424 General Military Hospital, Thessaloniki, [3]Department of Clinical Therapeutics, University of Athens School of Medicine, [4]Endocrinology and Diabetes, [5]Medical Research, 251 Hellenic Air Force & VA General Hospital, Athens, Greece*
E-mail: stergios@endo.gr

Background and Aims: There is evidence for possible bidirectional interplay between hepatic and bone metabolism. The primary aim of this study was to evaluate the serum sclerostin and dickkopf (DKK)-1 levels in patients with nonalcoholic fatty liver disease (NAFLD), untreated for metabolic bone disease, and their association with the disease severity.
Methods: Thirteen and 14 patients with biopsy-proven nonalcoholic simple steatosis (SS) and steatohepatitis (NASH), respectively, and 20 controls of similar gender, age, body mass index (BMI) and waist circumference (WC) were consecutively enrolled. Serum sclerostin, DKK-1, bone-specific alkaline phosphatase (BALP), carboxy-terminal telopeptides of Type I collagen (CTX), 25-hydroxy vitamin D [25(OH)D] and insulin, as well as standard biochemical and hematologic tests were measured. Lumbar spinal (LS) dual energy X-ray absorptiometry (DXA) was also performed.
Results: There was a trend towards decrease in serum sclerostin levels from the controls (76.1±6.8) to SS (53.5±6.4) and NASH (46.0±8.1 pmol/l) patients (p = 0.009); in adjusted pairwise comparisons (Bonferroni correction), sclerostin was significantly higher in the controls than NASH patients (p = 0.012), whereas not statistically different between controls and SS (p = 0.091), or SS and NASH patients (p = 1.0). Serum DKK-1 did not differ between groups (p = 0.135), though it showed a trend for U-shaped distribution (controls 35.8±2.8; SS 27.3±2.9; NASH 36.8±4.4 pmol/l). There was not between group differences in age, BMI, WC, BALP, CTX, 25(OH)D, and LS DXA, whereas liver function tests, insulin and insulin resistance, as expected, were progressively increased from the controls to SS and NASH. After adjustment for gender, BMI, age, log(alanine aminotransferase), CTX, white blood cells and erythrocyte sedimentation rate, between group differences remained significant for sclerostin, and non-significant for DKK-1. Regarding specific histological lesions, DKK-1 levels were marginally lower in NAFLD patients with lower (≤33%) steatosis grade (27.7±3.1) than those with steatosis >33% (38.8±4.7 pmol/l; p = 0.049). No statistically significant differences of sclerostin or DKK-1 were observed in fibrosis grade, portal or lobular inflammation or ballooning.
Conclusions: Serum sclerostin levels were lower in NASH patients compared to the controls, whereas similar DKK-1 levels were observed between groups. These findings warrant further research.

P1018

SIGNIFICANT CORRELATION BETWEEN VISCERAL FAT AREA AND CONTROLLED ATTENUATION PARAMETER

K.S. Jung[1], K.J. Kim[2], J.Y. Park[1], Y.E. Chon[1], B.K. Kim[1], S.U. Kim[1], D.Y. Kim[1], S.H. Ahn[1], K.-H. Han[1]. *[1]Department of Internal Medicine, [2]Division of Endocrinology, Yonsei University College of Medicine, Seoul, Korea, South*
E-mail: jks1029@yuhs.ac

Background and Aims: This study is designed to investigate the relationship between controlled attenuation parameter (CAP) and visceral fat area (VFA).
Methods: A total of 304 consecutive patients who underwent both of transient elastography and abdominal fat CT during regular health check up at one tertiary center in Korea were enrolled prospectively. To obtain VFA, the visceral and peripheral adipose regions were calculated according to the intervertebral position of L4–5. Clinical, metabolic measurement, and laboratory data were also evaluated. In this study, significant steatosis is defined when CAP value is ≥250 dB/m.
Results: The mean age (165 male, 139 female) was 56.5 years and mean body mass index (BMI) was 24.1 kg/m^2. Twenty-two patients (7.2%) had diabetes mellitus and 44 (14.5%) had hypertension. In univariate analysis, the patients with significant hepatic steatosis had higher BMI, waist/hip ratio, VFA, peripheral fat area, fasting glucose level, triglyceride (TG) level, and alanine aminotransferase (ALT) levels (all $P < 0.05$). In multivariate analysis, VFA (odds ratio [OR] 1.010; 95% confidence interval [CI] 1.001–1.019; $P = 0.028$) and TG (OR 1.006; 95% CI 1.001–1.011; $P = 0.022$) were selected as independent risk factor for significant hepatic steatosis. When the study population was stratified into three groups (VFA ≤100 cm^2, VFA 100.1–200 cm^2, VFA >200 cm^2), patients with a higher VFA were at a greater risk of significant hepatic steatosis with OR 4.838 (P < 0.001; 95% CI 2.912–8.039) for VFA 100.1–200 cm^2; OR 7.474 (P < 0.001; 95% CI 2.462–22.693) for VFA >200 cm^2. In sub analysis of 110 patients with BMI <23 kg/m^2, only VFA was significantly related with hepatic steatosis (OR 1.006; 95% CI 1.001–1.011; P = 0.022).
Conclusions: Our data demonstrated that VFA was significantly related with significant hepatic steatosis assessed by CAP, suggesting that surveillance of hepatic steatosis is needed for patients with central obesity.

P1019

THE IMPACT OF METABOLIC SYNDROME ON ALT LEVELS AMONG THE LARGE MULTIETHNIC COHORT OF NORTH AMERICAN PATIENTS WITH CHRONIC HEPATITIS B INFECTION ENROLLED IN THE HEPATITIS B RESEARCH NETWORK (HBRN)

M. Khalili[1], M. Lombardero[2], J. Feld[3], M. Shuhart[4], R. Chung[5], N. Terrault[1], K. Kowdley[6], M. Lisker-Melman[7], M. Ghany[8], W.R. Kim[9], A. Sanyal[10], A. Lok[11], Hepatitis B Research Network (HBRN).
[1]University of California San Francisco, San Francisco, [2]University of Pittsburgh, Pittsburgh, United States; [3]University of Toronto, Toronto, Canada; [4]University of Washington, Seattle, [5]Massachusetts General Hospital, Boston, [6]Swedish Medical Center, Seattle, [7]Washington University, St. Louis, [8]National Institutes of Health, Bethesda, [9]Stanford University, Palo Alto, [10]Virginia Commonwealth University, Richmond, [11]University of Michigan, Michigan, United States
E-mail: mandana.khalili@ucsf.edu

Background and Aims: Due to rise in obesity, metabolic syndrome (MS) is prevalent in western countries affecting about 25% of adults in United States. MS is associated with adverse liver disease outcomes including disease progression and hepatocellular carcinoma (HCC). However, the impact of MS on liver disease markers among patients with chronic hepatitis B infection (CHB) living in North America (NA) have not been well studied. We sought to determine the prevalence of MS and its influence on ALT levels at cohort entry and change in ALT over time in a large multi-ethnic NA cohort of patients infected with HBV.
Methods: Adult patients with CHB (HBsAg+ >6 months) who were not pregnant and without liver decompensation, HCC, liver transplant, HIV or current antiviral therapy from 21 US/Canada centers were evaluated. MS was defined as presence of at least 3 of the 5 standard criteria including high population-based waist circumference, blood pressure, glucose and triglyceride levels, and low HDL. Data were assessed at baseline and ALT and HBV DNA were followed over a median of 2.3 years.
Results: 973 patients were included in the analysis: median age 43 yrs, 48% female, 73% Asian (12% black, 11% white), and 82% were born outside US/Canada (28% migrated >20 yrs ago). Participants had a mean of 3 ALT measurements. MS was present in 20% and

those with MS were older (median age 55 vs 40 yrs), more likely to be male (59% vs 51%) black (20% vs 10%), and have HBV DNA <20,000 IU/mL (69% vs 54%), but less likely to be HBeAg-positive (14% vs 29%). In multivariable analysis adjusted for age, gender, race, alcohol use, HBV DNA, and HBeAg, ALT levels at baseline were 1.13 times higher in those with MS than those without MS (log_2 ALT estimate 0.17, 95% CI 0.001–0.35, p = 0.049). However, when controlling for age, gender, race at baseline and HBV DNA levels over time, MS had no significant effect on change in ALT levels over time (log_2 ALT estimate 0.08, p = 0.1); this result was independent of baseline ALT and constant over time.
Conclusions: In this large NA multi-ethnic cohort with chronic HBV, MS was prevalent and was associated with higher baseline ALT levels. Although MS did not influence change in ALT over short term, longer follow-up maybe needed to better characterize the full impact of MS on ALT over time. These results highlight importance of interventions to reduce ALT through weight loss and viral suppression especially among at-risk ethnic minorities and older patients.

P1020
EFFECTS OF URSODEOXYCHOLIC ACID AND PIOGLITAZONE LONG THERAPY ON HEPATOCYTES CHANGES IN NASH PATIENTS
N. Virstyuk[1], O. Deltsova[2], S. Geraschenko[2], L. Kovalchuk[3]. *[1]Therapy, [2]Histology, [3]Medical Biology and Genetics, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine*
E-mail: natalya1727@rambler.ru

Background and Aims: The aim of this study was to investigate the effects of ursodeoxycholic acid (UDCA) and pioglitazone long therapy on electronomicroscopic, morphometrical and cytogenetic changes of hepatocytes and insulin resistance (IR) in NASH patients.
Methods: In 27 NASH patients [age 47.3±6.9 yr; body mass index (BMI) 33.9±3.5 kg/m^2] and 12 healthy volunteers [age 44.3±5.5 yr; BMI 24.2±2.8 kg/m^2] obesity and IR were determined by BMI and HOMA-IR. Circulating insulin levels were measured by the immuno-assay method. Electron-microscopic, morphometrical, cytogenetic examinations of hepatocytes and hepatocyte nuclei were investigated. 15 NASH patients were treated with 10–15 mg/kg/day of UDCA (group I), 12 NASH patients were treated with 10–15 mg/kg/day of UDCA + pioglitazone 15–30 mg/day for two years (group II).
Results: After therapy, the condensed chromatin content was decreased in hepatocyte nuclei in group II (p < 0.05). The quantity of the pathologically changed nuclei was decreased in hepatocytes more than 2.6 times and 1.3 times (p < 0.05) in groups I and II vs. patients before treatment. In group II the area of the hepatocytes profile (AHP) was increased – up to 176.40±13.08 μm^2 vs. 128.73±11.74 μm^2 (p = 0.01) before treatment and vs. 182.17±2.54 μm^2 (p > 0.05) in control; in group I – 138.84±11.76 μm^2 vs. 129.25±11.03 μm^2 (p > 0.05) before treatment and vs. 182.17±2.54 μm^2 (p = 0.03) in control. After therapy, one patient (8.33%) in group II and eight (53.33%) in group I had an AHP from 50.0 to 150.0 μm^2 vs. 10 (83.3%) and 12 (80.0%) patients accordingly before treatment; in healthy volunteers AHP ranged from 100.0 to 250.0 μm^2 (85.42%). The area of the nuclear profile of NASH patients in group II was increased – up to 32.45±2.89 μm^2 vs. 21.52±2.17 μm^2 (p = 0.03) and vs. 35.32±0.60 μm^2 in control (p > 0.05), in group I – 25.86±2.45 μm^2 vs. 21.83±2.15 μm^2 (p > 0.05) before treatment and vs. 35.32±0.60 μm^2 in control (p = 0.04). Compared with group I, HOMA-IR increased in group II after UDCA + pioglitazone therapy (p < 0.02).
Conclusions: The UDCA + pioglitazone combination in long-term use for two years has metabolic effects with beneficial cytoprotective properties and improves electronomicroscopic, morphometrical and cytogenetic markers of the hepatocytes and hepatocyte nuclei in NASH patients.

P1021
EFFECTS OF URSODEOXYCHOLIC ACID AND PIOGLITAZONE LONG THERAPY ON NASH COURSE
N. Virstyuk[1], O. Deltsova[2], S. Geraschenko[2]. *[1]Therapy, [2]Histology, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine*
E-mail: natalya1727@rambler.ru

Background and Aims: Non-alcoholic steatohepatitis (NASH) occurs during the progression of non-alcoholic fatty liver disease. The aim of this study was to investigate the effects of ursodeoxycholic acid (UDCA) and pioglitazone on lipid metabolism, markers of insulin resistance (IR), angiogenesis and fibrosis and histological liver changes in NASH patients.
Methods: In 43 NASH patients [age, 47.2±6.9 yr; body mass index (BMI), 34.4±3.6 kg/m^2] and 12 healthy volunteers [age, 44.3±5.5 yr; BMI, 24.2±2.8 kg/m^2] obesity and IR were determined by BMI, *dyslipidemia* and HOMA-IR. Circulating insulin, leptin, *fibroblast growth factor basic* (FGF-b), vascular endothelial growth factor (VEGF), and type IV collagen levels were measured by the immuno-assay method. Histologic liver changes and morphometrical parameters of the hepatocytes were determined. 16 NASH patients had been without medical treatment (group I), 15 NASH patients were treated with 10–15 mg/kg/day of UDCA for two years (group II), 12 NASH patients were treated with 10–15 mg/kg/day of UDCA+pioglitazone 15–30 mg/day for two years (group III).
Results: In patients of group I a statistically significant increase of HOMA-IR (p = 0.002) and circulating triglycerides (p = 0.009), low density lipoprotein cholesterol (LDLC) (p = 0.007), leptin (p = 0.003), FGF-b (p = 0.007), VEGF (p = 0.005), and type IV collagen (p = 0.01) were noted; this associated with an increase of the histological parameters: steatosis (p = 0.01), inflammation (p = 0.04), ballooning (p = 0.03), and fibrosis (p = 0.01). After treatment, in patients of groups II and III we observed reductions in circulating triglycerides (p = 0.02 vs. p = 0.007), LDLC (p = 0.04 vs. p = 0.009), type IV collagen (p = 0.04 vs. p = 0.01) and histological parameters: steatosis (p = 0.04 vs. p = 0.01), inflammation (p = 0.03 vs. p = 0.009), ballooning (p = 0.03 vs. p = 0.01). Compared with groups I and II, in the UDCA+pioglitazone group HOMA-IR (p = 0.01), circulating leptin (p = 0.02), FGF-b (p = 0.03), and VEGF level (p = 0.01) decreased, which were associated with a reduction in fibrosis (p = 0.02).
Conclusions: The UDCA+pioglitazone combination for two-year use has metabolic, angiogenic, anti-inflammatory and antifibrotic effects in NASH patients and reduces progression of NASH course.

P1022
FIBRO SCAN AND COGNITIVE DYSFUNCTION IN OBESE INDIVIDUALS WITH METABOLIC RISK FACTORS
N. Assy[1,2], A. Abosaleh[3], H. Assly[3], M. Grosovski[4], N. Bar Guy[3]. *[1]Department Med A, Galilee Medical Center, Naharyia, Israel; [2]Faculty of Medicine, Bar Ilan University, Safed, Italy; [3]Liver Unit, Ziv Medical Center, Safed, [4]Biotechnology, Ort Braude College, Carmiel, Israel*
E-mail: assy.n@ziv.health.gov.il

Background and Aims: *Background:* The metabolic syndrome (MS) may be associated with cognitive impairment and increase in oxidative stress. *Aim:* To document the association between MS and cognitive impairment in metabolically healthy obese (MHO), and in metabolically unhealthy obese (MAO) individuals.
Methods: 60 obese individuals aged 49±10 years (52% male) were enrolled. Obesity was defined as BMI >30 kg/m^2. MS was defined according to ATP III guidelines. Obese individuals were divided into two groups: group 1, MHO (≤2 components of MS), and group 2, MAO (>2 components of MS). Cognitive dysfunction was determined by MOCA – Montreal cognitive assessment score (MOCA 11–21, dementia; MOCA 19–25, mild cognitive impairment;

or MOCA 25–30, normal test score). Fibro scan (XL probe), Inflammation (CRP), pro oxidants (MDA), antioxidants activity (PON, GSH) and insulin resistance (HOMA) were measured.
Results: Of the 30 MAO individuals, 13% developed dementia, 51% had mild cognitive impairment, and 36% had normal cognitive score as compared to 3%, 7%, and 90% in the MHO group respectively. There was a significant difference in liver stiffness (Normal <6.0 kPa, 7±3 vs. 5.2±2.7 kPa, $p < 0.001$), liver fat measurement (CAP normal <270 dB/m, 337±51 vs. 280±20, $p < 0.001$), CRP (9±6 vs. 7±6, $P < 0.001$), MDA (5.9±0.8 mM vs 4.3±0.7 mM, $P < 0.01$), Paroxonase (0.06±0.01 mM vs. 0.12±0.08 mM, $P < 0.001$), GSH (27.2±2.4 vs. 28.4±2.3, $P < 0.03$), and HOMA (6±5.5 vs. 2.5±1, $P < 0.02$) levels between the two groups respectively. Correlations between cognitive score and components of MS was strong with blood pressure ($r = -0.252$), abdominal girth ($r = -0.26$), and liver stiffness measurements ($r = -0.256$). Multivariate analysis accounting for confounders showed that Fibro scan ($T = 2.5$), abdominal girth ($T = -2.1$, $P < 0.04$) and age ($T = -3.0$, $P < 0.009$) were the most powerful predictors of cognitive dysfunction.
Conclusions: There is a significant cognitive impairment and increase in oxidative stress in MAO (50%). Whether treatment of MAO would improve cognitive impairment remains to be determined.

P1023
QUANTIFICATION OF LIVER, PANCREAS, KIDNEY AND VERTEBRAL BODY MRI-PDFF IN NONALCOHOLIC FATTY LIVER DISEASE

I.S. Idilman[1], A. Tuzun[2], B. Savas[3], R. Idilman[2], M. Karcaaltincaba[1].
[1]Hacettepe University Faculty of Medicine, [2]Gastroenterology, [3]Pathology, Ankara University School of Medicine, Ankara, Turkey
E-mail: ipolater@yahoo.com

Background and Aims: A recent magnetic resonance technique – magnetic resonance imaging-estimated proton density fat fraction (MRI-PDFF) –gives quantitative information of fat deposition in liver and has been shown to have a good correlation with both magnetic resonance spectroscopy and liver biopsy. Apart from this, it has a potential for quantifying the fat fraction in other tissues. The aim of the present study was to determine liver, pancreas, kidney and vertebral fat deposition in nonalcoholic fatty liver disease (NAFLD) patients by MRI-PDFF and to evaluate the relationships among them.
Methods: A total of 41 biopsy proven NAFLD patients underwent MRI-PDFF with IDEAL-IQ. MRI protocol included T1-independent volumetric multi-echo gradient-echo imaging with T2* correction and spectral fat modeling. The MR examinations were performed on a 1.5 HDx MRI system. MRI-PDFF measurements were obtained from liver, pancreas, renal cortex and sinus and vertebral body. Liver biopsy specimens were retrieved from the archives and evaluated by one pathologist according to NASH-CRN.
Results: The median age of the patients was 47 years. The median interval between liver biopsy and MRI examination was 16 days. Mean liver, pancreas, renal cortex, renal sinus, T12 and L1 vertebral body MRI-PDFF was 18.7%, 5.7%, 1.7%, 51%, 43.2% and 43.5%, respectively. A close correlation was observed between liver MRI-PDFF and histologic steatosis in terms of the quantification of both percentage of steatotic hepatocytes ($r_s = 0.809$, $p < 0.001$) and steatosis grade ($r_s = 0.848$, $p < 0.001$). However, no correlation between either liver MRI-PDFF or histological steatosis, and other organ MRI-PDFFs was observed. A good correlation between pancreas and vertebral body MRI-PDFFs, and pancreas and renal sinus MRI-PDFFs was observed. Diabetic patients had higher average pancreas MRI-PDFF compared to non-diabetics (12.2% vs. 4.8%; $p = 0.028$).
Conclusions: Based on the present study, pancreas PDFF is well correlated with vertebral body and renal sinus fat PDFF independent of liver PDFF. Diabetes increases pancreas PDFF in NAFLD patients.

P1024
POPULATION, PRESCRIPTION AND EFFECTIVENESS OF ADOMET TREATMENT FOR INTRAHEPATIC CHOLESTASIS IN CHRONIC LIVER DISEASE DUE TO NON ALCOHOLIC LIVER DISEASE (IHC IN NALD) IN THREE POST MARKETING SURVEILLANCE STUDIES IN RUSSIA, UKRAINE AND INDIA

M. Ouwens[1], S. Sander-Struckmeier[2], J. Platon[3]. *[1]Biometrics Established Pharmaceuticals EPD, Abbott Healthcare Products B.V., Weesp, Netherlands; [2]Gastroenterology Established Pharmaceuticals EPD, Abbott Laboratories GmbH, Hannover, Germany; [3]GastroIntestinal Established Pharmaceuticals, Abbott Products Operations AG, Allschwil, Switzerland*
E-mail: mario.ouwens@abbott.com

Background and Aims: Three non-interventional, prospective, multi-centre post-marketing observational surveillance studies (PMOS) in Russia, Ukraine and India including 525 subjects with intrahepatic cholestasis in chronic liver disease due to *non-alcoholic liver disease* (IHC in NALD) were performed. In these studies, AdoMet (S-Adenosyl-L-methionine) was prescribed according to current medical practice. This research provides insight into prescription mode, patient population and effectiveness.
Methods: In Russia, subjects received AdoMet start-up therapy (iv or im 400 or 800 mg) for 2 weeks and then oral maintenance therapy for 4 weeks (400 to 1600 mg tablets). In India, all subjects started on tablets, with effectiveness evaluation at baseline and around 42 days. In Ukraine, subjects started on either injections or tablets. Measurements were taken at two weeks and two months.
Results: In total, 98 subjects were included in Russia, 185 in Ukraine and 242 subjects in India. In India, 44% of subjects were on 1200 mg tablets and 55% on 800 mg tablets. In Russia, 47% of subjects were on 800 mg IV, 53% on 400 mg IV. In Ukraine, 46% of subjects were on 400 mg IV, 20% on 800 mg IV, 23% on 800 mg tablets and 11% on other.
63% was male, with mean age 45 years. Steatosis was the most often indicated medical history (90% in Russia, 57% in India and 25% in Ukraine), followed by chronic hepatitis (70% in Ukraine, 26% in India and 17% in Russia).
Table 1 provides the reductions in laboratory values and symptoms.
In Russia and Ukraine, the majority of laboratory values and symptoms were significantly better at end of treatment than at switch from start-up injection therapy to oral maintenance therapy.
Conclusions: Large reductions in GGT, AST, ALT, total bilirubin, conjugated bilirubin and ALP and symptoms were found with Adomet treatment in patients with IHC due to NALD for each country.

Table 1.

	Ukraine (N = 185)			Russia (N = 98)			India (N = 242)		
	BL	End	% Reduction	BL	End	% Reduction	BL	End	% Reduction
ALP (IU/L)	242	127	47%	174	110	37%	187	143	23%

P1025

INCREASING BURDEN OF NASH/CRYPTOGENIC CIRRHOSIS IN CONTRIBUTION TO END-STAGE LIVER COMPLICATIONS IN ASIA-PACIFIC

W.M. Loo[1], S.G. Lim[1], K. Madhavan[2], M. Da Costa[2], Y.Y. Dan[1].
[1]*Division of Gastroenterology and Hepatology,* [2]*Division of Hepatobiliary and Pancreatic Surgery, Department of Surgery, National University Health System, Singapore, Singapore*
E-mail: wai_mun_loo@nuhs.edu.sg

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is increasingly recognised as a leading cause of liver morbidity and mortality globally. The prevalence of NAFLD is rapidly rising due to the epidemic surge in obesity and Diabetes Mellitus. NAFLD consists of a spectrum including non-alcoholic steatohepatitis (NASH), and 20% of patients with NASH progress to cirrhosis. Studies indicate that the majority of hepatocellular carcinoma (HCC) in cryptogenic cirrhotic patients is associated with prior NAFLD or other features of the metabolic syndrome. However, its disease burden in the Asia-Pacific region remains unknown. We aimed to conduct a retrospective analysis of the contribution of NASH/cryptogenic cirrhosis to liver disease burden in a major tertiary care hospital in Singapore.
Methods: A retrospective analysis of data from the National University Hospital Singapore from 1997 to October 2013 was carried out. The objective was to determine the contribution of NASH/cryptogenic cirrhosis over 2 different time periods from 1997 to 2004 and 2005 to 2013. We looked at 2 separate cohorts of patients: those who presented with HCC and those who had undergone liver transplantation surgery for end-stage liver disease.
Results: 806 patients were diagnosed with primary HCC from 1997 to October 2013. Of these patients, 72 (9%) had been established with NASH/cryptogenic cirrhosis. For the HCC cohort from the period of 1997 to 2004, 2 out of 42 patients (5%) were diagnosed with NASH/cryptogenic cirrhosis and subsequently 70 out of 764 patients (10%) from 2005 to 2013. For the transplant group, there were 5 patients with NASH/cryptogenic cirrhosis out of 53 patients (9%) who underwent liver transplantation from 1997 to 2004 and 9 NASH/cryptogenic cirrhotic patients out of 76 (12%) who did so from 2005 to 2013. Majority of the patients had underlying Hepatitis B cirrhosis.
Conclusions: These figures demonstrate a definite increasing burden of NASH/cryptogenic cirrhosis over the years in end-stage liver complications. NASH will likely transcend viral hepatitis as the main aetiology of liver disease burden in the Asia-Pacific region in the near future and this underlies the imperative need to address this ongoing epidemic.

