Results: JNK activation in human DILI was observed in fibrotic areas, infiltrating cells and hepatocytes. Microarray analysis performed in livers and primary hepatocytes (WT compared with $JNK^{\Delta hepa}$) revealing up-regulation of cell death, metabolism, oxidative stress (ROS) and pro-inflammatory related genes in $JNK^{\Delta hepa}$ hepatocytes. $JNK^{\Delta hepa}$–APAP treated mice displayed significantly increased ALT, AST and GLDH, as well as visible severe hepatic haemorrhage. To better characterise the molecular mechanism behind the *in vivo* findings, we next isolated primary hepatocytes from WT and $JNK^{\Delta hepa}$ mice. After 12 h of APAP treatment the morphology of $JNK^{\Delta hepa}$ primary hepatocytes evidenced cytoplasmic projections, loss of cell contact and detachment. Concomitant with these results, we detected a large amount of mitochondrial ROS, TUNEL- and necrotic markers, suggesting a dramatic change of the mitochondrial membrane potential, leading to necrotic cell death, associated with overexpression of RIP-3 and p65 but absence of pJNK and p-c-Jun induction. Since our results indicated that the SP600125-dependent effect in protecting against APAP-induced necrosis could be mediated via RIP-3, we isolated primary hepatocytes from RIP-$3^{-/-}$ mice, which clearly evidenced protection against APAP-induced necrosis.
Conclusions: Compound function *Jnk1* and *Jnk2* in hepatocytes is protective against APAP-DILI. Our results question the current hypothesis that JNK inhibition is a treatment option for APAP-DILI, and thus earlier results using JNK inhibitors overlooked the unspecific inhibition of necrotic cell death.

MECHANISTIC INSIGHT INTO ACETAMINOPHEN-INDUCED HEPATIC TIGHT JUNCTION DISRUPTION USING A HUMAN HepaRG-BASED LIVERBIOCHIP IMPEDANCE BIOSENSOR

W. Gamal[1], P. Treskes[2], K. Morgan[2], C. Chesne[3], V. Shevchenko[3], J.N. Plevris[2], P.O. Bagnaninchi[4], L.J. Nelson[2]. *[1]Institute for Biomedical Engineering, [2]Hepatology, University of Edinburgh, Edinburgh, United Kingdom; [3]BioPredic International, Rennes, France; [4]MRC Centre for Regenerative Medicine; Institute for Biomedical Engineering, University of Edinburgh, Edinburgh, United Kingdom*
E-mail: lnelson1@staffmail.ed.ac.uk

Background and Aims: Acetaminophen (APAP) hepatotoxicity remains the leading cause of acute liver failure. Intrinsic pathophysiological mechanisms include GSH/ATP depletion, mitochondrial dysfunction, and oxidative stress, culminating in the physical disruption of cellular integrity, and cell death. HepaRG cells are considered surrogates for primary human hepatocytes, with intact Phase I-III drug metabolism/ functional polarity, suitable for APAP toxicity studies. Hepatic tight junctions (TJs) maintain polarity essential for bile secretion, drug transporters and CYP450 expression. Cholestatic drugs, which induce leaky TJs, can generate toxic mechanisms (similar to APAP) in HepaRG cells, including ROS-mediated disruption of TJ-associated F-actin. However, mechanistic insight into APAP-induced TJ disruption in hepatocytes is lacking. Our aim was to investigate dose-dependent effects of APAP on TJs in HepaRG cells using a non-invasive/real-time impedance-based biosensor array (LiverBioChip), correlated with biochemical and morphological phenotypic assays.
Methods: Differentiated HepaRGs were cultured to confluence on 96-well (96-idf20) electrode arrays. On day 8, following 24 h Rifampicin-CYP3A4 induction, APAP time-/dose-response [0–20mM] was monitored with quantitative impedance, |Z|,

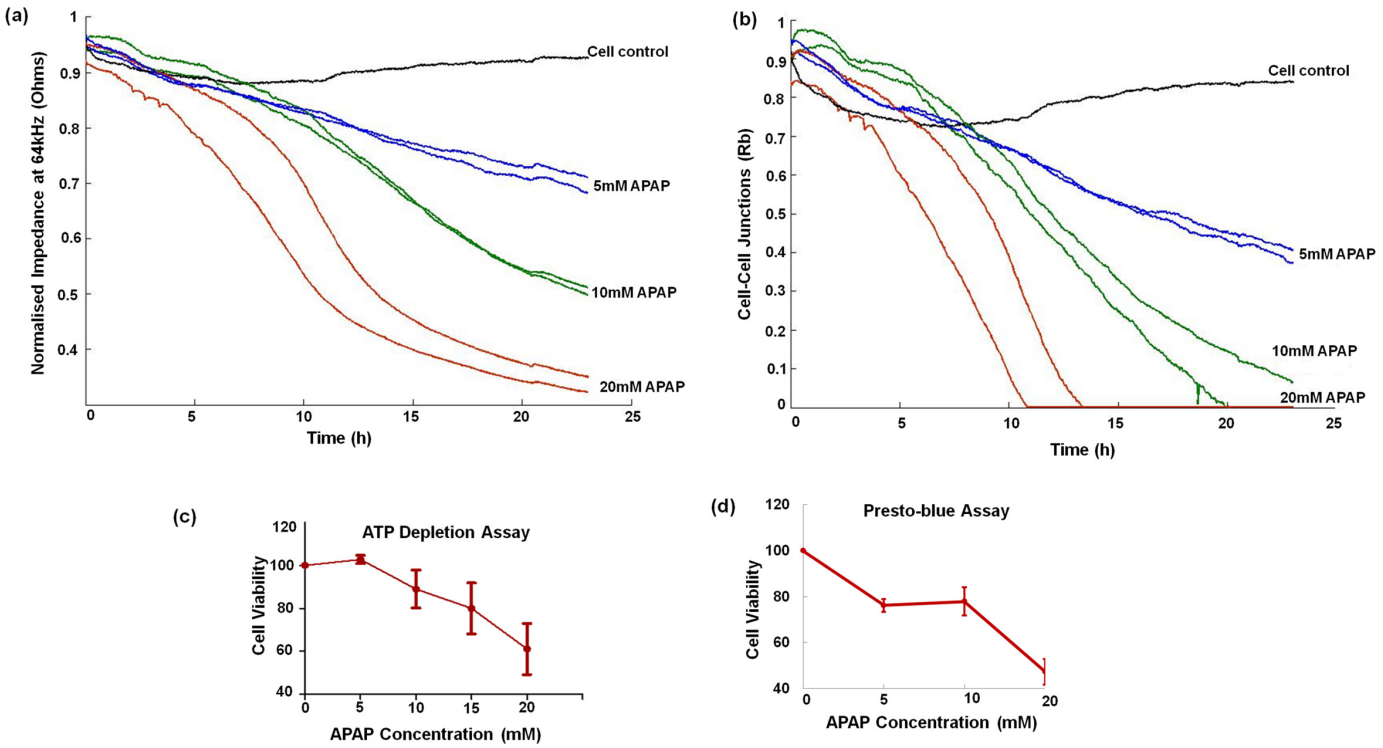

Figure 1 (abstract P1085). Acetaminophen challenge. Dose-dependent effects on: (a) Total impedance (cell behavior index); (b) Tight junction changes (Rb) showing early dose-dependent disruption of Tjs, even at sub-toxic APAP levels (5mM). Impedance data correlated with endpoint hepatotoxicity. (c) ATP depletion, and (d) Prestoblue live-cell viability assays at 24 hours.

measurements (180s intervals; f = 4 kHz) for 96 h post-induction; to detect the TJ parameter (Rb), using |Z|-spectra modeling. Correlative hepatotoxicity/phenotypic assays were performed: (i) ATP-depletion; Prestoblue (PB: live-cell viability); (ii) Phorbol Ester (disrupts TJ integrity); (iii) Expression of TJs: ZO-1; TEM-Ultrastructure; (iv) M30/M65 apoptosis/necrosis cell death kits.
Results: Real-time |Z| monitoring showed highly-sensitive/temporal dose-response to APAP, whilst subsequent |Z|-spectra modelling reflected early disruption of TJs (Figure 1). Endpoint ATP-depletion and PB assays correlated with |Z| changes (24 h). Ultrastructural imaging coupled with ZO-1 confirmed disruption to TJ-barrier function, prior to cell death (type 2 blebbing). M30/M65 assays showed apoptosis (M30) as a pre-dominant early event (measured at 12 h) in response to APAP >10mM, as TJ integrity detected by impedance (Rb) fell to 50% of controls.
Conclusions: LiverBioChip provides a continuous/quantitative real-time indicator of hepatic TJ integrity; revealing early, dose-dependent disruption of TJs even at sub-toxic APAP levels (5mM). This platform may provide mechanistic insight into hitherto unknown effects of APAP, including mode of cell death.

P1086
COMPLEX EFFECTS OF ADENOSINE RECEPTOR ANTAGONISTS IN MODELS OF LIVER FIBROSIS

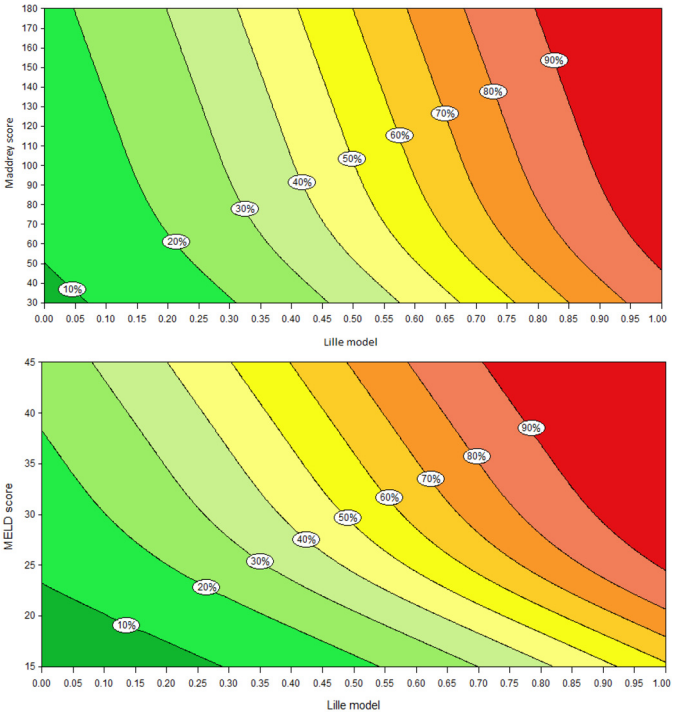
R. Surabattula[1], Y.O. Kim[1], K.-S. Park[1], T. Resa[1], P. Olinga[2], S. Robson[3], D. Schuppan[1,3]. *[1]Institute of Translational Immunology, University Medical Center of Johannes Gutenberg University, Mainz, Germany; [2]Department of Pharmaceutical Technology and Biopharmacy, University of Groningen, Groningen, Netherlands; [3]Division of Gastroenterology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States*
E-mail: rasuraba@uni-mainz.de

Background and Aims: There are four known subtypes of adenosine receptors (AR; namely A_1, A_{2A}, A_{2B} and A_3), but the role of ARs in fibrosis is not fully explored. We investigated the antifibrotic effect of a spectrum of subtype specific AR antagonists in liver fibrosis.
Methods: The AR antagonists: DPCPX for A_1R; ZM241385, 8-(3-Chlorostyryl) caffeine, SCH-58261, and KW6002 for A_{2a}R; Enprofylline, Xanthine amine congener (XAC), and Alloxazine for A_{2b}R; MRS1523 for A_3R were tested in two murine liver fibrosis models. Six week old female C57BL/6 mice were orally gavaged with increasing doses of CCl_4 for 2 weeks (n = 5/group) and received a low (0.5 mg/kg/d) or high dose i.p. (2 mg/kg/d) of antagonists in the second week. Mdr2KO mice received the antagonists from age 6 to 10 weeks of age (n = 6/group). Vehicle was used for control groups. Mice were analyzed for liver collagen (hydroxyproline, Sirius red morphometry), serum biochemistry (AST, ALT, ALP, creatinine, total bilirubin), and qPCR for fibrosis related transcripts [procollagen α1(I), α-SMA, TGFβ1, integrin β6, and TIMP-1]. The intrahepatic cAMP levels of A_2R antagonists treated mice were measured.
Results: The A_1R antagonist DPCPX did not show any significant effect on fibrosis progression. Among the A_{2a}R antagonists, the most specific and active drug, SCH-58261, modestly aggravated fibrosis in both models at the low dose. Among the A_{2b}R antagonists, low dose Alloxazine significantly attenuated collagen accumulation, decreased procollagen α1(I) and integrin β6 mRNA expression, but upregulated TGFβ1 transcripts at the high dosein both models. Enprofylline (equipotent for both A1 and A2R) and XAC tended to increase fibrosis at all doses in both models, possibly due to their lower specificities compared to Alloxazine. Finally, the A_3R antagonist MRS1523 significantly aggravated all fibrosis related parameters at the low dose. Effective antagonism of adenosine R antagonists was demonstrated by suppression cAMP levels.
Conclusions: We demonstrated an antifibrotic effect of A_{2b}R and A_3R inhibition, and a profibrotic effect of A_{2a}R inhibition. In some instances divergent dose-dependent anti-fibrotic effects of adenosine receptor antagonists may be due to overlapping specificities in some cases, a narrow therapeutic window, and to different cell types addressed at variant doses.

P1087
PREDICTION OF DEATH AS A CONTINUUM OF RISK OF MORTALITY IN SEVERE ALCOHOLIC HEPATITIS BASED ON BASELINE AND DYNAMIC MODELS

A. Louvet[1], J. Labreuche[2], F. Artru[1], J. Boursier[3], J. O'Grady[4], S. Naveau[5], R. Carithers[6], E. Diaz[7], G. Lassailly[1], A. Cannesson-Leroy[1], V. Canva-Delcambre[1], S. Dharancy[1], T. Morgan[8], A. Duhamel[2], P. Mathurin[1]. *[1]Maladies de l'appareil digestif, Hôpital Huriez, [2]Biostatistics, CHRU de Lille, Lille, [3]Hepatology, CHU, Angers, France; [4]Liver unit, King's College, London, United Kingdom; [5]Hépato-gastroentérologie, Hôpital Antoine-Béclère, Clamart, France; [6]Veterans Affairs, Puget Medical Centre, Seattle, United States; [7]Hépato-gastroentérologie, Hôpital Germon et Gauthier, Béthune, France; [8]Veterans Affairs, Healthcare System, Long Beach, United States*
E-mail: alexandre.louvet@chru-lille.fr

Background and Aims: Several scoring systems have shown their accuracy to predict survival of patients with severe alcoholic hepatitis (AH) but their use is mainly based on one or two cut-offs. This assessment is based on pre-treatment measures of disease severity for static models (MELD score, Maddrey discriminant function DF) but also on-treatment models which assess early improvement in liver function (Lille model). Combining information from these two types of models may help in assessing outcome of patients as a continuum of probabilities of dying.
Methods: Based on a large international database of patients with severe AH (Maddrey DF≥32) treated with corticosteroids, we combined information from static models (Maddrey DF or MELD score) and from the Lille model. Contour lines were built to assess the probability of death at 6 months.



Results: 897 patients were included: age 50.6 years, 58.5% of males, bilirubin 156 μmol/l, prothrombin time 20.2 s, creatinin 8 mg/l, DF 55, MELD 25.2, Lille model 0.34. Six-month survival was 64.1%.

Figure (top) gives the probability of death using DF at day 0 (Y-axis) and Lille model at day 7 (X-axis). As an example, a patient admitted with a DF at 100 with a Lille model at day 7 of 0.25 has a probability of death of 27% at 6 months, which increases at 72.3% if Lille model is 0.7. The likelihood of the joint-effect model was improved in comparison to a model based solely on Lille model ($p = 0.016$). We conducted a second analysis Lille-MELD on a subgroup of 638 patients for whom MELD score was available (Figure, bottom). The efficacy of the joint-effect model was also better as compared to each model alone ($p < 0.001$). As an example, a patient admitted with a MELD score at 28 with a Lille model of 0.25 has a probability of dying of 27% at 6 months, which increases at 69.7% if Lille model is 0.7. The two combinations (Lille+Maddrey DF and Lille+MELD) showed good discrimination and calibration, the latter meaning that predicted survival fitted the observed survival. Using the Akaike information criterion, we found that the combination Lille+MELD was a better fitting prognostic model as compared to the combination Lille+Maddrey DF.

Conclusions: We propose a new approach that predicts the outcome of patients with severe alcoholic hepatitis in terms of a continuum risk of mortality. This may be helpful not only to improve management of patients but also to develop trials for future strategies.

P1088

MORPHOMETRICAL QUANTIFICATION OF FIBROSIS CORRELATES WITH CLINICAL CIRRHOSIS STAGE AND PREDICTS LONG-TERM SURVIVAL IN PATIENTS WITH ALCOHOLIC CIRRHOSIS

L. Binder[1], F. Rainer[1], J. Haybaeck[2], S. Xu[3], W. Spindelboeck[1], A. Wee[3], R. Stauber[1], C. Lackner[2]. *[1]Department of Internal Medicine, [2]Institute of Pathology, Medical University of Graz, Graz, Austria; [3]Department of Pathology, National University of Singapore, Singapore, Singapore*
E-mail: rudolf.stauber@medunigraz.at

Background and Aims: Histological subclassification of cirrhosis may allow for the definition of severe fibrosis stages with different clinical severity and prognosis. Recently the Laennec fibrosis scoring system was found to correlate with the clinical cirrhosis stage and grade of portal hypertension. However, the value of histological staging is limited by intra- and interobserver variability. We therefore aimed to determine the relationship between morphometrically quantified fibrosis measured as collagen proportionate area (CPA) using digital assisted image analysis and clinical stage of septal fibrosis and cirrhosis as well as long-term survival in patients with alcoholic liver disease (ALD).

Methods: Liver biopsies of 149 consecutive ALD-patients, without other cause of liver disease were studied. CPA was quantified using Tissue Studio ® software (Definiens™). The data were externally validated at the National University of Singapore. In addition fibrosis was staged semiquantitively using the clinical research network (CRN) and Laennec systems. Clinical stages at the the time of liver biopsy were determined according to D'Amico. Complete follow up and outcome data were available from all patients.

Results: Mean CPA values progressively increased with Laennec fibrosis stage (stage 0: 1.4±0.8%, stage 1: 3.5±2.6%, stage 2: 8.8±6.1%, stage 3: 14.6±9.2%, stage 4: 21.1±11.8%, stage 5: 34.8±14.0%, stage 6: 48.1±12.4%; $p = 0.000$ by ANOVA) and with clinical D'Amico stage (stage 1: 12.5±13.7%, stage 2: 30.0±19.8%, stage 3: 40.2±18.2%, stage 4: 35.7±18.2%; $p = 0.000$ by ANOVA). On ROC analysis, a CPA of 35% was identified as best cut-off for discrimination of cirrhosis. In patients with septal fibrosis or cirrhosis (CRN stage >2), Kaplan–Meier analysis revealed an association of 5-year survival to CPA (cut-off 35%, $p = 0.035$) but not to Laennec fibrosis stage ($p = 0.294$).

Conclusions: These findings suggest that morphometrical subclassification yields two fibrosis stages with distinct clinical outcomes. CPA measurements may favorably substitute for semiquantitative histological fibrosis staging used in ALD while avoiding intra- and interobserver biases which limit the utility of conventional histological fibrosis staging.

P1089

CELLULAR SENESCENCE AND LIPOPOLYSACCHARIDE/TOLL-LIKE RECEPTOR 4 SIGNALING IN ALCOHOLIC STEATOHEPATITIS

G. Alpini[1], K. McDaniel[2], Y. Han[3], H. Francis[2], F. Meng[2]. *[1]Medicine, [2]Scott & White Healthcare, [3]Texas A&M HSC College of Medicine, Temple, United States*
E-mail: fmeng@sw.org

Background and Aims: Cellular senescence is a stress-responsive program limiting the proliferation of damaged cells and leading to stable cell-cycle arrest. Accumulation of senescent hepatocytes may contribute to loss of functional hepatic mass and lead to liver decompensation and fibrosis. The current study aimed to characterize the functional role of cellular senescence during alcoholic-induced hepatitis.

Methods: Senescence related gene expression was assessed using a Cellular Senescence PCR Array and/or real-time PCR analysis. Cellular senescence and viability were measured by SA-β-gal Activity and MTS assay. The upstream modulators of senescence were defined in ethanol/LPS treated hepatocytes and cholangiocytes in vitro, and in ethanol fed mice and TLR-4 knockout mice in vivo.

Results: We identified that 5 week of ethanol feeding significantly increased total liver histopathology score and hepatocellular senescence by PCR array and SA-β-gal assay. The up-regulation of hepatic senescence initiators, PAI-1 and EGR1, were further verified by real-time PCR assay. Treatment of N-Heps and HiBECs with ethanol (86 mM) and LPS (20 ng/ml) for 72 hr significantly increased PAI-1 and EGR1 expression, along with the enhanced SA-β-gal activity. Silencing of PAI-1 decreased *ethanol and LPS*-induced *senescence* in both N-Heps and HiBECs, whereas inhibition of EGR1 only reduced the senescence and increased viability in N-Hep cells. Interestingly, silencing of PAI-1 and EGR1 also reduced the pro-fibrotic markers, α-SMA and TIMP-1 in N-Hep cells, whereas silencing of LPS receptor TLR4 decreased these markers in the same group of N-Hep cells, suggesting LPS-mediated cellular senescence during alcohol-induced liver fibrosis. Furthermore, the expression of TLR4 and the verified LPS related senescence markers, including E2F1, ID1 and IGFBP3 were significantly altered in ethanol-fed mice liver specimens compared to controls. TLR4 knockout mice displayed less sensitivity to alcoholic injury, along with reduced PAI-1 and EGR1 levels and recovered expressions of α-SMA and TIMP-1.

Conclusions: Our results show that PAI-1 and EGR1 are the critical regulator of LPS induced cellular senescence and alcoholic hepatitis. The findings provide new insight into the function of LPS regulated cellular senescence and increase opportunities for the development of novel treatment paradigms for the management of alcoholic liver diseases.

P1091

ONE YEAR EFFECTIVENESS OF BACLOFEN TREATMENT IN 100 ALCOHOL-DEPENDENT PATIENTS

C. Barrault[1], H. Lison[2], F. Roudot-Thoraval[3], A. Garioud[2], V. Béhar[1], I. Rosa-Hézode[4], D. Belloula[2], M. Medmoun[2], C. Fourny[1], G. Pulwermacher[5], H. Hagège[4], J.-F. Cadranel[2]. *[1]Addiction and hepatology unit, Centre hospitalier intercommunal de Créteil, Créteil, [2]Hepatology unit, Groupe Hospitalier Public du Sud de l'Oise, Creil, [3]Public health unit, Henri Mondor, [4]Hepatology unit, Centre hospitalier intercommunal de Créteil, Créteil, [5]Addiction and hepatology unit, Groupe Hospitalier Public du Sud de l'Oise, Creil, France*
E-mail: camille.barrault@chicreteil.fr

Background and Aims: Several studies have suggested efficacy of Baclofen (BAC) at low or high dose in reducing alcohol consumption. Since March 2014, Temporary Recommendation for Use of BAC has

been allowed by the French drug agency (ANSM) in this indication. The aim of the study was to assess effectiveness and safety of BAC at 12 months in alcohol-dependent patients with or without liver cirrhosis.