P1026

THE EVALUATION OF NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD) AND ITS ASSOCIATE FACTORS IN PSORIASIS PATIENTS USING ULTRASONOGRAPHY AND THE CONTROLLED ATTENUATION PARAMETER (CAP) MEASURED WITH TRANSIENT ELASTOGRAPHY

A. Sobhonslidsuk[1], J. Pongpit[1], A. Thakkinstian[2], S. Porntharukchareon[1], P. Kaewdoung[1], K. Promson[1], W. Stitchantrakul[3], D. Saengwimol[3], S. Petraksa[1], N. Rajatanavin[1].
[1]*Medicine,* [2]*Section for Clinical Epidemiology and Biostatistic,* [3]*Research center, Ramathibodi hospital, Mahidol University, Bangkok, Thailand*
E-mail: teasb@hotmail.com

Background and Aims: Psoriasis is linked to metabolic syndrome and nonalcoholic fatty liver disease (NAFLD). Fatty liver can be diagnosed by ultrasonography (US) but sensitivity is reduced when steatosis <30%. Controlled attenuation parameter (CAP) measures liver fat base on ultrasound signal acquired by transient elastography (TE, Fibroscan®). We aimed to estimate the prevalence of fatty liver, to identify factors associated with fatty liver and to assess the performance of CAP for assessing fatty liver in psoriasis patients.
Methods: A cross-sectional study was performed in psoriasis patients without liver diseases. Subjects underwent US and CAP measured by TE. Fatty liver appeared as an increased echogenicity on US. Grading of fatty liver was classified as mild, moderate or severe degree. Performance of TE required 10 successful shots, IQR <30% and success rate >60%. Factors with p-value of univariate analysis <0.20 were simultaneously entered logistic regression model. An optimal cut-off of CAP was determined using Youden index. Diagnostic parameters were estimated. P-value <0.05 was taken as statistical significance.
Results: 168 psoriasis patients were enrolled. TE failure occurred in 3 patients. Seventy-five patients (45.5%) were males with age of 49.22 (14.0) years. Diabetes, hypertension, dyslipidemia and metabolic syndrome were found in 31 (18.8%), 55 (33.3%), 88 (53.3%) and 83 (50.7%) patients. Fatty liver was detected in 105 (63.6%)

Table (abstract P1026): Univariate and multivariate analysis of factors relating to the presence of fatty liver

	Normal liver	Fatty liver by US	p value	Univariate analysis			Multivariate analysis

[a] Mean (SD), [b] n (%).

patients. Fifty-six (33.9%), 38 (23.0%) and 11 (6.7%) patients had mild, moderate and severe fatty liver. Mean CAP and liver stiffness measurement in normal, mild, moderate and severe fatty liver were 182.93 (41.8), 247.96 (43.0), 307.86 (39.1), 329.27 (32.5) dB/m, and 4.28 (1.7), 5.02 (3.4), 6.05 (2.1), 9.16 (4.3) kPa. After adjusting for hypertension and BMI, CAP was associated with fatty liver with OR 1.05 (95% CI 1.03–1.07, $p < 0.001$). The optimal cutoffs of CAP for mild and severe fatty liver were 238 and 315 dB/m yielding the Areas Under ROC curves (AUROC), sensitivity and specificity of 0.92, 79.05%, 95.00% and 0.90, 81.82%, 88.31%. Hypertension (OR 7.94, 95% CI: 1.05–60.00; $p = 0.045$), BMI 23–25 kg/m^2 (OR 71.02, 95% CI: 6.51–774.43; $p = 0.000$) and BMI >25 kg/m^2 (OR 35.32, 95% CI: 3.64–343.14; $p = 0.002$) were associated with fatty liver.

Conclusions: Sixty-four percents of psoriasis patients have fatty liver by US. Hypertension, overweight, obesity and CAP are related to fatty liver. CAP using TE can be used to evaluate fatty liver in psoriasis patients.

P1027

DO LEPTIN PROFILE AND INSULIN RESISTANCE FAVOR OXIDATIVE STRESS AND DISEASE SEVERITY IN NON-ALCOHOLIC FATTY LIVER DISEASE?

B. Canbakan[1], H. Senturk[2], I. Hatemi[1], E. Koroglu[1], M. Tuncer[1], K. Atay[1], N. Kepil[3]. *[1]Gastroenterology, Istanbul Universtiy Cerrahpasa Medical Faculty, [2]Gastroenterology, Bezmi Alem University Medical faculty, [3]Pathology, Istanbul Universtiy Cerrahpasa Medical Faculty, Istanbul, Turkey*
E-mail: canbakbil@gmail.com

Background and Aims: Leptin (L) promotes oxidative stress (OS) and the fibrogenesis. We aimed to evaluate the association between L levels, OS parameters, apoptosis and histopathological findings in Non alcoholic fatty liver disease (NAFLD) with and without IR.

Methods: Fifty-eight NAFLD patients were studied (M/F:31/27 mean age 47.4±6.3). Thirty-six NAFLD patients with IR were compared with 22 subjects without IR. For the determination of oxidative stress, malondialdehyde (MDA), and superoxide dismutase (SOD) activities were measured in serum and in tissue specimens. Glutathione (GH) was measured in tissue homogenates. Nitric oxide (NO) and TNF-alpha receptor (TNF-sRp55) levels were measured in serum. For apoptotic activity immunohistochemistry was performed for caspase-3 and 8, transcription nuclear factor kB (NF-kB), and antiapoptotic Bcl-2 protein. Multivariate regression analysis and ROC curve were used to identify the independent predictors for NASH.

Results: In bivariate analysis serum leptin levels didn't show any significant correlation with steatosis grade, necroinflammatory grade and stage. In linear regression analysis serum NO, tissue MDA, caspase-3, caspase-8, and stage were independently associated with increased leptin levels. HOMA-IR index correlated positively with the necroinflammatory grade, the stage, caspase-3 and 8 levels. Patients with IR had significantly higher steatosis grade, necroinflammatory grade, stage, caspase-3, caspase-8, TNF-sRp55, serum NO, tissue MDA, GH and serum leptin levels than those without IR. Using serum leptin levels the ROC curve for distinguishing between non-alcoholic steatohepatitis (NASH) and simple steatosis didn't show any respective sensitivity and specificity (AUROC=0.46). In multivariate regression analysis increase of tissue MDA, serum NO levels, caspase-3 and caspase-8 levels were risk factors for NASH and increase of leptin activity had preventive effect against NASH (OR:0.048; %95 CI:0.006–0.68, $p = 0.04$).

Conclusions: IR in NAFLD is associated with increased oxidative stress, hepatocyte apoptosis and histopathological disease severity. In patients with IR oxidative stress parameters, apoptotic caspase levels and stage were independently associated with increased L levels and increased L activity showed preventive effect against NASH. These data indicate that NAFLD patients with IR may have increased risk for disease progression and leptin may have a preventive effect against oxidative stress, apoptosis and liver fibrosis.

P1028

IMPAIRED AEROBIC CAPACITY AND CARDIAC AUTONOMIC CONTROL IN SEDENTARY POSTMENOPAUSAL WOMEN WITH NONALCOHOLIC FATTY LIVER DISEASE (NAFLD)

S.M. Duarte[1], R.E. Rezende[1], J.T. Stefano[1], L.A. Perandini[2], T. Dassouki[2], A.L. Sa-Pinto[2], H. Roschel[2], B. Gualano[2], F.J. Carrilho[1], C.P. Oliveira[1]. *[1]Gastroenterology LIM 07, [2]Reumatology, University of São Paulo School of Medicine, São Paulo, Brazil*
E-mail: cpm@usp.br

Background and Aims: Aerobic capacity indexes and cardiac autonomic control have been associated with cardiovascular risk in general populations. It is important to investigate whether these parameters are also impaired in Nonalcoholic fatty liver disease (NAFLD) patients as compared with healthy controls. The aim of this study was to compare the aerobic capacity and cardiac autonomic control between postmenopausal women with or without NAFLD (CTRL) and investigate this relation according to hepatic severity.

Methods: Thirty-seven physically inactive postmenopausal women (age: 55.8±1.4 years; BMI: 33.0±0.7 kg/m^2) biopsy-proven NAFLD and twenty-four CTRL (age 55.8±0.7 years; BMI: 29.0±1.0 kg/m^2) performed a cardiopulmonary exercise test to assess the aerobic capacity indexes [i.e., time at ventilatory anaerobic threshold (VAT), time at respiratory compensation point (RCP), time to exhaustion and maximal oxygen uptake (VO_2max)] and heart rate recovery of the first and second minutes after the end of the test (i.e., HRR1min and HRR2min).

Results: NAFLD patients showed lower time to exhaustion (11.2±0.3 *vs.* 12.5±0.4 min, $p = 0.026$) and time at RCP (8.9±0.4 *vs.* 10.1±0.4 min, $p = 0.047$) when compared to CTRL. Additionally, time at VAT presented a tendency to be lower in NAFLD patients when compared with CTRL (4.6±0.2 *vs.* 5.2±0.3 min, $p = 0.067$). The HRR1min and HRR2min showed also a tendency to be lower in NAFLD patients compared with CTRL ($p = 0.05$ and $p = 0.059$, respectively). No significant changes were noted in the time at RCP between fibrosis degree 0/1/2 in comparison to degree 3/4 (8.5±2.5 *vs.* 10.2±1.8 min, $p = 0.078$). HRR2min showed a tendency to be higher in fibrosis degree 0/1/2 when compared to fibrosis degree 3/4 ($p = 0.093$).

Conclusions: NAFLD patients showed lower aerobic capacity and an impaired cardiac autonomic control, which are indexes independently associated with risk of cardiovascular events. However, these findings require future investigations in large population-based studies.

P1029

RACIAL-ETHNIC DISPARITIES IN LIVER DISEASE MORTALITY IN THE UNITED STATES

C.E. Ruhl[1], A. Unalp-Arida[2]. *[1]Social & Scientific Systems, Inc., Silver Spring, MD, [2]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD, United States*
E-mail: cruhl@s-3.com

Background and Aims: Chronic liver disease and cirrhosis was the 12th leading cause of death in the U.S. in 2011 and the mortality rate varies among racial-ethnic groups. Age-adjusted liver disease mortality per 100,000 was 32.3 for Hispanics compared with 21.6 for both non-Hispanic whites and non-Hispanic blacks (http://wonder.cdc.gov/). We examined factors explaining racial-ethnic differences in liver disease mortality in a U.S. population-based prospective study.

Methods: Data were analyzed from 17,681 adult non-Hispanic white, non-Hispanic black, and Mexican American participants in

the third U.S. National Health and Nutrition Examination Survey, 1988–1994. Participants were followed through 2011 for mortality as identified by death certificate diagnoses. Hazard rate ratios (HR) for mortality were calculated using Cox proportional hazards regression to adjust for factors associated with both race-ethnicity and mortality.

Results: Mexican Americans had adverse measures of socio-economic status and were more likely to have obesity and diabetes compared with non-Hispanic whites at baseline. During up to 23 years of follow-up, there were 201 deaths with liver disease, including viral hepatitis and primary liver cancer, as the underlying or a contributing diagnosis. In age- and sex-adjusted analysis, liver disease mortality was twice as high among Mexican Americans compared with non-Hispanic whites, while there was no statistically significant difference for non-Hispanic blacks (Table). Adjustment for hepatitis B or C infection or for non-alcoholic fatty liver disease (NAFLD) risk factors (BMI, waist-to-hip ratio, diabetes) attenuated the association of Mexican American ethnicity with higher liver disease mortality. With adjustment for socioeconomic status (SES; education, income) and health insurance, Mexican American ethnicity was not statistically significantly associated with higher liver disease mortality. Results were similar with simultaneous adjustment for all of the above factors. Limiting analyses to deaths with liver disease as underlying cause had little effect on relationships.

Table: Liver disease mortality HR (95% CI) compared with non-Hispanic whites

Adjusted for	Non-Hispanic blacks	Mexican Americans
Age, sex	1.6 (1.0–2.5)	2.2 (1.3–3.5)
Age, sex, viral hepatitis	1.3 (0.7–2.2)	2.0 (1.2–3.5)
Age, sex, NAFLD risk factors	1.4 (0.8–2.5)	1.9 (1.1–3.4)
Age, sex, SES, insurance	1.2 (0.6–2.1)	1.3 (0.6–2.7)
All factors listed above	0.9 (0.5–1.8)	1.3 (0.6–2.5)

Conclusions: In the U.S. population, lower socio-economic status and lack of health insurance made a greater contribution to higher liver disease mortality among Mexican Americans than did viral hepatitis or NAFLD risk factors.

P1030
THE PRESENCE OF WHITE MATTER LESIONS IS NOT ASSOCIATED WITH NON-ALCOHOLIC FATTY LIVER DISEASE BUT WITH ITS HISTOLOGICAL SEVERITY

S. Petta[1], A. Tuttolomondo[2], C. Gagliardo[3], R. Zafonte[4], G. Brancatelli[3], D. Cabibi[5], C. Cammà[1], V. Di Marco[1], L. Galvano[4], A. Licata[1], F. Magliozzo[4], G. Merlino[4], M. Midiri[3], A. Pinto[2], A. Craxì[1].
[1]Section of Gastroenterology, Di.Bi.MI.S University of Palermo, Italy; [2]Sezione di Medicina Interna, DiBiMIS, University of Palermo, Italy; [3]Department of Radiology, University of Palermo, Italy; [4]Medicina Generale Palermo, [5]Cattedra di Anatomia Patologica, University of Palermo, Italy, palermo, Italy
E-mail: petsa@inwind.it

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) has been associated with increased cardiovascular risk, including coronary artery disease and cerebrovascular events. No studies however assessed the potential relationship between NAFLD and subclinical cerebrovascular alterations. We tested the correlation between NAFLD and its histological severity with vascular white matter lesions (WML) in patients with biopsy-proven NAFLD and in non steatosic controls.

Methods: The anthropometric, biochemical and metabolic features were recorded in 77 consecutive biopsy-proven NAFLD (Kleiner score), and in 35 controls with normal ALT, without chronic liver diseases, and without ultrasonographic evidence of steatosis. All patients underwent minimental test (MMT) and magnetic resonance assessment of WML. MMT was considered pathologic if <23. WML were classified according to the Fazekas score in absent (0/III), or present (mild I/III; moderate II/III, and severe I/III). For purpose of analyses all controls, as plausible, were considered without NASH and without F2–F4 liver fibrosis.

Results: WML were found in 26% of the entire cohort (29/112), even if of a moderate-severe grade in 5 patients only. The prevalence of WML was similar in NAFLD compared to no NAFLD (27% vs 23%; $p = 0.62$). Age ≥50 yrs, female gender, type 2 diabetes, arterial hypertension, presence of NASH (35% vs 18%, $p = 0.05$) and presence of F2–F4 fibrosis (43% vs 17%, $p = 0.003$) were associated with WML presence ($p \leq 0.01$). At multivariate analysis age >50 yrs (OR 3.44, 95% CI 1.01–11.6, p 0.04), female gender (OR 3.71, 95% CI 1.28–10.7, p 0.01), and F2–F4 fibrosis (OR 3.39, 95% CI 1.17–9.84, p 0.02) were maintained as factors independently associated with WML. When considering NAFLD patients only, we confirmed F2–F4 fibrosis as the only independent predictor of WML (OR 4.24, 95% CI 1.14–15.7, p 0.03). A pathological MMT was found in 10/112 patients (9%) – all of them with NAFLD. Specifically the prevalence of an alterated MMT was 17% in patients with WML and 8% in those without.

Conclusions: The presence of WML is not asociated with NAFLD but with its histological severity. Clinical implications of this issue need to be assessed by longitudinal studies. The ability of MMT to detect subclinical WML was poor.

P1031
COMPARISON OF CLINICAL, BIOCHEMICAL, AND HISTOPATHOLOGICAL PROFILES BETWEEN NAFLD IN ASIAN-INDIANS AND UNITED STATES ADULTS

S.P. Singh[1], A. Patel[2], M.K. Panigrahi[3], L. Viswanathan[4], S.K. Kar[1], S.A. Harrison[5]. *[1]Department of Gastroenterology, S.C.B. Medical College, CUTTACK, [2]Division of Gastroenterology and Hepatology, Department of Medicine, Carl R. Darnall Army Medical Center, Fort Hood, Texas, [3]Department of Gastroenterology & Hepatobiliary Sciences, IMS & SUM Hospital, Bhubaneswar, India; [4]Department of Medicine, [5]Division of Gastroenterology and Hepatology, Department of Medicine, San Antonio Military Medical Center, Fort Sam Houston, Texas, United States*
E-mail: spsingh.cuttack@gmail.com

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is one of the most common liver disorders in Asian and Western countries. The epidemiological and demographic character of NAFLD patients differs with geographic variation. Studies across ethnicities in the United States (U.S.) reveal a higher prevalence in Hispanics and African-Americans with limited studies involving Asians. Data suggest that Asian-Indian patients tend to have different characteristics than their counterparts in the West. This study is the first attempt at comparing the characteristics of Asian-Indian and U.S. NAFLD patients.

Methods: A retrospective analysis of clinical, biochemical and histological parameters was performed for 633 Asian-Indian NAFLD patients with 451 U.S. NAFLD patients. Comparisons among the study cohort included clinical (i.e.: age, gender, BMI, diabetes, hypertension, etc.), biochemical tests (i.e.: liver function tests, lipid profile, fasting blood sugar), hepatic ultrasound and hepatic histology.

Results: The majority of U.S. NAFLD patients (82.3%) were over 40 years of age compared to 51.3% of Asian-Indian patients ($\chi^2 = 109.55$; $p < 0.001$). There was significant difference in gender prevalence between U.S. (male 56.3%) and Asian-Indians (male 81.7%) ($\chi^2 = 82.442$; $p < 0.001$). U.S. patients had higher rates of obesity (BMI 32.6 ± 5.3 kg/m^2 versus 26.2 ± 3.4 kg/m^2; $p < 0.001$). With respect to co-morbid conditions, U.S. patients had a higher prevalence of both diabetes and hypertension (diabetes 42.1% vs. 33%, and hypertension 56.8% vs 29.7%, respectively; $p < 0.001$). U.S. NAFLD patients have significantly

higher ALT levels compared to Asian-Indians (ALT 82.78±71.30 versus 53.66±37, p < 0.001). Histological comparison showed that a greater proportion of U.S. patients had more advanced liver disease at time of diagnosis compared to Asian-Indians (Stage 3 fibrosis 10.42% vs. 0%, respectively, and Stage 4 fibrosis 2.66% vs. 0%, respectively, p < 0.001).
Conclusions: Significant differences between Asian-Indian and U.S. NAFLD patients exist. Further study is needed to better understand mechanistically why these differences exist.

P1032
PATIENTS WITH METABOLIC SYNDROME AND NAFLD: ASSESSMENT OF OBESITY AND HEART FIBROSIS DEGREE
T. Deeva[1], O. Drapkina[1], V. Ivashkin[1]. [1]*I.M. Sechenov First Moscow State Medical University, Moscow, Russia*
E-mail: deeva_ta@mail.ru

Background and Aims: to investigate level of obesity and heart fibrosis in patients with metabolic syndrome (MetS) and nonalcoholic fatty liver disease (NAFLD).
Methods: The research has included 76 patients, from them 43 patients were with MetS (72.1%, 31 out of 43, with NAFLD) (basic group), 33 patients without MetS (control group). Epicardial fat thickness was evaluated by transthoracic echocardiogram. Besides the above we conducted noninvasive evaluation of the fraction of fibrosis of the myocardium using a new original method – we used echocardiography, then we obtained the resulting images in "jpeg" format and analyzed them using software "Image J v.1.4 (NIH, 2009)". The level of leptin was investigated.
Results: Patients in the basic group had significantly higher epicardial fat thickness than control (4.67±1.7 and 2.66±1.15 mm, p < 0.001). The average volume fraction of fibrosis in the interventricular septum had significant difference in the groups studied (22.6±4.45% in the MetS group and 16.5±3.95% in the controls, p < 0.001). The average level of leptin in the group with MetS and NAFLD was significantly higher in comparison with control (41.89±33.28 vs 17.64±16.87 ng/ml, p < 0.001). Positive correlation was revealed between the level of leptin and weight, the body mass index, the degree of obesity, abdominal obesity, waist circumference, epicardial fat thickness, degree left ventricular hypertrophy (LVH), hepatic and pancreatic steatosis (p < 0.05).
Conclusions: (1) Patients with MetS and NAFLD have epicardial fat thickness significantly higher than control, leptin level is correlated with obesity of the whole body and hearts, which can be a predictor of cardiovascular disease. (2) Relationship has been found between the level of leptin and diseases related to MetS: NAFLD, pancreatic steatosis, LVH. (3) We propose the new method of noninvasive assessment of the volume fibrosis fraction. More strongly pronounced septal fibrosis was found in patients with MetS and NAFLD.

P1033
VITAMIN D DEFICIENCY, NOT VITAMIN D INTAKE WAS INDEPENDENT RISK FACTOR OF ABNORMAL LIVER ENZYME
H.H. Nam[1], D.W. Jun[1], W.K. Saeed[1], T.Y. Kim[1]. [1]*Internal Medicine, Hanyang University, Seoul, Korea, South*
E-mail: noshin@hanyang.ac.kr

Background and Aims: Several reports showed that serum vitamin D deficiency associated with prevalence and progression of liver disease. But it is not uncertain whether vitamin D intake also has pivotal role in serum vitamin D deficiency and abnormal liver enzyme.
Methods: We used the data from Korean National Health and Nutrition Examinations (2008–2011). A total of 27,463 people were included. Vitamin D deficiency was defined as below 20 ng/mL of 25-OH-vitamin D.
Results: Serum vitamin D was positive correlation with body mass index, fasting glucose, and aminotransferase activity. Both vitamin D intake and inhabitable area (urban or rural area) were independent risk factor of serum vitamin D. Although the total amount of vitamin D uptake was lower in rural area and Blue-collar workers compare to urban and White-collar subjects, serum vitamin D was high in rural area. Amount of vitamin D intake did not show any correlation with aminotransferase activity as well as metabolic parameters. Vitamin D deficiency, not vitamin D intake was independent risk factor of abnormal liver enzyme only in obese and blue collar subjects.
Conclusions: Vitamin D deficiency was a risk factor of elevated aminotransferase level and prevalence of metabolic syndrome in obesity. But amount of vitamin D intake did not show any association with metabolic parameters as well as liver chemisty.

P1034
CHARACTERISATION OF THE PREVALENCE AND RISK FACTORS FOR BIOPSY-PROVEN NON-ALCOHOLIC STEATOHEPATITIS AMONG PATIENTS WITH GALLSTONES: A PROSPECTIVE STUDY
C. Garcia-Monzon[1], J. Vargas-Castrillon[2], J.L. Porrero[3], M.T. Alonso[3], O. Bonachia[3], M.J. Castillo[3], A. Marcos[3], E. Quiros[3], B. Ramos[3], C. Sanchez-Cabezudo[3], S. Villar[3], A. Saez[1], J. Rodriguez de Cia[3], E. Del Pozo[1], L. Vega[4], S. Soto-Fernandez[5], O. Lo Iacono[5], M.E. Miquilena-Colina[1], and Liver Research Unit, Santa Cristina University Hospital, Instituto de Investigación Sanitaria Princesa, CIBERehd, Madrid, Spain. [1]*Liver Research Unit, Santa Cristina University Hospital,* [2]*Liver Research Unit, Santa Cristina University Hospital,* [3]*General and Abdominal Surgery, Santa Cristina University Hospital,* [4]*Satatistics and Methodology Units, Instituto de Investigación Sanitaria Princesa, Madrid,* [5]*Gastroenterology Service, Hospital del Tajo, Aranjuez, Spain*
E-mail: cgmonzon@salud.madrid.org

Background and Aims: Whether a link exists between gallstones and non-alcoholic steatohepatits (NASH) remains unclear. Only three studies have reported the prevalence of NASH among gallstones patients showing rates varying widely from 18% to 77%. There are, however, major limitations on these reports due to selection biases as well as the lack of well-defined criteria of definite NASH on liver histology. Therefore, we aimed to prospectively determine the prevalence and risk factors for biopsy-proven definite NASH among unselected patients with gallstones.
Methods: Patients referred for laparoscopic cholecystectomy due to gallstones were offered to participate in the study. Anthropometric and laboratory evaluation, abdominal ultrasound and a liver biopsy during the surgical procedure were performed to each participant. Definite NASH was diagnosed using the Kleiner's histological scoring system.
Results: Two hundred and fifteen consecutive patients with gallstones were included. Prevalence of NASH was 10.2% whereas that of simple steatosis (SS) was 41.4%. Gallstones patients with NASH had a higher mean homeostatic model assessment (HOMA) score than those with SS ($P = 0.015$). Noteworthy, NASH was 2.5-fold more frequent in patients with gallstones who had metabolic syndrome than in those who did not ($P < 0.001$). Fatty liver on ultrasound was observed in 90.9% of gallstones patients with NASH compared with 61.8% of those with SS ($P = 0.044$). Using multivariate logistic regression analysis, increased HOMA score (OR, 3.47; 95% CI, 1.41–8.52; $P = 0.007$) and fatty liver on ultrasound (OR, 23.27; 95% CI, 4.15–130.55; $P < 0.001$) were the only factors independently associated with NASH. The sensitivity and specificity of the combination of the 2 NASH predictors were 83% and 77%, respectively. The area under the ROC curve was 0.897; 95% CI: 0.836–0.958, $P < 0.001$.
Conclusions: The prevalence of NASH among patients with gallstones is lower than estimated previously, but NASH is frequent particularly in those gallstones patients with concurrent metabolic syndrome. The combination of an increased HOMA score with fatty

liver on ultrasound has a good accuracy for predicting NASH in patients with gallstones. Based on these results, we propose that gallstones patients who have preoperative evidence of both insulin resistance and fatty liver on ultrasound are considered to undergo a needle liver biopsy during cholecystectomy for early diagnosis of NASH at high-risk patients.

P1035

ELF TEST IS A RELIABLE NON INVASIVE TEST FOR FIBROSIS IN NAFLD SUBJECTS

L. Miele[1], T. De Michele[2], M.A. Isgrò[3], G. Marrone[1], C. Cefalo[1], M. Biolato[1,4], G.L. Rapaccini[5], A. Gasbarrini[1], C. Zuppi[2], A. Grieco[1].
[1]Internal Medicine, [2]Laboratory Medicine, Catholic University, [3]Laboratory Medicine, Catholic University of Rome, [4]Catholic University, [5]Internal Medicine, Catholic University of Rome, Rome, Italy
E-mail: l.miele@yahoo.it

Background and Aims: The identification of fibrosis in patients with nonalcoholic fatty liver disease (NAFLD) is important for prognosis and selection of patients candidates for therapeutic interventions. The reference standard for detecting liver fibrosis is liver biopsy; however, such an invasive procedure, it can be painful and hazardous, and assessment subjective and prone to sampling error. Recently, the serum Enhanced Liver Fibrosis (ELF) Test has been developed for staging liver fibrosis in patients with chronic liver diseases. The aim of our study was to evaluate the ELF Test performance in predicting fibrosis stage in an independent adult cohort of NAFLD patients.
Methods: 82 patients (mean age 46 years) with suspected NAFLD were enrolled undergoing percutaneous liver biopsy and serum sampling. Fibrosis was assessed and scored by using the modified Brunt classification (F0 = no fibrosis; F1 = perisinusoidal/periportal; F2 = perisinusoidal and portal/periportal; F3 = bridging fibrosis; F4 = cirrhosis). The ELF test was determined in all patients by means of an algorithm combining hyaluronic acid, amino-terminal propeptide of type III collagen and tissue inhibitor of metalloproteinase 1. Diagnostic accuracy was assessed determining the area under receiver operating characteristic curves (AUCs).
Results: The distribution of fibrosis stages in our cohort was as follows: F0 = 7.3% (n = 6), F1 = 39.0% (n = 32), F2 = 35.4% (n = 29), F3 = 6.1% (n = 5), F4 = 12.2% (n = 10). The ELF Test had an AUC of 0.988 (95% confidence interval [CI] 0.967–1.008; P < 0.001) for distinguishing cirrhosis, 0.948 (CI 0.883–1.014; P < 0.001) for severe fibrosis, 0.682 (CI 0.568–0.797; P = 0.005) for significant fibrosis and 0.658 (CI 0.401–0.915; P = 0.200) for any fibrosis. ELF scores were significantly higher in patients with severe fibrosis/cirrhosis in respect to ones with no/mild/moderate fibrosis (median 11.26 *vs.* 8.53; P < 0.001). Severe fibrosis and cirrhosis were correctly identified in 91% of patients.
Conclusions: In our cohort of NAFLD patients, the ELF test was able to discriminate severe fibrosis and cirrhosis with an excellent diagnostic accuracy. It may result useful for the selection of cases with more advanced fibrosis stage and for therapeutic follow-up, thus avoiding liver biopsy.

P1036

OBESITY, T2DM, METABOLIC SYNDROME INFLUENCE MORTALITY IN NAFLD IN A COHORT OF MEXICAN PATIENTS

L.A. Perez-Arredondo[1], P. Cordero-Perez[1], G. Alarcon-Galvan[1,2], R.F. Martinez-Macias[1], A. Silvera-Linares[1], L.E. Munoz-Espinosa[1].
[1]Liver Unit Department of Internal Medicine, [2]Pathology Department, Universidad Autonoma de Nuevo Leon, Monterrey, Mexico
E-mail: lperez1212@hotmail.com

Background and Aims: The spectrum of non alcoholic fatty liver disease (NAFLD) comprises non alcoholic fatty liver (NAFL), non alcoholic steatohepatitis (NASH) and cirrhosis. Recently, it has been positioning as one of the most frequent causes of chronic liver disease (CLD). Mexico has the second highest worldwide prevalence of obesity and type 2 diabetes mellitus (T2DM) is present in 14% of general population. The aim of this study was to evaluate the influence that metabolic factors had in the natural history of NAFLD in Mexican patients.
Methods: NAFLD diagnosis was made in patients who drank <30 g/day on males, <20 g/day on females. Other etiologies of CLD were ruled out. Demographic, anthropometric, biochemical, US data and comorbidities were registered. All patients had liver biopsy and/or FibroMax. Group 1 (G1): 41 NAFL patients and group 2 (G2): 80 NASH patients. Comorbidities were compared between admission and last visit. Kaplan–Meier curves (KM) were calculated evaluating the development of cirrhosis, its complications and mortality or liver transplant (LT).
Results: During follow-up obesity decreased in both groups, however HBP increased significantly in G1 as T2DM, HBP, dyslipidemia and metabolic syndrome (MS) increased in G2 (Table). Forty patients had cirrhosis initially, and in G2 four patients developed it. Cirrhosis was diagnosed in 44/121 (36%) patients. Twelve out of 121 (10%) patients died/LT, 11 of them were cirrhotic. Causes of death: liver related 9/12 (75%), cardiovascular causes 2/12 (17%) and infection 1/12 (8%). KM curves demonstrated that patients with obesity (p = 0.041), T2DM (p = 0.002) and metabolic syndrome (p = 0.001) had higher mortality/LT. The development of cirrhosis during follow-up was not influenced by comorbidities.

Table: Progression of comorbidities in NAFL and NASH

Comorbidity	Group 1 (n = 41)			Group 2 (n = 80)		
	Admission	Last visit	*P*	Admission	Last visit	*P*
Obesity	18	15	0.687	45	40	0.210
T2DM	11	14	0.250	34	48	<0.001
HBP	8	14	0.031	31	38	0.016
Dyslipidemia	32	35	0.250	56	66	0.002
MS	11	14	0.250	42	46	<0.001

Conclusions: Patients with NASH developed more comorbidities than patients with NAFL in the long term follow-up. Patients with obesity, T2DM and MS had higher mortality/LT. However the development of cirrhosis during follow-up was not influenced by comorbidities. The most common cause of death in NAFLD was liver related.

P1037

INFLUENCE OF PREDICTOR VARIABLES ON FIBROMAX RESULTS

N. Sargsyants[1], A. Melkonyan[2], Y. Kazanchyan[2]. *[1]Infectious Diseases, Armenicum Clinical Center, [2]Promtest, "Promtest" Diagnostic Laboratory, Yerevan, Armenia*
E-mail: sknarina70@mail.ru

Background and Aims: Among the noninvasive alternatives to liver biopsy in patients at risk of chronic liver diseases, several studies have demonstrated the predictive value of FibroMax (*BioPredictive, France*). FibroMax includes 5 tests: FibroTest (quantitative assessment of fibrosis), ActiTest (quantitative assessment of necroinflammatory activity in chronic viral hepatitis C and B), SteatoTest (quantitative assessment of steatosis), NashTest (categorical diagnosis of nonalcoholic steatohepatitis) and AshTest (quantitative assessment of alcoholic steatohepatitis). The aim of the study is evaluation of predictor variables influence of Fibromax results.
Methods: 80 patients were involved in the study (86% male), 21–68 years old (42.4±10.2). Statistic analysis was done by SPSS 11.0. Multiple regression was used for estimation of independent or predictor variables (gender, age, BMI, fasting glucose, triglycerides, cholesterol, AST, ALT and GGT) influence on

five Fibromax tests. Predictor variables were coding as dichotomous or categorical. Gender (male, female), fasting glucose, triglycerides, cholesterol, AST, ALT and GGT (normal, abnormal) are considered as dichotomous. According to BMI patients were divided: <25, 25–30 and >30. By age, patients were subdivided into the following groups: <30, 31–40, 41–50 and >50 years old. By fibrosis degree patients were subdivided into 3 groups: 1: F from 0 to 2; 2: F2,3; 3: F3,4. According to necroinflammation activity subdivision was done into the following groups: 1: A from 0 to 1; 2: A 1–2; 3: A 3. By steatosis degree separation: 1: S from 0 to 1; 2: S1–2; 3: S2–3. Nash- and AstTests divide correspondingly on 1, 2 and 3.

Results: According to ANOVA results models for all 5 tests are significant. By using all the predictors simultaneously: for FibroTest 26% (adjusted $R^2 = 0.261$) of the variance can be predicted from the independent variables with significance of age and cholesterol ($p = 0.001$, $p = 0.08$); for ActiTest – 75% (adjusted $R^2 = 0.746$) with significance of ALT, AST, GGT ($p < 0.001$); for SteatoTest – 51% (adjusted $R^2 = 0.509$) with significance of BMI, TG, GGT ($p < 0.001$, $p = 0.002$, $p < 0.001$); for NashTest – 23% (adjusted $R^2 = 0.233$) with significance of gender, BMI, GGT ($p = 0.058$, $p = 0.019$, $p = 0.053$); for AshTest – 13% (adjusted $R^2 = 0.133$) with significance of gender, AST ($p = 0.007$, $p = 0.057$).

Conclusions: Multiple regression has shown that using of all predictor variables simultaneously for prediction of all five Fibromax tests results are significant with predisposing role of particular predictors for different tests.

P1038

NON-ALCOHOLIC FATTY LIVER DISEASE IS A COMMON FINDING IN ASYMPTOMATIC, UNCOMPLICATED TYPE 2 DIABETES MELLITUS PATIENTS ASSESSED BY MULTIPARAMETRIC MAGNETIC RESONANCE LIVER IMAGING

E. Levelt[1,2], P. Michael[1,3], C. Kelly[4], M. Mahmod[1], J. Francis[1], J. Schneider[1], K. Clarke[2], S. Neubauer[1]. *[1]Oxford Centre for Clinical Magnetic Resonance Research, [2]Department of Physiology, Anatomy and Genetics, [3]Translational Gastroenterology Unit, University of Oxford, [4]Perspectum Diagnostics, Oxford, United Kingdom*
E-mail: eylem.levelt@dpag.ox.ac.uk

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is considered to be prevalent among patients with long standing type 2 diabetes mellitus (T2DM). Compared with non-diabetics, T2DM patients are at higher risk of more advanced forms of NAFLD, such as steatohepatitis (NASH) and fibrosis. Magnetic resonance techniques are increasingly being used in the assessment of liver disease and have been shown to have a high degree of sensitivity and specificity for diagnosis and staging in a histology comparison study.

We used a multiparametric MR protocol for detailed assessment of liver disease in asymptomatic patients with uncomplicated T2DM and relatively short disease duration.

Methods: 32 patients with T2DM with median diabetes duration of 6.5 [IQR 1.5–8] years and 15 age matching non-diabetic controls (56±1, vs 52±3 years respectively, $p = 0.210$) were recruited. T2DM patients were taking only oral antidiabetic therapies. All participants had a multi-parametric MRI scan including T1 mapping and T2* mapping (for iron quantification) which were used to calculate the liver inflammation and fibrosis (LIF) score (0–4 continuous scale; 0 no disease, 4 severe disease) measuring liver extracellular fluid (reflecting fibrosis and inflammation) and ^{1}H MR spectroscopy (^{1}H MRS) for liver lipid quantification. All scans were analysed by a blinded operator.

Results: The mean LIF score was significantly elevated in T2DM patients (1.95±0.17 vs 0.87±0.1, $p < 0.001$) compared to healthy volunteers. Mean liver fat content for T2DM was 12±1.3% compared to 3±0.7% in normal controls ($p < 0.001$). The mean hepatic iron content assessed by T2* mapping was not different between diabetics and the controls (1.34±0.05 vs 1.3±0.03 respectively, $p = 0.493$). There was a strong correlation between the degree of steatosis measured by ^{1}H MRS and LIF scores ($r = 0.775$, $p < 0.001$). 8 out of total 32 patients with T2DM (25%) had elevated plasma alanine aminotransferase (>40 unit/L), and 16 T2DM patients (50%) had LIF score >2.

Conclusions: Significant NAFLD defined as LIF >2 is present in asymptomatic T2DM patients with minor or no ALT elevations. A multi-parametric MRI liver protocol allows a detailed non-invasive tissue characterisation of liver parenchyma, and identification and quantification of fibrosis, steatosis and iron content. This method promises to answer to a pressing need for a reliable, quick, non-invasive screening, staging and monitoring tool for diabetic liver disease.

P1039

A REVIEW OF OUTCOMES OF LIVER BIOPSIES IN HIV-INFECTED PATIENTS WITHOUT HEPATITIS CO-INFECTION 2002–2012

R.A. Lever[1], R. Lombardi[2], E. Tsochatzis[2], C. Smith[3], N. Marshall[4], A. Rodger[3], S. Bhagani[1]. *[1]Department of Infectious Diseases, Royal Free Hospital, [2]Institute for Liver and Digestive Health, [3]Research Department of Infection and Population Health, UCL, [4]Department of HIV Medicine, Royal Free Hospital, London, United Kingdom*
E-mail: robert.lever@gmail.com

Background and Aims: Liver disease is an important cause of morbidity and mortality in HIV infected patients in the presence and absence of chronic viral hepatitis. Liver biopsy is the gold standard for the investigation of these diseases and with increasing use of non-invasive measures of liver disease we performed a review of liver biopsy results at our institution in HIV infected patients without chronic viral hepatitis

Methods: We examined all HIV infected patients without evidence of chronic viral hepatitis co-infection who underwent liver biopsy at the Royal Free Hospital between January 2002 and December 2012. Basic demographic information, indications for biopsy and biopsy results were recorded

Results: *Demographics:* During the study period 143 liver biopsies were performed on 126 individuals from a total HIV positive cohort of 4456 patients (2.8%). All individuals had negative serology for HCV and HBV prior to biopsy. 94 patients (74.6%) were male with a mean age of 49.6 years at biopsy. The mean time between HIV diagnosis and biopsy was 8.1 years (range 0.1 years to 29 years). 18% of patients were asymptomatic from their HIV at the time of biopsy, 43% were symptomatic and 37% had a diagnosis of AIDS ($n = 126$). Indications for biopsy: 69% of biopsies were performed for deranged liver function tests; 12% for evaluation of a mass or potential neoplasm; 5% for assessment of presumed cirrhosis and 4% for presumed NAFLD ($n = 143$).

Biopsy results: Steatosis was noted in 45.4% of biopsy samples with 18.8% showing moderate/severe changes. Fibrosis was noted in 18.8% of biopsy samples with 2.8% being cirrhotic ($n = 143$).

Diagnoses made on liver biopsy: Granulomas were present in 10 biopsies (7%); cholestasis was present in 4 biopsies (2.8%); lymphoma was diagnosed in 8 biopsies (5.6%); definite drug reactions in 6 cases (4.2%); tuberculosis in 8 biopsies (2.8%) and autoimmune hepatitis in 3 patients (2.1%) ($n = 143$).

Conclusions: We report a 10 year retrospective analysis of biopsies in HIV positive/hepatitis negative patients. A large proportion of biopsies demonstrate evidence of steatosis with nearly 20% showing moderate or severe steatosis. This correlates with reported elevated prevalence of fatty liver disease in HIV positive individuals. Notably diagnoses other than steatosis were identified in 25.9% of biopsy specimens suggesting an ongoing role for the use of biopsy as compared to non-invasive tests. Further work will be required to define the HIV population in which liver biopsy is most useful diagnostically.

P1040

SHORT-TERM LOW-DOSE THIAZOLIDINEDIONES CAN BE A USEFUL BRIDGING THERAPY IN NASH PATIENTS WITHOUT SIDE EFFECTS

S. Park[1], M. Lee[1], I.H. Moh[1], S. Shin[1]. [1]*Division of Gastroenterology and Hepatology, Hallym University Medical Center, Seoul, Korea, South*
E-mail: sanghoon@hallym.or.kr

Background and Aims: Thiazolidinediones (TZDs) improve insulin resistance and have shown effect in the treatment of NASH. However, only low-dose TZDs are available in non-diabetic patients in South Korea due to national health insurance reimbursement policy. Meanwhile, administration of low-dose TZDs can be used more safely while TZDs have adverse effects such as edema, fatigue, and weight gain. We assessed the effect of low-dose TZDs in non-diabetic NASH patients.
Methods: We conducted a prospective study of biopsy proven NASH patients without diabetes from 2003 through 2013. Patients were treated with low-dose TZDs (rosiglitazone 4 mg or pioglitazone 15 mg, once daily) for 12 weeks. AST, ALT, ALP, total protein, albumin, total cholesterol, triglyceride, fasting blood glucose (FBS), body mass index, and HOMA-IR were measured at baseline and after 12 weeks. Data were compared with Wilcoxon Signed Rank Test.
Results: Twenty-eight patients were enrolled. Ten cases were female with a mean age of 36.3±13.7 years. After 12 weeks, a significant decrease in AST (71.1±42.8 to 37.3±16.9, $p < 0.01$), ALT (121.7±60.1 to 59.8±34.1, $p < 0.01$), FBS (104.2±28.1 to 97.9±15.3, $p = 0.013$) and HOMA-IR (2.3±1.5 to 1.9±1.1, $p = 0.039$) levels was observed without weight gain or other side effects. TZDs did not affect plasma ALP, total protein, albumin, total cholesterol, and triglyceride.
Conclusions: Twelve weeks administration of low-dose TZDs in non-diabetic NASH patients showed beneficial effects on liver function without side effects. Low-dose TZDs can be used as a useful bridging therapy while weight loss by dietary control and exercise takes time to be effective.

P1041

RAPID IMPROVEMENT OF HEPATIC STEATOSIS AS ASSESSED BY CONTROLLED ATTENUATION PARAMETER AFTER A TWO WEEK PROTEIN-ENRICHED LOW-CALORIE DIET (HEPAFAST)

A. Arslanow[1], M. Teutsch[2], H. Walle[2], F. Lammert[1], C.S. Stokes[1].
[1]*Department of Medicine II, Saarland University Medical Center, Homburg,* [2]*Bodymed AG, Kirkel, Germany*
E-mail: anita.arslanow@uks.eu

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) has become one of the most prevalent liver diseases. NAFLD increases the risk of fibrosis and cirrhosis and is the most rapidly growing indication for liver transplantation in patients with hepatocellular carcinoma. Previous intervention studies have been hampered by the need for liver biopsies and the lack of alternative inexpensive methods for the quantitative measurement of liver fat contents. Hence the primary aim of this study was to avail of the controlled attenuation parameter as quantitative tool for the assessment of therapeutic effects of a two-week low-calorie diet.
Methods: In this prospective single center study, 59 patients with NAFLD received a 14-day low-calorie liver specific diet (HEPAFAST) containing 1000 kcal per day (41% protein, 29% carbohydrate, 24% fat and 6% fiber). The following parameters were assessed at baseline and after 14 days: hepatic fat contents using controlled attenuation parameter (CAP) during transient elastography (FibroScan); body composition with bioimpedance analysis; and serum liver function tests and lipid profiles using standard clinical-chemical assays.
Results: All 59 patients (median age 55 years, range 25–78; 51% women; median BMI 31.7 kg/m^2, range 22.4–43.5) successfully completed the study. A significant reduction in hepatic steatosis (14.1%; $P < 0.0001$) was observed after only 2 weeks: The median CAP score decreased from 293 dB/m (range 177–400) at baseline to 263 dB/m (100–353). In parallel, BMI decreased significantly ($P < 0.0001$), and 30.5% could be reclassified into a lower BMI category. Moreover, body and visceral fat contents were significantly ($P < 0.0001$) reduced by 7%. Serum triglyceride, total LDL, and the LDL/HDL index as well as g-GT activities also decreased significantly (all $P < 0.001$). Interestingly, 11 patients (72% women) demonstrated a CAP increase by 3% after the 2-week intervention despite improvements in body composition, thus were classified as hepatic non-responders. In contrast, a subgroup analysis of the responders revealed a decrease of 16% in median CAP scores from 308 to 261 dB/m.
Conclusions: This elastography-based non-invasive study shows, for the first time, improvements in hepatic steatosis, as quantified non-invasively by CAP, after a short-term protein-enriched low-calorie diet. The dietary intervention not only reduced body weight but improved both body and liver compositon in NAFLD. Compartment- and sex-specific HEPAFAST effects should be investigated further.

E-mail: crosso3@cittadellasalute.to.it

Background and Aims: Adipose tissue insulin resistance (IR) and elevated adipose free fatty acid (FFA) flux are prominent features in NAFLD. De novo lipogenesis (DNL) is up to 3-fold higher in subjects with fatty liver and is not suppressed on fasting. When DNL is stimulated, the production of saturated FAs is increased and the oxidation of FAs of any source is reduced. Both mechanisms can favor inflammation and IR. We measured FFA flux/composition and used a surrogate index of DNL (DNLi) to evaluate their relationship with histological features in a group of non-diabetic subjects with biopsy-proven NAFLD.
Methods: Hepatic and adipose tissue-IR indices were derived from [$^2H_5$]glycerol and [$^2H_2$] glucose kinetics in a group of non-diabetic NAFLD patients in the basal state ($n = 40$) and after a 4 h oral glucose load test ($n = 20$). Gas chromatography mass spectrometry was used to assess FFAs composition. DNLi was derived as the ratio palmitic/linoleic acid.
Results: Fasting plasma glucose/insulin, lipid profile, hepatic/adipose tissue IR indices and DNLi were similar in the two groups. Fasting DNLi was associated with triglycerides (TG) and FFAs levels and with adipose tissue IR ($r = 0.597$, $r = 0.330$ and $r = 0.394$, respectively). Among histological features, fasting DNLi significantly correlated with steatosis ($r = 0.364$, $P = 0.02$) and NAS score ($r = 0.306$, $P = 0.05$). After the glucose load, TG levels initially increased despite elevated insulin levels, suggesting a significant contribution of DNL. Accordingly, DNLi consensually increased with TG levels ($r = 0.749$, $P < 0.005$) and was significantly related to the degree of fibrosis (r_s=0.514, $P = 0.02$).
Conclusions: Oral glucose load is associated with changes in DNL and hepatic triglyceride synthesis that can favor liver fibrosis in patients with NAFLD.
Funded by FP7/2007–2013 under grant agreement no. HEALTH-F2-2009-241762 for the project FLIP and by PRIN 2009ARYX4T.

P1043

EXERCISE REDUCES LIVER FAT, VISCERAL FAT AND CIRCULATING TRIGLYCERIDES, BUT NOT CIRCULATING INFLAMMATORY MARKERS IN NON-ALCOHOLIC STEATOHEPATITIS

D. Houghton[1], C. Thoma[2], K. Hallsworth[3], K.G. Hollingsworth[4], C.P. Day[5], Q.M. Anstee[3], M.I. Trenell[3]. *[1]ICM, [2]Newcastle Upon Tyne, [3]ICM, [4]Newcastle Magnetic Resonance Centre, [5]Medical Sciences Faculty Office, Newcastle University, Newcastle Upon Tyne, United Kingdom*

E-mail: david.houghton@ncl.ac.uk

Background and Aims: Non-alcoholic steatohepatitis (NASH) represents steatosis and ballooning degeneration, inflammation and fibrosis. Current treatments for NASH are limited, with no studies to date reporting the effects of exercise in people with NASH. Studies in NAFLD show promising effects on liver lipid but the effect on inflammation and visceral fat, key mediators of fibrosis, are not known. *Aims:* Determine the effect of a 12-week exercise intervention on liver lipid and circulatory inflammation in people with NASH.

Methods: 24 participants (mean age 52±14 years, BMI 33±6) with histologically characterised NASH (NAFLD Activity Score ≥5) received either: resistance exercise (n = 12) or continue standard care (n = 12) over 12 weeks and maintained baseline weight. Participants were not undergoing insulin sensitising treatment, dietary change or regular activity. Subjects with heart/kidney disease or in vivo ferrous material were excluded. Liver lipid content, subcutaneous and visceral adiposity were assessed using magnetic resonance techniques, inflammation, fibrosis markers, insulin sensitivity were assessed at baseline and at 12 weeks.