Methods: Between June 2010 and September 2013, 100 consecutive patients from 2 liver and alcohology units were included in this prospective open label study. Patients provided written consent before treatment initiation. BAC was orally administered at a dose of 15 mg/day and weekly increased until alcohol indifference was obtained. The treatment was associated to social-psychological support and medical care.

Results: BAC was started in 100 patients (75 males, mean age 53±9 years): 65 were cirrhotic and 16 had a chronic pancreatitis. After 1 year, 86 patients were still involved in the follow up, 83 were treated with BAC, 9 were lost of follow-up, 4 were dead and 1 had been transplanted. At a mean BAC dosage of 40 mg/day [30–210], mean daily alcohol consumption (DAC) was reduced from 106 to 18 g/day ($p < 0.001$). A decrease of the DAC >50% was observed in 77 patients. Among them, a "low consumption group" of 64 patients was identified: 44 were completely abstinent and 20 drunk less than 30 g/day. No predictive factor of response was identified. In this group, a significant improvement of consumption biomarkers was observed: decrease of mean γGT activity from 4.8N to 2N ($p < 0.001$), mean ASAT activity from 2.6N to 1.1N ($p < 0.001$) and mean erythrocyte globular volume from 100.6 to 92.8 μ^3 and increase of mean platelets count from 171000 to 193000/mm^3 ($p = 0.032$). In the 39 cirrhotic patients of the "low consumption group", total bilirubin serum concentration significantly decreased from 34.2 to 19.5 μmol/L ($p = 0.026$), prothrombin time increased from 69 to 77% ($p < 0.001$) and albuminemia increased from 34.2 to 37.2 g/L ($p = 0.07$). Twenty patients (20%) reported minor side effects leading to a treatment withdrawal in 2 cases. No liver or renal function deterioration occurred in cirrhotic patients.

Conclusions: In our cohort, baclofen treatment associated to a global care led to a dramatic reduction of alcohol consumption. This effective treatment is well tolerated and associated with a significant improvement of consumption biomarkers and of liver function tests in cirrhotic patients.

P1092

SPECIFIC-SIZED HYALURONAN FRAGMENTS DIFFERENTIALLY REGULATE LPS SIGNAL TRANSDUCTION IN KUPFFER CELLS AFTER ETHANOL FEEDING TO RATS

P. Saikia[1], K.A. Pollard[1], M.R. McMullen[1], L.E. Nagy[1,2]. [1]*Center For Liver Disease Research, Pathobiology, Cleveland Clinic,* [2]*Molecular Medicine, Case Western Reserve University, Cleveland, United States*
E-mail: saikiap@ccf.org

Background and Aims: Hyaluronan (HA), a major component of extracellular matrix, is ubiquitously present in many tissues. During acute and chronic inflammation or tissue injury, reactive oxygen species and matrix metalloproteinases increase HA turnover, resulting in the local and systemic accumulation of HA fragments of different molecular weights. Depending on their size, HA fragments can have either anti-inflammatory, anti-angiogenic and immunosuppressive function or pro-inflammatory function. HA is recognized as an important damage associated pattern molecule (DAMP) that regulates innate immunity. HA has been used as an indicator of liver injury for decades; however, it is not known if HA contributes to the pathophysiology of chronic ethanol-induced liver injury. Chronic alcohol consumption is associated with an increase in the sensitivity of macrophages to signaling via TLR4.

Here we have tested the hypothesis that specific-sized HA fragments differentially regulate LPS-mediated signaling via TLR4 in Kupffer cells, the resident macrophage in the liver.

Methods: Primary cultures of Kupffer cells were isolated from rats chronically exposed to ethanol via the Lieber-DeCarli diet or pair-fed control diets.

Results: Kupffer cells from ethanol-fed rats were more sensitive to stimulation with LPS, resulting in increased expression of mRNA for the pro-inflammatory cytokine, TNFα. Challenge of Kupffer cells with specific-sized HA fragments (from 7 kDa to 2000 kDa) had no effect on TNFα mRNA expression. However, when Kupffer cells were pre-treated with HA fragments for 5 h prior to LPS challenge for 60 min, specific-sized HA fragments differentially suppressed or stimulated TNFα mRNA expression. When Kupffer cells were pre-treated with HA fragments of 35kDa, the sensitization of Kupffer cells from ethanol-fed rats to LPS returned to pair-fed values. In contrast, pre-treatment with 74kDa HA had a synergistic effect in production of TNFα, increasing expression in Kupffer cells from both ethanol- and pair-fed rats. HA fragments, of 7kDa or 2000kDa, had no effect on TNFα production.

Conclusions: In summary, these data suggest that specific-sized HA fragments differentially regulate TLR4-mediated signaling in Kupffer cells and that HA 35kDa fragments may play a protective role in alcoholic liver disease by decreasing the production of inflammatory mediators by Kupffer cells.

CHARACTERIZATION OF ACETAMINOPHEN THERAPEUTIC MISADVENTURE: A SINGLE CENTRE EXPERIENCE

A. Louvet[1], C. Vanveuren[1], S. Dharancy[1], A. Cannesson-Leroy[1], F. Artru[1], G. Lassailly[1], V. Canva-Delcambre[1], P. Mathurin[1].
[1]*Maladies de l'appareil digestif, Hôpital Huriez, Lille, France*
E-mail: alexandre.louvet@chru-lille.fr

Background and Aims: Therapeutic doses of acetaminophen may provoke acute liver failure, the so-called "therapeutic misadventure with acetaminophen" but this entity has never been evaluated with a prospective design. Such study would help determining prerequisites of this condition and assessing outcome.

Methods: Single-centre prospective study in which patients were included with severe acute liver failure related to acetaminophen as follows: acetaminophen overdose (AO) or intake at a therapeutic dose (≤6 g/day), referred to as acetaminophen therapeutic misadventure (ATM). Chronic drinkers were defined by an alcohol consumption ≥30 g/day.

Results: From 2002 to 2014, 271 patients were included, 205 AO and 66 ATM. ATM occurred only in chronic drinkers (89.4%) or in patients who had starved for several days (10.6%). By definition, acetaminophen intake was higher in AO as compared to ATM: 16 g vs. 3.15 g ($p < 0.001$). In 70% of patients, intake was below the daily 4 g dose classically regarded as safe. No patient developed ATM after a single intake of acetaminophen as confirmed by a median time of intake at 4 days vs. 1 in AO ($p < 0.001$). At admission, patients with ATM were older than AO (age 44 vs. 30.1 years; $p < 0.001$) and had a deeper impairment of liver function (prothrombin time 30.7 vs. 22.1 s, $p < 0.01$; albumin 32.7 vs. 38.1 g/l, $p < 0.001$; bilirubin 47.1 vs. 25 mg/l, $p < 0.001$; lactate 3.31 vs. 1.95 mmol/l, $p = 0.009$). At admission, transaminases were not different between ATM and AO: AST 4138 vs. 3983 IU/l ($p = 0.1$), ALT 2416 vs. 3831 IU/l ($p = 0.22$). In ATM and AO, we found a predominance of females: 63.6% and 56.6% ($p = 0.31$) and percentage of chronic drinkers was 89.4 vs. 36.6% ($p < 0.001$), respectively. As expected in acetaminophen poisoning, we observed a dramatic drop after 3 days by 67% vs. 50.2% ($p < 0.001$) in ALT and by 93.6 vs. 89.4% ($p = 0.02$) in AST in ATM and AO respectively. One-month overall survival was 84.6% in ATM and 92.6% in AO ($p = 0.05$). On the global cohort, only the number of King's College criteria (risk ratio 3.15, 95% CI: 2.04–4.88, $p < 0.001$) independently predicted 1-month mortality, whereas albumin, age and alcohol consumption did not ($p = 0.13$, 0.41 and 0.75 respectively).

Conclusions: Therapeutic misadventure with acetaminophen is not a rare condition and occurs after several days of acetaminophen

intake at a dose <6 g/day, mainly in chronic alcohol drinkers. Its outcome is worse as compared to acetaminophen overdose. Physicians must be aware of the risk of therapeutic doses of acetaminophen in chronic drinkers.

P1094

HIGH LONG-TERM MORTALITY IN DECOMPENSATED ALCOHOLIC LIVER DISEASE (ALD) INCLUDES AN EXCESS OF NON LIVER-RELATED DEATHS

E. Taylor[1], A. Aljoudeh[1], E. McFarlane[1], M. Karajeh[1], D. Gleeson[1].
[1]*Liver unit, Sheffield Teaching Hospitals, SHEFFIELD, United Kingdom*
E-mail: aaljoudeh@hotmail.com

Background and Aims: Long-term mortality in ALD is not well characterised. We have previously (Al-Joudeh, J Hepatol 2013 58: S211) reported high long-term mortality in 249 patients [162 men, mean age (range) 50 (27–87) years] admitted consecutively to our unit between 1/4/1998 and 31/12/2005 with first presentation of decompensated ALD (Child grade B or C). Here, we aimed to assess further the causes of death in this cohort.
Methods: We reviewed hospital records, and death certificates and contacted surviving patients and GPs to assess who had died, the causes of death and the patients' overall alcohol-drinking behaviour subsequent to the index hospital admission (classified as: abstinent, continued drinking but reduced and did not reduce). We collected data on cardiovascular risk factors from hospital records.
Results: Median (range) follow up was 3.6 (0–16) years. By 1/7/2014, 44 of the 249 patients remained alive (including one of only 2 patients transplanted), 6 were lost to follow up and 199 had died (including the other transplanted patient). 154 deaths were due to complications of liver disease (only 5 due to hepatocellular carcinoma) and 45 to non-liver causes (16 extra-hepatic malignancy, 13 cardiovascular disease, 7 cerebral haemorrhage and 9 other causes). Mortality from non-liver causes was (mean±SEM) 10±3% and 30±5% after 5 and 10 years respectively. Standard Mortality Ratio (compared to the regional population) was 16.0 (95% CI 13.7–18.2) for all-cause death and was 3.6 (2.6–4.7) if only non-liver deaths were considered and cases censored following liver-related death (or transplant). The estimated excess of deaths from non-liver causes (32) exceeded the number of all-cause deaths within the first 30 days (27). Predictors of liver-related death were baseline prognostic scores (Maddrey, Glasgow, MELD and Child), but not for deaths after first four months of follow up; also, serum albumin on discharge from ($p = 0.006$) and drinking behaviour subsequent to ($p < 0.001$) index admission. In contrast, non-liver death showed no association with these variables, or with smoking status, presence of arterial disease, diabetes, treatment for hypertension or hyperlipidaemia or social deprivation index. Non-liver related death was significantly associated with age ($p = 0.012$).
Conclusions: Patients with first presentation of decompensated ALD have high long-term mortality, including previously undocumented excess mortality unrelated to liver disease.

P1095

ROLE OF MACROPHAGE MIGRATION INHIBITORY FACTOR IN A MODEL OF CHRONIC-BINGE ETHANOL EXPOSURE IN MICE

K.L. Poulsen[1], M.R. McMullen[1], S. Roychowdhury[1,2], L.E. Nagy[1,2].
[1]*Center for Liver Disease Research, Pathobiology, Cleveland Clinic,* [2]*Molecular Medicine, Case Western Reserve University, Cleveland, United States*
E-mail: poulsek@ccf.org

Background and Aims: The innate immune system is a critical factor in the development and progression of Alcoholic Liver Disease (ALD) in both human and animal studies. Macrophage Migration Inhibitory Factor (MIF) is an important innate immune regulator previously identified as a key contributor to liver injury in mice after chronic ethanol feeding. MIF is a pleiotropic protein with cytokine and chemokine properties and may therefore mediate liver injury directly and/or indirectly via immune cell recruitment. While chronic ethanol exposure results in steatosis and modest inflammation in the liver, it does not model more acute, severe alcoholic hepatitis. Here, we have tested the hypothesis that MIF also contributes to liver injury in response to the chronic-binge model of ethanol exposure in mice that more closely models more severe alcoholic hepatitis.
Methods: Wild-type C57Bl/6J and $MIF^{-/-}$ female mice were fed a liquid diet of ethanol for 10 days (5% v/v) then acutely binged with ethanol (5 g/kg) on day 11.
Results: After chronic-binge ethanol exposure, WT mice had increased liver damage compared to pair-fed mice, as assessed by ALT and AST activities. Surprisingly, ALT and AST activities were higher in $MIF^{-/-}$ mice versus WT mice after chronic-binge, suggesting that MIF protects from the acute inflammatory response elicited by chronic-binge ethanol exposure, contrasting with the disease-promoting role of MIF during chronic ethanol exposure. $MIF^{-/-,}$ but not WT mice, had increased TNF mRNA in response to the ethanol, which further implicated MIF as protective in a model of chronic-binge ethanol exposure. $MIF^{-/-}$ mice, however, were protected from excessive triglyceride accumulation in the liver, suggesting that ethanol-induced steatosis is MIF-dependent. In contrast, chronic-binge increased IL-1β, Ly6G and CD11b expression in both WT and $MIF^{-/-}$ livers, which indicated immune cell-recruitment and inflammasome activation were each MIF-independent responses.
Conclusions: Taken together, these results indicate that MIF differentially contributes to liver injury in the Chronic-Binge model, protecting from inflammation and hepatocyte injury, while contributing to steatosis.

MIXED LINEAGE PROTEIN KINASE 3 CONTRIBUTES TO ETHANOL-INDUCED LIVER INJURY

S. Roychowdhury[1,2], M.R. Mcmullen[1], L.E. Nagy[1,2]. [1]*Center for Liver Disease Research, Pathobiology, Cleveland Clinic,* [2]*Molecular Medicine, Case Western Reserve University, Cleveland, United States*
E-mail: roychos@ccf.org

Background and Aims: The progression of alcoholic liver disease (ALD) is associated with death of hepatocytes by both apoptosis and necrosis/necroptosis. Specific pathways of cell death may influence progression of ALD, with hepatocyte death by apoptosis driving fibrotic responses, while death by necrosis/necroptosis and release of DAMPs leading to sterile inflammatory responses. Understanding the pathways regulating apoptosis vs. necrosis/necroptosis after chronic ethanol exposure is critical to the design of appropriate therapeutic interventions for each stage of ALD. We have recently reported that caspase-independent programmed cell death, termed necroptosis, is a primary driver of hepatocyte cell death after chronic ethanol exposure. Since activation of c-jun N-terminal kinase (JNK) contributes to receptor interacting protein 3 (RIP3)-mediated necroptosis and mixed lineage kinase 3 (MLK3) contributes to JNK activation, here we tested the hypothesis that MLK3-dependent JNK activation is critical for ethanol-induced liver injury.
Methods: Female C57BL/6 (wild-type) and MLK3-deficient mice were chronically exposed to ethanol via the Lieber-DeCarli diet.
Results: In wild-type mice, chronic ethanol feeding increased plasma ALT/AST, a marker of hepatocyte injury, hepatic triglyceride content and expression of pro-inflammatory cytokines. Ethanol-induced hepatocyte injury was associated with increased expression of RIP3 protein, an indicator of necroptotic cell death, as well as the accumulation of both TUNEL-positive cells and

M30/CK18-cleavage staining, indicators of hepatocyte apoptosis. Indicators of oxidative stress, including the accumulation of 4-HNE-protein adducts and JNK phosphorylation, were also increased. In contrast, mice deficient in MLK3 were protected from ethanol-induced increases in plasma ALT/AST, pro-inflammatory cytokines and hepatic protein expression of RIP3. Ethanol-induced JNK phosphorylation and oxidative stress were also attenuated in MLK3-deficient mice. However, MLK3-deficiency did not affect ethanol-induced steatosis or hepatocyte apoptosis.
Conclusions: Taken together, these results suggest that MLK3 participates in the development of ethanol-induced oxidative stress, activation of JNK and induction of necroptotic programmed hepatocyte death. Pharmacological intervention of this pathway could be targeted as a potential therapeutic strategy to suppress necroptosis-induced inflammation and hepatocyte injury in patients with ALD.

Background and Aims: Drug-induced autoinmune hepatitis (DI-AIH) is a particular clinical phenotype of hepatotoxicity, poorly defined. Its prevalence in cohorts of patients with DILI is unknown. We aimed to characterize phenotypes and used drugs in DI-AIH, from a large cohort of DILI patients, and in idiopathic autoimmune hepatitis (AIH) to improve differential diagnosis between both entities.
Methods: Demographic and clinical variables in 21 patients out of 1013 included in the Spanish-Latin DILI Registry presenting with typical AIH clinical and analytical features including serum detectable titers of ANA and/or ASMA, as well as high gammaglobulin levels after the initiation of different drug therapies were compared with 51 patients diagnosed with idiopathic AIH at Mendaro and Mondragon Hospitals, Gipuzkoa, Spain.
Results: Both cohorts demonstrated similar age and gender distribution, with 38% males (mean age 58 years ±16) in the DI-AIH cohort. Hypertension and diabetes mellitus were more frequent in DI-AIH patients, 33% vs 12% ($p = 0.023$) and 14% vs 2% ($p = 0.038$), respectively. Other underlying autoimmune diseases were less frequent in DI-AIH (24% vs 33%). The more frequent drugs triggering DI-AIH and the co-medications in AIH patients were statins (19% vs 12%), NSAIDs (10% vs 12%), antibiotics (24% vs 2%) and anti-TNF (10% vs 2%). At presentation patients with DI-AIH exhibited jaundice in the 62% vs 31%, higher total bilirubin levels [6 times the upper limit of normal (×ULN) vs 2×ULN, $p = 0.001$], AST (23×ULN vs 11×ULN, $p = 0.001$), ALT (27×ULN vs 14×ULN, $p = 0.001$) and GGT (9×ULN vs 5×ULN, $p = 0.02$). No significant differences were observed in ALP values. Advanced fibrosis (F3–F4) in liver biopsy was observed in 18% of DI-AIH vs 25.5%. The DI-AIH group required steroid therapy less frequently than the AIH group (81% vs 93%) achieving complete response in 100% of cases vs 92% in AIH.
Conclusions: DI-AIH is more severe than idiopathic AIH at diagnosis, presenting most frequently with jaundice, but liver histology demonstrating a minor grade of fibrosis. Statins are increasingly being identified as potential triggers for DI-AIH and could be actually the unidentified trigger behind many cases of "true idiopathic" AIH.

E-mail: imcaliz@uma.es

Background and Aims: It has been suggested that metabolic risk factors may play a role in DILI presentation. Hence, the aim of this study was to determine the influence of diabetes and dyslipidemia in the clinical profile of DILI.
Methods: 864 DILI cases included in the Spanish DILI Registry were compared according to the presence or absence of diabetes and dyslipidemia.
Results: DILI patients with (n = 121) dyslipidemia were significantly older than those without (n = 743), 64 vs 52 years, ($p < 0.001$) and had on average a higher BMI, 27 vs 25 ($p = 0.017$). Duration of treatment of the causal agent and time to DILI onset did not differ significantly between the groups. In terms of DILI severity, only four severe and fatal cases (3%) were present among the patients with dyslipidemia, while 95 (13%) were found among normolipemic patients ($p = 0.009$). Persistent liver damage more than one year after DILI onset was seen in 30% of the patients with dyslipidemia and 22% of non-dyslipidemia patients. The mean value of total bilirubin at onset was lower in patients with dyslipidemia (5.4 vs 7 ×ULN, $p = 0.018$).
Comparing diabetic (n = 103) with non-diabetic (n = 737) DILI patients, higher mean age (66 vs 52, $p < 0.001$) and BMI (28 vs 25, $p < 0.001$) were observed in the former group. Similarly, duration of treatment of the DILI causal agent and time to DILI onset were longer in the diabetic group, 158 vs 78 days ($p = 0.001$) and 140 vs 71 days ($p = 0.002$), respectively. No differences were found with regards to DILI severity. In the diabetic group 28% of the cases had persistent hepatic injury after one year from DILI onset versus 22% in the non-diabetic group.
In patients with both diabetes and dyslipidemia (n = 33), duration of treatment of the causal agent and time to DILI onset were both

significantly longer compared to patients with none or only one of the conditions (n = 831), 162 vs 84 days ($p = 0.05$) and 157 vs 76 days ($p = 0.037$), respectively. Forty percent of the patients with diabetes and dyslipidemia demonstrated persistent hepatic damage more than year from DILI onset compared to 22% in those without these cardiovascular risk factors.

Conclusions: Patients with dyslipidemia manifested less severe forms of DILI, while diabetic patients required longer treatment time prior to DILI initiation. Persistent damage more than one year from DILI onset was higher in patients with both dyslipidemia and diabetes.

P1099

SARCOPENIA AS A PROGNOSTIC FACTOR IN PATIENTS WITH SEVERE ALCOHOLIC HEPATITIS

D.S. Song[1], J.M. Yang[1], U I. Chang[1], S.W. Choi[1], S.H. Cho[1]. [1]*Internal medicine, The Catholic University of Korea, Seoul, Korea, South*
E-mail: dsman@catholic.ac.kr

Background and Aims: Sarcopenia has emerged as an independent predictor of clinical outcomes in a variety of clinical conditions. The aim of this study was to examine the association between the sarcopenia and the early mortality (90-days) or overall survival in the patients with severe alcoholic hepatitis (SAH).

Methods: Eighty-one consecutive patients with SAH [Maddrey's discriminant function (DF) ≥32] were retrospectively analyzed. Skeletal muscle cross sectional area was measured on a computed tomography (CT) image at the L3 level, and sarcopenia was defined using previously established cutpoints

Results: Sixty-six patients were male (81.5%), and mean age was 49.6±9.8 years with median follow-up of 7.4 months. Overall 90-day mortality was 30.9% and 55 patients (67.9%) had sarcopenia. There were no significant differences in baseline characteristics between patients with sarcopenia and without sarcopenia except high Glasgow Alcoholic Hepatitis Score (GAHS) in sarcopenic group (8.73±1.25 vs 8.23±1.24). By univariate logistic regression analysis, presence of infection (OR, 2.47; $P = 0.065$), hepatic encephalopathy (HE) (OR, 9.00; $P < 0.001$), spleen size (OR, 0.77; $P = 0.036$), INR (OR, 7.89; $P = 0.002$), serum creatinine (OR, 1.73; $P = 0.014$), and leukocyte count (HR, 1.03; $P = 0.037$) appeared to be potential risk factors of short-term mortality ($P < 0.1$). However, sarcopenia was not associated with 90-day mortality (OR, 2.40; $P = 0.125$). By multivariate logistic regression analysis, INR (OR, 6.92; $P = 0.016$) and HE (OR, 6.13; $P = 0.018$) were independently associated with 90-days mortality. Although not statistically significant, sarcopenia tended to have association with HE (OR, 2.90; $P = 0.082$) at the time of admission. By Kaplan–Meier method, sarcopenic group had shorter overall survival time (47.7 vs. 29.3 months, $P = 0.072$) and 90-day survival (76.7 vs 62.3 days, $P = 0.103$) than non-sarcopenic group, although there were no statistically significant differences. GAHS was the most accurate predictive factor for early mortality among DF, ABIC (Age, Bilirubin, INR, Creatinine), Child–Pugh, and Model for end-stage liver disease score (AUROC – 0.785).

Conclusions: Sarcopenia is frequent complication in patients with SAH. Sarcopenia was not associated with early mortality. However, although not significant, sarcopenia appear to be associated with overall survival. In addition, sarcopenia is likely to be associated with HE, which is important prognostic factor for short term mortality.