Results: Resistance exercise produced a significant reduction in liver lipid content (−13±24 vs. 6±15%, P < 0.05), visceral fat (1876±530 vs. 1698±500 cm^2, P < 0.05) and plasma triglycerides (2.2±1.0 vs. 1.7±0.8 mmol/L, P < 0.05). There was no effect of exercise on circulatory inflammation (IL6: 1.4±0.8 pg/mL to 1.7±1.7 pg/mL vs. 2.4±4.6 pg/mL to 2.1±2.9 pg/mL; TNFα: 2.2±0.6 pg/mL to 2.4±0.8 pg/mL vs. 2.3±0.7 pg/mL to 2.3±0.8 pg/mL, P > 0.05) or abdominal adiposity (VAT: 187±54 cm^2 to 170±50 cm^2 vs. 170±72 cm^2 to 211±112 cm^2; SAT: 337±181 cm^2 to 317±158 cm^2 vs. 389±121 cm^2 to 394±112 cm^2, P > 0.05). Metabolically, there was no effect of exercise on HbA1c (51±14 mmol/mol to 49±12 mmol/mol vs. 46±11 mmol/mol to 49±12 mmol/mol, P > 0.05), HOMA IR (2.3±1.4 to 1.9±0.8 vs. 1.9±1.1 to 1.7±1.1, P > 0.05) or 2hour glucose levels or liver enzymes (ALT: 53±25 U/L to 52±18 U/L vs. 81±59 U/L to 71±52 U/L; AST: 41±14 U/L to 45±12 U/L vs. 59±41 U/L to 58±45 U/L, P > 0.05).

Conclusions: This is the first study reporting the effects of exercise on liver lipid, body composition and circulating inflammation in patients with histologically defined NASH. Exercise produces a significant reduction in liver lipid, visceral fat and plasma triglycerides but no effect on body weight, abdominal adiposity, or circulatory markers of inflammation. These results suggest that exercise alone may be insufficient to target the mediators of NASH and warrants further exploration.

RANDOMISED, PLACEBO-CONTROLLED CLINICAL TRIAL: LONG-TERM RESVERATROL TREATMENT FOR NON-ALCOHOLIC FATTY LIVER DISEASE

S. Heebøll[1], S. Hamilton-Dutoit[2], Y.K. Hellberg[2], H. Stødkilde-Jørgensen[3], N. Jessen[4], S.B. Pedersen[5], H. Grønbæk[1]. *[1]Department of Hepatology and Gastroenterology, [2]Institute of Pathology, [3]MR Research Centre, [4]Research Laboratory for Biochemical Pathology, [5]Department of Endocrinology, Aarhus University Hospital, Aarhus, Denmark*

E-mail: saraheeb@rm.dk

Background and Aims: 'The obesity epidemic' has led to an increase in obesity-related conditions including non-alcoholic fatty liver disease (NAFLD), for which effective treatments are in demand. The polyphenol resveratrol (RSV) prevents the development of experimental NAFLD in numerous *in vitro* and *in vivo* studies through anti-inflammatory, anti-oxidant and AMPK/SIRT1 activating effects. We hypothesized that RSV would alleviate NAFLD in a randomized, placebo-controlled, double-blind, clinical trial.

Methods: 28 overweight, non-diabetic patients with transaminasemia and histological NAFLD were recruited for the trial and randomized to placebo or RSV 500 mg t.i.d. for 6 months. 26 patients completed the trial and underwent repeated clinical investigation, blood work and MR spectroscopy. 19 patients also committed to a repeat liver biopsy.

Results: There was a decrease in liver steatosis as assessed by MR spectroscopy in RSV treated patients from 31% to 23% (P = 0.03), in placebo treated patients from 32 to 30%, however there was no statistical difference between the two treatment arms (P = 0.38). RSV treatment was no better than placebo to improve histological NAFLD activity score (P = 0.59), steatosis (P = 0.22) or fibrosis (P = 0.75). We detected no difference in ALT (P = 0.51) or in the level of other plasma markers of liver injury when comparing the RSV and placebo groups. Similarly, we observed no improvements in markers of the metabolic syndrome (central obesity, plasma lipids, glucose tolerance, blood pressure).

Conclusions: In contrast to findings in experimental NAFLD, high-dose, long-term RSV treatment had no consistent therapeutic effect in alleviating clinical or histological NAFLD.

P1045

ULTRA-HIGH-FIELD MR-SPECTROSCOPY IN NAFLD AS NON-INVASIVE IN-VIVO TOOL FOR MONITORING CHANGES IN FAT AND ENERGY METABOLISM WITH POTENTIAL IDENTIFICATION OF NASH AND ADVANCED FIBROSIS BY SATURATION TRANSFER TECHNIQUE

S. Traussnigg[1], C. Kienbacher[1], M. Gajdošík[2], L. Valkovič[2], H. Hofer[1], P. Ferenci[1], F. Wrba[3], S. Trattnig[2], M. Krššák[2,4], M. Trauner[1]. *[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine III, [2]MR Centre-of-Excellence, Department of Radiodiagnostics, [3]Department of Clinical Pathology, [4]Division of Endocrinology and Metabolism, Department of Internal Medicine III, Medical University Vienna, AKH Wien, Vienna, Austria*

E-mail: stefan.traussnigg@meduniwien.ac.at

Background and Aims: With the rising incidence of non-alcoholic fatty liver disease (NAFLD) with potentially progressive steatohepatitis (NASH) non-invasive tools for risk stratification and treatment response assessment are urgently needed. We therefore used ultra-high-field magnetic-resonance-spectroscopy (MRS) as non-invasive tool to obtain novel mechanistic and pathogenetic insights into alterations of hepatic metabolism in NAFLD including ATP flux measured by saturation transfer technique.

Methods: MRS and liver biopsy were performed back-to-back in suspected NAFLD patients and data were correlated with histology. Hepatocellular lipid content (HCL) was measured by ^{1}H-MRS. 7.0-T ^{31}P-MRS was applied to determine phosphomonoester (PME), phosphodiester (PDE), phosphocreatine (PCr), ATP as well as total phosphate (TP). Additionally, saturation-transfer was measured to get a more dynamic in-vivo insight in energy metabolism.

Results: 30 patients (12 female) were included. Median age was 52 years (24–70). Histological diagnosis was simple steatosis (SS; n = 8) and NASH (n = 22).

Steatosis assessed by ^{1}H-MRS correlated well with histology (r = 0.704; p < 0.001). All NASH patients showed significantly higher values of steatosis compared to SS (r = 0.69, p < 0.001). PME, such as PE/TP ratio as marker of cell membrane alterations increased from low fibrosis (LF; 0–2) to advanced fibrosis (AF; 3+4) (r = 0.556; p = 0.002) assessed by ^{31}P-MRS. Conversely, GPC/PME+PDE decreased (r = −0.531, p = 0.004) and PCr/TP increased

(r = 0.458, p = 0.014) in cirrhosis and AF, respectively. γ-ATP as most robust marker of ATP was significantly lower in AF than LF (r = −0.376; p = 0.032), whereas the mean exchange rate constant (r = −0.485; p = 0.012) and the ATP flux (r = −0.431; p = 0.025) were lower in NASH than SS patients showing a dynamic energy change for NASH.

Conclusions: High field ^{1}H-MRS strongly correlates with histological grades of steatosis showing also differences between SS and NASH. In-vivo ^{31}P-MRS shows promising results indicating changes in hepatic cell membrane and energy metabolism in inflammation and fibrosis associated with NASH and AF. Non-invasive profiling in NAFLD appears feasible and may serve to assess therapeutic efficacy of new treatment approaches.

A ONE YEAR RETROSPECTIVE REVIEW OF NEW PATIENT ATTENDANCES AT A TERTIARY HEPATOLOGY CENTRE HIGHLIGHTING THE INCREASING CHALLENGE OF NAFLD AND THE NEED TO DEVELOP CLINICAL PATHWAYS

A. Srivastava[1], R. Gailer[2], S. Tanwar[1], P. Trembling[1], A. Warner[2], S. Morgan[2], K. Sennett[3], D. Thorburn[1], E. Tsochatzis[1], W. Rosenberg[1].
[1]*Department of Hepatology, UCL Institute of Liver and Digestive Health,* [2]*Primary Care, Camden CCG,* [3]*Primary Care, Islington CCG, London, United Kingdom*
E-mail: ankur.srivastava@nhs.net

Background and Aims: 25% of the UK population is overweight or obese. 75% will have NAFLD of whom 5% will have steatohepatitis and associated fibrosis. Identifying this subgroup at risk of chronic liver disease can be challenging as they are often asymptomatic. Non-invasive tests (NIT) of liver fibrosis including FIB4 and the Enhanced Liver Fibrosis (ELF) test have been validated in NAFLD and provide the opportunity to design pathways to stratify patient disease severity in primary care.

We performed a retrospective review of GP referrals to secondary care of patients with a final diagnosis of NAFLD. This will be followed by a prospective evaluation of a novel Camden and Islington CCG commisioned pathway using non-invasive tests to stratify liver fibrosis in patients with NAFLD.

Methods: All new GP referrals to the Royal Free London NHS Foundation Trust with a final diagnosis of NAFLD between 1/4/12 and 31/3/13 had their electronic patient records and patient notes reviewed. Demographic, clinical, laboratory and outcome data were recorded. The potential impact of the use of FIB4 was assessed. Prospectively FIB4 and ELF are being used to stratify patients prior to referral.

Results: In the retrospective analysis 112 patients with a final diagnosis of NAFLD were referred by GP's over 1 year. 74 patients (66%) had FIB4 <1.30 (low risk of advanced liver disease). FIB4 was indeterminate (1.30–3.25) in 36 (31%) who would be stratified with ELF in the new pathway.

Eighteen (16%) had a liver biopsy. Six (5%) had FIB4 <1.30, each of whom had a histological stage of ≤F2 fibrosis and could have avoided referral under the new pathway. Of 6 (5%) with confirmed cirrhosis on biopsy, one had FIB4 >3.25 and 5 had indeterminate FIB4 scores (1.30–3.25).

Conclusions: The NAFLD epidemic mandates new strategies to manage the increasing burden effectively. Those with advanced liver disease need specialist input, whilst those at low risk should have their risk factors aggressively addressed in primary care. Current approaches are ineffective in stratifying patients for referral. Using FIB4 alone, 66% of referrals could have been avoided but the majority of cirrhotic patients would not have been identified. We have implemented a novel primary care pathway integrating the use of FIB4 and ELF (to categorise FIB4 indeterminate cases) to stratify patients for management in primary or secondary care (Figure 1). Evaluation of clinical and cost effectiveness is underway.

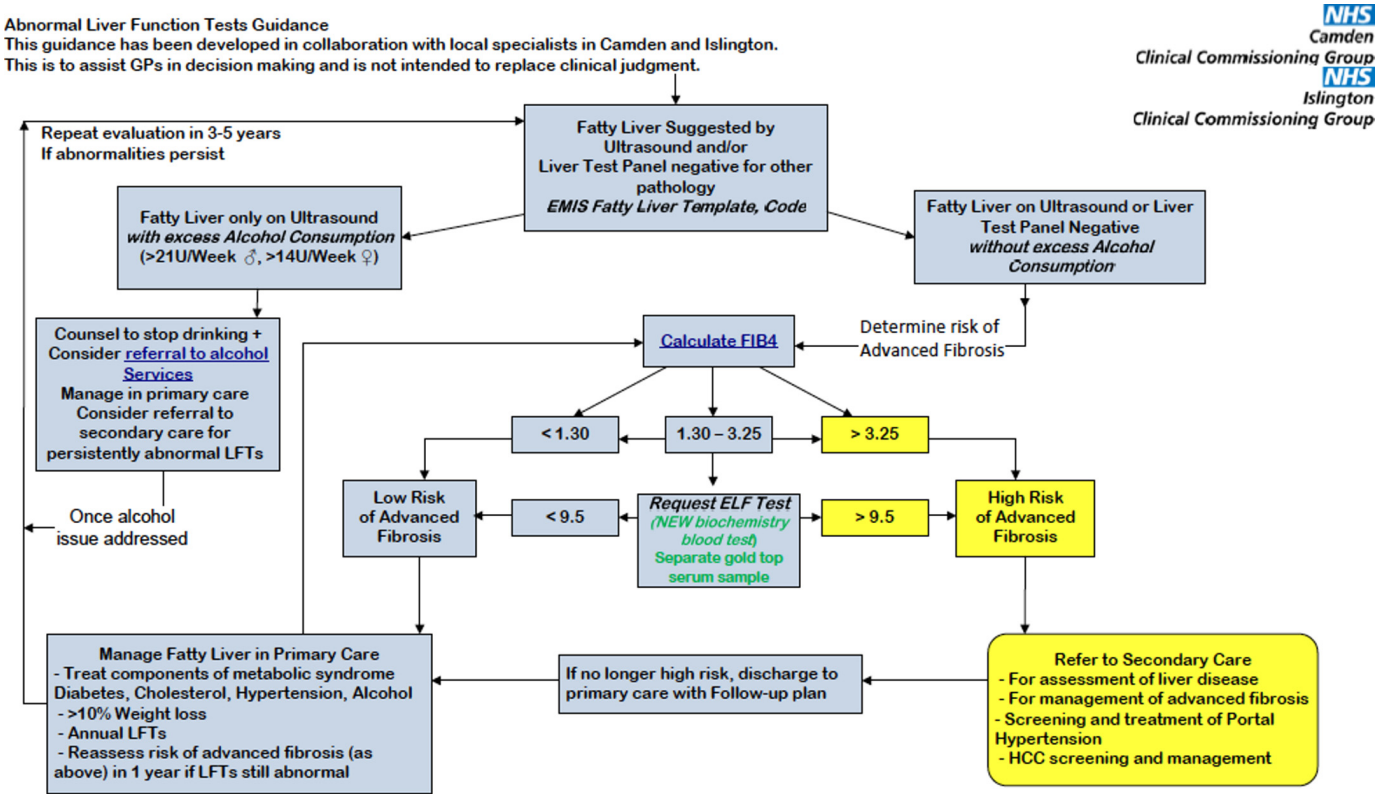

Figure 1 (abstract P1046). Abnormal liver function tests guidance.

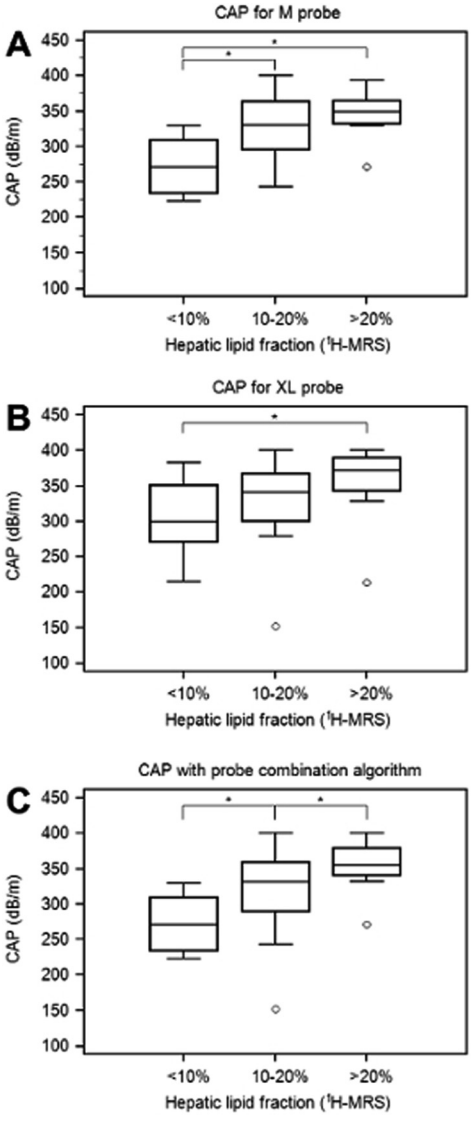
P1047

CONTROLLED ATTENUATION PARAMETER (CAP): COMBINATION OF M AND XL PROBE IMPROVES FEASIBILITY AND ACCURACY FOR DISCRIMINATING ADVANCED GRADES OF STEATOSIS

T. Karlas[1], N. Garnov[2], F. Lindner[3], H. Busse[4], N. Linder[4], A. Schaudinn[4], B. Relke[5], R. Chakaroun[6], M. Tröltzsch[3], V. Keim[3], J. Wiegand[3]. *[1]Department of Medicine, Neurology and Dermatology, Division of Gastroenterology and Rheumatology, [2]Department of Diagnostic and Interventional Radiology, Leipzig University Medical Center, IFB AdiposityDiseases, [3]Department of Medicine, Neurology and Dermatology, Division of Gastroenterology and Rheumatology, [4]Department of Diagnostic and Interventional Radiology, University Hospital Leipzig, [5]Internistische Hausarzt- und Diabetologische Schwerpunktpraxis Dr. Relke, [6]Department of Medicine, Neurology and Dermatology, Division of Endocrinology and Nephrology, University Hospital Leipzig, Leipzig, Germany*
E-mail: thomas.karlas@medizin.uni-leipzig.de

Background and Aims: Non-invasive steatosis quantification is of emerging importance for the characterization of patients with fatty liver disease. The controlled attenuation parameter (CAP) estimates steatosis during the measurement of liver stiffness with Fibroscan®. However, feasibility and accuracy of CAP measurement using the conventional M probe (CAP-M) is limited in obese subjects. We therefore compared applicability and diagnostic accuracy of CAP-M with the new CAP algorithm for the XL probe (CAP-XL), dedicated to obese patients.



Methods: Type 2 diabetic patients (n = 51) at risk for non-alcoholic fatty liver disease were evaluated with both CAP-M and CAP-XL. Skin-to-liver-capsule distance (SLD) at the measuring site was used for probe stratification (CAP-combined): CAP-M in cases with SLD <25 mm, CAP-XL for cases with SLD ≥25 mm. Proton magnetic resonance spectroscopy (^{1}H-MRS, liver segments II and VII) served as reference standard.

Results: 47 patients (49% female; age 65.2+8.5 years; body mass index 29.5+4.8 kg/m^2; 28% with SLD ≥25 mm) had valid ^{1}H-MRS and were included in the final analysis. CAP-M was feasible in 43 (91%), CAP-XL in 46 (98%) and CAP-combined in 46 (98%) cases, respectively. CAP values correlated with ^{1}H-MRS results: r = 0.4473 [0.1698; 0.6591] for CAP-M, r = 0.3238 [0.0369; 0.5613] for CAP-XL and r = 0.4186 [0.1460; 0.6321] for CAP-combined ($p < 0.05$ respectively).

CAP-M and CAP-XL values differed significantly between patients with low (<10% lipid fraction) and high (>20% lipid fraction) hepatic fat content (Figures A and B, *ANOVA $p < 0.05$). Only CAP-combined discriminated between all grades of steatosis (Figure C) and showed good diagnostic accuracy for detection of patients with >10% lipid fraction (n = 35; AUC 0.847, sensitivity 69%, specificity 100%) and >20% lipid fraction (n = 15; AUC 0.788, sensitivity 93%, specificity 68%).

Conclusions: CAP-XL optimizes applicability of non-invasive steatosis quantification, but is imprecise in cases with lower grades of steatosis if used alone. Combination of CAP-M and CAP-XL increases the accuracy for discriminating advanced stages of steatosis.

P1048

EFFECTS OF PROSTEATOGENIC TM6SF2 AND NCAN/SUGP1 VARIANTS ON HEPATIC STEATOSIS AND NON-INVASIVE MARKERS OF LIVER INJURY IN PATIENTS WITH CHRONIC LIVER DISEASES

A. Arslanow[1], C.S. Stokes[1], F. Grünhage[1], F. Lammert[1], M. Krawczyk[1]. *[1]Department of Medicine II, Saarland University Medical Center, Homburg, Germany*
E-mail: anita.arslanow@uks.eu

Background and Aims: Previously we demonstrated that the frequent genetic variant *PNPLA3* p.I148M is associated with increased hepatic steatosis quantified by controlled attenuation parameter (CAP) and fibrosis measured by liver stiffness (LS) in patients with chronic liver diseases (CLD). Recently single nucleotide variants in the *TM6SF2* gene (rs58542926) and the *NCAN/SUGP1* locus (rs10401969) have been reported as additional genetic determinants of fatty liver (Liu et al. *Nat Comm* 2014; DiStefano et al. *Acta Diabetol* 2014). Here, we investigate the associations between all of these variants and surrogate markers or liver injury, including CAP and LS, in patients with CLD.

Methods: In total, 174 patients with non-viral and non-cholestatic CLD (50% men, age 18–77 years) were recruited for the study. Hepatic steatosis was phenotyped by CAP during transient elastography (FibroScan). Genotyping was performed using Taqman assays. Statistical analyses included exact tests of Hardy–Weinberg equilibrium (HWE), association tests in contingency tables as well as non-parametric tests for continuous variables.

Results: Overall, the median CAP score was 285 dB/m (100–398), indicating moderate and severe steatosis in the majority of patients, but median LS was 6.1 kPa only (1.6–69.1). CAP values correlated with ALT activities (r = 0.236, P < 0.01) and LS (r = 0.174, P < 0.05). We observed the following allele frequencies, all of which were in HWE (P > 0.05): *TM6SF2* [EE] 139 (79.9%), [EK] 33 (19.0%), [KK] 2 (1.1%); *SUGP1* [CC] 137 (78.7%), [CT] 34 (19.5%), [TT] 3 (1.7%). Carriers of the *TM6SF2* and *SUGP1* risk alleles presented with significantly (all P < 0.05) increased serum ALT [57 U/l (26–168) *vs.* 44 U/l (9–2106)

and 58 U/l (26–168) *vs*. 44 U/l (9–2106), respectively]. In contrast to the common *PNPLA3* mutation p.I148M, neither *TM6SF2* nor *SUGP1* genotypes were significantly associated with higher CAP or LS, or with an increased risk of presenting CAP ≥238 dB/m, which is characteristic for liver steatosis (all P > 0.05).
Conclusions: Our study indicates that the *TM6SF2* and *NCAN/SUGP1* variants do not display marked effects on hepatic steatosis, but carriers of the risk alleles present with increased liver inflammation. Given the low frequencies of the *TM6SF2* risk genotypes in the general population, variant *PNPLA3* remains the clinically most relevant prosteato- and profibrogenic genetic factor.

P1049
LYSOSOMAL ACID LIPASE ACTIVITY IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE

D. Pastori[1], F. Baratta[1], L. Polimeni[1], F. Piemonte[2], G. Tozzi[2], S. Di Santo[1], D. Salzano[1], A. Pani[1], F. Violi[1], M. Del Ben[1], F. Angelico[1]. *[1]Internal Medicine and Medical Specialtis, Sapienza Università di Roma, [2]Bambino Gesù Children Hospital, Rome, Italy*
E-mail: daniele.pastori@uniroma1.it

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is considered the hepatic component of the metabolic syndrome. Nevertheless, some genetic factors influence the onset and progression of NAFLD. Lysosomal Acid Lipase (LAL) is a key enzyme in the lipid metabolism, and LAL deficiency causes accumulation of lipids and pre-mature atherosclerosis. There are no data on factors influencing LAL activity in patients with NAFLD.
Methods: NAFLD was diagnosed by ultrasonographic Hamaguchi's criteria in 200 subjects with no history of alcohol abuse, negative tests for HCV and HBV and for autoimmune liver disease. LAL activity was measured with dried blood spot using Lalistat 2, an inhibitor of LAL.
Results: Mean age was 52.2±11.0 years and 58% were male. In the whole cohort the median LAL activity was 0.77 [0.59–0.99] nmol/spot/h. We found a slightly reduced LAL activity in men than women (0.75 [0.57–0.95] vs. 0.82 [0.65–1.07], p = 0.079), and no correlation with age or Hamaguchi score. We found a significant difference between the lowest and the highest tertile of LAL activity for total cholesterol (206.8±39.7 mg/dl vs 192.9±34.7 mg/dl, p < 0.05), LDL-c (124.1±30.3 mg/dl vs 111.8±31.5 mg/dl, p < 0.05), AST (25 [19.0–34.5] UI/L vs. 21.0 [17.0–28.0] UI/L, p = 0.032), ALT (33.0 [23.0–52.5] UI/L vs. 28.0 [20.0–38.7] UI/L, p = 0.027), platelets (221.6±53.6 vs. 258.5±67.3 $\times 10^3/\mu l$, p = 0.001) and APRI index (0.31 [0.24–0.49] vs. 0.25 [0.18–0.31], p = 0.002). Furthermore, patients taking statins had a significant higher LAL activity (0.73 [0.55–0.95 vs. 0.91 [0.66–1.12], p = 0.008). A stepwise multivariable linear regression analysis showed that platelets (B: 0.540, p < 0.001), statin use (B: 0.185, p = 0.009), AST (B: −0.634, p = 0.006), APRI index (B: −0.573, p = 0.024) were independently associated with LAL activity.
Conclusions: This is the first report on LAL activity in NAFLD patients. LAL activity was inversely correlated with AST and APRI index and directly with platelet count. Statins use was positively associated with LAL activity. Understanding the role of LAL in NAFLD may provide novel insights in the pathogenesis of NA

P1050
ASSOCIATION OF FAMILY HISTORY OF METABOLIC TRAITS WITH AGE AT DIAGNOSIS AND SEVERITY OF NON ALCOHOLIC STEATOHEPATITIS (NASH) RELATED CIRRHOSIS

A.S. Bhadoria[1], C.K. Kedarisetty[2], V. Shasthry[3], M.K. Sharma[2], J. Benjamin[3], G. Kumar[4], A. Bhardwaj[1], S. Muralikrishna Shasthry[2], T. Vyas[2], S. Sarin[2]. *[1]Clinical Research, [2]Hepatology, [3]Clinical Nutrition, [4]Research, Institute of Liver and Biliary Sciences, New Delhi, India*
E-mail: ajeetsinghbhadoria@gmail.com

Background and Aims: Familial aggregation of metabolic traits (MTs) such as diabetes, hypertension, dyslipidemia, coronary artery disease and obesity with fatty liver disease, non alcoholic steatohepatitis (NASH) and advanced fibrosis is well documented. However, there is scarcity of data regarding such association with NASH related cirrhosis. We aimed to explore the association of positive family history (FH) of MTs with age at diagnosis, severity and complications of NASH related cirrhosis.
Methods: A cross-sectional study was conducted at a tertiary care centre and all in and out patients of cirrhosis with underlying aetiology as NASH were included during the period 2013–14. Other common etiologies (like ALD, HBC, HCV autoimmune etc) of cirrhosis were excluded. FH, demographic characteristics, medical history data, anthropometrical measurements and laboratory data were recorded. Positive FH for MTs was decided if at least one first degree relative had a history of any of these MTs.
Results: A total of 504 cirrhotics [age 53.1±12.3 yrs, male 392 (77.8%), female 112 (22.2%)] were enrolled. Positive FH for MTs was seen in 328 (65.1%) cases. Both parents had either DM or/and HTN in 159 (31.6%) and in one of the parents in 162 (32.2%) cases. History of 1–2, 2–5 or >5 MTs among parents was seen in 117 (23.3%), 148 (29.5%) and 12 (2.4%) cases, respectively. Sixty (11.9%) cases had a history of cirrhosis among their parents. Cirrhotics with positive FH had significantly lower age at diagnosis (48.1±10.7 vs 52.1±11.7 yrs), high BMI (28.5±5.3 vs 26.4±4.3 kg/m^2), high MELD (10.6±6.9 vs 9.3±3.4), high CTP (8.1±2.5 vs 6.9±2.1) and had more complications like ascites (46.6% vs 20.5%), variceal bleed (25.9% vs 14.2%), hepatic encephalopathy (25.9% vs 6.8%) and jaundice (15.5% vs 8.0%), (p < 0.05). Age, gender and BMI adjusted odds ratios were calculated. FH of MTs increased the risk of getting cirrhosis at an early age of <45 yrs (OR: 4.9, 95% CI 2.3–10.4), with MELD >15 (OR: 1.6, 95% CI 1.1–2.3), with Child C (OR: 3.2, 95% CI 1.6–6.1) and with one or more complications (OR: 4.9, 95% CI 3.2–7.6).
Conclusions: We conclude that a positive FH for MTs leads to an early and severe NASH related cirrhosis with high odds of development of complications. Further studies are needed to better understand the mechanistic pathway behind this association. Health education strategies to disseminate messages regarding severe liver disease among this high risk group with positive FH of MTs, is a prime requisite.

P1051
ALGINATE ENRICHED BREAD ATTENUATES CIRCULATING LIPIDS AND NON-ALCOHOLIC FATTY LIVER DISEASE

D. Houghton[1], P. Chater[2], M. Wilcox[3], I. Brownlee[3], M.I. Trenell[3], C. Seal[4], J. Pearson[5]. *[1]ICM, [2]Newcastle Upon Tyne, [3]ICM, [4]Human Nutrition Research Centre, [5]ICaMB, Newcastle University, Newcastle Upon Tyne, United Kingdom*
E-mail: david.houghton@ncl.ac.uk

Background and Aims: *Background:* Non-alcoholic fatty liver disease (NAFLD) affects up to one in three people of developed nations and is considered by some to be the hepatic manifestation of the metabolic syndrome. People with NAFLD have a high level of fat intake which may cause (1) high energy intake, (2) insulin resistance, and (3) hepatic de novo lipogenesis. Therapeutic interventions for NAFLD are limited. Alginates are

polysaccharides extracted from brown algae that are un-digestible in the upper gastrointestinal tract (GI). Specific alginates are able to inhibit the activity of pancreatic lipase and thus reduce fat digestion and absorption. The effect of alginates based in food upon fat absorption is not known, despite the therapeutic implications. *Aims:* To determine if alginate enriched bread inhibits fat digestion and circulatory lipids.

Methods: Twenty-nine ileostomy patients were fasted overnight and then fed either 100g alginate enriched bread (4% w/w wet dough) with 20g of butter, or 100g of control bread with 20g of butter a month apart in a double blind randomised cross over study. Both alginate and control bread were produced by Greggs Plc master baker. Effluent samples, blood samples, and wellbeing questionnaires were taken at baseline and then every 30 minutes for a total of 5 hours. Ileostomy patients were used to create a model to study fat absorption in the upper GI in isolation.

Results: The alginate bread produced a 20% increase in effluent weight at 300 minutes (2489g vs. 2010g, $P < 0.05$), a 31% increase in total effluent fat (376g vs. 264g, $P < 0.05$) and a significant correlation between fat content effluent weight ($r = 0.98$, $P < 0.05$). A small reduction in plasma triglycerides was reported when consuming alginate bread, however this was not significant ($P > 0.05$). There were no substantial differences in palatability between the two breads, apart from time point zero where subjects reported an increase in thirst (1.5 ± 1.5 vs. 0.5 ± 0.5, $P < 0.05$) and reduced fullness (2.2 ± 1.8 vs. 1.6 ± 1.6, $P < 0.05$) following consumption of alginate bread.

Conclusions: This is the first study to show that alginate enriched products reduce fat digestion in man. The data shows that alginate enriched products are able to attenuate fat digestion by up to 31%. Alginate enriched products hold potential as a therapeutic weight and metabolic management therapy, without side effects of other known pharmaceutical agents, and should be considered in NAFLD.

P1052

AN IMBALANCE BETWEEN Th17 AND Treg KEY TO PATHOGENESIS OF NON-ALCOHOLIC FATTY LIVER DISEASE IN MORBIDLY OBESE PATIENTS

P. Iruzubieta[1], M.T. Arias-Loste[1], A. Domínguez[2], A. López-Useros[2], C. Santa Cruz[3], Á. Estébanez[1], D. San Segundo[3], D. Ramos[1], A. Azueta[4], S. Llerena[1], C. Alonso[1], J. Cabezas[1], M. López Hoyos[3], J. Crespo[1]. *[1]Hepatology Unit and IDIVAL, [2]General Surgery, [3]Immunology Service and IDIVAL, [4]Anatomical Pathology Department and IDIVAL, University Hospital Marqués de Valdecilla, Santander, Spain*
E-mail: p.iruzubieta@gmail.com

Background and Aims: An adequate balance between Treg/Th17 is crucial for the stability of immune homeostasis; a change in this balance can lead to autoimmunity, chronic inflammation and the development of liver diseases. Therefore, the aim of our study was to assess a possible imbalance Treg/Th17 in morbidly obese (MO) patients before and after bariatric surgery (BS) and to correlate these results with the progression of NAFLD.

Methods: Prospectively, 49 MO patients undergoing BS and 17 healthy controls (HC) have been enrolled in our study. Peripheral blood (PB) rate of Treg (CD4+CD25highFOXP3+) and Th17 (CD4+CD161+CCR6+IL17+) were analyzed with flow cytometry before and, in 42 MO, 6 months after BS. Liver biopsies obtained during surgery were classified according to Brunt classification, and the rate of intrahepatic Treg (CD4+CD45+CD25highCD127lowFOXP3+) and Th17 were assessed by flow cytometry.

Results: According to liver histology, 29% of patients displayed a variable inflammatory infiltrate (NASH), 41% had simple steatosis (SS), 19% had normal histology (NH) and in 11% liver histology could not be determined. MO patients showed a significant lower rate of PB Treg when compared to HC (2.52 ± 1.45 vs 3.43 ± 1.23; $p = 0.029$), as well as a lower Treg/Th17 ratio (20.53 ± 31.36 vs 52.29 ± 41.92; $p = 0.003$). Regarding liver histology, we found no differences in the percentage of Treg or Th17 in PB. Nevertheless, we observed a higher rate of intrahepatic Treg and Th17 in patients with NASH compared to those with SS (Treg: 2.9 ± 1.81 vs 1.96 ± 0.7) (Th17: 1.49 ± 0.55 vs 1.18 ± 0.47), whereas Treg/Th17 ratio was lower (1.39 ± 0.71 vs 2.14 ± 1.35). Six months after BS, the rate of PB Treg and Th17 significantly increased when compared to baseline levels (Treg: 3.49 ± 1.15 vs 2.75 ± 1.44; $p < 0.001$) (Th17: 0.57 ± 0.8 vs 0.21 ± 0.24; $p = 0.023$). This increment was greater in the case of Treg, as reflected in the increase of Treg/Th17 ratio (24.88 ± 72.91 vs 18.58 ± 29.15; $p = 0.06$).

Conclusions: In the liver of morbidly obese patients with NASH, there is an increase in Treg and Th17 populations but with a decrease in the Treg /Th17 ratio compared to patients without NASH. This imbalance may be key to understand NASH pathogenesis in morbidly obese patients. In addition, we observed a considerable discrepancy between peripheral and intrahepatic Treg/Th17, suggesting that changes in adaptive immunity cells are confined to the liver and therefore, we should not over interpret peripheral blood results.

P1053

PREVALENCE OF PATATIN-LIKE PHOSPHOLIPASE DOMAIN CONTAINING 3 (PNPLA3) rs738409 C/G POLYMORPHISM IN PATIENTS WITH BONA-FIDE POST-NASH CIRRHOSIS

P. Gallo[1], U. Vespasiani Gentilucci[1], G. Galati[1], A. De Vincentis[1], L. Piccioni[2], E. Riva[2], A. Picardi[1]. *[1]Internal Medicine and Hepatology Unit, [2]Virology Section, University Campus Biomedico, Rome, Italy*
E-mail: paolo.gallo@unicampus.it

Background and Aims: The patatin-like phospholipase domain containing 3 (PNPLA3) rs738409 C/G single nucleotide polymorphism (SNP) has been consistently associated with steatosis and fibrosis in NAFLD populations undergoing liver biopsy, in which cirrhotic patients were very poorly represented. Since not all NAFLD with fibrosis evolve to cirrhosis, we aimed to determine the prevalence of this SNP in a group of patients with post-NASH cirrhosis.

Methods: Consecutive patients with *bona-fide* post-NASH cirrhosis were enrolled. A sample of patients with biopsy-proven non-cirrhotic NAFLD served as controls and results were also compared to published data from a population of Italian blood donors (Valenti L *et al.*, 2010). All other causes of liver disease were excluded and cirrhotic patients were required to have documentation of at least one of the followings preceding the diagnosis of cirrhosis: ultrasonographic steatosis; metabolic syndrome; diabetes mellitus; obesity. The C/G SNP was analyzed by pyrosequencing method in PyroMark_Q96 ID instrument.

Results: Thirty-six patients with *bona-fide* post-NASH cirrhosis and 45 patients with non-cirrhotic NAFLD were studied. Diagnosis of cirrhosis was histological in 13 cases and clinical in 23 cases. Among non-cirrhotic NAFLD cases, 33 were NASH and 12 non-NASH and fibrosis was as follows: 4 (F0); 21 (F1); 9 (F2); 11 (F3). Almost 80% of patients with post-NASH cirrhosis held at least a copy of the G allele and 56% carried the homozygote GG genotype, compared to 56% and 20% in the non-cirrhotic NAFLD group and 34% and <5% in blood donors, respectively (Table 1). Compared to the non-cirrhotic NAFLD group, carriage of the G allele [unadjusted OR 2.8 (1.05–7.47)], and particularly of the GG genotype [unadjusted OR 3.86 (1.50–9.95)], was strongly associated with post-NASH cirrhosis. In a multivariate model including age, sex, BMI, diabetes, and PNPLA3 rs738409 genotype, only age [years, OR 1.05 (1.05–1.19)] and presence of the G allele [OR 2.2 (1.11–4.48)], or better of the GG genotype [OR 4.13 (1.22–14.0)], were significantly associated with cirrhosis.

Genotype	Post-NASH cirrhosis	Noncirrhotic NAFLD	Unadjusted OR	p value	Italian blood donors [a]	Unadjusted OR	P value
CC	8 (22%)	20 (44%)	–	–	118 (66%)	–	–
CG	8 (22%)	16 (36%)	1.25 (0.38–4.07)	0.7	56 (31%)	2.11 (0.75–5.96)	0.16
GG	20 (56%)	9 (20%)	2.36 (1.33–4.16)	0.003	5 (2.8%)	13.5 (5.2–34.9)	<0.001

[a] Valenti L et al., 2010.

Conclusions: Prevalence of the PNPLA3 rs738409 C/G SNP, and particularly of the GG genotype, is extremely high in patients with *bona-fide* post-NASH cirrhosis and significantly higher than that in non-cirrhotic NAFLD patients, suggesting that most of NASH cases progressing till cirrhosis require the contribution of an altered PNPLA3 function.

P1054
LIVER ENZYMES, ADIPONECTIN AND VITAMIN D LEVELS AS PREDICTORS OF DIABETES – DATA FROM THE HEINZ NIXDORF RECALL STUDY

J. Kälsch[1], L.P. Bechmann[1], D. Heider[2], P. Manka[1,3], H. Kälsch[4], J.-P. Sowa[1], S. Moebus[5], U. Slomiany[5], K.-H. Jöckel[5], R. Erbel[4], G. Gerken[1], A. Canbay[1]. *[1]Department of Gastroenterology and Hepatology, University Hospital, University Duisburg-Essen, Essen, [2]Department of Bioinformatics, Straubing Center of Science, University of Applied Science Weihenstephan-Triesdorf, Straubing, Germany; [3]Regeneration and Repair Group, The Institute of Hepatology, Foundation for Liver Research, London, United Kingdom; [4]Department of Cardiology, West-German Heart Center, [5]Institute of Medical Informatics, Biometry and Epidemiology, University Hospital, University Duisburg-Essen, Essen, Germany*
E-mail: ali.canbay@uni-due.de

Background and Aims: Key features of the metabolic syndrome are insulin resistance and diabetes. The liver as central metabolic organ is not only affected by the metabolic syndrome as non-alcoholic fatty liver disease (NAFLD), but may contribute to insulin resistance and metabolic alterations. Thus we aimed to identify potential associations between liver injury markers and diabetes in the population-based Heinz Nixdorf Recall Study.
Methods: Demographic and laboratory data were analyzed in participants (n = 4814, age 45 to 75y). Metabolic profile included body-mass-index (BMI; kg/m^2), type-2-diabetes rate, as well as blood levels of adiponectin, vitamin D, and C-reactive protein (CRP).
Results: ALT and AST values were significantly higher in male subjects than in females. Mean BMI was 27.9 kg/m^2 and type-2-diabetes was present in 656 participants (13.7%). Adiponectin and vitamin D both correlated inversely with BMI. ALT, AST, and GGT correlated with BMI, CRP, and HbA1c and inversely correlated with adiponectin levels. Utilizing machine learning techniques, a computational model was built with a high accuracy for the prediction of diabetes from blood parameters. Moreover, the model identified adiponectin, GGT, and vitamin D levels as highly important for the prediction.
Conclusions: Transaminase levels were closely associated with the BMI and the risk for diabetes, even within normal ranges. Transaminase levels and adiponectin were inversely associated and represent predictors of diabetes in this cohort. Re-assessment of current normal range limits should be considered, to provide a more exact indicator for chronic metabolic liver injury, in particular to reflect the situation in diabetic, overweight or obese individuals.

P1055
THE MACROPHAGE ACTIVATION MARKER SOLUBLE CD163 IS INDEPENDENTLY ASSOCIATED WITH THE SEVERITY OF NAFLD IN MORBID OBESITY AND REDUCED BY BARIATRIC SURGERY

K. Kazankov[1,2], J. Tordjman[2,3], H.J. Møller[4], H. Vilstrup[1], C. Poitou[2,3], P. Bedossa[5,6], J.-L. Bouillot[7], K. Clement[2,3], H. E-mail: konskaza@rm.dk

Background and Aims: Macrophages play an important role in non-alcoholic fatty liver disease (NAFLD). Soluble CD163 (sCD163) is a specific marker of macrophage activation. We aimed to measure sCD163 in morbidly obese patients with varying degrees of NAFLD before and after bariatric surgery (BS).
Methods: Demographic, clinical and biochemical data, and plasma sCD163 measured by ELISA, of 196 patients were collected preoperatively and 3, 6 and 12 months after BS leading to significant weight loss. Peroperative liver biopsies were assessed for the NAFLD Activity Score (NAS), Kleiner fibrosis score and the FLIP algorithm. In a subset, CD163 immunohistochemistry and real-time quantitative PCR for CD163 mRNA were performed.
Results: sCD163 was higher in patients with NAS ≥5 compared to those with NAS <5 [2.4 (2.0–3.1) vs. 1.9 (1.5–2.3) mg/L, p < 0.001] and in patients with bridging fibrosis (F ≥3) compared to lower fibrosis stages [2.6 (2.0–4.9) vs. 2.0 (1.5–2.4) mg/L, p = 0.001]. Preoperative sCD163 was independently associated with both the NAS (p = 0.002) and the fibrosis score (p = 0.024). sCD163 decreased after BS and was greatly reduced after 12 months, more rapidly so in patients with NAS ≥5 (p < 0.001) and NASH according to the FLIP algorithm (p = 0.03). Immunohistochemistry showed CD163-positive macrophages aligning fat-laden hepatocytes and forming microgranulomas in patients with NASH. CD163 mRNA expression did not vary with NAS.
Conclusions: sCD163 increased in parallel with the severity of NAFLD in morbid obesity, indicating macrophage activation. Bariatric surgery reduced sCD163 even in patients with severe liver injury and fibrosis, suggesting full reversibility of macrophage activation associated with improved insulin sensitivity.

P1056
INSULIN RESISTANCE AND LIVER DAMAGE ARE ASSOCIATED WITH EARLY SIGNS OF LEFT VENTRICULAR SYSTOLIC DYSFUNCTION IN PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE, INDEPENDENTLY OF DIABETES, HYPERTENSION AND DYSLIPIDEMIA

E. Vanni[1], L. Mezzabotta[1], R. Faletti[2], M. Morello[3], A. Marengo[1], G. Battisti[2], S. Frea[3], M. Cannillo[3], E. Mosso[1], C. Rosso[1], L. Bergamasco[4], A. Gastaldelli[5], M. Rizzetto[1], E. Bugianesi[1]. *[1]University of Turin, Department of Medical Sciences, Division of Gastroenterology, [2]University of Turin, Department of Surgical Sciences, Institute of Radiology, [3]University of Turin, Department of Medical Sciences, Division of Cardiology, [4]University of Turin, Turin, [5]Cardiometabolic Risk Unit, CNR, Institute of Clinical Physiology, Pisa, Italy*
E-mail: ester.vanni@unito.it

Background and Aims: Nonalcoholic Fatty Liver Disease (NAFLD) has been associated with subclinical cardiovascular disease (CVD).

This study was undertaken to evaluate the relationship between metabolic parameters, histologic features and parameters of cardiac morphology and function in NAFLD subjects.
Methods: Nineteen non-diabetic, non-dyslipidemic, non-hypertensive patients with biopsy-proven NAFLD (17 men, age 41±8 years, BMI 26.8±3 kg/m^2) and 9 healthy controls (5 men, age 30±2 years, BMI 22.5±2 kg/m^2) underwent transthoracic echocardiography and cardiac MRI to evaluate cardiac morphology and function. Endogenous glucose production (EGP) and lipolysis were assessed by stable isotope tracers. Hepatic Insulin resistance (IR) as EGP x fasting insulin, Oral Glucose Insulin Sensitivity (OGIS), adipo-IR as free fatty acids (FFAs) x fasting insulin were calculated.
Results: Despite the absence of diabetes, hypertension and overt dyslipidemia, NAFLD patients had significantly higher concentration of FFAs than controls ($p < 0.05$) and higher total saturated and monounsaturated levels ($p < 0.05$). In NAFLD basal Hepatic-IR (NAFLD vs controls: 92±34 vs 52±18 umol/min kg*mU/L) and Adipo-IR (NAFLD vs controls: 21±10 vs 11±5 mmol/L*mU/L) were significantly increased ($p < 0.03$ for all NAFLD vs controls) and OGIS significantly reduced (NAFLD vs controls: 11.0±1.64 vs 13.1±1.1 mg/kg min, $p = 0.005$). The end-systolic LV diameter (30.4±3.7 vs 27.2±3.5 mm, $p = 0.044$) was significantly higher in patients than in controls, suggesting subclinical systolic dysfunction. In NAFLD patients, both hepatic-IR and adipo-IR directly correlated with MRI end-systolic LV volume (ESV) ($r = 0.63$, $p = 0.004$ and $r = 0.54$, $p = 0.018$, respectively), while OGIS was inversely related to end-systolic LV diameter ($r = -0.48$, $p = 0.037$) and ESV ($r = -0.48$, $p = 0.036$). At liver biopsy, steatosis ≥33% was associated with increased ESV ($p = 0.047$), suggesting early systolic dysfunction. Similarly, ESV was increased in patients with fibrosis (69.2±16.9 vs 94.5±31.4 cc, $p = 0.018$), whereas the ejection fraction (51±7 vs 59±7%, $p = 0.034$) and cardiac index (2.9±0.7 vs 3.8±0.9, $p = 0.03$) were significantly reduced.
Conclusions: In NAFLD subjects metabolic derangements and histological features are associated with subclinical systolic LV dysfunction, independently of diabetes, hypertension and dyslipidemia.

NON-ALCOHOLIC LIVER FATTY DISEASE AND SUBCUTANEOUS ADIPOCYTE SIZE IN HUMAN MORBID OBESITY

Y. Liu[1,2,3], H. Azrak[3], P. Bedossa[4], J. Aron-Wisnewsky[1,2], J. Tordjman[1,2], K. Clément[1,2], V. Miette[3], M. Sasso[3]. *[1]Institute of Cardiometabolism and Nutrition, Pitié-Salpêtrière Hospital, [2]Inserm UMR U1166, équipe 6, Nutriomique, UPMC, Cordeliers Research Center, [3]Echosens, Paris, [4]Pathology Department, Beaujon Hospital, Assistance, Publique-Hôpitaux de Paris, Clichy, France*
E-mail: yuejun.liu@inserm.fr

Background and Aims: Non-alcoholic liver fatty disease (NAFLD) is one of common liver comorbidities in obesity and is associated with increased liver related morbidity and mortality. During adipose tissue expansion in obesity, adipocyte hypertrophy significantly influences adipocyte biology and is subsequently associated with obesity-associated comorbidities such as type 2 diabetes. However its link with liver injury in obesity remains unclear. The aim of this study was to investigate the relationships between liver histological injuries of NALFD and subcutaneous adipocyte size in morbid obesity.
Methods: 78 morbidly obese subjects (BMI 45.9±6.8 kg/m^2) candidate for bariatric surgery were recruited. The adipocyte diameters of subcutaneous adipose tissue (scAT) from needle biopsy, bioclinical parameters and liver stiffness measurement (LSM) measured by FibroScan before the surgery as well as per-operative liver biopsy (LB) samples were collected. LB was assessed by a single anatomo-pathologist. Fibrosis stage, steatosis and ballooning grades and the presence of NASH were assessed using the SAF score [Pierre Bedossa. *Hepatology* 60, 565–575 (2014)].
Results: LB evaluation showed that: 19 patients had NAFLD and 23 had NASH. Patients distribution was as follows: steatosis: (S0, n = 19; S1, n = 26; S2, n = 21; S3, n = 12); ballooning: (G0, n = 45; G1, n = 23; G2, n = 10); fibrosis: (F0, n = 46; F1, n = 21; F2, n = 6; F3, n = 4; F4, n = 1). NASH (123.58±14.1 μm) and NAFLD (116.92±9.06 μm) patients had larger adipocytes compared to those whose liver were normal (113.13±6.83 μm). Adipocyte diameter was associated with liver fibrosis (rho=0.35, $p = 0.003$), steatosis (rho=0.36, $p = 0.004$), ballooning (rho=0.439, $p < 0.001$) and LSM (rho=0.397, $p = 0.003$). Among them, ballooning grades was independently correlated with adipocyte diameters ($p < 0.001$). In addition, concerning BMI at 20 years old, NASH (26.5±6.7 kg/m^2) and NALFD (29.0±9.2 kg/m^2) patients were significantly less obese at early adulthood compared to those whose liver were normal (32.9±7.1 kg/m^2).
Conclusions: Our study shows that having a larger adipocyte size is associated with severe liver histological injuries, especially ballooning, a key feature of NASH in morbidly obese subjects. On contrary, adipose tissue expansion at early adulthood might be less deleterious to liver. Further studies are required to evaluate whether the decrease of adipocyte size after weight loss induced by bariatric surgery is associated with improved liver injury.