E-mail: hee82@catholic.ac.kr

Background and Aims: Alcoholic hepatitis often leads to acute-on-chronic liver failure (ACLF), characterized by acute hepatic decompensation of chronic liver disease, organ failure and high short-term mortality. The aim of this study was to assess the performance of proposed scores specific for ACLF in predicting short-term mortality among patients with alcoholic hepatitisAlcoholic hepatitis often leads to acute-on-chronic liver failure (ACLF), characterized by acute hepatic decompensation of chronic liver disease, organ failure and high short-term mortality. The aim of this study was to assess the performance of proposed scores specific for ACLF in predicting short-term mortality among patients with alcoholic hepatitis

Methods: We retrospectively collected data from 350 patients with acutely decompensated alcoholic liver disease with active alcoholism from January 2013 to December 2013 at 21 academic hospitals in Korea. The performance for predicting short-term mortality was calculated for chronic liver failure-sequential organ failure assessment (CLIF-SOFA), APASL ACLF Research Consortium (AARC) liver failure grade, Maddrey's discriminant function (DF), Age, bilirubin, international normalized ration and Creatinine score (ABIC), Child-Turcotte-Pugh (CTP), Model for end-stage liver failure (MELD), and MELD-Na.

Results: The 28-day and 90-day mortality were 12% and 18%, respectively. The area under receiver operating characteristic curve (AUROC) of CLIF-SOFA, AARC liver failure, DF, ABIC, CTP, MELD, and MELD-Na were 0.85 (0.77–0.91), 0.83 (0.77–0.90), 0.81 (0.74–0.89), 0.80 (0.72–0.88), 0.75 (0.66–0.84), 0.84 (0.77–0.91), and 0.83 (0.76–0.90) for 28-day mortality, and 0.83 (0.77–0.89), 0.81 (0.75–0.88), 0.81 (0.74–0.88), 0.80 (0.74–0.87), 0.74 (0.66–0.81), 0.84 (0.78–0.90), and 0.86 (0.80–0.91) for 90-day mortality, respectively.

Conclusions: The proposed scores specific for ACLF, such as CLIF-SOFA or AARC liver failure score, showed comparable predictive ability for short-term mortality compared to other scoring systems in patients with alcoholic hepatitis

CYTOCHROME P4502E1 AS A DRIVING FORCE IN THE PROGRESSION OF ALCOHOLIC LIVER DISEASE

H.K. Seitz[1], H. Qin[1], K. Glassen[1], R. Waldherr[2], C. Flechtenmacher[2], G. Millonig[1], T. Peccerella[1], F. Stickel[3], P. Schirmacher[2], T. Bruckner[4], S. Mueller[1]. *[1]Alcohol Resarch Department, University of Heidelberg, Salem Medical Center, [2]Department of Pathology, University of Heidelberg, Heidelberg, Germany; [3]Hepatology, Clinic Beau Site, Bern, Switzerland; [4]Biostatistics, University of Heidelberg, Heidelberg, Germany*
E-mail: helmut_karl.seitz@urz.uni-heidelberg.de

Background and Aims: One mechanism by which alcoholic liver disease (ALD) progresses from pure fatty liver to fibrosis, cirrhosis, and hepatocellular cancer (HCC) is oxidative stress. The induction of cytochrome P4502E1 (CYP2E1) by alcohol results among others in the generation of reactive oxygen species (ROS). Experimental data in rats underline the key role of CYP2E1 since ALD (Gouillon et al, Proc Soc Exp Biol Med 224, 302: 2000) as well as hepatic adenoma development (Ye et al, Hepatobil Surg Nutr 1, 5: 2012) could be partially prevented by the concomitant administration of the specific CYP2E1 inhibitor chlormethiazole. In addition, it was found that CYP2E1 induction leads to the formation of various highly carcinogenic exocyclic etheno DNA-adducts. The purpose of the present study was to investigate CYP2E1 induction in non cirrhotic ALD and to correlate CYP2E1 with various histological parameters including hepatic fat, inflammation, fibrosis, and carcinogenic etheno DNA adducts.
Methods: Hepatic biopsies from 97 patients with a history of chronic alcohol intake (>60 g/day over 20 years) diagnosed as non-cirrhotic ALD were carefully histologically determined using various scores for for steatosis, inflammation, and fibrosis. In addition, CYP2E1, and 1,N^6-etheno-2′-deoxyadenosine (εdA), the most important etheno DNA-adducts, were determined immunohistologically (Wang et al, Hepatology 50, 453: 2009), and correlated with each other.
Results: A significant correlation was found between CYP2E1 and εdA ($p < 0.0003$), between CYP2E1 and fibrosis ($p < 0.03$), and between fibrosis and lobular inflammation ($p < 0.0001$). The amount of alcohol consumed correlated significantly with serum ALT activity, ($p < 0.03$), MCV ($p < 0.02$), inflammation ($p < 0.004$), and fibrosis ($p < 0.05$), but not with CYP2E1.
Conclusions: The data presented emphasize for the first time a causal role of CYP2E1 in the fibrotic progression of ALD and possibly in the pathogenesis of alcohol mediated hepatocarcinogenesis.

P1102

NO HISTOLOGICAL FEATURES OF ALCOHOL INDUCED STEATOHEPATITIS CAN IDENTIFY PATIENTS AT RISK OF CIRRHOSIS AND PREMATURE DEATH

S. Semb[1], S. Neermark[1,2], S. Dam-Larsen[3], M.B. Franzmann[4], J. Albrectsen[4], T. Kallemose[5], U. Becker[1,2], F. Bendtsen[1]. *[1]Gastro Unit, Hvidovre Hospital, University of Copenhagen, Hvidovre, [2]National Institute of Public Health, University of Southern Denmark, [3]Department of Medicine, Køge Hospital, University of Copenhagen, Køge, [4]Department of Pathology, [5]Clinical Research Center, Hvidovre Hospital, University of Copenhagen, Hvidovre, Denmark*
E-mail: synnesemb@hotmail.com

Background and Aims: Whereas almost all heavy alcohol abusers develop steatosis, only 20–30% progress to cirrhosis. The prognostic impact of early stages of histological ALD on risk of cirrhosis has only sparsely been studied. Our aim was to determine the risk of cirrhosis and premature death in patients with biopsy verified alcoholic steatohepatitis (ASH), and to compare prognosis to alcoholic pure fatty liver (AFLD) and the general population. Secondary aims were to identify clinical, biochemical and histological parameters with prognostic significance.
Methods: Patients with AFLD and ASH diagnosed during the period 1976–1987 were identified through the pathology register at Hvidovre Hospital, Denmark. Medical records were reviewed, and supplementary data was retrieved from the Danish National Hospital Registry and the Registry of Causes of Death. All biopsies were re-examined, morphological findings were assessed regarding steatosis, lobular inflammation, hepatocyte ballooning and fibrosis. Outcomes analysed were overall mortality and a diagnosis of cirrhosis. Cox proportional hazard models adjusted for age and gender were used to analyse the differences in mortality, and the prognostic effect of histological and biochemical parameters.
Results: 225 patients with AFLD and 114 patients with ASH were followed for a median of 13 and 9.7 years. Median age at baseline was 49.8 and 51.2 years, respectively. During follow-up, 93.3% of patients with AFLD died and 55.8% (126/224) developed cirrhosis, whereas 96.5% of patients with ASH died and 58.9% (66/112) developed cirrhosis. Median age at death was 63.7 and 63.6 years, respectively. Mortality was significantly higher in patients with ASH compared to patients with AFLD ($p = 0.03$) and the general population ($p < 0.001$), but no histological or biochemical parameters with prognostic significance for mortality were identified.
Conclusions: Histologically verified alcoholic liver disease is associated with a grave prognosis, and the presence of steatohepatitis indicates an increased mortality compared to patients with pure steatosis. However, none of the histological characteristics defining steatohepatitis can independently identify patients at risk for premature death.

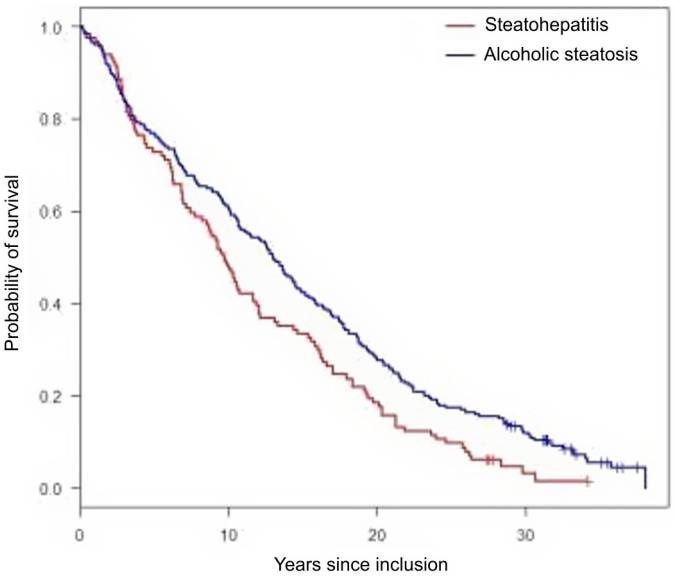

Figure: Kaplan–Meier plot for mortality – alcoholic steatosis and steatohepatitis.

P1103

PORTAL HYPERTENSIVE BLEEDING INDEPENDENTLY PREDICTS MORTALITY IN PATIENTS HOSPITALIZED FOR ALCOHOLIC HEPATITIS

W. Kim[1], S.H. Kim[1], H.Y. Kim[1], Y.J. Jung[1]. *[1]Seoul Metropolitan Government Seoul National University Boramae Medical Center, Seoul, Korea, South*
E-mail: wonshiri@yahoo.com

Background and Aims: Gastrointestinal bleeding (GIB) is often accompanied by patients with alcoholic hepatitis (AH). The aims of the present study were (1) to identify the etiologies of GIB in patients hospitalized for AH; (2) to investigate the clinical characteristics and long-term survival outcomes of patients

hospitalized for AH according to the presence or absence of GIB; (3) to identify factors associated with long-term mortality.
Methods: A hospital-based, retrospective cohort comprised consecutive patients who were hospitalized for AH between 1999 and 2014. Those patients were dichotomized into two groups: those who experienced GIB once or more (GIB group) and those who never experienced GIB till death or censoring (NGIB group). GIB group was dichotomized into another two groups: those whose bleeding focus of the 1st GIB was found to be portal hypertensive bleeding (PHB group) and those of non-portal hypertensive bleeding (NPHB group). Clinical characteristics and long-term survival outcomes of patients hospitalized for AH according to the presence or absence of GIB and PHB were investigated. Risk factors for long-term mortality in AH patients were also analyzed using the Cox regression method.
Results: A total of 331 patients hospitalized for AH were included in this study. Among them, 131 patients experienced GIB at admission or during follow up. Of the 131 patients, the most common cause of GIB was esophageal varix. Using the log rank test, GIB group had worse survival outcome compared with NGIB group (log rank test, p = 0.029) PHB group had worse survival outcome compared with the NPHB group (log rank test, p = 0.001). There was no significant difference in survival rate between the NPHB group and NGIB group. In the multivariable analysis of all AH patients, alcohol dose, ascites, encephalopathy, MDF and MELD were associated with mortality. In the multivariable analysis of GIB group, MELD score (HR, 1.09; 95% CI, 1.055–1.128; $P < 0.001$) and the presence of PHB (HR, 2.37; 95% CI, 1.060–5.277; $P = 0.035$) were found to be independently associated with mortality.
Conclusions: Portal hypertensive bleeding and high MELD scores showed worse survival outcomes in AH patients with gastrointestinal bleeding. Therefore, the prompt endoscopic examination may help physicians to stratify the risk of mortality in AH patients with GIB.

P1104
EXPRESSION OF LIVER-SPECIFIC CYTOCHROME P450 ISOENZYMES AND OXYGENASES IN C3A CELLS PRIOR TO AND AFTER TREATMENT WITH THE ELAD LIVER SUPPORT SYSTEM
L.K. Landeen[1], J. Lapetoda[1], J. Van Allen[1], N. Heredia[1], J. Brotherton[1], R. Ashley[1]. [1]*Research & Development, Vital Therapies, Inc., San Diego, United States*
E-mail: llandeen@vitaltherapies.com

Background and Aims: Acute-on-chronic liver failure (ACLF) and acute liver failure (ALF) are characterized by impaired liver function, multi-organ failure, and high short-term mortality. Cell-based support of liver function could be of therapeutic benefit. The ELAD System provides extracorporeal exposure to human hepatoblastoma-derived C3A cells and is under evaluation in several clinical trials for various liver disease indications. The aims of this study were to characterize the expression levels of liver-specific cytochrome P450 isoenzymes (CYP) and oxygenases in ELAD C3A cells during clinical trial production and after use in clinical treatment.
Methods: Monolayer C3A cells were harvested for mRNA isolation and analyzed on TaqMan Human CYP450 and Oxygenases Array Plates (ABI) using routine RT-PCR methods. ELAD C3A hollow-fiber cartridges were recovered at production maturity and after 5 days of clinical use in alcohol-induced liver disease (AILD) subjects and processed as above. Expression levels vs. controls ($2^{-\Delta\Delta Ct}$ method) were set as ≤0.25-fold decrease and ≥10-fold increase for down- and up-regulation, respectively, using the housekeeping gene GUSB (lowest %CV for all samples).
Results: Approximately two-thirds of the 92 total gene targets evaluated were detected in C3A cells. Among these included CYP1A2, CYP2C9, CYP2C19, CYP2D6, CYP3A4, and CYP3A5, which are collectively responsible for metabolizing nearly 90% of all drugs. Up-regulation in monolayer vs. ELAD cartridge C3A cells was observed for CYP17A1, TYR, CYP7A1, CYP4A11/CYP4A22, CYP2C9, CYP11B2, CYP2A6, CYP2A7, CYP2C19, CYP51A1, and CYP3A7, whereas down-regulation was observed for CYP19A1, CYP24A1, and SC4MOL. Up-regulation in ELAD C3A cells prior to vs. after subject treatment was observed for ALOX5, CYP11B1, CYP11B2, CYP2A6, and CYP2A7, whereas down-regulation was noted for TYR and CYP51A1. C3A cells from subject-recovered ELAD cartridges exhibited differences in up- or down-regulation between individual subjects among 16–22 different gene targets.
Conclusions: This study provides supporting evidence that the C3A cells comprising the ELAD System exhibit a diverse expression of various critical liver metabolic enzymes, and is supportive of previous studies using drug metabolites as evidence of the presence of selected CYPs. It also illustrates that unique responses can be observed in cell-based therapies as a result of dynamic interactions with individual patients' unique physiologies.

P1105
IMMUNOLOGIC BASIS OF CLOPIDOGREL HYPERSENSITIVITY AND DETECTION BY LYMPHOCYTE TOXICITY ASSAY
M.G. Neuman[1], A. Cheema[2], R.M. Nanau[3]. [1]*Pharmacology and Toxicology, In Vitro Drug Safety and Biotechnology, University of Toronto,* [2]*Intervention Cardiology, St. Michael Hospital,* [3]*In Vitro, Dug Safety and Biotechnology, Toronto, Canada*
E-mail: m_neuman@rogers.com

Background and Aims: Clopidogrel is a commonly prescribed platelet inhibitor for patients diagnosed with acute coronary syndrome or undergoing stent placement. Hypersensitivity reaction (HSR) after clopidogrel initiation manifesting clinically as elevated transaminases in the presence of dermatotoxicity are recognized complication affecting up to 3% of treated patients.
Our primary objective is to characterize the cellular and immunologic mechanism of clopidogrel HSR and describe a novel lymphocyte toxicity assay (LTA) for the laboratory confirmation of diagnosis in affected individuals. We also aim to understand the immune and pathophysiological mechanism(s) of clopidogrel-HSRs.
Methods: Blood from 19 patients with a clinically confirmed diagnosis of clopidogrel HSR and 6 tolerant controls were analyzed for hematologic and an immunologic response during the active phase of clopidogrel HSR. LTA was performed after a minimum of 12 months post clopidogrel discontinuation. Pro-inflammatory cytokine and anti-inflammatory cytokine profiles and apoptotic (M-30) and necrotic (M65) assays were performed in all patients.
Results: The hematological screen identified a significant increase in circulatory neutrophils and a significant decrease in circulatory lymphocyte counts with no change in the eosinophil counts. The mean percentage LTA values were significantly higher for clopidogrel HSR compared to control patients (20±6 vs. 7±4%, p = 0.0004). The levels of TNF-α levels were also significantly higher for the clopidogrel HSR group compared to controls (116±49 vs. 29±9 pg/mL). ROC curves for LTA demonstrated excellent utility for the diagnosis of clopidogrel HSR (AUC=0.97, p = 0.003) and an LTA >16% showed a sensitivity of 86% and a specificity of 100% for the diagnosis of clopidogrel HSR.
Conclusions: Clopidogrel HSR is a significant immune-mediated phenomenon. This adverse event may be diagnosed and prevented by the use of the laboratory LTA. The LTA to Clopidogrel hypersensitivity provides a framework to study *in vitro* cell assay that is useful for patient diagnosis and drug monitoring.

P1106

ALCOHOL-RELATED LIVER DISEASE PATIENTS' BELIEFS ABOUT THEIR ILLNESS AND FACTORS THAT INFLUENCE THEIR SELF-MANAGEMENT – A PATIENT SURVEY

M. Lau-Walker[1], J. Presky[2], I. Webzell[2], T. Murrells[1], N. Heaton[2]. [1]*Florence Nightingale Faculty of Nursing & Midwifery, King's College London,* [2]*Institute of Liver Studies, King's College Hospital NHS Foundation Trust, London, United Kingdom*
E-mail: margaret.lau-walker@kcl.ac.uk

Background and Aims: Research in a variety of long term illnesses suggests patients' illness beliefs are a more influential factor for patient recovery than the severity of the illness. However, research into illness belief and medication adherence of patients with alcohol-related liver disease (ALD) is sparse. This study aims to determine the association between illness belief and self-management and, more specifically, adherence to medication and provide the evidence-base for the development of an effective and personalised framework to support self-management in patients with alcohol-related liver disease.
Methods: A cohort of 159 patients with ALD patients who attended the Liver Outpatient Clinic at the King's College Hospital NHS Foundation Trust (October 2012 to November 2013) completed a set of validated instruments measuring illness beliefs, self-management, beliefs about medication, emotional states and quality of life.
Results: The mean age of enrolled patients was 52 years (range 27–80), 67% male, 26% live on their own, 61% had no previous history of other chronic illness. Their average MELD and Audit C scores were 11.0 (range 6–28) and 3.5 (range 0–12) respectively.
Multiple regression analyses were performed on Anxiety (variation explained by Illness perception components adjusting for the demographic and illness characteristic = 42%) and Depression HAD scores (40%), Self-management Chronic illness (47%) and Liver summary scores (25%) and Quality of life ED-5Q your state of health today (25%). The two most consistent illness belief components across all outcome measures were 'comprehension' and 'identity'.
Regression analysis found that the illness perception components were statistically associated with beliefs about medicines questionnaire (BMQ) components: 'comprehension' associated with 'concern' ($p = 0.005$); 'identity' associated with 'necessity' and 'concern' ($p = 0.005$; $p = 0.043$ respectively), and 'treatment control' associated with 'necessity' and 'differential' ($p = 0.047$; $p = 0.039$ respectively).
Conclusions: Interventions designed to improve the understanding of patients with ALD of their illness and strategies to manage their symptoms are likely to improve their self-management, quality of life and reduce anxiety and depression. More specifically, medication adherence in patients with alcoholic liver disease is likely to be improved by an intervention that improves ALD patient's understanding, management of symptoms and sense of control.

P1107

UNCONSIDERED MISUSE OF ACETAMINOPHEN IS ONE OF THE CAUSAL COFACTORS OF ACUTE LIVER FAILURE IN ADULTS WITH SEVERE DENGUE FEVER

M. Gelu-Simeon[1], C. Francoz[2], P. Ichai[3], A. Cabie[4], E. Saillard[5], C. Hermann[6], P. Bedossa[7], M. Sebagh[8], F. Durand[9], D. Samuel[10], J. Bernuau[11]. E-mail: jrbernuau@yahoo.fr

Background and Aims: In recent years, dengue fever extended over various areas beyond tropical and subtropical areas. Fifty to hundred millions cases of dengue occur annually. Acetaminophen (ACT), no more than 4g daily, is officially recommended as an antipyretic. Adults with dengue often have discrete liver blood tests abnormalities but uncommonly develop acute liver failure (ALF). Our aims were to itemize potential cofactors, and determine whether ACT toxicity could be a causal factor, of ALF in patients with dengue.
Methods: Review of previously published and strictly selected case reports of adults with dengue and ALF (DALF), and of the files of similar patients who were refered to us.
Results: Among 61 cases of adults with DALF, the survival rate was 82% or 50%, depending on whether they were, or were not, given intravenous *N*-acetylcysteine (*IV NAC*). Itemized causal factors of DALF include viral infection of liver tissue, virus-related immunopathological mechanisms, acute hypovolemia due to acute plasma leakage, the systemic inflammatory response syndrome and acute episodes of hyperthermia. ACT hepatotxicity was only recently mentioned. Seven adults with dengue, recent ingestion of ACT and serum aminotransferase activity above 25 times the normal value, were hospitalized in 2 liver intensive care units. Four patients with severe coagulopathy but without grade III-IV encephalopathy when they received *IV NAC*, survived; 2 of them had recent unintentional acetaminophen overdose, one developed DALF, the other with centrilobular liver necrosis did not; the 2 other patients, developed mediolobular liver necrosis-associated DALF and one required liver transplantation (LT). Among the 3 patients with grade III-IV encephalopathy and hypotension when they received *IV NAC*, all died after protracted shock; 2 of them had massive liver necrosis, including one rechallenged with ACT despite increased serum aminotransferases after unrecognized ACT unintentional overdose.
Conclusions: in adults with DALF, various morphological kinds of liver necrosis suggest various etiologies, life-saving LT may be required, and unconsidered misuse of ACT may cause ACT-induced hepatotoxicity and DALF. Accordingly, *IV NAC* is beneficial to hospitalized patients with dengue and serum aminotransferases raised 25 times above normal without encephalopathy.

P1108

ELEVATED ACETALDEHYDE LEVELS ARE DETRIMENTAL TO THE HEPATIC ANTIOXIDANT SYSTEM

V.B. Patel[1], R. Ghazali[1], K. Mehta[1], V. Preedy[2]. [1]*Biomedical Sciences, University of Westminster,* [2]*Nutrition & Dietetics, King's College London, London, United Kingdom*
E-mail: v.b.patel@westminster.ac.uk

Background and Aims: Acute (binge) and chronic alcohol drinking is a major public health issue leading to alcoholic liver disease.

One of the consequences of binge drinking is a marked elevation in acetaldehyde levels, however this effect on the hepatic antioxidant system has not been fully explored and may explain the increased susceptibility to oxidative stress.
Methods: Male Wistar rats were injected with an acute amount of alcohol (75 mmol/kg) pre-treated with and without the acetaldehyde dehydrogenase inhibitor cyanamide (0.5 mmol/kg) and sacrificed after 24 hours. Control animals were injected with saline (0.15 mol/L). Hepatic cytosolic and mitochondrial fractions were prepared and analysed for oxidative stress. Measurements included reduced and oxidised glutathione, oxidised proteins, catalase, glutathione peroxidase, glutathione reductase, superoxide dismutase.
Results: Our findings showed that alcohol alone led to significantly lower glutathione peroxidase and superoxide dismutase activity in the mitochondria and cytosol, with glutathione reductase activity increased in both compartments; catalase activity remained unchanged. This correlated with increased mitochondrial protein oxidation and slightly lower glutathione levels. These effects were exacerbated when acetaldehyde levels were increased, but with catalase activity also significantly lower and corresponded to increased cytosolic protein oxidation and depletion of cytosolic glutathione levels.
Conclusions: In conclusion, some compensatory mechanisms are induced to replenish the lower glutathione levels; however under conditions of elevated acetaldehyde levels, greater alteration to the antioxidant enzyme capacity occurs, leading to significant cytotoxic injury.

P1109
INCIDENCE, MORTALITY, AND READMISSION RATE OF PATIENTS HOSPITALIZED FOR ALCOHOLIC HEPATITIS IN KOREA: A NATIONWIDE EPIDEMIOLOGIC STUDY

W. Kim[1], J.Y. Lee[1], M.H. Hong[1], J. Kim[2]. [1]*Seoul Metropolitan Government Seoul National University Boramae Medical Center,* [2]*Laboratory of Biostatistics II, Graduate School of Public Health, Seoul National University, Seoul, Korea, South*
E-mail: wonshiri@yahoo.com

Background and Aims: Alcoholic hepatitis (AH) ranks among the most costly diseases in Korea. However, accurate hospitalization incidence, mortality, and contributing factors have never been investigated yet. This study aims to provide the nationwide incidence of hospitalization, mortality, and readmission rate in patients with AH in Korea.
Methods: Using database of the Korean Health Insurance Review and Assessment service, we identified total inpatient cases based on ICD-10 diagnoses of AH (K70.1) and surveyed concomitant cirrhosis and alcohol use disorder (AUD) from 2008 to 2012. Standardized hospitalization incidence and mortality rates were calculated using data of medical services provided to patients hospitalized for AH. Logistic regression analysis was performed to identify risk factors for in-hospital mortality. Follow-up data for those admitted in 2008 were analyzed to find risk factors for readmission.
Results: The standardized incidence rate of hospitalization per 10^5 population per year decreased from 19 in 2008 to 14 in 2012. The inpatient mortality rate ranged from 0.2 to 0.5% per year. In-hospital mortality was significantly higher in older patients (OR, 1.63; 95% CI, 1.17–1.58) and in those with cirrhosis (OR, 4.4; 95% CI, 2.78–6.94). The readmission rate of patients admitted in 2008 was 34.0%. Male sex (OR, 1.46; 95% CI, 1.24–1.73) and low economic status (OR, 2.34; 95% CI, 2.13–2.57) were associated with readmission, while old age (OR, 0.96; 95% CI, 0.97–0.99), cirrhosis (OR, 0.77; 95% CI, 0.60–0.98), and urban residency (OR, 0.67; 95% CI, 0.59–0.76) were inversely associated with readmission. AUD tended to increase the risk of re-hospitalization but did not reach statistical significance (OR, 1.13; 95% CI, 0.99–1.27; $P = 0.051$).
Conclusions: This study captured the epidemiology of patients hospitalized for alcoholic hepatitis in Korea. These results offer us valuable information to decide on the priorities of public health policies associated with alcoholic liver disease burdens.

P1110
ALCOHOL LIVER DISEASE IS MORE FREQUENT AND MORE SEVERE THAN CHRONIC VIRAL HEPATITIS IN JAILS OF A FRENCH DISTRICT

C. Bonny[1], G. Lamblin[1], A. Lenat-Guyot[2], C. Henquell[3], C. Nicolas[1], S. Dydymski[4], B. Pereira[5], C. Jacomet[4], A. Abergel[1]. [1]*Department of Hepatology, CHU de Clermont-Ferrand,* [2]*Care Unit in Prisons, Prisons of Clermont-Fd and Riom,* [3]*Department of Virology,* [4]*Department of Infectious diseases,* [5]*Department of research clinical, CHU de Clermont-Ferrand, Clermont-Ferrand, France*
E-mail: cnicolas@chu-clermontferrand.fr

Background and Aims: This sub-study was carried out as part of the prospective study PRODEPIST whose objectives were: (1) to promote detection of viral hepatitis, HIV, addictive behaviour, hepatitis B vaccination and (2) to evaluate liver fibrosis.
Methods: HCV and HBV detection were offered to 702 people at entrance and before exit of two prisons from June 2012 to December 2013. Alcohol dependence was assessed with CAGE test (Ramirez et al. 1988). Fibrosis was evaluated by Fibromètre® and/or transient elastometry (Fibroscan®) in patients with chronic hepatitis B or C and/or alcohol dependence since January 2013.
Results: 357 out of 702 detainees (51%) agreed to participate to the PRODEPIST study. 94.1% were male; median age was 30 years (25–39), median duration of detention was 183 days (92–396). A positive HCV serology was found in 4.7% (16/342) of inmates and positive RNA in 1.5% (5/342). Two inmates were from Georgia, 2 from France and 1 from Italy. These 5 patients were treated for 24 weeks by peg-interferon, ribavirin and telaprevir. Two prisoners out of 347 (0.6%) were positive for HBsAg, 7.5% (26/347) had anti-HBc antibodies and 49.3% (171/347) had anti-HBs antibodies. Vaccination was offered to 149 people who had a negative viral serology B; 81 accepted (54.4%). Addictive behaviors were frequent in this population: 83.8% were tobacco smokers (294/351), 42.6% (145/340) smoked cannabis and 24.1% (79/327) had an opiate addiction. 179 out of 337 detainees had consumed alcohol (53%) and 70% of patients evaluated by the CAGE test were alcohol dependent (69/98). Seventy-five prisoners were screened for fibrosis either by Fibromètre® (n = 26) or by Fibroscan® (n = 33) or by the two methods (n = 16). Significant fibrosis was found in 12 inmates (HCV 4 and alcohol 8) out to 75, that is 16% (2 were F2, 3 F3 and 7 F4). In the group of prisoners with alcohol dependence, 12.5% (8/64) had significant fibrosis (≥F2).

	Assessment of liver fibrosis (total number=75; nb alcohol=64; nb HCV=10; nb HBV=1)				
Evaluation method	Fibromètre® N=26	Fibroscan® N=33	Fibroscan® and Fibromètre® N=16	Total N=75	%
< F2	20	30	13	63	84.0
Alcohol	18	29	10		
HCV	2	1	2		
HBV	0	0	1		
F2	1	0	1	2	2.7
Alcohol	1	0	1		
HCV	0	0	0		
F3	1	2	0	3	4.0
Alcohol	0	2	0		
HCV	1	0	0		
F4	4	1	2	7	9.3
Alcohol	3	1	0		
HCV	1	0	2		

16%

Conclusions: HCV prevalence was 4.7% (comparable to the study PREVACAR 2010, 4.8%). Prevalence of HBS Ag is very low, and vaccination has been performed in 50% of inmates with negative HBV serology. Alcohol is a major problem in this population (53% were alcohol consumers and 70% are dependent) and is the leading cause of fibrosis in prison (12% of these abusers have significant fibrosis).

P1111

VARIABLES ASSOCIATED WITH ALCOHOL RELAPSE AND PSYCHOSOCIAL INTERVENTIONS TO PREVENT ALCOHOL RELAPSE IN LIVER TRANSPLANT PATIENTS FOR ALCOHOLIC LIVER DISEASE: A SYSTEMATIC REVIEW

I. Ranasinghe[1], I. Norman[2], M. Lau-Walker[2]. *[1]Florence Nightingale School of Nursing and Midwifery, King's College of London, [2]Florence Nightingale School of Nursing and Midwifery, King's College London, London, United Kingdom*
E-mail: iyoni.i.ranasinghe@kcl.ac.uk

Background and Aims: Liver transplantation is the primary treatment choice for alcohol liver disease. However, alcohol relapse is a particular problem for this population with a reported 10–50% risk. This review aims to identify alcohol relapse variables, and establish the effectiveness and explore the active ingredients of psychosocial interventions in preventing alcohol relapse, in alcohol liver disease patients pre or post-liver transplant.
Methods: Mixed method systematic review involving three parallel syntheses: (1) alcohol relapse variables; (2) psychosocial intervention effectiveness; (3) active ingredients of these psychosocial interventions (i.e. a component analysis). Medline, CINAHL, EMBASE, and PsychInfo were searched in November 2013 for published literature. Grey literature searched in Web of Science, Clinical Trials Register, and Electronic Theses Online Service.
Synthesis 1: Systematic search for and appraisal of prospective studies, retrospective studies, and cross-sectional surveys. Syntheses 2/3: Systematic search for and appraisal of 'randomised controlled trials', 'controlled before and after studies', and 'before and after studies in a single group'.
Results: 23 papers included: 10 cohort, 11 case–control, 1 qualitative, and 1 randomised controlled trial.
Five variables out of nineteen were alcohol relapse predictors (i.e. Synthesis 1): (1) <12 months pre-transplant abstinence; (2) presence of children; (3) poor pre-transplant psychosomatic evaluation; (4) non-compliant with post-transplant treatment plan; (5) active insurance policies at transplant.
One psychosocial intervention paper did not report treatment effectiveness (i.e. Synthesis 2). The remaining three papers reported relapse rate reduction: Alcohol Addiction Unit (odds ratio 0.23), Structured Management (odds ratio 0.32), pre- and post-transplant Substance Abuse Treatment (odds ratio 0.27 compared to no substance abuse treatment; odds ratio 0.23 compared to pre-transplant substance abuse treatment only). With confidence intervals not reported, the uncertainty level around the odds ratio is unclear. Furthermore, a theoretical basis was not discussed; thus, the active ingredients could not be identified (i.e. Synthesis 3).
Conclusions: Randomised controlled trials to further investigate the predictive validity of the five main variables and ascertain the long-term benefits of the tentative yet promising results of the most effective intervention i.e. structured management.

P1112

BACLOFEN: MAINTENANCE OF ABSTINENCE IN ALCOHOL DEPENDENT PATIENTS ATTENDING LIVER CLINIC

L. Owens[1,2], A. Rose[3], A. Thompson[2], M. Pirmohamed[2], I. Gilmore[1], P. Richardson[1]. *[1]Hepatology, Royal Liverpool Hospital, [2]Department of Molecular and Clinical Pharmacology, [3]Psychology, University of Liverpool, Liverpool, United Kingdom*
E-mail: lynno@liv.ac.uk

Background and Aims: Alcohol induced liver disease (ALD) is the predominant cause of alcohol-related mortality in the UK. Therefore helping patients with ALD to quit is a primary treatment goal. However, current licensed pharmacotherapies are contraindicated for patients with ALD. Baclofen has shown efficacy in the promotion of abstinence in patients with severe alcohol dependence including those with ALD.
Aim: The primary aim of this study was to measure the effectiveness and tolerability of Baclofen in maintaining abstinence in this difficult to treat group, and to determine if this resulted in a reduction in standard measures of liver damage gamma-glutamyltransferase (GGT), alanine aminotransferase (ALT), bilirubin (BiL) and fibroelastography (fibro).
Methods: An observational prospective clinical audit was performed. Patients with ALD were transferred to our hepatology alcohol clinic (HAC) for ongoing support and treatment, and commenced on Baclofen at 10 mg three times daily (TDS), titrated according to tolerability and response up to 30 mg TDS. Primary outcome measures were severity of physical dependence (SADQ score) and biochemical markers of liver damage. These were compared at baseline, and 1 year.
Setting: Acute Hospital Trust.
Participants: 243 patients referred to Hepatology for investigation of abnormal liver function and heavy drinking.
Results: Of the 243 patients commenced on Baclofen in our HAC, 151 (85 female, 66 male) have completed 1 year follow-up (F/U) of which 130 (86%) have remained engaged. 10 have died. All patients had a diagnosis of ALD of which 67 had cirrhosis, 15 had Hep C and 9 had pancreatitis. Comparison of baseline (B/L) and 1 year biochemical markers showed a reduction in GGT ($\chi^2 = 66.8$, $P < 0.0001$) and BiL ($\chi^2 = 82.6$, $P < 0.0001$). There was also in significant difference in mean ALT ($P = 0.005$, 95% CI = 3 to 16). Fibro scores between B/L and F/U were available for 22 patients with 19 scans showing improvements ($\chi^2 = 20.4$, $P < 0.0001$). Between B/L and F/U there was a significant reduction in alcohol consumption ($P < 0.0001$, 95% CI = 10 to 22). And the presence of physical dependence ($\chi^2 = 77.4$, $P < 0.0001$) as categorised by SADQ.
Conclusions: Baclofen is well tolerated in this very difficult to treat, high risk patient group. It has a positive impact on alcohol consumption, and overall measures of liver function and harm. A RCT is needed to confirm the benefit of Baclofen in this patient group.

P1113

HUMAN KERATIN 8 VARIANTS PROMOTE MOUSE ACETAMINOPHEN HEPATOTOXICITY COUPLED WITH JNK ACTIVATION AND PROTEIN ADDUCT FORMATION

N. Guldiken[1,2], Q. Zhou[3], O. Kucukoglu[2], M. Rehm[2], K. Levada[1], L.P. James[4], C. Trautwein[1], M. Bishr Omary[5], P. Strnad[1,2]. *[1]IZKF and Department of Internal Medicine III, University Hospital Aachen, Aachen, [2]Department of Internal Medicine I, University Hospital Ulm, Ulm, Germany; [3]Department of Medicine, Palo Alto VA Medical Center, CA; and Stanford University Digestive Disease Center, Stanford, [4]Arkansas Children's Hospital Research Institute and Department of Pediatrics, University of Arkansas for Medical Sciences, Little Rock, [5]Department of Molecular & Integrative Physiology, University of Michigan Medical School, Ann Arbor, United States*
E-mail: ngldiken@gmail.com

Background and Aims: Keratins 8 and 18 (K8/K18) are the intermediate filaments proteins of simple-type digestive epithelia,

and provide important cytoprotective function. K8/K18 variants predispose humans to chronic liver disease progression and to poor outcomes in acute acetaminophen (APAP)-related liver failure. Given that K8 G62C and R341H/R341C are common K8 variants in European and North American populations, we studied their biological significance using transgenic mice.
Methods: Mice that overexpress the human K8 variants R341H or R341C were generated and used together with previously described mice that overexpress wild-type (WT) K8 or K8 G62C. Mice were injected with 600 mg/kg APAP intraperitoneally, or underwent bile duct ligation (BDL). Livers were evaluated by microarray analysis, quantitative RT-PCR, immunoblotting, histological and immunological staining, and biochemical assays.
Results: Under basal conditions, the K8 G62C/R341H/R341C variant-expressing mice did not show an obvious liver phenotype or altered keratin filament distribution, while K8 G62C/R341C animals had aberrant disulphide-crosslinked keratins. Animals carrying the K8 variants displayed limited gene expression changes but had lower nicotinamide N-methyl transferase levels and were predisposed to APAP-induced hepatotoxicity. The more pronounced liver damage was accompanied by increased and prolonged JNK activation; elevated APAP protein adducts; K8 hyperphosphorylation at S74/S432 with enhanced K8 solubility; and prominent pericentral keratin network disruption. No differences in APAP serum levels, liver inflammation, glutathione or ATP levels were noted. BDL resulted in similar liver injury and biliary fibrosis in all mouse genotypes.
Conclusions: Expression of the human K8 variants G62C, R341H, or R341/C in mice predisposes to acute acetaminophen hepatotoxicity, thereby providing direct evidence for the importance of these variants in human acute liver failure.

P1114

A METABOLOMICS APPROACH TO IDENTIFY EXCRETORY METABOLITE SIGNATURE IN PATIENTS WITH SEVERE ALCOHOLIC HEPATITIS NON RESPONSIVE TO GLUCO-CORTICOSTEROID THERAPY

J.S. Maras[1], S. Sharma[1], S. Das[1], S. Sm[2], S. Hussain[1], C. Junot[3], R. Moreau[4], S.K. Sarin[2]. *[1]Research, [2]Hepatology, Institute of Liver and Biliary Sciences, New Delhi, India; [3]Laboratoire d'Etude du Métabolisme des Médicaments, Institut de Biologie et de Technologie de Saclay, Saclay, [4]INSERM, Centre de Recherche Biomédicale Bichat-Beaujon, Paris, France*
E-mail: shvetanks@gmail.com

Background and Aims: Severe alcoholic hepatitis (SAH) still remains a major cause of liver related mortality. In the absence of a suitable therapy, beneficial role of corticosteroid therapy has been well documented, though some patients do not respond to treatment (recognizable only after 7 days post-treatment). The aim of this study was to identify the urinary metabolite signature capable of predicting non-responsiveness to the therapy at baseline and at follow-up. We also intended to gain insights into molecular mechanisms that are associated with non-response to corticosteroids.
Methods: A comprehensive urinary metabolome profiling of SAH patients (n = 60) was performed by high resolution UPLC-MS at baseline, Day 4 and Day 7. Urine samples were classified into discovery phase [responders (R; n = 20) and non-responders (NR; n = 3)] and the results validated on 37 blinded samples (R, n = 32; NR, n = 5). Multivariate analysis was used to identify significantly different metabolites between R and NR, followed by correlation of metabolic signatures with pathways involved and clinical outcome.
Results: A total of 1250 metabolites were annotated [KEGG-HMDB-METLIN databases]. Of them 183 metabolites were validated based on spectral analysis on MRM. In positive mode, 16%, 20% and 26%, while in the negative mode 10%, 30% and 36% metabolites varied significantly ($p < 0.05$) at day-0, day-3 and day-7 respectively between R and NR. A set of metabolites could categorically and significantly identify non-responders at baseline. Some of the key metabolites belonged to primary and secondary bile acids, tryptophan-metabolic pathway and arginine-proline-metabolic pathway. Enrichment analysis identified metabolites to be of hepatocytic origin [$p < 0.01$], and were predicted to be associated to fumaric aciduria, bilary aterisa and cirrhosis [$p < 0.05$]. Validation of these metabolites on blinded samples confirmed the findings. PLS-DA and cluster analysis differentiated NR from R significantly. Levels of the metabolic signature significantly correlated to the severity indices and Lille score [$r^2 > 0.3$, $p < 0.05$] respectively.
Conclusions: The metabolic composition of SAH patients varies with time and treatment with steroids. The metabolites were able to stratify NR from R even at baseline. The proposed metabolomic approach may become a clinical tool for early assessment of treatment response in severe alcoholic hepatitis.

P1115

ERK AND P38 ACTIVATION ARE CENTRAL MEDIATORS OF IRINOTECAN-INDUCED STEATOHEPATITIS

A. Mahli[1], M. Saugspier[1], W. Thasler[2], M. Müller[1], A. Bosserhoff[3], C. Hellerbrand[1]. *[1]University Hospital Regensburg, Regensburg, [2]Ludwig-Maximilians-University Munich, Munich, [3]University of Erlangen, Erlangen, Germany*
E-mail: claus.hellerbrand@ukr.de

Background and Aims: Preoperative chemotherapy for hepatic resection of colorectal liver metastases is associated with the development of chemotherapy-associated steatohepatitis (CASH) which increases the risk of perioperative morbidity and mortality. Here we aimed to unravel the molecular mechanisms of irinotecan induced CASH.
Methods: Primary human hepatocytes were treated with irinotecan *in vitro*. Mice were injected with irinotecan (50 mg/kg every three 3 days for 3 weeks), and control mice were injected with vehicle only. Furthermore, we analyzed liver tissues of previously untreated patients with metastatic colorectal cancer and without underlying liver disease (i) treated with single-agent irinotecan (n = 6) or (ii) without chemotherapy (n = 6).
Results: Irinotecan caused a dose-dependent induction of lipid accumulation and pro-inflammatory gene expression *in vitro*. Furthermore, irinotecan induced the accumulation of free fatty acids, the formation of reactive oxygen species (ROS) and ERK-activation. Pre-incubation with ROS-scavengers or ERK-inhibitor almost completely inhibited irinotecan-induced inflammatory gene expression but had only a slight effect on lipid accumulation. Analysis of autophagy related genes, LC3 modification and p62 degradation revealed that irinotecan dose dependently inhibited autophagy, a cellular mechanism known to affect cellular lipid homeostasis. MAPK p38 is a known inhibitor of autophagy and we found that irinotecan induced p38 activation while pretreatment with a p38 inhibitor diminished irinotecan effects on autophagy as well as on cellular lipid accumulation in hepatocytes *in vitro*. Also in the liver of mice and patients treated with irinotecan we found significant steatosis, ROS-formation and inflammation accompanied by increased ERK- and p38-activation and a concomitant reduction of markers of autophagy in comparison to normal liver tissue.
Conclusions: ERK and p38 activation are critical mediators of irinotecan-induced steatohepatitis which suggests inhibition of these pathways as promising therapeutic regime for prevention of CASH.

P1116
ARE MEGAMITOCHONDRIA A CELLULAR SURVIVAL STRATEGY FOR ETHANOL-INDUCED LIVER TOXICITY?

E. Palma[1], A. Riva[1], R. Williams[1], S. Chokshi[1]. [1]*Institute of Hepatology – Foundation for Liver Research, London, United Kingdom*
E-mail: e.palma@researchinliver.org.uk

Background and Aims: A characteristic histological feature of alcoholic liver disease (ALD), known since the 1970s, is the presence of megamitochondria (MM) in hepatocytes. In a recent study conducted in more than 100 patients, the presence of MM was associated with a lower risk of death within 90 days (Altamirano *et al.*, Gastroenterology, 2014). Mitochondria are dynamic organelles and their shape is intimately involved with their function, under physiological conditions the changes in mitochondrial morphology are regulated by mitochondrial-shaping proteins (MSP). However, the mechanisms driving MM formation, their role, function and involvement in the pathogenesis of ALD is currently unknown, which is the aim of this study.
Methods: Human precision cut liver slices (PCLS) and hepatoma cells VL-17A (positive for ADH/CYP2E1) were cultured with EtOH alone or in combination with FFA, to induce hepatotoxicity. Cell viability was evaluated by FACS (AnnexinV/PI positive cells) or ATP quantification. Post-treatment, changes in the mitochondrial shape were assessed by confocal and electron microscopy; MSP expression and activation was also analysed by Western blot on isolated mitochondria. Additionally, mitochondrial functionality was evaluated in intact cells using the Seahorse Bioscience analyser. Changes in inflammatory cytokine production were assessed by Cytokine Bead Array.
Results: The toxic effect of EtOH (+/− FFA) was confirmed by an increase in the percentage of dead cells or a reduction in ATP levels. Cells that survived the toxic insult showed a dramatically increased proportion of MM; however they also had a compromised ability to grow. Mitochondrial functionality, in terms of coupling efficiency and spare respiratory capacity, was also impaired. Pro inflammatory cytokine profile was found in the supernatants of these cultures. This was associated with a reduced expression and activity in the MSP related to mitochondrial fragmentation.
Conclusions: Cellular survival strategies, in the face of a chronic toxic stimulus, are a necessary requirement to ensure continuing functionality of the organ. We show here that growth retarded hepatocytes, which survived the EtOH insult, are characterized by a dramatic formation of MM, suggesting this as a mechanism to avoid death. We also show for the first time the involvement of MSP in this pathway, raising the potentiality for the use of these proteins as therapeutic targets and biomarkers in ALD.