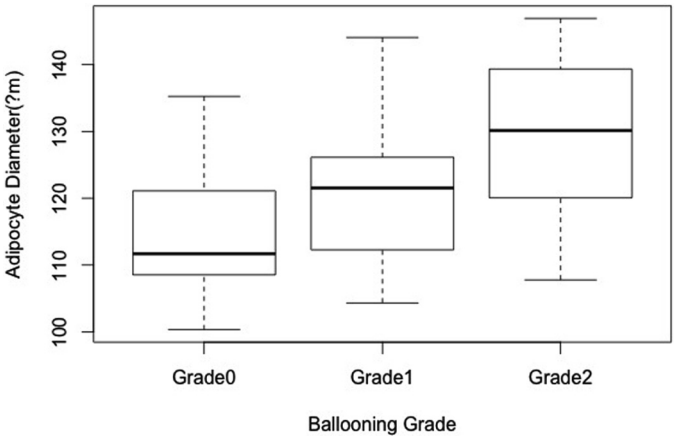

Figure: Boxplot of adipocyte diameter according to liver ballooning grade.

INCREASED EPICARDIAL FAT AND EARLY SIGNS OF IMPAIRED DIASTOLIC AND SYSTOLIC LEFT VENTRICULAR FUNCTION IN NON-DIABETIC, NON-DYSLIPIDEMIC, NORMOTENSIVE PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE

E. Vanni[1], A. Marengo[1], R. Faletti[2], M. Morello[3], L. Mezzabotta[1], G. Battisti[2], S. Frea[3], M. Cannillo[3], E. Mosso[1], C. Rosso[1], L. Bergamasco[4], M. Rizzetto[1], E. Bugianesi[1]. *[1]University of Turin, Department of Medical Sciences, Division of Gastroenterology, [2]University of Turin, Department of Surgical Sciences, Institute of Radiology, [3]University of Turin, Department of Medical Sciences, Division of Cardiology, [4]University of Turin, Turin, Italy*
E-mail: ester.vanni@unito.it

Background and Aims: Nonalcoholic Fatty Liver Disease (NAFLD) has been associated with subclinical cardiovascular disease (CVD) and increased CVD morbidity and mortality. This study was undertaken to (1) ascertain whether NAFLD patients have abnormal epicardial fat, left ventricular (LV) morphology and function, (2) determine the relative contribution of epicardial, visceral and hepatic fat to LV dysfunction.
Methods: Nineteen non-diabetic, non-dyslipidemic, non-hypertensive patients with biopsy-proven NAFLD (17 men, age 41±8 years, BMI 26.8±3 kg/m^2) and 9 healthy controls (5 men,

age 30±2 years, BMI 22.5±2 kg/m^2) underwent transthoracic echocardiography and cardiac MRI to quantify epicardial fat and cardiac morphology and function. An abdomen MRI was performed in all subjects to quantify visceral and hepatic fat.
Results: The end-systolic LV diameter (30.4±3.7 vs 27.2±3.5 mm, p = 0.044) and the left atrial area (19.6±3.3 vs 14.9±2.5 cm^2, p = 0.02) were significantly higher in patients than in controls. Indices of LV diastolic function, namely the early diastolic septal and lateral mitral annular velocities, were significantly impaired in NAFLD (9.7±2.6 vs 12.9±2.57 and 13.3±3.5 vs 16.4±1.6 cm/s, vs controls respectively; p < 0.03 for both). Similarly, the ratio of early to late diastolic mitral inflow (E/A ratio) was significantly reduced in patient than in controls (1.2±0.2 vs 1.5±0.2, p = 0.004) suggesting an early diastolic dysfunction. Epicardial fat in NAFLD patients was significantly increased compared to controls, both at echocardiography and at MRI (5.93±2.25 vs 0.26±0.5 mm, 228.1±112.8 vs 66.8±25.2 cm^3, respectively, p = 0.001). In NAFLD patients, but not in controls, epicardial fat positively correlated with end-systolic LV diameter (r = 0.46, p = 0.046) and inversely with the ejection fraction (EF). Epicardial fat was tightly related to visceral fat (r = 0.58, p = 0.03), but not to hepatic fat. Visceral fat inversely correlated with EF, whereas hepatic fat directly correlated with the end systolic LV volume (r = 0.63, p = 0.004).
Conclusions: Non diabetic, non-dyslipidemic, normotensive NAFLD patients show early signs of both diastolic and systolic LV dysfunction. Epicardial, visceral and hepatic fat are increased and associated with parameters of early systolic dysfunction.

SEVERITY OF CORONARY ARTERY DISEASE IS ASSOCIATED WITH NON-ALCOHOLIC FATTY LIVER DISEASE
F. Schoelzel[1], F. Seeger[2], J. Bojunga[1], S. Fichtlscherer[2], J. Rey[3], E. Herrmann[3], A.M. Zeiher[2], S. Zeuzem[1], M. Friedrich-Rust[1].
[1]Department of Internal Medicine 1, [2]Department of Internal Medicine 3, J.W. Goethe-University Hospital, [3]Institute of Biostatistics and Mathematical Modelling, Faculty of Medicine, J.W. Goethe-University, Frankfurt am Main, Germany
E-mail: fabian.schoelzel@stud.uni-frankfurt.de

Background and Aims: Recent studies showed a significant association between non-alcoholic fatty liver disease (NAFLD) and coronary artery disease (CAD). Previous studies have reported good diagnostic accuracy of transient elastography (TE) for the non-invasive assessment of liver fibrosis, and of controlled attenuation parameter (CAP) for assessment of hepatic steatosis. The aim of the present study was to evaluate whether presence and severity of CAD are associated with presence and severity of NAFLD.
Methods: Patients who underwent invasive coronary angiography were enrolled in this prospective study between December 2011 and October 2014. All patients received at least 10 TE and CAP measurements using the FibroScan® M-probe (Echosens, Paris, France). Quality criteria for TE (10 successful measurements, IQR/median ≤0.30) and CAP (10 successful measurements) were respected. Clinical relevant CAD (rCAD) was defined as presence of stenosis with at least 75% reduction of the luminal diameter with the need for coronary revascularization. NAFLD was determined by CAP ≥234 dB/m, corresponding to >5% hepatocytic fat content. Non-alcoholic steatohepatitis (NASH) was determined by TE-values ≥7.9 kPa in the presence of hepatic steatosis and absence of echocardiographic signs of congestive or right-sided heart failure. Significance level was specified as p < 0.05.
Results: 576 patients were enrolled in the study. 71 (12.3%) patients were excluded due to CAP-failure, 125 (21.7%) due to TE-failure. Therefore, a total of 505 patients [78% male; mean age 66±12 years; mean body mass index 27.3±4.6 kg/m^2] were available for analysis of NAFLD, 451 for analysis of NASH. 356/505 (70.5%) patients had rCAD, 361/505 (71.5%) were diagnosed with NAFLD, and 35/451 (7.8%) with NASH. Patients with rCAD had significantly higher mean CAP-values than patients without rCAD (273±61 vs. 261±66 dB/m; p = 0.038) and tended to higher degrees of steatosis (p = 0.037). While NAFLD was significantly more often diagnosed in patients with rCAD as compared to patients without (75.0% vs. 63.1%, p = 0.0094), no significant difference was found for the diagnosis of NASH (7.9% vs. 7.5%, p = 1.0).
Conclusions: Our findings demonstrate that clinical relevant CAD is frequently associated with the presence of NAFLD. Besides cardiological follow-up, these patients should also receive hepatological monitoring of NAFLD to enable the diagnosis of NASH and prevent its potential sequelae.

P1060
MINIMALLY INVASIVE DIAGNOSIS OF NAFLD AND DISCRIMINATION BETWEEN NAFL AND NASH BY AUTOANTIBODY SIGNATURES
K. Staufer[1], R. Stauber[2], C. Theek[3], M. von Darl[3], S. Traussnigg[1], C. Kienbacher[1], C. Lackner[2], P. Steindl-Munda[1], P. Schulz-Knappe[3], M. Trauner[1]. *[1]Medical University of Vienna, Vienna, [2]Medical University of Graz, Graz, Austria; [3]Protagen AG, Dortmund, Germany*
E-mail: Katharina.Staufer@meduniwien.ac.at

Background and Aims: Reliable diagnosis and discrimination of non-alcoholic fatty liver (NAFL) and steatohepatitis (NASH) still requires liver biopsy. Moreover, auto-antibodies add to differential diagnostic challenges in NAFLD/NASH. In this study, we aimed to identify novel serum biomarkers diagnostic for NAFLD and distinctive of NAFL/NASH.
Methods: A pilot cohort of patients with biopsy proven NAFLD was compared to age- and sex-matched healthy controls. In a non-hypothesis driven approach, serum samples were analysed for the presence of novel auto-antigens using a bead-based Luminex technology.
Results: The cohort consisted of 48 NAFLD patients (NAFL n = 34: 75% male; median±SD age: 42±12.4 y; NASH n = 14: 50% male; median±SD age: 52±13 y; p = n.s.) and 20 healthy controls (60% male; median±SD age: 48±15 y). Univariate analysis identified several antigens distinctive of NAFLD (best AUC: 0.865 [CI: 0.744; 0.987], sensitivity: 85.2% [CI: 0.699; 1.000], specificity: 60.0% [CI: 0.350; 0.850]), as well as discriminating between NAFL and NASH (best AUC: 0.821 [CI: 0.683; 0.959], sensitivity: 75% [CI:0.656; 0.859], specificity: 60% [CI: 0.219; 0.981]). According to multivariate analysis, 3 novel single antigens predictive of NAFLD were identified, so far known to be involved in cell growth, cell differentiation, and hepatic lipid metabolism, with AUC, sensitivities and specificities between 0.759–0.791, 76–84%, and 54–65%, respectively.
Conclusions: Using a bead-based Luminex screen we identified single serum markers discriminative for NAFL vs. NASH. Additionally, as confirmed by multivariate analysis, 3 novel immunological biomarkers diagnostic for NAFLD were identified. These markers may provide novel mechanistic and prognostic insights into NAFLD and may be more stable than metabolomic signatures.

P1061

THE MACROPHAGE ACTIVATION MARKER SCD163 AND THE APOPTOSIS MARKER CYTOKERATIN-18 ARE BOTH PREDICTORS OF DISEASE SEVERITY IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE

K. Kazankov[1], F. Barrera[2,3], H.J. Møller[4], C. Rosso[5], E. Bugianesi[5], E. Vanni[5], S. Esmaili[2], M. Eslam[2], D. McLeod[6], B.M. Bibby[7], H. Vilstrup[1], J. George[2], H. Grønbæk[1]. *[1]Department of Hepatology and Gastroenterology, Aarhus University Hospital, Aarhus, Denmark; [2]The Storr Liver Centre, University of Sydney and Westmead Hospital, Westmead, Australia; [3]Department of Gastroenterology, Pontificia Universidad Católica, Santiago, Chile; [4]Department of Clinical Biochemistry, Aarhus University Hospital, Aarhus, Denmark; [5]Division of Gastroenterology and Hepatology, Department of Medical Sciences, University of Torino, Torino, Italy; [6]Department of Anatomical Pathology, Institute of Clinical Pathology and Medical Research (ICPMR), Westmead Hospital, Westmead, Australia; [7]Department of Biostatistics, Aarhus University, Aarhus, Denmark*
E-mail: konskaza@rm.dk

Background and Aims: Macrophages play an important role in non-alcoholic fatty liver disease (NAFLD). Cytokeratin-18 (CK-18) is an extensively investigated apoptosis biomarker of NAFLD and NASH. We hypothesized that a specific macrophage activation marker soluble (s)CD163, and CK-18 would both contribute to the prediction of disease activity and fibrosis in NAFLD.
Methods: Associations of sCD163 and CK-18 with biochemical and histological measures of hepatic inflammation and fibrosis were investigated in two independent cohorts of 171 and 174 NAFLD patients. Demographic, clinical, biochemical, and metabolic data were recorded at the time of liver biopsy; sCD163 and CK-18 were measured by specific ELISAs.
Results: Both sCD163 and CK-18 increased in parallel with the severity of NAFLD and were independently associated with the Kleiner fibrosis score and the steatosis score in both cohorts. In multiple logistic regression analysis, both sCD163 and CK-18 were significant predictors of severe activity (NAS ≥5) and advanced fibrosis (F ≥3). A fibrosis score based on sCD163 and CK-18 improved the prediction of advanced fibrosis than either sCD163 or CK-18 alone and showed excellent Areas Under the Receiver Operating Characteristics curve (AUROCs) in both the estimation [0.88 (95% CI: 0.82–0.94)] and the validation [0.83 (95% CI: 0.75–0.92)] cohorts. In contrast, the prediction of NAS ≥5 was not improved by a score based on both variables compared to the one based on sCD163 alone.
Conclusions: Both sCD163 reflecting macrophage activation and the apoptosis marker CK-18 are independently associated with liver injury and fibrosis in NAFLD. Combining sCD163 and CK-18 as markers of different pathophysiological events in a predictive model improves the prediction of advanced fibrosis.

P1062

IRON METABOLISM IN CHILDREN WITH NONALCOHOLIC FATTY LIVER DISEASE

M. Flisiak-Jackiewicz[1], M. Kłusek-Oksiuta[1], E. Tarasów[2], E. Koc-Żórawska[3], M. Wojtkowska[4], D. Lebensztejn[1]. *[1]Dept. of Pediatrics, Gastroenterology & Allergology, [2]Dept. of Radiology, [3]Dept. of Nephrology and Transplantation with Dialysis Unit, Medical University of Bialystok, [4]Dept. of Radiology, University Children Hospital, Bialystok, Poland*
E-mail: m_flisiak@op.pl

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) nowadays is regarded as the most frequent cause of liver pathology. The studies on adults population have suggested that iron overload plays a significant role in pathogenesis of NAFLD and progression from simple steatosis to nonalcoholic steatohepatitis (NASH). Therefore, the aim of the study was to evaluate serum concentration of selected parameters of iron metabolism in obese children with NAFLD.
Methods: The study comprised 111 obese children (age range 7–17) with the initially suspected liver disease (hepatomegaly and/or increased ALT activity and/or liver steatosis in ultrasound). Viral hepatitis (HCV, HBV), autoimmune (AIH) and selected metabolic liver diseases (Wilson's disease, alfa-1-antitrypsin deficiency, cystic fibrosis) were excluded. The degree of liver steatosis in ultrasound (USG) was graded according to Saverymuttu scale. The total intrahepatic lipid content was assessed by magnetic resonance proton spectroscopy (^{1}HMRS). Serum iron, ferritin, hepcidin levels, total iron-binding capacity (TIBC), soluble transferrin receptor (sTFR) was measured in all participants. In 45 patients hemojuvelin (HJV) level was also assessed. In addition, AST to Platelet Ratio Index (APRI) was calculated and used as a noninvasive test for predicting liver fibrosis.
Results: NAFLD was confirmed in 39 children. Serum ferritin, hepcidin levels and TIBC were significantly higher in children with NAFLD than in obese patients without NAFLD. NAFLD children demonstrate also significantly higher ALT and GGT activities, APRI, insulin resistance (HOMA-IR), BMI, waist circumferences and total amount of lipids in ^{1}HMRS. We found significant correlations of serum iron ($r = 0.19$), ferritin ($r = 0.31$), hepcidin ($r = 0.37$) levels as well as TIBC ($r = 0.25$) with liver injury (ALT/GGT activity). Correlation was also demonstrated between APRI and ferritin ($r = 0.41$), hepcidin (0.31) and TIBC (0.24). Moreover, TIBC correlated with the degree of liver steatosis in USG ($r = 0.23$).
Conclusions: Elevated serum concentrations of selected parameters of iron metabolism observed in children with NAFLD and their association with liver injury and APRI suggest the role of iron metabolism in pathogenesis of fatty liver and progression to NASH.

P1063

EVALUATION OF TRANSIENT ELASTOGRAPHY (FIBROSCAN®) FOR THE MEASUREMENT OF LIVER STIFFNESS IN MORBIDLY OBESE PATIENTS BEFORE BARIATRIC SURGERY

M. Rau[1], J. Weiss[1], I. Hering[1], G. Bender[2], C. Jurowich[3], T. Kudlich[1], A. Geier[1]. *[1]Department of Internal Medicine II, [2]Department of Internal Medicine I, [3]Department of General and Visceral Surgery, University Hospital Würzburg, Würzburg, Germany*
E-mail: rau_m@ukw.de

Background and Aims: *Background:* Non-alcoholic fatty liver disease (NAFLD) has a rising prevalence in the western world. In severely obese patients undergoing bariatric surgery the estimated prevalence is about 90%, and a substantial number of these patients may have end-stage liver disease with liver cirrhosis. Fibroscan as a non-invasive diagnostic tool to measure liver stiffness has a good accuracy in various liver diseases. In severely obese patients few data exist about technical feasibility and accuracy of liver stiffness measurement by Fibroscan®. *Aims:* To analyse non-invasive liver stiffness measurement by Fibroscan® in morbidly obese patients undergoing bariatric surgery compared to liver histology.
Methods: Prospective patient cohort with 158 morbid obese NAFLD patients. Fibroscan measurement was performed with XL probe. Fibroscan® examination was successful with 10 valid measurements, success rate >60% and interquartile range of measurements (IQR)/median (M) of liver stiffness ≤0.3 or IQR/M ≥0.3 with a median of liver stiffness <7.1 kPa.
Results: In the cohort 158 NAFLD patients were included and 79 patients had liver biopsies (NAFL n = 55, NASH n = 24). The patients were morbidly obese with a mean BMI of 49.1 kg/m^2 (SD 10.4). In 43.4% Fibroscan® measurement with XL-probe was technically feasible. Failure of Fibroscan® measurement was more frequent in patients with a higher BMI, a higher weight and a higher NAFL fibrosis score ($p < 0.05$). In patients with valid Fibroscan® measurement, 10 patients with NASH had a significantly higher

liver stiffness 9.3±5.5 kPa in comparison to 25 patients with NAFL 6.3±2.6 kPa ($p < 0.05$). Patients with early fibrosis (F1 and F2) could not be differentiated by Fibroscan® measurement from patients with no fibrosis.
Conclusions: Non-invasive liver stiffness measurement is feasible in severe obese patients with XL probe. NASH patients could be differentiated from patients with NAFL. Transient elastography is useful in clinical evaluation before bariatric surgery.

P1064
ASSOCIATION BETWEEN PNPLA3 I148M POLYMORPHISM AND NONALCOHOLIC FATTY LIVER DISEASE (NAFLD) IN THE INDIAN CONTINENT
D. Rangegowda[1], S. Sharma[2], K.N. Chandan Kumar[1], R. Maiwal[1], C. Vashista[1], M.K. Sharma[1], V. Bhatia[1], A.S. Bhadoria[2], A. Rastogi[3], S. Sarin[1]. *[1]Hepatology, [2]Research, [3]Pathology, ILBS, New Delhi, India*
E-mail: drdevurgowda@gmail.com

Background and Aims: Single nucleotide polymorphism characterized by a C-to-G change encoding an isoleucine-to-methionine substitution at 148 in the human, patatin-like phospholipase 3 (PNPLA3) has been reported to be associated with non-alcoholic fatty liver disease (NAFLD) and advanced liver disease. We investigated the genotype frequency of PNPLA3 rs738409 in NAFLD patients and its association with different biochemical and histological features.
Methods: A hospital-based cross sectional study was conducted on NAFLD patient attending OPD at tertiary care centre in New Delhi to determine the distribution of PNPLA3 genotypes among NAFLD. Liver biopsy was done in 216 patients. We analysed the rs738409 polymorphism by TaqMan assay in all NAFLD patients and assessed its association with biochemical and histological features of NASH.
Results: A total of 310 NAFLD patients were included. Simple fatty liver was seen in 124 patients (40%) (mean age 40.9±14 years, male 73.4 5%, mean BMI 25.8±5.7 kg/m^2, lean 33.3%). There were 120 patients (38.7%) in precirrhotic NASH (Mean age 38.2±11.8 years, male 85.8%, mean BMI 24.8±5 kg/m^2, lean 42%) and 66 patients (21.3%) in NAFLD related cirrhosis (mean age 52.6±11.3 years, male 83.3%, mean BMI 25.6±4.68 kg/m^2, lean 35.2%). PNPLA3 genotypes were CC type in 121 (39%), CG type in 88 (28.40%) and GG type in 101 (32.60%) in all NAFLD patients. Prevalence of homozygous (GG) type was 33/124 (26.6%) in fatty liver, 31/120 (25.8%) in NASH and 37/66 (56.1%) in cirrhotic patients (p value <0.001). There was no influence of PNPLA 3 genotypes on clinical (BMI, AST, ALT, insulin, triglycerides, VLDL, cholesterol, liver stiffness measurement) as well as histological features (steatosis, ballooning, lobular inflammation and fibrosis) in precirrhotic NASH (p value >0.5). There was also no association between the presences of PNPLA 3 in lean (BMI <23 kg/m^2) versus obese (>23 kg/m^2) NAFLD patients.
Conclusions: GG type was significantly more common in NAFLD related cirrhotic patients as compared to simple fatty liver and NASH. The PNPLA3 rs738409 polymorphism neither correlated with histological features like steatosis severity, hepatocellular ballooning, lobular inflammation and fibrosis nor with biochemical parameters of NASH patients.

P1065
LOVASTATIN'S AND PENTOXIFYLLINE'S EFFECTS IN PATIENTS WITH NONALCOHOLIC STEATOHEPATITIS
E.C. Rezi[1], R. Mihaila[2], L. Nedelcu[3], C. Domnariu[2]. *[1]Internal Medicine Department, Polisano Medical Clinic, [2]Medical Faculty, Lucian Blaga University, Sibiu, [3]Transilvania Univeristy, Brasov, Romania*
E-mail: crimuntean@yahoo.com

Background and Aims: Today, there is no ideal treatment for nonalcoholic steatohepatitis (NASH). We performed a multicentric prospective study in order to assess the lovastatin and pentoxifylline efficiency administrated in patients with NASH
Methods: A number of 87 patients with NASH were included in the study, out of which 59 were with NASH and dislypidemia and were treated with lovastatin (10 mg/day), and 28 patients were with NASH, but without dislypidemia and were treated with with pentoxifylline, 400 mgx3/day.
Results: Regarding the lovastatin-treated group, the following results were obtained: the level of aspartate aminotransferase (AST) decreased after the first and second month of treatment ($p = 0.0196$, $p = 0.032$); the level of alanine aminotransferase (ALT) decreased after the first and second month of treatment ($p = 0.0335$, $p = 0.021$). The gamma-glutamyl transferasis (GGT) level decreased during the two months of treatment ($p = 0.079$, respectively $p = 0.253$). The level of cholesterol decreased after the first and second month of treatment ($p = 0.00029$, respectively $p = 0.00028$). The APRI score of liver fibrosis in the 3 months of treatment, decreased from the average initial value of 0.188 to 0.142, respectively to 0.102 after the second month of treatment ($p = 0.030$).
Regarding the pentoxifylline-treated group, the following results were obtained: the level of AST decreased after the first month and second month of treatment ($p = 0.018$, $p = 0.16$); the level of ALT significantly decreased after the first and second month of treatment ($p = 0.033$, $p = 0.126$). The GGT level decreased after the first and the second month of treatment ($p = 0.107$, respectively $p = 0.123$). The APRI score decreased from the average initial value of 0.1587 to 0.1135 after the first month of treatment and to 0.133 after the second month of treatment ($p = 0.022$).
Conclusions: Both drugs significantly decreased the levels of transaminases in patients with NASH. Lovastatin reduced the cholesterolemia in the dislypidemic patients. The decrease of the APRI score suggests that both drugs may have benefic effects on the liver histology, too. Our research pleads for the individual treatment in patients with NASH, taking into account the present components of the metabolic syndrome.