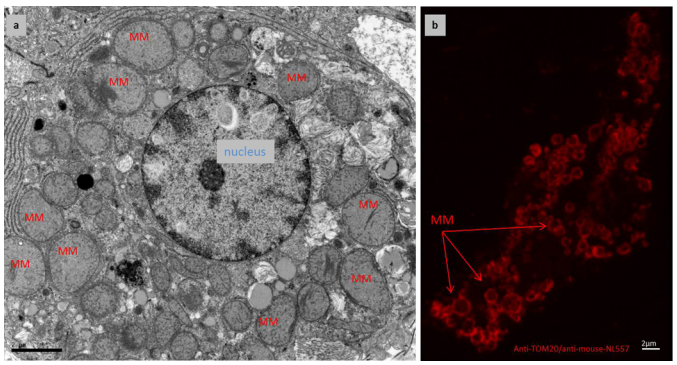

Figure: Ethanol-induced megamitochondria (MM) formation visualized (a) by electron microscopy in human PCLS and (b) by confocal microscopy in VL-17A cells.

HISTOLOGIC FINDINGS IN LIVER BIOPSY OF ALCOHOLIC CIRRHOSIS PATIENTS AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION

G.R. Burganova[1], S.R. Abdulkhakov[2], A.A. Gumerova[1], I.M. Gazizov[1], M.A. Titova[1], A.P. Kiyasov[1]. [1]*Department of Morphology and General Pathology,* [2]*Kazan (Volga region) Federal University, Kazan, Russia*
E-mail: guzel.burganova@gmail.com

Background and Aims: So far there is no effective antifibrotic treatment in alcoholic liver cirrhosis (ALC). One of the novel treatment options is using of autologous hematopoietic stem cells (HSC). Sinusoids capilliarization and myofibroblasts activation are key events in liver fibrogenesis. The purpose of the study was evaluation of the effect of HSC autotransplantation on these processes in patients with alcoholic cirrhosis.
Methods: The study was performed on liver biopsies of 12 patients with ALC taken before the injection of autologous peripheral blood HSCs mobilized by GCSF into celiac trunk, 3 and 12 months after the procedure. Biopsies were stained immunohistochemically with antibodies against CD34 and a-SMA. CD34 is absent in endothelial cells of normal liver however it appears in case of their capillarization. A-SMA is a marker of myofibroblasts.
Results: Before transplantation we observed the great number of CD34-positive cells predominantly in portal areas as well as some positive cells in septa and in parenchyma. A-SMA-positive myofibroblasts were mainly localized in periportal zones and portal tract infiltration areas. 3 months after transplantation the number of CD34-positive cells and myofibroblasts markedly decreased; remaining cells were located mainly around portal tracts. 12 months after transplantation the number of CD34 and a-SMA-positive cells increased again but didn't reach initial levels. The number of cells correlated with the severity of infiltration.
Conclusions: We suggest that transplantation of HSCs in patients with ALC is safe and effective procedure leading to decreasing of myofibroblasts number and restoring of normal sinusoids' structure. However this procedure should be probably repeated in a year.

P1118
Hsp72 OVEREXPRESSION PROTECTS FROM ACETAMINOPHEN AND MCD LIVER INJURY

K. Levada[1,2], N. Guldiken[1,2], F.-R. Mo[1], C. Trautwein[1], P. Strnad[1]. [1]*Department of Medicine III and IZKF, University Hospital Aachen, Aachen,* [2]*Department of Internal Medicine I, University Medical Center Ulm, Ulm, Germany*
E-mail: kateryna.levada@gmail.com

Background and Aims: Heat shock protein (Hsp) 72 is a molecular chaperone which is upregulated in a response to a variety of stress situations and possesses broad cytoprotective functions. The hepatic function of Hsp72 remains largely unknown.
Methods: To study the importance of Hsp72 in the liver, we generated transgenic mice overexpressing Hsp72 under the control of a tissue-specific tetracycline-inducible system and crossed them with animals carrying the tetracycline-responsive transactivator under the control of the liver activator protein promoter (Hsp72-LAP mice). Acute liver injury was induced by a single intraperitoneal injection of acetaminophen (800 mg/kg). Long-term feeding (8 weeks) with methionine choline-deficient diet (MCD) was used to induce lipotoxic liver damage.
Results: Hsp72-LAP mice displayed doxycycline-regulated, robust Hsp72 overexpression in hepatocytes, but not in the other tissues or cell types. Eighteen hours after acetaminophen injection, a significantly lower liver injury was noted in Hsp72-LAP mice in comparison to single transgenes (ALT: 933 vs. 1977, $p < 0.05$). No differences in acetaminophen metabolism were seen, but overexpression of Hsp72 protected from formation of APAP protein adducts ($p = 0.027$) and JNK hyperphosphorylation. After MCD-

feeding, Hsp72-LAP mice displayed lower ALT levels than wild type animals (72 vs. 314, p = 0.02). Overexpression of Hsp72 did not affect the extent of MCD-diet induced metabolic changes but ameliorated MCD-induced NF-κB activation and the resulting complex and hepatic inflammation.
Conclusions: Our results suggest that Hsp72 overexpression protects against specific modes of liver injury.

P1119
ELEVATED LEVELS OF CIRCULATING BACTERIAL DNA IN ALCOHOLIC HEPATITIS IDENTIFIES PATIENTS WHO WILL NOT RESPOND TO CORTICOSTEROID

N. Vergis[1], S. Atkinson[1], S. Knapp[1], V. Patel[2], C. Antoniades[1], E. Forrest[3], M. Thursz[1], Trial Group STOPAH (Royal Liverpool Hospital, Liverpool, United Kingdom, Derby Royal Hospital, Derby, Addenbrooke's Hospital, Cambridge, Clinical Trials Unit, University of Southampton, Southampton, University of Newcastle, Newcastle, Royal Hallamshire Hospital, Sheffield, Edinburgh Royal Infirmary, Edinburgh, Leicester Royal Infirmary, Leicester, Aintree Hospital, Liverpool, Bristol Royal Infirmary, Bristol, King's College Hospital, London, Royal Free Hospital, London, Southampton General Hospital, Southampton, Queens Medical Centre, Nottingham, Glasgow Royal Infirmary, Glasgow, United Kingdom). *[1]Imperial College, [2]King's College, London, [3]Glasgow Royal Infirmary, Glasgow, United Kingdom*
E-mail: n.vergis@imperial.ac.uk

Background and Aims: Prednisolone has been shown to improve 28-day survival in alcoholic hepatitis (AH). However, use of this therapy is associated with increased infections that could explain the limited benefit of corticosteroid beyond 28 days. Interestingly, a large body of data suggests that bacterial translocation plays an important role in the pathogenesis of AH. The present study sought to elucidate the impact of prednisolone in patients with elevated circulating bacterial DNA (bDNA).
Methods: DNA was extracted, pre-treatment (Day 0), from the whole blood of 156 patients recruited to the multi-centre *Steroids or Pentoxyfilline for Alcoholic Hepatitis* (STOPAH) study. Patients were matched for MELD, age, gender, therapy and the presence of infection. Subsequently, real-time PCR was performed using a Taqman probe targeting a region within a 380bp fragment of bacterial 16S rDNA for bDNA quantification. Levels of bacterial DNA were compared to Maddrey's discriminant function (mDF), SIRS score, Lille score, the development of an infectious serious adverse event within the first 7 days of therapy, and mortality.
Results: bDNA levels correlated with mDF although this did not achieve statistical significance [r = 0.146, $p = 0.07$]. However, there was strong correlation between bDNA levels and Lille model [r = 0.29, $p = 0.0016$]. The Day 0 level of circulating bDNA in Lille non-responders (>0.45) was higher than in Lille responders (<0.45) [21 vs 14 pg/ml; $p = 0.02$]. Importantly, this association was only seen in patients treated with prednisolone [prednisolone treated: r = 0.4, $p = 0.0046$ vs no prednisolone: r = 0.18, p = ns]. Day 0 bDNA level >18.4 pg/ml in prednisolone treated patients was strongly associated with Lille non-response [odds ratio 6, $p < 0.0001$].

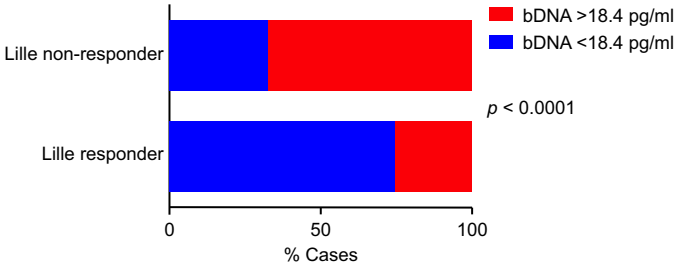

Figure: Pre-treatment bacterial DNA level predicts subsequent Lille response in alcoholic hepatitis.

There was no association between Day 0 bDNA level and the development of infection (22 vs 19 pg/ml, p = ns); SIRS criteria (r = 0.02, p = ns), 28-day or 90-day mortality (18 vs 21 pg/ml, p = ns and 17 vs 21 pg/ml, p = ns).
Conclusions: Pre-treatment circulating bDNA levels may be used to predict poor outcome in AH. Further, patients with elevated circulating bDNA are unlikely to respond to prednisolone therapy and so could be spared the infectious complications associated with this agent. Further work should validate these findings in a larger cohort of AH patients.

P1120
DAY-4 LILLE SCORE – FOR EARLY PREDICTION OF STEROID RESPONSE IN SEVERE ALCOHOLIC HEPATITIS

S. Muralikrishna Shasthry[1], G. Kumar[2], V. Shasthry[3], M. Sharma[1], A.S. Bhadoria[2], S. Sarin[1]. *[1]Hepatology, [2]Research, [3]Clinical Nutrition, Institute of liver and biliary sciences, New Delhi, India*
E-mail: shasthry@gmail.com

Background and Aims: Steroids are the mainstay of treatment of severe alcoholic hepatitis (SAH). Introduction of the Lille score has helped in identification of steroid non-responders (Lille score >0.45) as on day 7. This however requires prolonged hospitalization and often increases the risk of infection. This study was conducted to assess the correlation of day-4 Lille score with day-7 Lille score, so as to define response to steroids early.
Methods: All consecutive patients with SAH admitted at ILBS between March 2013 and March 2014, without contraindications to steroids were enrolled into a prospective study to receive 40 mg prednisolone per day. The steroid response was assessed at day 7 by Lille score as responder (<0.45) or non-responder (>0.45). Lille score was also calculated on day 4 using bilirubin level as per day 4 in the place of day 7 bilirubin value, using the online Lille model formula (www.lillemodel.com).
Results: Of 164 patients with SAH during the study period, 50 patients were started on steroids – men (98%), mean age 39.4±8.9 yr. At admission, ascites was present in 48 (96%), bilirubin 19.3±10.3 mg/dl, creatinine 0.53±0.25 mg/dl, albumin 2.43±0.43 g/dl and PT 24.38±4.99 s. Alcoholic hepatitis severity parameters were DF 77.8±26.6, MELD 24.9±3.67, MELDNa 28.6±4.46, GAH 8.14±0.8, and CTP 10.96±0.92. 40 out of 50 responded to steroids (80%) with a Lille score of <0.45.

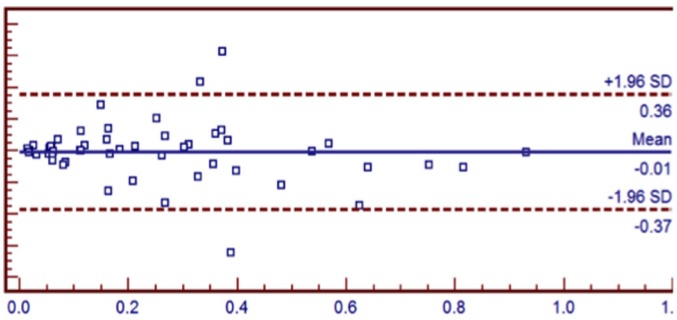

Figure 1. Average of Lille score-day 4 and Lille score-day 7*. *The Bland–Altman graph (only 3 outliers).

Mean Lille score on day 7 was 0.255±0.22 and on day 4 was 0.261±0.25. The paired difference in the day 4 and day 7 Lille score was 0.0065±0.186, p = 0.80, meaning thereby that both the scores are comparable. The day 7 Lille score could be predicted from the day 4 Lille score by using the formula, Day 7 Lille = 0.923 × day 4 Lille. The coefficient of correlation (R) between day-4 and day-7 Lille score was 0.864 with R^2 as 0.747. The reliability coefficient of day 4 Lille score in predicting the day 7 Lille score was 0.825 (CI 0.695–0.902).

The agreement between day 4 and day 7 Lille scores was 0.827 (95% CI 0.695–0.902, p ≤ 0.001). Bland and Altman graph showed agreement between Lille score day 4 and day 7 in 47 patients (94%).
Conclusions: Day 4 Lille score is equally good in predicting the steroid response and hence can be used in place of the currently used day 7 score, so that steroid response could be assessed early for deciding future treatment options for non-responders, such as GCSF or liver transplantation.

P1121

HOMOZYGOSITY FOR THE Ile148Met VARIANT IN PNPLA3 IS SIGNIFICANTLY ASSOCIATED WITH REDUCED SURVIVAL FOLLOWING AN EPISODE OF SEVERE ALCOHOLIC HEPATITIS

S. Atkinson[1], M. Way[2], J. Mellor[3], A. McQuillin[4], M. Morgan[2], M. Thursz[1]. *[1]Department of Hepatology, Imperial College London, [2]UCL Institute for Liver & Digestive Health, Department of Medicine, Royal Free Campus, University College London, London, [3]Clinical Trials Unit, University of Southampton, Southampton, [4]Molecular Psychiatry, Faculty of Brain Sciences, University College London, London, United Kingdom*
E-mail: stephen.r.atkinson@gmail.com

Background and Aims: The non-synonymous variant Ile148Met (I148M, rs738409) in PNPLA3 is associated with an increased risk of developing significant alcohol-related liver injury. Recently it has been shown that carriage of this variant confers a significant negative effect on survival in patients with established alcohol-related cirrhosis (Way et al. Hepatology 2014; 60(Suppl 1): 781A–782A: 1203abs). Alcoholic hepatitis is a distinct clinical syndrome characterised by jaundice and liver impairment often arising on a background of established cirrhosis. In those with severe disease, defined by a Maddrey discriminant function ≥32, mortality may exceed 30% at 28 days. Abstinence from alcohol is a major determinant of long-term outcome in those who survive initially. It is not known whether carriage of the I148M mutation in PNPLA3 further influences outcome.
Methods: The rs738409 PNPLA3 variant was genotyped in 899 British cases with severe alcoholic hepatitis, recruited through the *Steroids or Pentoxifylline for Alcoholic Hepatitis* – STOPAH trial and in 1,188 white British and Irish controls with alcohol dependence but no evidence of liver injury, despite prolonged drinking, recruited at UCL. Patients who survived at least 90 days after initial presentation and in whom 1-year survival data were available (n = 554) were classified into four groups based on their PNPLA3 IL148Met genotype (minor allele G) and their subsequent drinking behaviour categorized as abstinent or drinking. Kaplan–Meier analysis was used to examine the relationship between to PNPLA3 Ile148Met genotype and survival; patients were censored at death/transplantation; the log rank test was used to assess differences in survival curves.
Results: A significant increase in the mean allele frequency of rs7254880 was observed between cases and controls (29.4% vs 18.8%, $p = 5.74 \times 10^{-15}$; odds ratio 1.80). Overall 1-year mortality in the group surviving beyond 90 days was 19.9%. Individuals homozygous (GG) for the 148Met allele in rs738409 had a significantly decreased 1-year survival despite abstinence from alcohol compared with their counterpart (CC vs. GG, 10.3% vs. 28.6%, p = 0.035; CG vs. GG, 11.9% vs. 28.6%, p = 0.046).
Conclusions: In patients surviving an episode of alcoholic hepatitis, homozygosity for the mutant allele in rs738409 is associated with a significantly increased risk of mortality at 1 year despite abstinence from alcohol. Genotyping may help identify individuals more at risk in whom additional support may be required.

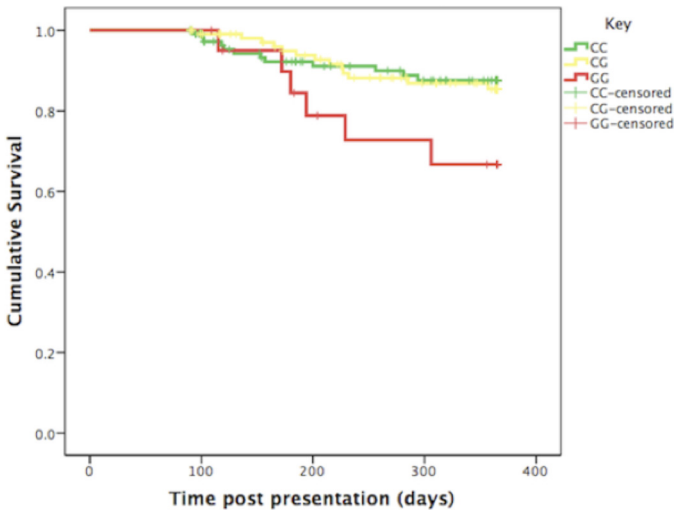

Figure: Kaplan–Meier survival curves. Abstinent drinkers following severe alcoholic hepatitis grouped by rs738409 genotype.

P1122

ALTERNATIVELY ACTIVATED M2 MACROPHAGES PROMOTE HEPATOCYTE DIFFERENTIATION IN HEPATIC PROGENITOR CELL MEDIATED LIVER REGENERATION IN ACUTE ON CHRONIC LIVER FAILURE PATIENTS

A. Kumar[1], D. Kumar[1], S. Rooge[1], S. Shubham[1], A. Bhat[1], C. Syal[1], A. Rastogi[2], C. Bihari[2], V. Pamecha[3], S.K. Sarin[4]. *[1]Research, [2]Pathology, [3]HPV Surgery, [4]Hepatology, Institute of Liver and Biliary Sciences, Vasant Kunj, Delhi, New Delhi, India*
E-mail: dr.anupamkumar.ilbs@gmail.com

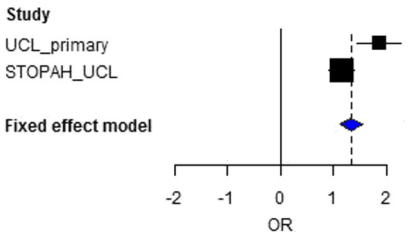
Background and Aims: Macrophages play myriad roles in liver degeneration and regeneration. The changing microenvironment of different setting of liver disease affects the polarization of macrophage and how different subtypes affects hepatic regeneration remains unclear. Aim: To understand the effect of liver microenvironment on the plasticity of liver macrophage and their role in regeneration.
Methods: M1/M2 macrophage marker genes expression by using qRT-PCR in biopsy/explants in ACLF, ALF, CLD. Ki67, CK-19 staining for the nature of liver regeneration. CD68 (tissue macrophages) CD163 (M2 macrophages) for analysis of macrophages in liver tissue from patients with ACLF, ALF, and CLD (n = 15, 21 and 22). Expression of CD68, CD163 were correlated with hepatocyte self-replication, HPC activation and maturation.
Results: qRT-PCR result show increase in M2 gene markers CD163, CD206 & TGM2 and decrease in M1 markers iNOS & CD80 in ACLF comparison to CLD, and increase in M2 gene markers CD163, CD206 & TGM2 and decrease in M1 markers in iNOS & CD80 in ACLF comparison to ALF. IHC analysis shows increase in Ki67+ hepatocytes in ALF vs ACLF. Further, the number of CK19+ HPC and its maturational lineages was increased in ACLF than ALF and CLD. Spearman correlation showed CD163 positivity and M2/M1 ratio is associated with HPC differentiation to hepatocyte. PCR analysis of PU.1 and Myb suggest that increase in PU.1 expression in ACLF in comparison to ALF & CLD suggesting that major population of M2 in ACLF are kupffer cells.
Conclusions: M2 are the major population in ACLF which are kupffer cell origin and promotes differentiation of HPC to hepatocyte.

P1123

A FUNCTIONAL VARIANT IN TM6SF2 ASSOCIATES WITH ALCOHOL-RELATED CIRRHOSIS RISK IN A BRITISH AND IRISH POPULATION

M.J. Way[1,2], S. Atkinson[3], A. McQuillin[2], M.R. Thursz[4], M.Y. Morgan[1].
[1]Institute for Liver and Digestive Health, [2]Molecular Psychiatry, University College London, [3]Department of Hepatology, [4]Institute for Liver and Digestive Health, Imperial College London, London, United Kingdom
E-mail: Michael.way.11@ucl.ac.uk

Background and Aims: A large region of linkage disequilibrium at 19p13, containing several genes including *NCAN* and *TM6SF2,* has been significantly associated with multiple lipid-related traits as well as non-alcohol-related fatty liver disease (NAFLD) and alcohol-related liver disease (ALD). A recent exome wide association analysis of NAFLD, identified the SNP rs58542926 (Gln167Lys) in *TM6SF2* as the primary variant driving associations within the 19p13 region. It is known that both NAFLD and ALD share a common genetic background but it is not known whether rs58542926 in *TM6SF2* influences ALD risk.
Methods: The exploratory population (UCL exploratory) comprised 317 cases with biopsy-proven alcohol-related cirrhosis and 330 controls who had been misusing alcohol for >15 years but had no evidence, on biopsy, of alcohol-related liver injury; all were of British or Irish extraction. The replication population (STOPAH-UCL replication) comprised 819 cases with clinically diagnosed severe alcoholic hepatitis, recruited through the *Steroids or Pentoxifylline for Alcoholic Hepatitis* (STOPAH) trial and 847 controls with an extensive history of alcohol misuse but no significant liver damage; all were of British or Irish descent. The SNP rs58542926 in *TM6SF2* (minor allele T) was genotyped using K-Biosciences Competitive Allele Specific PCR genotyping platform. Primary allelic association and fixed-effects meta-analyses were performed in PLINK v1.7. Forest plots were generated in the R package "meta".
Results: A highly significant allelic association was observed in the UCL exploratory population samples between the mutant allele in rs58542926 and cirrhosis risk (minor allele frequency cases 10.7%: controls 6.1% [$p = 0.0026$, odds ratio = 1.86]). This allelic association was not significant in the replication cohort although the directionality of effect mirrored that in the exploratory population ($P = 0.27$, odds ratio = 1.15). A fixed effects meta-analysis showed thatrs58542926 remains significantly associated with alcohol-related liver disease risk ($P = 0.012$, odds ratio = 1.31; Figure).
Conclusions: These analyses provide the first evidence that the functional SNP rs58542926 in *TM6SF2* significantly associates with alcohol-related liver disease risk.



P1124

PRIMARY HEPATOCELLULAR DAMAGE LOWERS ALCOHOL CONSUMPTION AND SUPPRESSES PERIPHERAL FAT MOBILIZATION IN ALD PATIENTS WITH GENETIC VARIANT I148M IN PNPLA3

V. Rausch[1], T. Peccerella[1], L. Pawella[2], K. Lackner[3], E. Yagmur[4], F. Stickel[5], S. Herzig[6], H.-K. Seitz[1], T. Longerich[2], B. Straub[2], S. Mueller[1]. *[1]Dept. of Medicine and Center for Alcohol Research, Salem Medical Center and University of Heidelberg, [2]Institute of Pathology, University Clinic Heidelberg, Heidelberg, Germany; [3]Institute of Pathology, Medical University Graz, Graz, Austria; [4]Medical Laboratory Center, Mönchengladbach, Germany; [5]Institute of Clinical Pharmacology and Visceral Research, University of Bern, Bern, Switzerland; [6]Joint Division Molecular Metabolic Control, German Cancer Research Center (DKFZ), Center for Molecular Biology (ZMBH) and University Hospital Heidelberg, Heidelberg, Germany*
E-mail: vanessa.rausch@uni-heidelberg.de

Background and Aims: PNPLA3 GG has been identified as major genetic progression factor of ALD and NAFLD, however, its function remains largely unknown. To get more insights into the (patho)physiology of PNPLA3, we here studied 180 clinical, histological and molecular parameters in a large well-characterized ALD cohort prior and after alcohol withdrawal.
Methods: 512 patients with ALD and a mean daily alcohol consumption of 181 g/day were genotyped for PNPLA3. In addition, laboratory tests, liver stiffness (LS) and steatosis (CAP) were measured prior and after 5–6 days of complete alcohol withdrawal. Liver histology was obtained in 80 patients with additional immunostainings for LD-associated proteins in 47 samples. Expression of mRNA transcripts was analyzed in 24 patients.
Results: In contrast to PNPLA3 CC (39.2%) and GC carriers (52.6%), GG carriers (8.2%) drank less alcohol over a shorter time and almost no liquor ($P < 0.001$) without showing a pronounced NAFLD phenotype (weight, BMI, diabetes). LS was significantly elevated in G carriers (median 18 vs. 11 kPa) and highly correlated with histological signs of fibrosis ($r = 0.800$) and liver damage (ballooning, $r = 0.700$; lobular inflammation, $r = 0.340$) but not with steatosis. In CG carrier, LS decreased significantly from 17.6 to 12.7 but to a lesser extent in GG carriers most likely due to a slower resolution of liver damage. Moreover, hepatic fat content (CAP) was only slightly higher in GG carriers and decreased equally in all genotypes by 30 dB/m. Surprisingly, key molecules that are important for lipolysis and backflow of free fatty acids to the liver were drastically reduced in the G carriers. This included the liver-synthesized serum protein ApoA1 and both hepatic mRNA and protein levels of the lipid droplet-associated protein Plin5 and the recently identified hepato-protective factor transcriptional cofactor transducin beta-like-related 1 (TBLR1).
Conclusions: In patients with ALD, PNPLA3 GG status seems to primarily cause hepatocyte damage rather than steatosis per se resulting in a reversible, inflammation-mediated increase of LS. Thus, PNPLA3 GG-associated liver damage could be an important novel factor contributing to impaired peripheral fat mobilization in humans.

P1125

ALCOHOL INDUCES PATHOLOGICAL AS WELL AS PROTECTIVE MECHANISMS IN STEATOTIC HEPATOCYTES

A. Mahli[1], W.E. Thasler[2], M. Müller[1], H.K. Seitz[3], C. Hellerbrand[1].
[1]University Hospital Regensburg, Regensburg, [2]Ludwig-Maximilians-University Munich, Munich, [3]University of Heidelberg, Heidelberg, Germany
E-mail: claus.hellerbrand@ukr.de

Background and Aims: Epidemiologic studies proposed an effect of even moderate alcohol consumption on the risk to develop non-alcoholic steatohepatitis (NASH) as well as on the progression from simple steatosis to NASH in obese individuals.

The aim of this study was to establish an *in vitro* model to study the effect of moderate alcohol levels on steatotic hepatocytes.
Methods: Lipid accumulation in primary human hepatocytes was induced by incubation with the fatty acid oleate. Subsequently, steatotic and control hepatocytes were incubated with up to 50 mM alcohol.
Results: In this dose range, alcohol alone had only a minimal effect but further increased oleate induced lipogenesis and cellular triglyceride content, as well as lipid peroxidation and NFkappaB-mediated pro-inflammatory gene expression. Alcohol and steatosis also synergistically induced CYP2E1 expression and activity, whereas CYP2E1 inhibition blunted the joint pathological effects of alcohol and steatosis. Surprisingly, analysis of autophagy related genes, LC3 modification and p62 degradation revealed that alcohol induced autophagy in steatotic but not in control hepatocytes via synergistic activating effects on c-Jun N-terminal Kinase (JNK). Further induction of autophagy with rapamycin ameliorated the joint effect of alcohol and oleate stimulation on cellular lipid accumulation and inflammatory gene expression while inhibition of autophagy with 3-methyl adenine further enhanced the dual pathological effects.
Conclusions: Our model indicates that alcohol and steatosis synergistically induce pathological as well as protective mechanisms in hepatocytes *via* CYP2E1. These findings may have important implications for the prognosis and treatment of alcoholic liver disease particularly in obese individuals.

P1126
PHARMACOLOGICAL TREATMENTS FOR SEVERE ALCOHOLIC HEPATITIS: A NETWORK META-ANALYSIS

E. Buzzetti[1], M. Kalafateli[1], D. Thorburn[1], B. Davidson[2], E. Tsochatzis[1], K. Gurusamy[2]. *[1]UCL Institute for Liver & Digestive Health, Royal Free Hospital, [2]Division of Surgery, UCL and Royal Free Hospital, London, United Kingdom*
E-mail: buzzetti.elena@gmail.com

Background and Aims: The optimal pharmaceutical treatment of severe alcoholic hepatitis remains controversial. We performed a systematic review and network meta-analysis of different pharmacological interventions for the treatment of such patients (DF >32 or hepatic encephalopathy).
Methods: We included randomized controlled trials (RCTs) of various pharmacological interventions compared with each other or with placebo. We conducted network meta-analyses following the National Institute for Health and Care Excellence Decision Support Unit guidance to compare multiple interventions simultaneously for each of the primary (mortality, adverse events, health-related quality of life) and secondary outcomes (cirrhosis, decompensation, HCC, liver transplantation) and only included trials in which participants could receive any of the interventions being assessed (transitivity assumption). We obtained a network plot to ensure that the trials are connected by treatments. We conducted a Bayesian network meta-analysis and calculated the odds ratios (OR) with 95% credible intervals (CrI) for assessing the effect of treatment.
Results: We included 21 RCTs on different treatment regimens of severe alcoholic hepatitis, comprising of 1765 patients.
The combination of steroids and N-acetylcysteine (NAC) was the most effective treatment in reducing 1 month mortality (20 trials; 1494 patients; OR = 0.12, 95%CrI 0.04–0.36) followed by steroids and pentoxifylline alone and the combination of the two (OR = 0.44, 95%CrI: 0.26–0.76; OR = 0.43, 95%CrI: 0.24–0.77; OR = 0.40, 95%CrI 0.17–0.90, respectively).
A total of 660 and 1299 patients included in 8 and 11 trials respectively were analyzed for 3-months and 12-months mortality. NAC plus steroids, and steroids and pentoxyfylline monotherapy were statistically significant compared to placebo for these periods. Pentoxyfylline showed the best efficacy in reducing episodes of liver decompensation (8 trials, 955 patients; OR = 0.26, 95%CrI 0.13–0.53) and liver-related mortality (12 trials, 797 patients; OR = 0.26, 95%CrI 0.13–0.51) compared to placebo. Nutritional therapy also showed a marked positive effect on one-year mortality (OR = 0.17, 95%CrI 0.06–0.52).
Conclusions: In patients with severe alcoholic hepatitis, the administration of steroids in combination with NAC, and steroids and pentoxyfylline alone or combined appear to reduce 1, 3 and 12-month mortality. Combining NAC to steroids should be further assessed by RCTs in such patients.

P1127
RESPONSE TO STEROID TREATMENT IN SEVERE ACUTE NON-ACETAMINOPHEN DRUG-INDUCED LIVER INJURY

M. Sebode[1], M. Sandmann[2], T. Krech[2], A.W. Lohse[1], C. Schramm[1]. *[1]I. Department of Medicine, [2]Department of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*
E-mail: marcialsebode@web.de

Background and Aims: Idiosyncratic drug-induced liver injury (DILI) is a leading cause of acute liver failure. It is still a matter of debate whether steroid treatment provides benefit for severe DILI and could prevent progression to liver failure.
Methods: All cases of non-acetaminophen DILI who were admitted to our department between 2010 and 2014 and who received a liver biopsy were analyzed retrospectively. Median initial dose of prednisolone treatment was 1 mg per kg body weight before steroids were tapered. Liver histologies were re-evaluated and the grade of hepatic inflammation was quantified by the modified Hepatic Activity Index (mHAI) score.
Results: 72 cases of DILI were analyzed. The most commonly implicated drugs were antibiotics (26.4%), phenprocoumon (15.3%) and non-steroidal anti-rheumatic drugs (13.9%). Most patients (71%) reached at least a DILIN severity score 3 (raised ALT or AP and total bilirubin level >2.5 mg/dl and hospitalization). 10 patients (13.9%) progressed to liver transplantation (LTX) or died (3 patients are still alive after LTX, 4 patients died after LTX and 3 patients were not eligible for LTX because of older age and comorbidities). These patients had a significantly higher initial MELD score than patients who recovered (32 vs 16; $p < 0.0001$). 60 patients (83%) received prednisolone treatment. Patients treated with prednisolone and an mHAI score ≥6 showed a significantly better response to treatment than patients with an mHAI score <6, measured by the decline of ALT from the day of starting prednisolone until day 3 (ΔALT 311 vs. 111 U/l; median reduction of 28.8% vs. 17.1%; $p = 0.04$) or measured by the decline of serum bilirubin from the day of starting prednisolone until week 4 (Δbilirubin 4.4 vs. 3.2 mg/dl; median reduction of 75.4% vs. 62.3%; $p = 0.02$). In prednisolone-treated patients who progressed to liver transplantation and/or died, serum bilirubin levels rose from the day of starting prednisolone until day 3 of treatment (Δbilirubin 0.7 mg/dl; median rise of 3.7%), whereas in patients under prednisolone who recovered, bilirubin levels fell (Δbilirubin 0.9 mg/dl; median reduction of 25%; $p = 0.02$).
Conclusions: Histological grading of liver inflammation could guide steroid treatment in severe DILI. A rise of bilirubin levels on day three after the start of steroids may indicate poor prognosis. Prospective studies are needed to evaluate if early steroid treatment can prevent fatal outcomes in severe DILI.

P1128

HEPATOCYTES DIFFERENTIATION FROM URINE CELLS DERIVED TRANSGENE FREE INDUCED PLURIPOTENT STEM CELLS

A. Kumar[1], D. Kumar[1], S. Shubham[1], S. Rooge[1], C. Bihari[1], M.M. Panicker[1], S.K. Sarin[4]. [1]*Institute of Liver and Biliary Sciences, Vasant Kunj, Delhi,* [2]*Neurology Department, NCBS, Bangalore, Bangalore, India*
E-mail: dr.anupamkumar.ilbs@gmail.com

Background and Aims: Reprogramming of somatic cells into pluripotent stem cells by using exogenous factors, hold great promises in development of personalized regenerative medicine and can produce valuable in vitro models of diseases. iPSCs have been generated from multiple sources including skin, extra embryonic tissues, which have their own advantages or disadvantages. The ideal cell source should be easily accessible, susceptible, and universal. Urine is the most easily accessible sample which can be collected from any individual. In the present study, we have generated iPSCs. from urine cells that has the potential to differentiate into hepatic lineages
Material and Methods: Urine samples were collected in sampling bottles. Exfoliated urine cells were isolated and cultured from adult human urine. After the appearance of colonies at 2–3 weeks, these cells were reprogrammed to iPSCs using commercially available "Keisuke Okita plasmid". Appeared stem cell like colonies were further characterized for stemness by studying the expression of pluripotent markers and by in-vitro tri-lineage differentiation.
Results: Stem cell like colonies generated from urine cells (urine iPSCs) on immunocytochemistry, were found to be positive for different pluripotent markers like OCT3/4, nanog, They also exhibited robust diffentation property when cultured as Embryoid bodies without growth factors. And differentiated in to hepatocytes like cells showing marker of Hepatocytes like albumin.
Conclusions: We document here for the first time, generation of transgene free urine cell derived induced pluripotent stem cells showing pluripotency. These UiPSCs are advantageous over from other sources as this process is purely non-invasive and generates transgene free iPSCs.

P1129

IDENTIFICATION OF PXR-HAPLOINSUFFICIENCY BY NEXT GENERATION SEQUENCING IN A PATIENT WITH ANABOLIC STEROID-INDUCED CHOLESTASIS

M. Krawczyk[1], R. Liebe[2], J. Raszeja-Wyszomirska[3], P. Milkiewicz[3], F. Lammert[1]. [1]*Department of Medicine II, Saarland University Medical Center, Homburg,* [2]*Department of Medicine II, University of Heidelberg, University Hospital Mannheim, Mannheim, Germany;* [3]*Liver and Internal Medicine Unit, Department of General, Transplant and Liver Surgery of the Medical University of Warsaw, Warsaw, Poland*
E-mail: marcin.krawczyk@uks.eu

Background and Aims: Use of anabolic steroids (AAS) is increasing among amateur athletes (Evans-Brown et al. *Lancet* 2008). Many AAS users report side effects, including severe cholestasis in selected cases. The lack of genome-wide association study signals for drug-induced liver injury (DILI) beside the known major histocompatibility complex risk alleles supports the concept that strong genetic determinants of DILI may be largely drug-specific and reflect rare genetic variations.
Methods: A 32-year-old Caucasian male with no significant medical history was admitted to our department with acute AAS-induced cholestasis. He had taken AAS for two months. Acute jaundice and pruritus developed two weeks after termination of AAS. Laboratory tests revealed increased serum bilirubin level but normal alkaline phosphatase and aminotransferase activities. There were no signs of biliary obstruction, and other viral and non-viral liver dieases were excluded. Liver biopsy showed blunt cholestasis. To investigate the genetic predisposition for this severe cholestatic phenotype, we performed targeted next generation sequencing (NGS: Illumina MiSeq) covering all coding sequences of selected genes (*ABCB4, ABCB11, ATP8B1, ABCC2, ABCG5/8, CIRH1A, CLDN1, JAG1, NOTCH2, NR1H4, NR1I2, VIPAR, VPS33B, UGT1A*) involved in hepatobiliary transport. This revealed the presence of a heterozygous 2 base pair deletion in exon 1 of the pregnane X receptor (PXR: nuclear receptor *NR1I2*). The mutation results in a frameshift (c.43_44del: p.R15fs), which causes complete loss of functional protein from the affected allele and thereby haploinsufficiency of PXR. Under therapy with prednisone, rifampin and ursodeoxycholic acid as well as albumin dialysis, pruritus and jaundice normalized, and the patient was discharged without any signs of persistent liver disease.
Conclusions: To our knowledge this is the first case report of a patient with inherited PXR insufficiency who developed acute AAS-induced cholestasis. Our results pinpoint the genetic predisposition to develop cholestasis after use of AAS, and further NGS-based studies are encouraged to determine the full spectrum of private mutations in nuclear receptor genes that increase the risk of drug-induced cholestasis.

P1130

ALCOHOLIC LIVER DISEASE: EFFECT OF HEPATOCYTES AND MACROPHAGES CO-CULTURE IN THE INFLAMMATORY RESPONSE

V. Marin[1], P.J. Giraudi[1], C. Tiribelli[1,2], N. Rosso[1]. [1]*Centro Studi Fegato, Fondazione Italiana Fegato,* [2]*Department of Medical Sciences, University of Trieste, Trieste, Italy*
E-mail: natalia.rosso@csf.units.it

Background and Aims: Macrophage migration Inhibitory Factor (MIF) is a pleiotropic cytokine involved in the pathogenesis of several acute and chronic inflammatory diseases, such as Alcoholic Liver Disease (ALD). Few information is available about MIF regulation between hepatocytes and macrophages in response to ethanol (EtOH). The aim of this work is to elucidate if the cross talk between these two cell types has any effect in the hepatic inflammatory response.
Methods: Co-culture (transwell system) of hepatocytes (HuH7) and differentiated macrophages (THP1+100nM PMA) were exposed for 24 h to 25mM EtOH; monocultures of each cell type were used as controls (CTRL). We assessed the gene expression of MIF and its receptor CD74 as well as TNF-α. In order to correlate gene expression with MIF functionality we also quantified the amount of released cytokine into the culture medium by ELISA (all data are reported in Table 1).

Table 1. Summary of the obtained data both in monoculture and co-culture system in response to ethanol exposure

	Folds (mean±SD)			
Cell type	MIF	CD74	TNF-α	MIF-release
Effect of 25mM EtOH in monoculture. Folds vs. untreated controls				
Hepatocytes	1.6±0.2*	1.0±0.1	2.6±1.1**	1.1±0.2
Macrophages	0.7±0.01	1.0±0.5	0.8±0.2	0.74±0.03
Effect of 25mM EtOH in co-culture. Folds vs. 25mM EtOH-treated monoculture				
Hepatocytes	1.12±0.43	5.54±0.18***	41.4±4.6***	3.09±1.3*
Macrophages	1.0±0.29	1.33±0.05*	0.25±0.06*	3.84±1.5*

*p < 0.05.; **p < 0.01; ***p < 0.001.

Results: In line with previously published data we confirmed that, in hepatocytes, EtOH induces the up-regulation of TNF-α. Furthermore we found that, in terms of gene expression, MIF follows the same trend of increase, even if the amount of released MIF was unchanged. Expression of CD74 was barely detectable in hepatocytes. Conversely, macrophages monocultures exposed to EtOH did not show any changes on the parameters under study.
Interestingly, we observed that in the co-culture system only hepatocytes presented a dramatic increase in TNF-α gene

expression, whereas macrophages presented a decrease. Moreover, in co-culture both hepatocytes and macrophages increased the release of MIF and with no changes at mRNA level. These data demonstrate that there is a synergic inflammatory response to EtOH when cells are cultured together. Furthermore, we observed a significant up-regulation of CD74 in co-cultured hepatocytes, which lead to the conclusion that cells are responding differently when macrophages are present in the system.

Conclusions: In conclusion, our data suggest that EtOH deleterious effect has hepatocytes as target cells. In addition, we showed that injured hepatocytes are able to modulate macrophages response, which (once activated) contribute to perpetrate the inflammatory state by increasing the production of MIF.

P1131
AUTOIMMUNE HEPATITIS-LIKE DRUG INDUCED LIVER INJURY

Y.S. de Boer[1], A.S. Kosinski[2], T.J. Urban[3], Z. Zhao[4], N. Long[3], N. Chalasani[5], J.H. Hoofnagle[6], the Drug-Induced Liver Injury Network. *[1]Liver Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases, NIH, Bethesda, [2]Duke Clinical Research Institute, Durham, [3]Division of Pharmacotherapy and Experimental Therapeutics, University of North Carolina, Chapel Hill, [4]Department of Laboratory Medicine, Clinical Center, NIH, Bethesda, [5]Division of Gastroenterology and Hepatology, Indiana University School of Medicine, Indianapolis, [6]Liver Disease Research Branch, National Institute of Diabetes and Digestive and Kidney Diseases, NIH, Bethesda, United States*
E-mail: y.deboer@vumc.nl

Background and Aims: Drug induced liver injury (DILI) can mimic many acute and chronic liver diseases including idiopathic autoimmune hepatitis (AIH). Hepatotoxic medications most commonly associated with an autoimmune presentation include nitrofurantoin, minocycline, methyldopa and hydralazine. The aim of this study was to characterize the clinical and serological features of DILI from these 4 agents.

Methods: Among over a thousand DILI cases enrolled in the U.S. Drug-Induced Liver Injury Network (DILIN) between 2004 and March 2014, 88 probable, highly likely and definite cases were included; 42 due to nitrofurantoin, 28 to minocycline, 11 to methyldopa and 7 to hydralazine. Available baseline (BL; n = 64) and follow up (FU; n = 39) sera were tested for antibodies to nuclear antigen (ANA), to Actin (AAA) and Soluble Liver Antigen (SLA) using the same ELISA kits as well as IgG levels. Genotype data on the AIH associated *HLA-DRB1*0301* and *HLA-DRB1*0401* alleles were available in 52 patients, which were compared with 4432 racially matched controls.

Results: The 88 cases included 80 women (91%) with a wide range in latency to onset (4 to 2162 days), predominantly hepatocellular injury (74%) and high rate of severe injury (25%). At BL, 46 of 64 patients (72%) tested positive for ANA, 39 (61%) for AAA, but none for SLA. IgG levels were elevated in 25 (39%) and were above 1.1 times ULN in 22 (25%). An autoimmune score (AIS) was derived from the degree of elevation in IgG, ANA, AAA or SLA (each as 0, 1+ or 2+). Autoimmune features (score ≥2) were more common with nitrofurantoin (82%) and minocycline (73%) than methyldopa (55%) or hydralazine (43%) (P = 0.16). FU specimens showed a decline in IgG levels and loss of ANA reactivity in 30% and AAA in 35% of initially positive subjects as well as a decrease in AIS (BL: 3, range 0–6, vs FU: 2, range 0–4; P < 0.001). These changes were not associated with corticosteroid therapy, which was used in 58% in this cohort. The *HLA-DRB1*0301* (15%) and *HLA-DRB1*0401* (9%) alleles were not overrepresented in this cohort when compared to controls (13% and 10% respectively). In addition, no patient was homozygous for these alleles and there was no association with autoimmune phenotype.

Feature	Nitrofurantoin	Minocycline	Methyldopa	Hydralazine
n	42	28	11	7
Female gender (%)	42 (100)	22 (79)	11 (100)	5 (71)
Latency to onset, (days), median (range)	561 (4–2162)	294 (29–1350)	81 (17–238)	108 (13–208)
Hepatocellular, n (%)	28 (67)	23 (82)	11 (100)	3 (43)
Severe, n (%)	11 (26)	2 (7)	2 (18)	1 (14)
Fatal, n (%)	5 (12)	0 (0)	0 (0)	1 (14)
Baseline serum sample available, n	28	19	10	7
ANA +, n (%)	23 (79)	15 (79)	4 (40)	4 (57)
AAA +, n (%)	23 (79)	10 (53)	4 (40)	2 (29)
IgG >ULN	12 (43)	6 (32)	5 (50)	2 (29)
Autoimmune phenotype (≥2), n (%)	23 (82)	14 (74)	6 (60)	3 (43)

Conclusions: Autoimmune like DILI occurs in most but not all patients with nitrofurantoin and minocycline liver injury and in at least half of those with methyldopa and hydralazine injury. The autoimmune phenotype decreases with recovery and is not associated with the typical HLA alleles found in idiopathic AIH.

P1132
REGULATION OF OXIDATIVE STRESS AND LIPID PEROXIDATION IN METHOTREXATE-INDUCED LIVER TOXICITY BY PRETREATMENT WITH TURMERIC

A. Rezaei Moghadam[1], A. Hamraghani[2], M. Khajoie Najad[3], M. Yazdi[3], J. Alizadeh[4], H. Marzban[4], M.J. Łos[5], S. Ghavami[4]. *[1]Young Researchers and Elite Club, Ardabil Branch, Islamic Azad University, Ardabil, Iran; [2]Clinical Pharmacy Department, School of Pharmacy, Shahid Beheshti University of Medical Sciences, [3]Department of of Veterinary Medicine, Tehran University, Tehran, Iran; [4]Department of Human Anatomy and Cell Science, College of Medicine, University of Manitoba, Winnipeg, Manitoba, Canada; [5]Department of Clinical and Experimental Medicine (IKE), Division of Cell Biology, and Integrative Regenerative Medicine Center (IGEN), Linköping University, Linköping, Sweden*
E-mail: armoghadm@hotmail.com

Background and Aims: Methotrexate (MTX) is an antimetabolite compound, which is broadly used in treatment of cancer and autoimmune diseases. MTX-induced hepatotoxicity limits its clinical application. Turmeric (TUR) contains various chemical constituents, has marked potential for preventing and treatment of several disorders. We investigated the efficacy of turmeric against hepatotoxicity caused by MTX.