P1066
NAFLD, FETUIN-A AND ATHEROSCLEROSIS BURDEN: DOES VASCULAR TOPOGRAPHY MATTER?
F. Nascimbeni[1], D. Romagnoli[1], E. Baldelli[1], V. Sirotti[1], S. Ballestri[2], M. Bertolotti[1], A. Lonardo[1]. *[1]Department of Biomedical, Metabolic and Neural Sciences, Nuovo Ospedale Civile di Modena, University of Modena and Reggio Emilia and Azienda USL of Modena, Baggiovara, Modena, [2]Department of Medicine, Division of Internal Medicine, Pavullo Hospital, Pavullo, Italy*
E-mail: fabio.nascimbeni@libero.it

Background and Aims: The pathogenic role of Fetuin-A (F-A) in atherosclerosis (Athero) burden in NAFLD is poorly defined. We assessed F-A serum levels and NAFLD prevalence in patients (pts) affected by Athero in different anatomical regions.
Methods: 149 consecutive pts with established Athero were recruited: 45 with coronarography-detected >50% coronary stenosis, 23 with severe carotid stenosis, 55 with symptomatic Athero of lower limbs and 26 with thoracic or abdominal aortic aneurysm. NAFLD diagnosis based on ultrasonography and exclusion of competing etiologies. Fetuin-A measured with ELISA. Multivariate analyses were conducted to assess the independent correlates of coronary artery disease (yes/no), NAFLD (yes/no) and F-A (continuous values).
Results: 78% of cases were male, mean age was 71±10 yrs. Mean BMI was 27±4 kg/m^2, 61% of pts had diabetes, 93% were hypertensive, 62% used lipid-lowering drugs and 50% had metabolic syndrome. NAFLD was detected in 54% of pts; mean F-A levels were 260±115 μg/ml. Coronary pts were significantly younger ($p = 0.008$), had lower HOMA ($p = 0.019$), less frequently diabetes ($p = 0.045$) and NAFLD (42% vs 60% $p = 0.050$), but higher diastolic

pressure ($p < 0.001$), total cholesterol ($p = 0.023$) and F-A levels (374 ± 124 vs 243 ± 63 $p < 0.001$) than non-coronary pts. NAFLD pts were significantly younger ($p = 0.044$), had higher BMI ($p < 0.001$), total cholesterol ($p = 0.001$) and triglycerides ($p = 0.002$) and more frequently metabolic syndrome ($p = 0.004$) than non-NAFLD pts. F-A was positively correlated with coronary artery disease, BMI, total cholesterol, diastolic and systolic pressure, metabolic syndrome and albumin and negatively with age and platelet count. At multivariate analysis: (1) coronary pts had higher F-A levels and less frequently NAFLD than non-coronary pts (independent of demographic and metabolic covariates); (2) NAFLD was positively associated with F-A levels, after adjustment for vascular topography; (3) F-A levels were independently positively associated with coronary artery disease and NAFLD and negatively with ALT and platelet count (independent of demographic and metabolic covariates).
Conclusions: The pathogenic interplay of NAFLD, F-A and Athero burden likely varies based on vascular topography.

P1067

ASSOCIATIONS BETWEEN ANTIDIABETIC AND STATIN THERAPY AND LIVER HISTOLOGY IN PATIENTS WITH TYPE 2 DIABETES AND NON-ALCOHOLIC FATTY LIVER DISEASE

F. Nascimbeni[1,2], J. Aron-Wisniewsky[3], R. Pais[2], J. Tordjman[3], F. Charlotte[4], P. Bedossa[5], T. Poynard[2], K. Clement[3], V. Ratziu[2].
[1]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Service d'Hépatogastroentérologie, Hôpital Pitié Salpetrière, Assistance Publique Hôpitaux de Paris, Université Pierre et Marie Curie, INSERM UMR_S 938, [3]Institute for Cardiometabolism and Nutrition (ICAN), [4]Department of Pathology, Université Pierre et Marie Curie, Hôpital Pitié Salpetrière, Assistance Publique Hôpitaux de Paris, [5]Pathology Department, Beaujon Hospital, University Paris Diderot, INSERM U773, Paris, France
E-mail: fabio.nascimbeni@libero.it

Background and Aims: Type 2 diabetes mellitus (DM) is a risk factor for progressive non-alcoholic fatty liver disease (NAFLD). Drugs commonly prescribed in DM patients (pts) affect insulin sensitivity and lipid profile and may impact liver histology. We studied if antidiabetic agents or statins were associated with non-alcoholic steatohepatitis (NASH) and significant fibrosis (SF).
Methods: A cross-sectional study of 346 diabetic pts with biopsy-proven NAFLD, 138 referred to a tertiary liver center and 208 morbidly-obese pts candidate to bariatric surgery. DM was defined as fasting glucose ≥7 mmol/l or HbA1c ≥6.5% and/or the use of antidiabetic treatment. NASH was defined according to the FLIP algorithm and SF as F2–4 Kleiner's stages.
Results: There were 60% women, mean age was 52 ± 11 yrs, median BMI 42 [21–74] kg/m^2, 76% had arterial hypertension (HTN); 54% hypertriglyceridemia, 80% low HDL-cholesterol, mean HbA1c was 7.4 ± 1.3%. 84% of pts were on antidiabetic therapy (sulfonylureas 33%, metformin 74% and insulin 24%) and 45% on statins. NASH and SF were present in 57% and 48% of pts, respectively. Statin-treated pts were older, more frequently male, hypertensive (90% vs. 64%, $p < 0.001$), dyslipidemic, with a poorer glycemic control (HbA1c 7.7 ± 1.5% vs. 7.1 ± 1.1%, $p > 0.001$) despite more frequent antidiabetic therapy (sulfonylureas 42% vs. 25%, $p = 0.001$; metformin 85% vs. 65%, $p < 0.001$; insulin 33% vs. 17%, $p = 0.001$) than those without statins; however, the prevalence of NASH (57% vs. 56%, $p = 0.868$) and SF (48% vs. 48%, $p = 0.945$) was not different between statin users and nonusers. NASH was more common in pts on metformin or insulin than in those not treated with these drugs (60% vs. 47%, $p < 0.03$; 68% vs. 53%, $p < 0.02$, respectively). SF was more common in those treated with sulfonylureas (57% vs. 44%, $p = 0.03$). Multivariate analyses including age, sex, BMI, HTN, dyslipidemia, glycemic control, antidiabetic and statins medications, ALT, GGT and cohort origin confirmed independent associations between insulin use and NASH [OR (95% CI): 2.3 (1.1–4.6), $p = 0.020$] and sulfonylureas use and SF [2.0 (1.1–3.6), $p = 0.028$]. Moreover, use of statins was independently and negatively associated with both NASH [0.6 (0.3–1.0), $p = 0.057$] and SF [0.5 (0.3–0.9), $p = 0.033$].
Conclusions: In diabetic pts with NAFLD, insulin and sulfonylureas appear to be associated with NASH and SF while statin use appears protective. These associations are independent of the baseline severity of the clinical condition. A wider use of statins may be warranted in these pts.

P1068

METFORMIN TREATMENT AMELIORATES LIVER INJURY INDICATING FATTY LIVER IN POLYCYSTIC OVARY SYNDROME

S. Tan[1], N. Vollmar[1], J.-P. Sowa[2], S. Benson[3], L.P. Bechmann[2], G. Gerken[2], D. Führer[1], A. Canbay[2]. *[1]Department of Endocrinology and Division of Laboratory Research, [2]Department of Gastroenterology and Hepatology, [3]Department of Medical Psychology and Behavioral Immunobiology, University Hospital, University Duisburg-Essen, Essen, Germany*
E-mail: ali.canbay@uni-due.de

Background and Aims: Polycystic ovary syndrome (PCOS) is associated with obesity and insulin resistance (IR), two key features of the metabolic syndrome. Non-alcoholic fatty liver disease (NAFLD) represents the liver manifestation of the metabolic syndrome. Its progressive form, non-alcoholic steatohepatitis (NASH), comprises a major health risk for affected patients. Metformin (MF) as insulin sensitizing agent leads to a decrease of hepatic IR and could thus possibly ameliorate NASH. The caspase 3-cleaved fragment of cytokeratin 18 (CK18), termed M30, has been established as a serum marker for NASH. This study was conducted to evaluate the influence of MF on serologic NASH in PCOS patients.
Methods: In 89 PCOS patients (age: 28.2 ± 5.2 yrs, BMI: 32.1 ± 8.8 kg/m^2), metabolic parameters, liver enzymes, and M30 were assessed at baseline and after six months MF treatment. Patients with IR at baseline were subdivided in one group with dissolved IR (PCOS-exIR) and persistent IR (PCOS-PIR) after treatment and compared to an initially insulin sensitive PCOS-group (PCOS-C).
Results: Reduction of liver enzymes by MF treatment was observed independently from achieved body weight loss in the PCOS-C and PCOS-exIR in comparison to the PCOS-PIR group. This was associated with decreasing prevalence of liver injury indicating fatty liver (−19.4 resp. −12.0% vs. 7.2%, $Chi^2 = 29.5$, $p < 0.001$). No change in mean M30 levels and NASH-prevalence was observed. In PCOS-PIR, ALT levels increased significantly accompanied by a nominal, not significant M30 increase.
Conclusions: MF improves liver enzymes in subgroups of PCOS patients without lowering hepatic apoptosis markers. Though, individuals with no improvement of IR exhibited a non-significant increase of liver enzymes and M30. This might suggest a stabilizing effect of MF on NAFLD, inhibiting progression of the disease. Further studies with more participants and a longer follow up period (>1year) are needed to elucidate the impact of MF on NAFLD in PCOS patients.

P1069

THE ASSOCIATION BETWEEN FATTY LIVER STATUS CHANGE AND INCIDENCE OF DIABETES MELLITUS IN JAPAN

K. Nagai[1], T. Tsuboya[2,3], H. Yamazaki[1], A. Tomonari[1], K. Tsuji[1], H. Maguchi[1]. *[1]Centre of Gastroenterology, Teine Keijinkai Hospital, Sapporo, Japan; [2]Social and Behavioural Sciences, Harvard School of Public Health, Boston, United States; [3]International and Community Oral Health, Tohoku University Graduate School of Dentistry, Sendai, Japan*
E-mail: kazu4439@gmail.com

Background and Aims: An association between fatty liver (FL) and diabetes mellitus (DM) has been reported. However, it is still uncertain if a change in fatty liver status affects DM incidence. The aim of our study was to assess the risk of future DM incidence in people whom fatty liver status had changed.
Methods: Eligible participants were those who had a health check in 2000, 2001, and at least once between 2002 and 2013. Those who had positive HBs antigen, positive HCV antibody, or DM in 2000 or 2001 were excluded, leading to the eligible 12,904 participants. The participants were divided into 4 groups; (1) "Improved FL" group (n = 234), which had FL in 2000 and no FL in 2001; (2) "Sustained FL" group (n = 1,146), which had FL in both 2000 and 2001; (3) "Newly developed FL" group (n = 760), which had no FL in 2000 but had FL in 2001; (4) "Non-FL group" (n = 10,764), which had no FL both in 2000 and 2001. Fatty liver was diagnosed using ultrasonography. DM was ascertained by fasting plasma glucose ≥126 mg/dL, HbA1c ≥6.5%, self-reported physician-diagnosed DM, or having any medication for DM. The outcome was cumulative incidence of DM during 2002–2013. Logistic regression model was used to estimate crude and multivariate odds ratios (ORs) and confidence interval (CI) for the association between DM incidence and the groups. Age, sex, family history of DM, overweight, hypertension, dyslipidaemia, frequency of exercise and smoking status in 2000 were adjusted in the multivariate model.
Results: During the follow-up period, cumulative incidence of DM was as follows: 2/234 (0.85%) in "improved FL", 35/1,146 (3.05%) in "sustained FL", 22/760 (2.89%) in "newly developed FL", and 50/10,764 (0.46%) in "non-FL". The multivariate ORs were 1.507 (95% CI 0.368–6.351) in "improved FL", 4.830 (95% CI 2.717–8.588) in "newly developed FL", and 5.024 (95% CI 2.977–8.479) in "sustained FL", compared with "non-FL". Comparing with "improved FL", multivariate ORs were 2.571 (95% CI 0.569–11.629) in "newly developed FL", and 3.492 (95% CI 0.825–14.787) in "sustained FL".
Conclusions: FL was a risk factor of future DM. The association between FL improvement and reduced incidence of DM appeared clinically significant, but was not statistically significant.

P1070

THE MARKER OF MACROPHAGE ACTIVATION SOLUBLE CD163 IS ASSOCIATED WITH LIVER HISTOLOGY IN CHILDREN WITH NON-ALCOHOLIC FATTY LIVER DISEASE

K. Kazankov[1], H.J. Møller[2], A. Alisi[3], R. De Vito[4], H. Vilstrup[1], V. Nobili[3], H. Grønbæk[1]. *[1]Department of Hepatology and Gastroenterology, [2]Department of Clinical Biochemistry, Aarhus University Hospital, Aarhus, Denmark; [3]Hepato-Metabolic Disease Unit and Liver Research Unit, [4]Unit of Pathology, "Bambino Gesù" Children's Hospital, IRCCS, Rome, Italy*
E-mail: konskaza@rm.dk

Background and Aims: Macrophages are involved in inflammation and fibrosis in non-alcoholic fatty liver disease (NAFLD). Soluble (s)CD163 is a specific marker for macrophage activation and in a previous study, sCD163 was increased in obese children with indices of NAFLD. We aimed to measure sCD163 in children with biopsy-proven NAFLD and associate it with clinical, biochemical and histological parameters of NAFLD.
Methods: We investigated 155 children with biopsy-proven NAFLD. Demographic, clinical and biochemical data were recorded. Liver biopsies were scored according to the NAFLD Clinical Research Network criteria. sCD163 was measured by ELISA.
Results: Soluble CD163 correlated with the body mass index standard deviation scores (r = 0.21, p = 0.05). sCD163 was associated with hepatocyte ballooning (rho=0.17, p = 0.03), but not steatosis or lobular inflammation. It showed a trend to association with the fibrosis score (rho=0.14, p = 0.09), and children with bridging fibrosis (F=3, n = 14) tended to have higher sCD163 compared to those with lower fibrosis stages [2.4 (IQR 1.7–2.9) vs. 1.8 (IQR 1.5–2.4) mg/L, p = 0.07]. The number of CD163 positive macrophages was associated with scores of steatosis, lobular inflammation and hepatocyte ballooning; however, the cell counts showed no association with sCD163 levels (r = 0.12, p = 0.24).
Conclusions: sCD163 reflecting macrophage activation was associated with histological parameters of liver injury and fibrosis, suggesting a role for macrophage activation in pediatric NAFLD. However, there was no association with CD163 immunohistochemistry.

P1071

THE ASSOCIATION BETWEEN SERUM LEVELS OF URIC ACID AND ALANINE AMINOTRANSFERASE IN A POPULATION-BASED COHORT

L. Rabinowich[1], O. Ben-Assuli[2], M. Green[3], A. Goldstein[4], A. Magid[3], V. Shalev[4], O. Shibolet[1], G. Chodick[4], S. Zelber-Sagi[1,3]. *[1]The Liver unit, Gastroenterology Department, Tel-Aviv Sourasky Medical Center, Tel Aviv, [2]Faculty of Business administration, Ono Academic College, Kiryat Ono, [3]School of Public Health, University of Haifa, Haifa, [4]MACCABI Institute for Health Services Research/ Medical Division, Maccabi Healthcare Services, Tel Aviv, Israel*
E-mail: liane.rabinowich@gmail.com

Background and Aims: Elevated serum uric acid is frequently observed in patients with the metabolic syndrome. A strong correlation exists between this syndrome and nonalcoholic fatty liver disease (NAFLD). Therefore, we aimed to test the association between uric acid and elevated alanine aminotransferase (ALT) in a large population-based cohort.
Methods: A cross-sectional study using real-world data from a large public health organization in Israel (Maccabi Healthcare System). The population consisted of individuals aged 20–60 years old who underwent blood tests for ALT and uric acid for any reason during 1997–2012. Individuals with secondary liver disease, celiac and inflammatory bowl-disease were excluded. Subgroup analysis was performed in subjects who were diagnosed with fatty liver in the medical records (n = 2,628). This database includes medical history, diagnoses, patient consultations, prescription drug purchase, laboratory and imaging tests.
Results: The study population included 82,608 people (32.5% men, mean age 43.91±10.15 years). Subjects in the upper quartiles (>5.6 mg/dL) of uric acid level were significantly (P < 0.001) more likely to have a poorer metabolic profile in terms of glucose, serum lipids, diabetes and hypertension. Categorizing serum uric acid into deciles demonstrated a significant positive dose-response association with the rate of elevated serum ALT (P for trend <0.001). In multivariate logistic regression analysis, controlling for potential confounders, the association between uric acid and elevated ALT persisted both in the total population (OR = 1.18, 95% CI 1.10–1.28; OR = 1.49, 1.38–1.62; OR = 2.10, 1.93–2.29, for the 2nd, 3rd and 4th quartiles respectively compared to the 1st) and in the subgroup of subjects who were diagnosed with fatty liver (OR = 1.77, 1.22–2.57, for the 4th quartile compared to the 1st). With stratification by gender or BMI categories, the association between uric acid and elevated ALT was maintained in all categories.

Conclusions: Serum uric acid is independently associated with elevated ALT, as a surrogate for NAFLD, and thus may serve as a serum marker and should be further investigated as a risk factor for NAFLD.

P1072

THE INTERACTION BETWEEN VISCERAL ADIPOSE AND HEPATIC TISSUE AFFECTS LIVER INJURY IN NAFL AND NASH PATIENTS

M. Schlattjan[1], J.-P. Sowa[1], S. Sydor[1], G. Gerken[1], L.P. Bechmann[1], A. Canbay[1]. *[1]Department of Gastroenterology and Hepatology, University Hospital, University Duisburg-Essen, Essen, Germany*
E-mail: ali.canbay@uni-due.de

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) and the more severe form non-alcoholic steatohepatitis (NASH) are the most common liver diseases in western countries. The interaction between liver and adipose tissue is fundamental for the development of NAFLD and NASH. Aim of this study was to investigate the interaction between adipose tissue and liver at the time of bariatric surgery.
Methods: Blood, visceral adipose tissue, and liver tissue samples were obtained from 40 (median age 46±8.6 y; 29 w/11 m; BMI 51.3±8.1 kg/m^2) morbidly obese patients undergoing bariatric surgery. Histopathological assessment of the biopsies was done according to the NAFLD activity score (NAS). Blood samples taken before surgery were analyzed for parameters of liver injury (M30, M65). Hepatic and adipose tissue mRNA levels of one gene for triacylglycerol regulation (CGI-58) and a central regulating gene for fatty acid storage and glucose metabolism (PPARγ2) were assessed by qrtPCR.
Results: CGI-58 mRNA expression was increased in adipose tissue of morbidly obese patients and showed a strong correlation to low density lipoprotein (LDL) in sera and with the NAS. In morbidly obese individuals mRNA of PPARγ2 was significantly upregulated in hepatic and adipose tissue. Moreover, PPARγ2 mRNA levels in adipose tissue were correlated significantly with hepatic PPARγ2 mRNA levels. The ratio of markers for apoptosis and necrosis (M30, M65) in serum also correlated significantly with mRNA levels of metabolic regulators in adipose tissue.
Conclusions: The presented data shows that adipose CGI-58 and PPARγ2 mRNA expression is associated on the one hand with mRNA expression in the liver and on the other hand with the grade of liver injury.

P1073

INTERLEUKIN 15 IN NONALCOHOLIC FATTY LIVER DISEASE AND OBESITY

O. Kurinna[1], G. Fadieienko[1], O. Babak[1], T. Solomentseva[1], K. Syntyk[1]. *[1]GI National Institute of Therapy of the National academy of medical sciences of Ukraine, Kharkiv, Ukraine*
E-mail: olena_kurinna@yahoo.com

Background and Aims: *Background:* Non-alcoholic fatty liver disease (NAFLD) and obesity represent widespread pathologies associated with low-grade inflammatory processes. Experimental data suggest crucial role of anabolic cytokine interleukin 15 (IL-15) in NAFLD development. Y. Cepero-Donates et al. showed that increased secretion of IL-15 promotes fat accumulation in the liver stimulating hepatic inflammatory response in mice.
The aim was to investigate IL-15 concentration in patients with NAFLD associated with obesity depending on steatosis degree and anthropological parameters. The study included 32 patients with NAFLD associated with obesity, 31 normal weight patients with NAFLD and 26 normal weight volunteers without hepatic steatosis.
Methods: NAFLD diagnosis and assessment were performed by abdominal ultrasound examination. Steatosis degree was evaluated using hepatorenal index (HRI). For all NAFLD patients other causes of hepatic steatosis were excluded. Obesity was measured using body mass index (BMI) and waist circumference (WC). Concentration of IL-15 were measured using enzyme-linked immunosorbent assay kit.
Results: The results showed that IL-15 concentration was significantly increased in patients with NAFLD comparing to control group ($p < 0.05$). Concentrations of IL-15 observed in NAFLD patients with concomitant obesity were significantly higher than those measured in NAFLD patients with normal weight ($p < 0.05$). In all NAFLD patients IL-15 correlated with HRI supporting its role in hepatic fat accumulation. Furthermore, in patients with NAFLD there was significant correlations of IL-15 concentration with BMI ($p < 0.05$) and WC ($p < 0.05$).
Conclusions: Patients with NAFLD and concomitant obesity might have more significant proinflamatory status that could be caused by adipose tissue dysfunction and cytokine synthesis abnormalities. Increased synthesis of IL-15 observed in NAFLD obese patients supports its role in hepatic lipid accumulation found in experimental studies. Further investigations are needed to explore correlations of IL-15 with histological findings in NAFLD obese patients.

P1074

NO EVIDENCE FOR PLATELET HYPERACTIVITY IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE

W. Potze[1], M.S. Siddiqui[2], S.L. Boyett[2], J. Adelmeijer[1], K. Daita[2], T. Lisman[1], A.J. Sanyal[2]. *[1]Surgical Research Laboratory, Department of Surgery, University Medical Center Groningen, Groningen, Netherlands; [2]Div. of Gastroenterology, Hepatology and Nutrition, Dept. of Internal Medicine, Virginia Commonwealth University School of Medicine, Richmond, VA, United States*
E-mail: j.b.w.potze@umcg.nl

Background and Aims: The mechanism of increased prevalence of cardiovascular disease in patients with non-alcoholic fatty liver disease (NAFLD) is unknown. Platelet activation has been implicated as a contributor of the increased risk of cardiovascular disease in the metabolic syndrome, but its role in NAFLD is unclear. We, therefore, assessed the platelet activation status in lean and obese individuals in comparison to patients with various histological severities of NAFLD.
Methods: Blood was drawn from 68 patients with biopsy-proven NAFLD (simple steatosis n = 24, NASH n = 22, and NASH cirrhosis n = 22), 20 lean controls (BMI <25 kg/m^2), 20 overweight controls (BMI >25 kg/m^2), and 15 patients with alcoholic (ASH) cirrhosis. Subjects with congenital coagulation disorders, recent infection (<2 weeks), anticoagulant or anti-platelet therapy, and recent transfusion with blood products were excluded. We studied basal and agonist-induced platelet activation using flow cytometry. In addition, we studied plasma levels of von Willebrand factor (VWF), the VWF-cleaving protease ADAMTS13, and the platelet activation marker soluble P-selectin.
Results: Basal platelet activation was comparable between lean and overweight controls, patients with NASH, and patients with NASH or ASH-related cirrhosis. There was only a slight increase in basal platelet activation in patients with simple steatosis compared to overweight controls. Agonist-induced platelet activation was decreased in patients with cirrhosis, most notably in patients with ASH-related cirrhosis, but similar between patients with non-cirrhotic NAFLD and controls. Plasma levels of VWF were increased in patients with NASH or ASH cirrhosis compared to all other groups; however levels were comparable between lean and overweight controls, patients with simple steatosis, and patients with NASH. ADAMTS13 levels were comparable between all patients and controls. Soluble P-selectin levels were mildly elevated in plasma from patients with NASH, NASH cirrhosis, or ASH cirrhosis compared to lean and overweight controls.

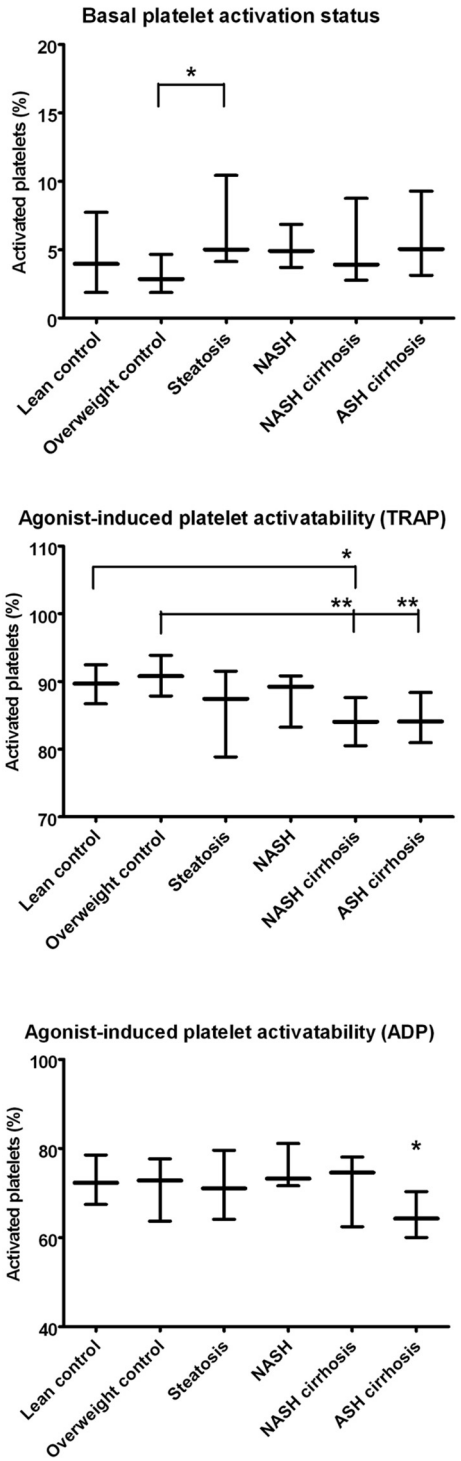

Figure 1. Basal and agonist-induced platelet activation in patients with various histologic severities of NAFLD and controls. The basal platelet activation status (A) and the agonist-induced platelet activatability in patients and controls using adenosine diphosphate (ADP) (B), or thrombin receptor activating peptide (TRAP) (C), as assessed by flow cytometry for P-selectin in patients with various histological severities of NAFLD and lean or overweight controls. Shown is the percentage of P-selectin positive platelets (median and interquartile range). Agonist-induced platelet activatability values were corrected for baseline values. $^{*}p < 0.05$, $^{**}p < 0.01$.