Methods: All experiments were performed on male Wistar albino rats that were randomly divided into six groups. Group one received saline orally for 30 days (control group), groups two and three received turmeric extract (100 mg/kg, 200 mg/kg respectively) orally for 30 days, group four received single dose, of MTX IP at day 30, groups five and six received turmeric extract (100 mg/kg) and (200 mg/kg) orally respectively for 30 days and single dose of methoterxate IP (20 mg/kg) at day 30. Four days after MTX injection animals were sacrificed and evaluated. Blood ALT and AST (markers for hepatocyte injury), ALP and bilirubin (sensitive markers of biliary function), albumin (reflect liver synthetic function) as well as the plasma TAS concentration (marker of antioxidant defenses) were determined. The cellular antioxidant defense activities were examined in liver tissue samples using SOD, CAT, and GSH-Px for the oxidative stress, and MDA for lipid peroxidation. In addition, liver damage was evaluated by histopathology.

Results: MTX significantly induced liver damage (P < 0.05) and decreased its antioxidant capacity while turmeric was hepatoprotective. Liver tissue microscopic evaluation showed that MTX treatment induced severe centrilobular and periportal degeneration, hyperemia of portal vein, increased artery inflammatory cells infiltration and necrosis, while all of histopathological changes were attenuated by turmeric (200 mg/kg).

Conclusions: Thus, pre-administration of turmeric extract can successfully attenuate MTX hepatotoxicity and improve the therapeutic index of MTX.

P1133

HEPATIC VENO-OCCLUSIVE DISEASE (SINUSOIDAL OBSTRUCTION SYNDROME) AFTER SOLID ORGAN VERSUS HEMATOPOIETIC STEM CELL TRANSPLANTATION: ARE THESE DIFFERENT DISEASE ENTITIES?

B. Bielawska[1], I. Siddiqui[2], O. Adeyi[2]. [1]*Medicine,* [2]*Laboratory Medicine and Pathobiology, University of Toronto, Toronto, Canada*
E-mail: bielawska.b@gmail.com

Background and Aims: The term sinusoidal obstruction syndrome (SOS) has replaced veno-occlusive disease (VOD) to describe hepatic venous outflow obstruction related to liver microvascular injury, since the target of injury is believed to be endothelial cells in the hepatic sinusoids, as demonstrated in animal models. Classically, SOS is described after hematopoietic stem cell transplantation (HCT), but it can also occur after solid organ transplantation (SOT). At our center, we have noted that patients with SOS/VOD in the context of SOT do not present with the classic acute syndrome as in HCT. The purpose of this study was to investigate the clinical, laboratory and histopathologic characteristics of HCT and SOT patients developing SOS/VOD to determine if these may be distinct disease entities.
Methods: Retrospective case series of HCT and SOT patients with a diagnosis of SOS/VOD at the University Health Network. All patients who had a clinical diagnosis of SOS/VOD and underwent liver biopsy were included. Patients with clinical and/or radiologic features of heart failure or large hepatic vein/IVC disease were excluded. Data including clinical presentation, medical history and laboratory parameters was collected and histopathology slides were reviewed. Descriptive data are presented.
Results: Between August 2001 and August 2014, five SOT (2 liver, 3 kidney) and three HCT patients met the study criteria. Mean time to liver biopsy was 45.6 days after HCT (range 30–60 days) and 8.3 years after SOT (range 1–14 years). HCT patients presented with a clinical syndrome of portal hypertension and liver dysfunction while SOT patients presented with asymptomatic ALP elevation. 1/5 SOT patients had exposure to azathioprine. Ascites was present in all HCT and none of the SOT patients. Mean bilirubin was 20.2 umol/L in the SOT group and 176.7umol/L in the HCT group. Liver histopathology of HCT cases revealed marked sinusoidal congestion, no fibrosis, and often patent hepatic venules. In SOT, histopathology revealed mild congestion, subsinusoidal fibrosis, and lost or remodeled hepatic venules.
Conclusions: SOS/VOD following SOT presents distinctly from that after HCT. Patients present late with asymptomatic ALP elevation without jaundice or ascites and have histological evidence of fibrosis and small vein remodeling. These findings raise the possibility that these may be distinct disease entities but further study is needed.

P1134

THE LEUKOCYTE MIGRATION INHIBITOR SOLUBLE CD18 INCREASES WITH SEVERITY OF HUMAN ALCOHOLIC HEPATITIS

S. Stoey[1], T.D. Sandahl[1], B. Deleuran[2], T. Vorup-Jensen[2], H. Vilstrup[1], T.W. Kragstrup[2]. [1]*Department of Hepatology and Gastroenterology, Aarhus University Hospital,* [2]*Department of Biomedicine, Aarhus University, Aarhus, Denmark*
E-mail: sidsel.stoy@post.au.dk

Background and Aims: The TNFα levels and macrophage activity markers such as soluble CD163 (sCD163) are very high in human alcoholic hepatitis. The β2 (CD18) family of integrins is shed from the surface of myeloid cells in response to TNFα forming the recently discovered soluble CD18 (sCD18), which binds to endothelial adhesion molecules. This is thought to inhibit extravasation of leukocytes and facilitate their efflux from tissues. It is not known whether this tissue inflammation moderating mechanism is intact in alcoholic hepatitis. We, therefore, measured the plasma levels of sCD18 in these patients.
Methods: We analysed blood samples from 50 patients with severe alcoholic hepatitis at diagnosis, at day 14 and at day 30 and from 20 healthy controls with in-house immunosorbant assays for sCD18 and sCD163.
Results: At the diagnosis of alcoholic hepatitis, the sCD18 concentration was increased by 30% in the patients compared with controls (median±IQR; 1907.3±1032 vs. 1472.5±646.2, $p = 0.01$). This did not change during the follow-up period. We found a positive correlation between sCD18 and sCD163 ($r = 0.53$ $p = 0.0001$). The levels of sCD18 correlated with disease severity according to the Child Pugh ($r = 0.41$ $p = 0.003$) and Glasgow Alcoholic Hepatitis Score ($r = 0.30$ $p = 0.04$).
Conclusions: The tissue inflammation-limiting shedding of sCD18 is induced in patients with alcoholic hepatitis in parallel with macrophage activation and disease severity, suggesting an anti-inflammatory mechanism that is operative within the picture of florid hepatic inflammation.

P1135

UTILITY OF LIVER BIOPSY IN ALCOHOLIC HEPATITIS: DATA FROM THE STEROIDS OR PENTOXYFILLINE IN ALCOHOLIC HEPATITIS (STOPAH) CLINICAL TRIAL

G. Petts[1], K. Lloyd[1], N. Vergis[2], H. Kudo[1], A. Quaglia[3], E. Forrest[4], M. Thursz[2], R. Goldin[1], STOPAH Trial Group. [1]*Histopathology,* [2]*Hepatology, Imperial College London,* [3]*Histopathology, Kings College London, London,* [4]*Gastroenterology and Hepatology, Glasgow Royal Infirmary, Glasgow, United Kingdom*
E-mail: g.petts@imperial.ac.uk

Background and Aims: The role of liver biopsy in the diagnosis of alcoholic hepatitis (AH) remains controversial. We sought to investigate this in patients recruited to *Steroids or Pentoxyfilline for Alcoholic Hepatitis* (STOPAH).
Methods: Patients with clinically diagnosed severe AH [Maddrey's discriminant function (mDF) >32] were recruited and liver biopsies were obtained either before or after administration of trial medication. Two independent histopathologists, blinded to treatment group and patient outcome, scored histological features of AH, including those described in the Alcoholic Hepatitis Histological (AHHS) and Kleiner NAFLD Activity (NAS) scores.
Results: 208 biopsies were received (19% of patients recruited to STOPAH). 93 samples were both of adequate quality and taken between admission and day 5 of treatment. Baseline serum markers of severe disease were associated with histological features of severe disease (e.g. serum bilirubin and bilirubinostasis, white cell count and biopsy inflammation; see Table 1).
Overall, 82/93 (88%) samples had histological features consistent with alcoholic steatohepatitis (ASH). In 59 cases data regarding indication for biopsy was available: 35/59 were obtained as routine clinical practice without diagnostic uncertainty. In these patients 31/35 (91%) biopsies were diagnostic for ASH. The 24/59 patients biopsied for diagnostic uncertainty had a lower biopsy diagnosis rate, 20/24 (83%) had histological features consistent with ASH.
69/82 cases with a diagnosis of ASH, had complete follow up data. In this cohort mortality at day 28 was 13% and 22% at 90 days. 42 (61%) patients were in the severe AHHS category and 46 (67%) were in the highest NAS category. Patients in the AHHS severe category had a significantly increased day 28 mortality rate (21% vs. 0%, Kruskal–Wallis $p = 0.01$). However there was no significant different at day 90 day or when using the NAS scoring system.
AHHS categorisation positively correlated with mDF and Glasgow Alcoholic Hepatitis Score (GAHS), however it did not correlate with

other clinical scores or predictors of outcome (see Table 1). There was no association between NAS categorisation and any clinical parameters (see Table 1).

Table 1

Clinical marker	Comment	Statisitical test, value
93 cases with biopsy taken between admission and day five of treatment		
Serum PT ratio	Higher PT ratio associated with advanced cirrhosis	
	Laennec classification:	Kruskal–Wallis, p = 0.01
	STOPAH classification:	Kruskal–Wallis, p = 0.01
Serum INR	Higher INR associated with advanced cirrhosis	
	Laennec classification:	Kruskal–Wallis, p = 0.01
Serum AST	Higher AST associated with more advanced steatohepatitis	
	Kleiner NAS classification:	Kruskal–Wallis, p = 0.03
Serum bilirubin	Higher bilirubin associated with more advanced steatohepatitis	
	AHHS classification:	Kruskal–Wallis, p = 0.003
	Kleiner NAS classification:	Kruskal–Wallis, p = 0.04
	Higher bilirubin associated with more biopsy hepatocellular bilirubinostasis	Kruskal–Wallis, p ≤ 0.0001
Serum white cell count	Higher white cell count associated with more severe lobular inflammation	
	Kleiner NAS classification:	Kruskal–Wallis, p = 0.001
	STOPAH classification:	Mann–Whitney U, p ≤ 0.0001
Serum neutrophil count	Higher neutrophil count associated with more severe biopsy PMN infiltrate	
	AHHS classification:	Kruskal–Wallis, p = 0.001
	STOPAH classification:	Mann–Whitney U, p ≤ 0.0001
69 cases from cohort above taken as routine clinical practice and with a histological diagnosis of steatohepatitis		
mDF	Maddrey's Discriminant Function	
	AHHS classification:	r_S = 0.223, p = 0.045
	Kleiner NAS classification:	r_S = 0.008, p = 0.940
GAHS	Glasgow Alcoholic Hepatitis Score	
	AHHS classification:	r_S = 0.300, p = 0.009
	Kleiner NAS classification:	r_S = 0.219, p = 0.060
MELD	Model of End-Stage Liver Disease	
	AHHS classification:	r_S = 0.175, p = 0.115
	Kleiner NAS classification:	r_S = 0.020, p = 0.860
Lille score	0.45 cut off	
	AHHS classification:	Kruskal–Wallis p = 0.107
	Kleiner NAS classification:	Kruskal–Wallis p = 0.574
Day 7 change in bilirubin	AHHS classification:	Kruskal–Wallis p = 0.371
	Kleiner NAS classification	Kruskal–Wallis p = 0.422

Conclusions: The findings demonstrate parallels between clinical and histological parameters and support the role of liver biopsy in cases of diagnostic uncertainty. Further work into the role of liver biopsy in predicting response to therapy in ASH is warranted.

P1136

MOST LIVER RELATED DEATHS ARE CAUSED BY ALCOHOL: AN AUDIT OF LIVER MORTALITY FROM TERTIARY CARE CENTER IN NORTH INDIA

V. Gupta[1], A. Kumar[1], P. Sharma[1], A. Arora[1]. [1]*Department of gastroenterology and hepatology, Sir Ganga Ram Hospital, New Delhi, India*
E-mail: varun_doc@yahoo.co.in

Background and Aims: Alcohol, hepatotropic viruses, and non-alcoholic steatohepatitis (NASH) are the most important causes of liver related deaths. The distribution of these causes among Indian patients dying of liver disease is unknown. This information will help in prioritizing healthcare efforts in preventing liver related deaths in India.

Methods: Records of all consecutive patients who had died due to liver-related causes in the Gastroenterology Department of Sir Ganga Ram Hospital, New Delhi, India, from Nov 2010 to Oct 2014 were analyzed. Patients dying due to non-hepatic cancers metastasizing to liver were excluded. Clinical presentation and immediate etiological causes of death were analyzed. In patients with multiple factors, the most immediate etiology was taken as the cause of death.

Results: Records of 401 consecutive patients were analyzed. Nine patients were excluded who had died of liver metastasis from non-hepatic cancers; hence 392 patients were included in the study (median age 50 [range 14–87] years, males 80%). Underlying chronic liver disease (CLD) was present in 86% (335/392) while in 14% (57/392) there was no underlying CLD. In CLD group most patients (71%, 237/335) had presented with complications of cirrhosis (such as end-stage liver disease, portal hypertension, sepsis etc.). Acute-on-chronic liver failure was the presentation in 29% (98/335) of CLD patients. Among patients without underlying CLD the most common presentation was with acute liver failure (68%, 39/57). Overall, the most common cause of liver-related death was alcohol, responsible for 30% (118/392) of deaths, followed by NASH/cryptogenic in 23% (91/392), hepatotropic viruses in 19% (73/392), bacterial/other infections in 12% (45/392), and drug-induced liver injury in 6% (24/392). In 5% cases the cause was some unidentified acute hepatic insult. The distribution of causes of death in various presentations is shown in the table.

Conclusions: Alcohol is the most important cause of liver related deaths in India and NASH/cryptogenic cirrhosis is the second important cause. Since, both these causes are preventable by increasing public awareness and implementing life-style measures, urgent attention should be paid towards these measures.

Table (abstract P1136).

	All patients (n = 392)	Underlying CLD (n = 335)		Non-CLD (n = 57)

Autoimmune and chronic cholestatic liver disease

P1137
INTEGRATED EFFICACY SUMMARY FOR OBETICHOLIC ACID IN SUBJECTS WITH PRIMARY BILIARY CIRRHOSIS

P. Invernizzi[1], R. Pencek[2], T. Marmon[2], L. MacConell[2], D. Shapiro[3]. *[1]Liver Unit and Center for Autoimmune Liver Diseases, Humanitas Clinical and Research Center, Rozzano (Milano), Italy; [2]Clinical Development, [3]Intercept Pharmaceuticals, Inc., San Diego, United States*
E-mail: pietro.invernizzi@humanitas.it

Background and Aims: Obeticholic acid (OCA), a modified bile acid and farnesoid x receptor (FXR) agonist, is currently in late-phase development for the treatment of primary biliary cirrhosis (PBC), a rare cholestatic liver disease. In two Phase 2 trials (3 months) and in the Phase 3 POISE trial (12 months) 5 mg to 50 mg OCA, once daily as monotherapy or add-on to UDCA, produced significant improvements in markers of cholestasis and inflammation. The objective of this integrated analysis was to evaluate the efficacy of ≤10 mg OCA, the proposed indicated doses for the treatment of PBC, as monotherapy or in combination with UDCA in an integrated fashion across the 3 trials compared to placebo.
Methods: Individual subject data from 3 completed, randomized, controlled double-blind trials of OCA once daily were pooled for this analysis (OCA ≤10 mg N = 201; placebo N = 134; OCA 25 mg N = 48; OCA 50 mg N = 57). All placebo subjects were pooled as were OCA doses of 5 mg, titration from 5 to 10 mg, and 10 mg (≤10 mg OCA). Inclusion criteria included ALP ≥1.67×ULN or total bilirubin >ULN but <2×ULN. Analyses were repeated based on baseline concomitant UDCA use. Efficacy was evaluated using a composite endpoint shown to correlate with long-term survival (ALP <1.67 ULN with a minimum 15% reduction and a normal bilirubin) (Lammers 2014) and assessment of liver biochemistry and inflammation.
Results: Baseline characteristics were generally similar between treatment groups. Baseline ALP was higher in monotherapy subjects compared to UDCA combination subjects. Efficacy data are presented in the Table. At the end of double blind treatment significantly more OCA-treated subjects achieved the composite endpoint compared to placebo when used as monotherapy or in combination with UDCA. OCA treatment was associated with statistically significant and clinically meaningful decreases in ALP as well as GGT, ALT, and AST. While the subjects in the monotherapy group had higher ALP at baseline than the OCA plus UDCA group, the two groups reached similar ALP levels by the end of the double-blind period. Pruritus was the most common adverse event associated with PBC and showed a dose-related increase in incidence with OCA.
Conclusions: In this pooled analysis, a significantly greater percentage of subjects with PBC treated with OCA with or without UDCA achieved a composite endpoint shown to correlate with long-term survival compared to placebo-treated subjects.

P1138
LONG-TERM OUTCOME OF PATIENTS WITH AUTOIMMUNE HEPATITIS RECEIVING MYCOPHENOLATE MOFETIL (MMF) AS FIRST LINE TREATMENT

K. Zachou[1], N. Gatselis[1], S. Gabeta[1], A. Saitis[1], G. Koukoulis[2], G.N. Dalekos[1]. *[1]Department of Medicine and Research Laboratory of Internal Medicine, [2]Department of Pathology, Medical School, University of Thessaly, Larissa, Thessaly, Greece*
E-mail: zachoukalliopi@gmail.com

Background and Aims: The natural history of autoimmune hepatitis (AIH) depends vastly on treatment. We have previously shown, that using MMF as first line therapy instead of conventional treatment with corticosteroids ± azathioprine, results in high rates of remission with fewer side effects, quick corticosteroid withdrawal and 0% non-response rate. In the present study we investigated the long term outcome of patients with AIH receiving MMF as front line treatment, with special emphasis on outcome after treatment withdrawal.
Methods: One hundred and five patients with well defined AIH [follow-up for 66 (3–168) months] were treated with prednisolone 1 mg/kg/day plus 1.5–2 g/day MMF. Treatment outcomes were defined according to International Autoimmune Hepatitis Group and AASLD guidelines. Patients were candidates for MMF withdrawal after being on treatment for at least 4 years and having complete response (CR) at least the last 2 years.
Results: 99/105 (94%) responded initially to treatment normalizing the aminotransferases and γ-globulins within 2 (1–18) months: 77 (73.3%) had CR [52/77 (67.5%) maintained the CR after prednisolone withdrawal], 22/77 (21%) achieved initial response but they relapsed during prednisolone withdrawal and 6/77 (5.7%) had partial response (PR). No patient was non-responder. Predictors of CR were acute disease presentation (p = 0.003) and shorter treatment duration (p = 0.01). None of the 80 non-cirrhotic patients developed cirrhosis during follow-up [63 (3–143) months]. 7/25 cirrhotic patients decompensated (28%), 4 died of liver related causes, 1 was transplanted and 4 developed HCC. So far, treatment was stopped in 31/105 patients after 60 (12–125) months. 23/31 (74%) remained in remission for 21 (3–84) months; 8/31 relapsed in 3.5 (2–7) months. Maintenance of response was associated with absence of cirrhosis at diagnosis (p = 0.05), shorter corticosteroid duration (p = 0.009), lower IgG levels on month 1 (p = 0.016) and 6 of treatment (p = 0.013). In multivariate analysis, no parameter could independently predict maintenance of remission after treatment withdrawal.
Conclusions: So far, MMF proved to be an efficient and safe first line treatment for AIH achieving the highest rates of maintenance of remission off treatment (74%) ever published though the remission

Table (abstract P1137).

	Monotherapy						Concomitant UDCA					
	Placebo (N=28)			≤10 mg OCA (N=31)			Placebo (N=106)			≤10 mg OCA (N=170)		
Composite Endpoint	End of DB	CMH p-value		End of DB	CMH p-value		End of DB	CMH p-value		End of DB	CMH p-value	
Percent response	4%			35%	0.0019		9%			48%	<0.0001	
	Base	End of DB	Δ	Base	End of DB	Δ	Base	End of DB	Δ	Base	End of DB	Δ
ALP, U/L	401 (207)	415 (235)	−45 (27)	451 (262)	254 (149)	−231 (26)***	307 (113)	300 (136)	11 (8)	308 (110)	208 (83)	−83 (7)***
Total bilirubin, μmol/L	11.4 (6.5)	12.9 (9.3)	−2.3 (1.1)	12.7 (8.0)	12.2 (7.9)	−4.4 (1.1)*	11.7 (6.9)	12.2 (8.0)	1.2 (0.7)	11.5 (6.7)	10.6 (6.5)	−1.0 (0.6)**
GGT, U/L	495 (367)	535 (455)	−48 (44)	564 (339)	186 (184)	−427 (42)***	251 (361)	250 (322)	14 (12)	242 (191)	105 (101)	−128 (10)***
ALT, U/L	80 (55)	80 (64)	11 (7)	84 (50)	50 (37)	−22 (7)***	52 (29)	49 (27)	1 (2)	56 (35)	36 (27)	−15 (2)**
AST, U/L	70 (36)	68 (45)	7 (6)	69 (37)	53 (35)	−7 (6)*	46 (23)	47 (34)	6 (2)	42 (20)	38 (34)	−6 (2)***

Baseline (Base) and End of Double-blind (DB) data are mean (SD); Δ = LS mean change from Baseline (SE); Composite endpoint analyzed with Cochrane–Mantel–Haenszel (CMH) test; P values for comparing OCA to placebo: *p < 0.05, **p < 0.002, ***p < 0.0001.

criteria used were strict. As relapse after treatment withdrawal is almost universal with conventional therapy, MMF seems a reasonable first line treatment of AIH.