Conclusions: The combined results of our study show that NAFLD is not associated with platelet hyperactivity or changes in pivotal proteins in primary haemostasis. The increased cardiovascular risk of these patients thus appears to be primarily related to classical cardiovascular risk factors, and not to liver disease-induced platelet activation.

P1075

IGFBP-1 SIGNIFICANTLY HELPS IN PREDICTING LIVER FAT IN NAFLD

E.M. Petäjä[1,2], Y. Zhou[2], M. Havana[3], A. Kotronen[1,2], J. Ihalainen[3], H. Yki-Järvinen[1,3]. *[1]University of Helsinki, [2]Minerva Foundation Institute for Medical Research, Helsinki, [3]Medix Biochemica, Kauniainen, Finland*
E-mail: elina.petaja@helsinki.fi

Background and Aims: Insulin-like growth factor binding protein 1 (IGFBP-1) is a protein exclusively produced by the liver and exclusively regulated by insulin, which might make measurement of this protein an ideal marker for NAFLD. We determined whether measurement of IGFBP-1 helps in non-invasive prediction of liver fat content in NAFLD compared to routinely available clinical and biochemical parameters and genotyping for the PNPLA3 I148M gene variant.

Methods: Liver fat content (proton magnetic resonance spectroscopy, ^{1}H-MRS), clinical and biochemical parameters as well as PNPLA3 genotype at rs738409 were measured in 391 subjects [age 43 (30–54) years, BMI 32.9 (28.1–39.8) kg/m^2, 47% with NAFLD], who were randomly divided into estimation and validation groups. Variables identified by univariate analysis in the estimation group were selected based on Akaike Information Criteria for multiple linear regression analysis. The F test was used to compare the ability of different models to predict liver fat.

Results: In multiple linear regression analysis, the final model i.e. the '% liver fat equation' included age, fasting serum (fS) IGFBP-1, interaction between fS-IGFBP-1 and fS-insulin, fS-triglycerides, fS-ALT and PNPLA3 genotype at rs738409 with an adjusted R of 0.59, $p < 0.0001$. These variables were all independent determinants of liver fat content. The model worked similarly in the estimation and validation cohorts. Exclusion of IGFBP-1 (F-test $p < 0.001$) or both IGFBP1 and the interaction term ($p < 0.0001$) significantly decreased the explanatory power of the model.

Conclusions: These data show that IGFBP-1 helps in the prediction of liver fat content in NAFLD even when routinely available clinical and biochemical parameters and the PNPLA3 genotype is taken into account However, the accuracy remains modest thus perhaps emphasizing the need to develop simple direct measures of liver fat content.

P1076

NON-ALCOHOLIC FATTY LIVER DISEASE IS NOT ASSOCIATED WITH PLASMA HYPERCOAGULABILITY

W. Potze[1], M.S. Siddiqui[2], S.L. Boyett[2], J. Adelmeijer[1], K. Daita[2], A.J. Sanyal[2], T. Lisman[1]. *[1]Surgical Research Laboratory, Department of Surgery, University Medical Center Groningen, Groningen, Netherlands; [2]Div. of Gastroenterology, Hepatology and Nutrition, Dept. of Internal Medicine, Virginia Commonwealth University School of Medicine, Richmond, VA, United States*
E-mail: j.b.w.potze@umcg.nl

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is associated with an increased risk of cardiovascular disease; however, it is unclear if subclinical hypercoagulability contributes to this risk. Therefore, we studied the coagulation status in patients with NAFLD.

Methods: We drew blood samples from 68 patients with biopsy-proven NAFLD (simple steatosis n = 24, NASH n = 22, and NASH cirrhosis n = 22), 20 lean controls, 20 overweight controls (BMI >25 kg/m^2), and 15 patients with alcoholic (ASH) cirrhosis. Haemostatic status was assessed by thrombin generation testing, thromboelastography (TEG), and a plasma-based clot lysis assay.

Additionally, plasma levels of proteins involved in clot formation and lysis were measured.
Results: Thrombin generation tested in the presence of thrombomodulin, the endogenous activator of protein C, was comparable between patients and controls. The functionality of the protein C system, however, was decreased in patients with NASH or ASH-related cirrhosis as evidenced by an increase in the ratio between thrombin generation in presence and absence of thrombomodulin. TEG test results were comparable between the lean and overweight controls, patients with simple steatosis, and patients with NASH. However, TEG revealed moderate hypocoagulability in both NASH and ASH cirrhosis as demonstrated by a prolonged K-time and a decreased angle and maximum amplitude. Plasma fibrinolytic potential was comparable between patients with NAFLD and both control groups, but accelerated fibrinolysis was observed in ASH cirrhosis. Both fibrinogen and factor VIII were comparable between all patients and controls. However, protein C and antithrombin were decreased in patients with NASH and ASH cirrhosis. Levels of plasminogen activator inhibitor 1 stepwise increased from healthy controls to patients with simple steatosis, and were still increased in patients with NASH and NASH cirrhosis, but levels were comparable between ASH cirrhosis and healthy controls. In contrast, levels of tissue plasminogen activator were increased in patients with cirrhosis.
Conclusions: The combined results of this study provides no evidence of a hypercoagulable status in patients with NAFLD regardless of the disease stage, which contrasts with previously published results in similar populations. Although the discrepancy between the studies is unclear, our study suggests that the role for haemostasis in the increased risk of thrombosis in patients with NAFLD is limited.

P1077

PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE HAVE SIMILAR GENERAL HEALTH PERCEPTIONS AS THOSE OF HEALTHY CONTROLS

L. Mlynarsky[1,2], D. Schlesinger[3], M. Webb[1,2], Z. Halpern[1,2], E. Santo[1,2], O. Shibolet[1,2], S. Zelber-Sagi[1,3]. *[1]Liver Unit, Dept. Gastroenterology, Tel-Aviv Medical Center, [2]The Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, [3]School of Public Health, Haifa University, Haifa, Israel*
E-mail: liatml@tlvmc.gov.il

Background and Aims: Although patients with non-alcoholic fatty liver disease (NAFLD) are generally asymptomatic, they report both physical and emotional lower quality of life and over-utilize medical services as compared to healthy controls. Fatigue and lack of confidence to exercise have been described in NAFLD patients. The study aim was to examine the association between NAFLD and general health perception.
Methods: A cross-sectional study in 213 subjects, with no known liver disease or history of alcohol abuse. The evaluation included: self-reported general health perception, physical activity habits, frequency of physician's visits, fatigue impact scale and abdominal ultrasound.
Results: There were 54% males, mean age 58±9.6 years and 70/213 had NAFLD. All anthropometric measures, liver enzymes and fasting glucose blood levels were significantly higher among NAFLD as compared to controls (age and gender were comparable). Reduced motivation for activity with physical effort (27.1% vs. 33.6%, P = 0.343) and actual need for reduced activity (20% vs. 19.6%, P = 0.781) as well as other parameters in the fatigue impact scale were equivalent between the NAFLD and the control groups. Time spent in leisure time physical activity was lower among the NAFLD subjects, however, fatigue and fear of physical harm as explanations for lack of physical activity were evenly reported between the groups (P = 0.436). Self-reported general health perception status did not differ between NAFLD and control groups. In a multivariate analysis, NAFLD was not associated with a lower self-reported general health perception (OR = 0.735, 95% CI 0.349–1.548, P = 0.417). Nevertheless, the odds for "very good" self-reported general health perception decreased with increasing level of BMI and age, and increased among males and those that exercised regularly. In terms of health service utilization, there was a significant difference in the reasons for family doctor visits (P = 0.016); NAFLD patients had more acute disease visits while controls had more routine checkups and chronic diseases visits.
Conclusions: Patients with NAFLD were comparable to controls in terms of fatigue and self-reported general health perception. Health service utilization due to chronic diseases was less common among the NAFLD group. Our results imply that fatty liver without clinically significant liver disease has a small impact on health perception.

P1078

THE EFFECT OF NON-ALCOHOLIC STEATOHEPATITIS ON ESTIMATED ISCHEMIC CARDIAC RISK

M. Mahamid[1], O. Abu-Elhija[1]. *[1]Sharee Zedek Medical Center, Nazareth, Israel*
E-mail: mahmudmahamid@yahoo.com

Background and Aims: Nonalcoholic fatty liver disease has been recognized as a major health burden; patients with nonalcoholic fatty liver disease typically meet the diagnostic criteria for the metabolic syndrome and therefore have multiple risk factors for cardiovascular disease.
Aim: to assess the effect of fatty liver disease on estimated coronary cardiac risk according to the Framingham calculation.
Methods: This prospective study included 150 patients with NASH, and the control group included 120 individuals without a medical history of NASH who were enrolled randomly from the Medicine Clinic the medical staff, The Framingham Heart Study risk equations were used for the calculation of 10-years' estimated cardiovascular risk based on systolic blood pressure, total cholesterol, HDL cholesterol, age, and sex.
Results: Compared with the control group, the NASH group had higher systolic blood pressure, diastolic blood pressure, total cholesterol, triglycerides and LDL cholesterol, but lower HDL cholesterol, the median 10-years cardiovascular risk was significantly lower (0.85% in the control group versus 1.72% in the NASH group, p < 0.05). Multivariate analysis showed that HDL-cholesterol <35 (OR = 3.0, 95% CI 2.4–4.1) and serum triglycerides levels >150 (OR = 2.3, 95% CI 2.2–3.1), male sex (OR = 2.2, 95% CI 2.1–3.1), and body mass index >25 (OR = 1.7, 95% CI 1.2–2.1) were associated with height 10-years cardiovascular risk.
Conclusions: 10-years cardiovascular risk among patients with hepatic steatosis is increased. Obesity, low HDL, high triglycerides level, male sex, appear the most predominant factor that influenced the increase 10-years cardiovascular risk.

P1079

PNPLA3 VARIANT p.I148M IMPROVES RESPONSE TO BARIATRIC SURGERY IN OBESE PATIENTS WITH FATTY LIVER DISEASE

M. Krawczyk[1], R. Jiménez-Agüero[2], J.M. Aluztiza[2,3], J.I. Emparanza[4], F. Lammert[1], J.M. Banales[2]. *[1]Department of Medicine II, Saarland University Medical Center, Homburg, Germany; [2]Department of Liver and Gastrointestinal Diseases, Biodonostia Research Institute – Donostia University Hospital (HUD), University of the Basque Country (UPV/EHU), [3]Osatek SA, [4]Clinical Epidemiology Unit, CASPe, CIBER-ESP, Biodonostia Research Institute – HUD, San Sebastian, Spain*
E-mail: marcin.krawczyk@uks.eu

Background and Aims: Obesity is the major trigger of fatty liver disease (FLD). This disorder is further favored by the *PNPLA3* (adiponutrin) p.I148M genotype, which may also predispose to liver cirrhosis and HCC (Krawczyk *et al. Semin Liver Dis* 2013). Currently, bariatric surgery is becoming a more frequent weight loss therapy,

however its effects on liver status with respect to the *PNPLA3* variant remain unknown.
Methods: We prospectively monitored 83 obese individuals (BMI 35–64 kg/m^2) before and after bariatric surgery. The *PNPLA3* p.I148M variant was genotyped using a fluorescent PCR-based assay. All patients underwent liver biopsy at the moment of surgery. Hepatic steatosis was determined before surgery using three different procedures, i.e. (A) Folch: biochemical determination of hepatic triglyceride contents; (B) semiquantitative histological steatosis grade: 0: no steatosis, 1: 1–33%, 2: 34–66%, 3: >66% steatosis; and (C) multi-echo MRI. One year later, steatosis was re-evaluated by MRI and Folch values were estimated with a novel MRI-based equation (Jiménez-Agüero *et al. BMC Med* 2014).
Results: Overall, 54 individuals (65%) carried the *PNPLA3* genotype [II] and 29 (35%) were carriers of at least one prosteatotic allele [M]. The number of individuals carrying this risk allele increased with the grade of steatosis before surgery (grade 0: 25%; 1: 32%; 2: 36%; 3: 42%). Presence of this allele was associated with increased hepatic triglyceride contents (P = 0.01), increased alkaline phosphatase activities (P = 0.01) and a trend to increased MRI-steatosis (P = 0.10). Of note, median weight loss after bariatric surgery was higher in individuals carrying the susceptible *PNPLA3* allele [M] as compared to carriers of genotype [II] (45 *vs.* 37 kg, P < 0.01). Accordingly, patients carrying the prosteatotic allele [M] demonstrated a higher decrease of liver fat one year after surgery as compared to individuals with the common genotype, based on both MRI fat fraction and estimated Folch values (P = 0.05 and P < 0.01, respectively). In regression analysis, the *PNPLA3* mutation outscored weight loss as predictor of FLD improvement (P = 0.05 vs. P = 0.10, respectively).
Conclusions: Obese patients with *PNPLA3*-associated steatohepatitis show better improvement of hepatic steatosis after bariatric surgery as compared to carriers of *PNPLA3* wild-type alleles. Bariatric surgery can reduce the harmful effects conferred by the *PNPLA3* mutation and obesity.

P1080
CHOLECYSTECTOMY IS A RISK FACTOR FOR FATTY LIVER DISEASE
Y. Gao[1], Q.-S. Shan[2], Y.-J. Zhang[1], X. Li[1], H.-F. Ji[1], X.-L. Guo[1], B.-R. Chi[1]. [1]*Hepatology, the First Hospital of Jilin University,* [2]*Pathogenobiology, College of Basic Medical Sciences, Jilin University, Changchun, China*
E-mail: sheph_med@163.com

Background and Aims: Risk factors for fatty liver disease are not well defined, cholecystectomy was considered as a risk factor for fatty liver disease recently. We investigated the association of gallstones and cholecystectomy with fatty liver disease in a regional study.
Methods: Among adult patients admitted in the First Hospital of Jilin University during 2013–2014, gallstone disease and fatty liver disease were diagnosed by abdominal computerized tomography scan or magnetic resonance imaging. Odds ratios (ORs) for the association of gallstone disease with fatty liver disease were calculated using logistic regression analysis to adjust for common associated factors.
Results: Among 59,765 adult patients, the prevalence of gallstones, cholecystectomy and fatty liver disease was 12.7%, 5.4% and 13.0%, respectively. Patients with cholecystectomy had lower age-sex-adjusted prevalence of fatty liver disease (8.6%) than those with gallstones (14.0%) or without gallstone disease (13.2%) ($P < 0.01$ for all comparisons). Controlling for numerous factors associated with both fatty liver disease and gallstone disease, multivariate-adjusted analysis confirmed the association of fatty liver disease with cholecystectomy [OR = 1.452; 95% confidence interval (CI): 1.3–1.7], but not with gallstones (OR = 1.0; 95% CI: 0.9–1.1).
Conclusions: The association of fatty liver disease with gallstone disease indicates that cholecystectomy itself may be a risk factor for fatty liver disease.

P1081
HYPERPLASTIC COLONIC POLYPS LINK TO NONALCOHOLIC STEATOHEPATITIS AND VITAMIN D DEFICIENCY
M. Mahamid[1], P. Kalman[1], D. Wengrover[1]. [1]*Sharee Zedek Medical Center, Jerusalem, Israel*
E-mail: mahmudmahamid@yahoo.com

Background and Aims: Nonalcoholic steatohepatitis (NASH) is an common disease that link with metabolic syndrome, the prevalence of NASH in Europe and USA range from 14% to 20%. This increase prevalence related directly to obesity epidemic seen in these populations. hyperplastic colon polyp is the most common colon polyp. About 90% of colon polyps are hyperplastic polyps (HP); most of the remaining 10% are adenomas. HP is associated with aging, diet high in fat and beef and low in fiber. Other risk factors are smoking, a lack of exercise resulting in weight gain.
Objectives: To investigate a possible association between NASH and HP.
Methods: The study included 123 patients diagnosed with biopsy proven NASH followed at our outpatient liver clinic during the period March 2010 to May 2013, as well as a control group matched for age and gender (see Table 1). All subjects underwent a complete work-up and medical examination, anthropometric measurements, full colonoscopy and laboratory tests. Laboratory tests included complete blood count, C-reactive protein (CRP), and vitamin D levels.
Results: Mean CRP values were significantly higher in the NASH group (1.1±0.7 mg/dl in the NASH group and 0.4±0.8 mg/dl in the control group, $P < 0.05$). Vitamin D levels were significantly decreased in the NASH group (11.32±10.18 ng/ml in the NASH group vs. 21.55±13.62 ng/ml in the control group, $P < 0.05$). Multivariate analysis showed that CRP (odds ratio 3.1, 95% confidence interval 2.6–4.2, $P = 0.04$) and serum vitamin D levels <30 ng/ml (OR 2.3, 95% CI 2.2–3.1, $P = 0.02$) were associated with NASH.
In the NASH group 14 adenomas were found compared with 16 in the control group (P = NS). HP were more common in the NASH group (28 versus 8 HP in the control group P < 0.05), all the HP found in the NASH group were in the left colon while 2/8 HP in the control group were located at the right colon.
Conclusions: We found a significant correlation between NASH and HP prevalence and vitamin D deficiency. NASH suggested being risk factor to development of HP.

P1082
FATTY ACID OXIDATION CHANGES IN EARLY-ONSET PRE-ECLAMPSIA, HELLP SYNDROME AND ANTIPHOSPHOLIPID SYNDROME AND ITS CORRELATION WITH OXIDATIVE STRESS AND ENDOTHELIAL INJURY IN HUMAN TROPHOBLASTS
H. Yu[1], Z. Yang[1], X. Ding[1], Y. Wang[2], Y. Han[1]. [1]*Department of Obstetrics and Gynecology, Peking University Third Hospital,* [2]*State Key Laboratory of Reproductive Biology, Institute of Zoology, Chinese Academy of Sciences, beijing, China*
E-mail: zi_yang@email.com

Background and Aims: Preeclampsia syndrome is a multifactorial pregnancy complications which serious threat to maternal-fetal health. We and others have found that abnormal of fatty acid oxidation or lipid metabolisms exist in some cases of preeclampsia syndrome. Especially, there is a relationship between the long-chain fatty acid oxidation disorders and severe pre-eclampsia HELLP syndrome or acute fatty liver of pregnancy. But the correlation between long-chain fatty acid oxidation dysfunction with oxidative stress and endothelial injury in the pathogenesis of preeclampsia is unclear. This study was designed to investigate the effects of

fatty acid oxidation changes in early-onset pre-eclampsia, HELLP syndrome and antiphospholipid syndrome (APS) and its correlation with oxidative stress and endothelial damage in trophoblast cells.
Methods: Primary human trophoblast cells and HTR8/SVneo cells were treated with serum from patients with early-onset severe PE (E-PE group), E-PE with HELLP (PE-HELLP group), APS (APS group) and normal pregnant women served as controls (NC group). Cells treated with various lengths of free fatty acids as long-chain, medium-chain and short-chain were also used as controls. Spearman correlation analysis was performed to evaluate the correlation between serum FFA concentrations, lipid droplet deposition and trophoblast invasion and COX-2, p38MAPK, P47phox and NF-kB protein expression.
Results: Cells in the E-PE group had more severe lipid droplet deposition and showed similar changes with long-chain FFA group. FFA levels in the PE-HELLP group increased significantly compared with the NC group ($P < 0.05$). In the E-PE, PE-HELLP and APS three study groups, COX-2, P38MAPK, P47phox and NF-kB protein expression significantly increased ($P < 0.05$), which were different correlated with FFAs concentration and trophoblast invasion.
Conclusions: The pathological serum from patients had different effects on lipid deposition in trophoblast cells and lead to reduction in trophoblast invasion ability, which was correlated with serum free fatty acid level. Varying degrees of long chain fatty acid oxidation disorders exist in some subset of E-PE, PE-HELLP and APS, which is relate with distinct oxidative stress pathways and different degrees of endothelial injury.
Supported by grant NNSF of China No. 81370723 and Beijing MNSF No. 71372215.

Alcoholic liver disease and drug induced liver disease

P1083
A NOVEL IN VITRO METHOD FOR INDIVIDUAL CAUSALITY ASSESSMENT OF IDIOSYNCRATIC DRUG-INDUCED LIVER INJURY (DILI)

A. Benesic[1,2], A. Leitl[1], A.L. Gerbes[1]. [1]*Liver Center Munich® – Department of Internal Medicine 2, University Hospital Munich, Munich,* [2]*MetaHeps GmbH, Martinsried/Planegg, Germany*
E-mail: andreas.benesic@med.uni-muenchen.de

Background and Aims: Drug-induced liver injury (DILI) is the major cause for acute liver failure in developed countries and accounts for a significant number of drug withdrawals and restrictions of use. While dose-dependent DILI is not a diagnostic challenge, the diagnosis of idiosyncratic DILI until now relies on exclusion of other causes and identification of the causative agent may be impossible in polymedicated patients [1].
Aim was to investigate whether hepatocyte-like cells derived from peripheral blood by a proprietary method (MetaHeps®) can be used to diagnose or exclude DILI in patients with acute liver injury.
Methods: Clinical data and blood samples were collected prospectively from patients presenting at the Liver Center Munich®, LMU university hospital with acute liver injury and intake of at least one drug with DILI concern. Acute liver injury was defined according to [2] as ALT≥5×ULN or AP≥2×ULN or ALT≥3 and Bilirubin≥2×ULN without history of liver disease or cirrhosis. RUCAM score was used for clinical DILI probability [3]. MetaHeps® were generated as described in [4] and exposed in vitro with the respective drugs. Toxicity was measured by increase in LDH release.
Results: Unequivocal cases of DILI (n = 10) and non DILI causes (n = 8) of acute liver injury were used as positive and negative controls to test the MetaHeps® performance. RUCAM score in DILI cases was 8 (7–10) and 5 (3–6) in non-DILI cases, respectively. MetaHeps® toxicity was 7.5 in DILI cases (0.3–16.1) and 0.7 in non-DILI cases (0.04–1.8), only 1 DILI case was missed by MetaHeps®.
As yet 51 cases have been investigated (31 DILI, 20 non-DILI) showing 94% sensitivity using MetaHeps® or RUCAM. MetaHeps® showed no false positive result (specificity 100%) whereas RUCAM was false positive in 6/20pts (specificity 70%).
ROC-analysis showed superior MetaHeps® performance (AUC 0.97; $p < 0.05$; Figure 1).
Interestingly, MetaHeps® were also able to identify the causative drug in polymedicated DILI patients.

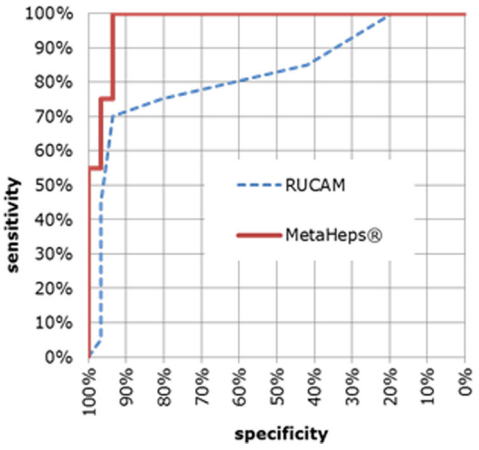

Figure 1.

Conclusions: MetaHeps® are a novel tool for diagnosis of DILI in individual patients allowing also for the identification of the causative agent in polymedication. The remarkable specificity of this promising test could save novel drugs by preventing false positive DILI diagnosis obtained with conventional scores.

E-mail: fcubero@ukaachen.de

Background and Aims: Acetaminophen (APAP)-induced liver injury has been extensively studied since APAP overdose is a leading cause of drug-induced hepatotoxicity (DILI) in Europe and the USA. JNK is strongly activated after APAP-DILI. However, the use of JNK inhibition as a therapeutic approach has considerably failed and new effective treatment options are urgently needed. In the present study, we hypothesized that compound function of *Jnk1* and *Jnk2* is essential for the maintenance of hepatocyte homeostasis during APAP-DILI.

Methods: JNK activation was first evaluated in human biopsies from DILI patients. Female and male mice carrying a compound deletion of *Jnk1* and *Jnk2* in hepatocytes ($JNK^{\Delta hepa}$), RIP-$3^{-/-}$ and control (WT) mice were subjected to APAP *in vivo* and *in vitro*. Additionally, we performed gene array and proteomics analysis in primary isolated hepatocytes and livers.