P1139

TESTOSTERONE SUPPRESSES HEPATIC INFLAMMATION BY THE DOWN-REGULATION OF IL-17, CXCL-9 AND CXCL-10 IN A MOUSE MODEL OF EXPERIMENTAL CHOLANGITIS

D. Schwinge[1], A. Carambia[2], A. Quaas[3], T. Krech[3], C. Wegscheid[4], G. Tiegs[4], I. Prinz[5], A.W. Lohse[6], J. Herkel[1], C. Schramm[1]. *[1]I. Department of Medicine, University Medical Center Hamburg-Eppendorf, [2]I. Department of Medicine, University Medical Center Hamburg Eppendorf, [3]Department of Pathology, [4]Experimental Immunology and Hepatology, University Medical Center Hamburg-Eppendorf, Hamburg, [5]Institute of Immunology, Hannover Medical School, Hannover, [6]I. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*
E-mail: d.schwinge@uke.de

Background and Aims: Most autoimmune liver diseases predominantly affect women. Here we aimed to elucidate how sex affects autoimmune hepatic inflammation in a novel and inducible mouse model of autoimmune cholangitis, which showed female preponderance similar to human autoimmune diseases.
Methods: Adoptive cell transfer of ovalbumin (OVA)-specific CD8+ T cells into mice expressing OVA peptide under control of the human keratin 14 promoter were performed.
Results: OT1–1 CD8+ T cell transfer resulted in portal inflammation and cholangitis in female, but not in male recipient mice. Recruitment of transferred CD45.1+CD8+ T cells into the livers of recipient male or female mice was similar. In contrast, the recruitment of endogenous CD45.2+CD4+ T cells into female livers was increased compared to male livers indicating a pro-inflammatory role for endogenous CD4+ T cells. Transfer of CD4+ T cells isolated from inflamed livers of K14-OVAp mice could cause liver inflammation in K14-OVAp recipient mice in the absence of OT-1 cells. Increased CD4+ T cell numbers were associated with increased frequencies of CD4+IL-17+ T cells, higher amounts of RORc mRNA and significantly higher production of IL-17 by hepatic nonparenchymal cells (NPCS) isolated from female compared to male mice [220.8 pg/ml female vs. 57.5 pg/ml male, $p < 0.017$]. Moreover, levels of T cell recruiting chemokines CCL-9 and -10 were increased in female livers. Cell transfer experiments into K14-OVApxIL17a/f ko female recipient mice confirmed that lack of endogenous IL-17 significantly decreased ALT levels and cholangitis severity compared to K14-OVAp IL-17 wild-type mice. IL-17 expression, CCL-9 and -10 expression and CD4+ T cell recruitment could be modulated by castration and hormone replacement studies. Male resistance to liver inflammation could be attributed to the protective effects of testosterone, which was shown to act directly on CD4+ T cells by suppressing TH17 differentiation in vitro
Conclusions: Testosterone was found to be the major determinant of the observed sexual dimorphism in our cholangitis model. IL-17 production by CD4+ T cells seems to increase cholangitis severity and may be modulated by testosterone directly. These results should stimulate future investigations of the influence of sex hormones on liver inflammation and the gender differences observed in human autoimmune liver diseases.

P1140

NGM282 DEMONSTRATES POTENT ANTIFIBROTIC ACTIVITY IN A MOUSE MODEL OF SEVERE CHOLESTATIC FIBROSIS

J. Luo[1], B. Ko[1], C. To[1], L. Ling[1], S. Rossi[1], A. DePaoli[1], H. Tian[1]. *[1]NGM Biopharmaceuticals, Inc, South San Francisco, United States*
E-mail: srossi@ngmbio.com

Background and Aims: NGM282 is an engineered recombinant protein variant of fibroblast growth factor 19 (FGF19) that retains CYP7a1 inhibition *via* FGFR4–b klotho binding but lacks the abnormal proliferative activity of FGF19. We have previously shown that NGM282 is hepatoprotective from cholestatic injury compared to obeticholic acid and bezafibrate in mice (Luo 2014). In the current study, we evaluated the anti-fibrotic effects of FGF19 and NGM282 in a mouse model of cholestatic fibrosis.
Methods: Cholestatic fibrosis was induced by bile duct ligation (BDL) in male FVB mice. Adeno-associated virus encoding green fluorescent protein (GFP) (as control), FGF19 or NGM282 were injected intravenously into mice *via* tail vein at 4 days before BDL surgery. Mice were euthanized 28 days after the BDL. Serum chemistry, liver histopathology and fibrosis gene expression analyses were conducted.
Results: FGF19 and NGM282 significantly reduced the Sirius red staining areas indicating reduction of fibrosis compared to GFP control (Figure 1). Additionally, fibrotic gene expression of Col1a, Ctgf, Tgfb1 and Timp1was suppressed by both of the molecules. Both FGF19 and NGM282 showed significantly less dilatation of bile ducts, vein and lymphatics and reduced bile duct proliferation and inflammation in H&E staining compared to untreated animals. Serum liver enzymes, bilirubin, total bile acids and survival rates were also substantially improved with the treatments.
Conclusions: Both FGF19 and NGM282 effectively prevented the animals from hepatic fibrosis and the associated pathological changes in a mouse model of cholestatic fibrosis as well as improving the biochemical markers of cholestasis. Suppression of hepatic bile acids synthesis may represent a novel therapy for the treatment and prevention of cholestatic fibrosis. We are actively pursuing the development of NGM282 in the clinical setting.

POST-TRANSLATIONAL REGULATION OF POLYCYSTIN 2 (PC2) EXPRESSION AS A NOVEL MECHANISM OF CHOLANGIOCYTE REACTION TO BILIARY DAMAGE AND REPAIR

C. Spirli[1], A. Villani[1], C.M. Morell[2], L. Fabris[3], R. Fiorotto[1], M. Strazzabosco[1,2]. *[1]Internal Medicine, Section of Digestive Diseases, Yale University, New Haven, CT, United States; [2]Department of Surgery and Interdisciplinary Medicine, University of Milano-Bicocca, Milan, [3]Department of Molecular Medicine, University of Padua, Padova, Italy*
E-mail: mario.strazzabosco@yale.edu

Background and Aims: In Polycystic Liver Diseases, defective PC2 leads to elevated production of cAMP, PKA-dependent activation of the ERK1/2 pathway, HIF1α-mediated VEGF production and stimulation of cyst growth and progression. Activation of the ERK/HIF1α/VEGF pathway in cholangiocytes is fundamental during repair from biliary damage. In this study we hypothesized that PC-2 levels can be modulated during biliary damage/repair, resulting in activation of the ERK/HIF1α/VEGF pathway.
Methods and Results: PC2 protein expression was significantly reduced in livers from mice undergoing cholangiocyte damage

(Mdr2$^{-/-}$-KO, bile duct ligation, treatment with dehydrocollidine – DDC). However, PC-2-gene expression was not reduced, suggesting that the decrease in PC2 protein content was due to increased degradation. To understand if factors involved in biliary damage influence PC2 protein expression, mouse cholangiocytes were treated with pro-inflammatory cytokines (IL-1β, IFNγ, TNFα), nitric oxide (NO) donors (DETAnonoate) and ER stressors (thapsigargin). Expression of PC2 protein was again significantly reduced, but not its gene expression. Noteworthy, downregulation of PC-2 was associated to increased ERK1/2 phosphorylation, HIF1α transcription activity, secretion of VEGF and phosphorylation of VEGFR2. Expression of Herp and NEK, ubiquitin-like proteins that promote PC2 degradation by increasing the retrotranslocation from the ER to the proteasome complex was also increased. Pre-treatment with the proteasome inhibitor MG-132 restored the expression of PC2 in cells treated with cytokines but not in cells treated with NO donors or with ER stressors. In the latter conditions, PC2 degradation was inhibited by LY294002, an inhibitor of PI3K that blocks the autophagosome formation and by blockade of lysosomes with chloroquine, suggesting a role for autophagy. Finally, treatment of DDC-treated mice with the proteasome inhibitor bortezomib, significantly reduced the extent of the liver damage and restored PC2 expression.

Conclusions: PC2 protein is modulated post-translationally by pro-inflammatory cytokines, ER-stressors and NO-donors and is reduced in mice with biliary damage. Down regulation of PC2 protein expression in cholangiocytes increases the ERK1/2/HIF1α pathway and VEGF secretion, thereby playing a pivotal role in the regulation of cholangiocyte response to biliary damage. Treatments able to restore PC2 expression (i.e. proteasome inhibitors) may represent a new therapeutic approach in biliary diseases.

P1142
NEXT GENERATION SEQUENCING ANALYSIS OF CHOLESTATIC PATIENTS REVEALS HIGH IMPACT VARIATION IN COMMON AND RARE CANDIDATE GENES: DISSECTING THE GENETIC ARCHITECTURE OF CHOLESTASIS

R. Liebe[1], A. Christmann[2], M. Krawczyk[3], P. Milkiewicz[4], F. Grünhage[3], C. Jüngst[3], F. Lammert[3]. *[1]Department of Medicine II, University of Heidelberg, University Hospital Mannheim, Mannheim, [2]Gemeinschaftspraxis für Humangenetik, [3]Department of Medicine II, Saarland University Medical Center, Homburg, Germany; [4]Liver and Internal Medicine Unit, Department of General, Transplant and Liver Surgery of the Medical University of Warsaw, Warsaw, Poland*
E-mail: marcin.krawczyk@uks.eu

Background and Aims: Cholestasis indicates bile secretory failure, which might be caused by environmental factors and gene variants, or combination of both. Although there is variability in underlying causes of hepatocellular cholestasis, selected patients present with chronic cholestasis of unknown etiology, and gene mutations of critical hepatobiliary transporters or their regulators may be suspected. Our *aim* now was to employ next-generation sequencing (NGS) to dissect genetic risk factors in adult patients with cholestatic liver disease of unknown etiology.

Methods: The full length coding sequences of a panel of genes known to be involved in regulation and transport of drugs and metabolites into bile were determined by NGS sequencing in patients with unexplained chronic cholestasis, as defined by an at least two-fold increase of serum alkaline phosphatase (AP) activities and ALT/AP ratio ≤2. Population frequency and biochemical impact of all detected variants were analysed. Rare, high-impact variants were also considered. Cholestasis NGS gene panel: *ABCB4, ABCB11, ABCC2, ABCG5, ABCG8, ATP8B1, CIRH1A, CLDN1, JAG1, NOTCH2, NR1H4, NR1I2, UGT1A1–10, VIPAR, VPS33B.*

Results: Full sequence analysis of 24 genes in 22 patients with cholestatic liver disease revealed heterozygosity for several high-impact variants that have previously been associated with cholestatic liver disease such as *ABCB11* p.G982R (PFIC2), *ABCB11* p.D482G (PFIC2), *ATP8B1* p.I661T (PFIC1/BRIC), *ATP8B1* p.D70N (BRIC/ICP) and *VPS33B* c.177+1G>A (ARC). New high-impact variants that are highly likely to result in non-functional protein (complete loss of splice site, frameshift deletion) were detected in *ABCB4 (MDR3)*, *NR1I2* (*PXR*) and *UGT1A7*. None of these variants were found among 62 000 individual sequences in the Exome Aggregation Consortium (ExAC) database. Rare, non-conservative variants of yet unknown biochemical impact detected in *ABCC2* (*MRP2*), *NOTCH2* and *NR1H4* (*FXR*) will also be presented.

Conclusions: Next-generation sequencing permits rapid and comprehensive analysis of a large panel of cholestasis-associated transcripts. Peculiar phenotypes appear more likely to result in the detection of novel pathogenic mutations. Correlating the results with systematic clinical phenotyping might result in improved genotype-phenotype correlations and lead to targeted chemical intervention such as chaperone-therapy.

P1143
THYROID HORMONE RECEPTOR BETA 1 (THRβ1) STIMULATES BILIARY PHOSPHATIDYLCHOLINE SECRETION VIA ABCB4 REGULATION – A NEW THERAPEUTIC APPROACH FOR CHOLANGIOPATHIES

T. Claudel[1], J. Gautherot[2], F. Cuperus[2], C. Fuchs[2], M. Trauner[2]. *[1]Hans Popper Laboratory of Molecular Hepatology Division of Gastroenterology & Hepatology Dept. of Internal Medicine III, [2]Hans Popper Laboratory of Molecular Hepatology Division of Gastroenterology & Hepatology Dept. of Internal Medicine III, Medical University of Vienna, Vienna, Austria*
E-mail: thierry.claudel@meduniwien.ac.at

Background and Aims: ATP-binding cassette protein subfamily B4/multidrug resistance transporter 3 (ABCB4/MDR3) mediates phosphatidylcholine (PC) biliary secretion. Since PC is essential for formation of mixed micelles counterating bile acid (BA) toxicity, defects in ABCB4 expression result in bile duct and cholestatic liver injury. Conversely up-regulating *ABCB4* pharmacologically may improve cholestatic liver and bile duct injury in cholangiopathies (e.g. PBC and PSC).

We investigated the role of triiodothyronine (T3) in *ABCB4* regulation in vitro (primary immortalized human cells) and in vivo (mice).

Methods: HepG2, IHH and HuH7 cells were incubated with T3 and specific THR alpha (THRa) and beta (THRb) agonists. Mice were fed a liver specific THRb agonist KB141, before assessment of bile composition/flow. Hepatobilary transporter/BA synthetic enzyme gene expressions was measured by Q-PCR.

Results: *ABCB4* gene expression and protein levels were increased in a time- and dose-dependent manner by T3 as well as liver specific THRb (GC1, KB2115, CGS23425 and KB141) but not THRa agonists in all human cell lines (up to 2 times; $p < 0.05$ after 24 h). In vitro actinomycin D, but not cycloheximide, treatment abolished *ABCB4* up-regulation by T3 revealing a direct transcriptional regulation. ABCB4 promoter in silico analysis mapped 7 potential THR response elements, but gel shifts assays identified only one THRb specific site 6kb upstream to the transcription start site. Interestingly, co-incubation of T3 and FXR agonists resulted in additive stimulation of ABCB4 up to 3 fold $p < 0.05$, while repressing CYP7A1 expression. Moreover, *Abcb4* was up-regulated (1.5 fold $p < 0.05$) in wild-type mice treated with KB141 which in turn increased biliary PC secretion 5 fold.

Conclusions: We identified THRβ1 as a novel activator of *ABCB4* in human and mouse. Moreover, FXR and THRb agonists may synergistically modify bile composition by increasing PC and reducing BA thus favouring less toxic bile and opening new therapeutic opportunities in cholangiopathies such as PBC and PSC.

HEPATOCYTE SPECIFIC EXPRESSION OF A DOMINANT STABLE FORM OF BETA-CATENIN RESULTS IN CHOLESTATIC LIVER DISEASE

U.J. Lemberger[1], C. Fuchs[2], M. Karer[3], C. Schöfer[4], T. Stojakovic[5], F. Wrba[6], M.M. Taketo[7], M. Trauner[8], C.H. Österreicher[9]. *[1]Institute of Pharmacology, Medical University Vienna, [2]Hans Popper Laboratory for Molecular Hepatology, Department of Internal Medicine, Medical Univeristy of Vienna, [3]Institute of Pharmacology, [4]Department of Cell and Developmental Biology, Medical University of Vienna, Vienna, [5]Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University of Graz, Graz, Graz, [6]Clinical Institute of Pathology, Medical University of Vienna, Vienna, Austria; [7]Graduate School of Medicine, Kyoto University, Kyoto, Japan; [8]Hans Popper Laboratory for Molecular Hepatology, Department of Internal Medicine, Medical University of Vienna, [9]Institute of Pharmacology, Medical University Vienna, Vienna, Austria*
E-mail: christoph.oesterreicher@meduniwien.ac.at

Background and Aims: The Wnt/β-catenin signaling pathway is an ancient, evolutionary preserved systems, which plays a crucial role in embryonic development, tissue homeostasis, wound healing and malignant transformation in a variety of different organs, including the liver. Continuous Wnt/β-catenin signaling and somatic mutations in exon 3 of the *ctnnb1* gene are observed in >30% of patients with liver cancer. To investigate the role of continuous β-catenin signaling in liver biology, we generated mice, which lack exon 3 of the *ctnnb1* gene specifically in hepatocytes.
Methods: Mice with a loxP flanked exon 3 of the *ctnnb1* gene were crossed to albumin-Cre or SA-CreERT2 mice to obtain mice with hepatocyte specific expression of a dominant stable form of β-catenin (catn ex3Δ hep mice). Catn ex3Δ hep mice were analyzed by serum biochemistry, histology, Sirius red staining, immunoblotting, immunohistochemstry, immunofluorescene, confocal microscopy, electron microscopy and mRNA profiling.
Results: Successful removal of exon 3 of the *ctnnb1* gene was confirmed by immunoblotting using whole liver tissue. Mice were born at the expected Mendelian ratio. $Ctnnb1^{CAhep}$ mice were smaller and their body weight was significantly reduced. Livers of $Ctnnb1^{CAhep}$ mice were significantly enlarged, differed in macroscopic appearance and the liver to body weight ratio was significantly increased. Serum ALT, AST and bile acid levels were significantly increased in $Ctnnb1^{CAhep}$ mice. Livers of $Ctnnb1^{CAhep}$ mice displayed a disturbed liver architecture, paucity of central veins, mitotic figures and proliferating cholangiocytes. Sirius red and desmin staining indicated a biliary type of fibrosis. $Ctnnb1^{CAhep}$ mice did not differ from Cre-negative controls with regards to expression of bsep as evaluated by qPCR, but expression of compensatory bile acid transporters including abcb4, mdr1a and mrp2 were significantly increased. $Ctnnb1^{CAhep}$ mice also displayed significantly reduced mRNA levels of ntcp but significantly increased levels of mrp4. mRNA data was confirmed at the protein level by immunoblotting. Expression of cyp7a1 the rate-limiting step in bile acid synthesis was significantly increased in $Ctnnb1^{CAhep}$ mice. In contrast, expression of cyp27, cyp8b1 and cyp2b10 was reduced in $Ctnnb1^{CAhep}$ mice. Similar results were obtained when exon 3 was removed in adult animals.
Conclusions: Expression of a dominant stable form of β-catenin in hepatocytes results in severe cholestasis and biliary type fibrosis.

ACTIVATION AND EPITHELIAL-TO-MESENCHYMAL TRANSITION OF BILIARY TREE STEM CELLS WITHIN PERIBILIARY GLANDS ARE INVOLVED IN THE PATHOGENESIS OF PRIMARY SCLEROSING CHOLANGITIS

G. Carpino[1], V. Cardinale[2], A. Renzi[3], J.R. Hov[4,5,6], T.H. Karlsen[4,5,6], D. Alvaro[2], E. Gaudio[3]. *[1]Department of Movement, Human and Health Sciences, University of Rome "Foro Italico", [2]Department of Medico-Surgical Sciences and Biotechnologies, [3]Department of Anatomical, Histological, Forensic Medicine and Orthopedics Sciences, Sapienza University of Rome, Rome, Italy; [4]Norwegian PSC Research Center, Department of Transplantation Medicine, Division of Cancer medicine, Surgery and Transplantation, [5]Research Institute of Internal Medicine, Division of Cancer medicine, Surgery and Transplantation, Oslo University Hospital Rikshospitalet, [6]K.G. Jebsen Inflammation Research Centre, Institute of Clinical Medicine, University of Oslo, Oslo, Norway*
E-mail: guido.carpino@uniroma1.it

Background and Aims: Primary sclerosing cholangitis (PSC) is characterized by fibrotic strictures of the extra-hepatic (EHBD) and/or intra-hepatic bile ducts (IHBD) leading to progressive cholestatic liver injury. The involvement of biliary tree stem cell (BTSC) compartment in the pathogenesis of PSC is virtually unknown. We investigated the BTSC compartment located in peribiliary glands (PBGs) of EHBDs and large IHBDs of human liver and its role in the development of the characteristic fibrosing PSC lesions.
Methods: Liver specimens containing EHBDs or large IHBDs were obtained from patients with PSC at different disease stages (n = 11) and, as controls, from normal livers (n = 6) and patients with primary biliary cirrhosis (n = 6). Specimens were processed for histology, immunohistochemistry and immunofluorescence.
Results: PSC is characterized by hyperplasia and mucinous metaplasia of PBGs that correlate with progression of the disease. PBG hyperplasia participates together with inflammation and fibrosis in determining the wall thickening of EHBD or large IHBD and is associated with the occurrence of dysplastic lesions. The increase of PBG mass is determined by the expansion of the BTSC transit-amplifying compartment, which sprout towards surface epithelium. In PSC, BTSCs and myofibroblasts generally display marked up-regulation of Hedgehog pathway markers. In ducts with onion-skin-like fibrosis, PBG cells express traits of epithelial-to-mesenchymal transition (EMT) co-localized with markers of Hedgehog pathway up-regulation and cellular senescence. PBGs were minimally affected in PBC.
Conclusions: BTSCs within PBGs are activated in the course of PSC, their proliferation being sustained by up-regulation of the Hedgehog pathway. BTSCs participate in the wall thickening of bile ducts and contribute, via EMT, to onion-skin-like fibrosis and thus the focal distribution of these lesions. PBG hyperplasia was associated with the occurrence of dysplasia in PSC and this could be involved in the development of cholangiocarcinoma in this disease.

P1146

RECURRENCE OF PSC AFTER LIVER TRANSPLANTATION IN THE NORDIC COUNTRIES

L. Lindström[1], A. Bergquist[2], K. Jörgensen[3], K. Boberg[3], P. Sangfelt[4], A. Rasmussen[5], H. Isoniemi[6]. *[1]Gastroenterology and Hepatology, Karolinska University Hospital, [2]Gastroenterology and Hepatology, Karolinska, Stockholm, Sweden; [3]Norwegian PSC research center, Clinic for specialized surgery and medicine, Oslo, Norway; [4]Gastroenterology and Hepatology, Medical Sciences Uppsala University, Uppsala, Sweden; [5]Surgical Gastroenterology Rigshospitalet, Copenhagen University Denmark, Copenhagen, Denmark; [6]Transplantation and liver surgery, Helsinki University central hospital, Helsinki, Finland*
E-mail: lina.lindstrom@karolinska.se

Background and Aims: Recurrence of primary sclerosing cholangitis (rPSC) has been reported to occur in about 20% of all

transplanted PSC patients. A number of riskfactors for recurrence have been described, but few findings have been consistent. In this study we aimed to identify and confirm riskfactors for rPSC in a large cohort of liver transplanted PSC patients.

Methods: All liver transplanted PSC patients in the Nordic countries (Denmark, Sweden, Norway, Finland) between 1984 and 2006 (n = 440) were included in the analysis. The diagnosis of recurrent PSC (rPSC) was based upon the Graziadei criteria. Risk factors for recurrence were assessed using a specific protocol, the Nordic liver transplant registry and a previous study database with extensive IBD data including immunosuppression, medical and surgical treatment for IBD. Survival data was analyzed using the Kaplan–Meier method, and risk factors for recurrence analyzed with uni- and multivariate Cox-regression analysis.

Results: We were able to include 313 patients in the final analysis; patients with no liver biopsy or cholangiography following transplantation (n = 70) were excluded from the study. For the survival analysis patients with follow up <6 months (n = 31) or cholangiocarcinoma in the explant (n = 26) were excluded. Patients with rPSC (n = 82; 26%) were significantly older than patients without rPSC (n = 231). The only risk factor associated to recurrence of PSC was age at transplantation; an intact colon did not influence the risk of developing rPSC, there was no difference in terms of gender, IBD or type of treatment after OLT. Patients with an intact colon at the time of transplantation had a significantly better survival (p = 0.04 Log Rank).

Conclusions: Recurrent PSC in the Nordic countries is more common than previously reported, with a rate of 26%. We found that age at transplantation is a risk factor for development of recurrent disease. An intact colon at transplantation is associated with a better long-term survival.

E-mail: m.h.harms@erasmusmc.nl

Background and Aims: Serum alkaline phosphatase (ALP) and bilirubin levels are characteristically elevated in primary biliary cirrhosis (PBC) and decrease of these levels is associated with improved prognosis. Therefore the criterion ALP <1.67×ULN together with bilirubin <1×ULN has recently been used as primary endpoint for evaluation of treatment of PBC patients in randomized controlled trials. However, validation of this response criterion is lacking. In the world's two largest independent PBC cohorts, from the national UK-PBC and the international Global PBC Study Group, we aimed to validate the use of ALP <1.67×ULN and bilirubin <1×ULN as a response criterion associated with improved prognosis.

Methods: Both cohorts are observational with long-term follow-up: the UK-PBC data is collected prospectively. The Global PBC data is a meta-analysis of individual patient data from established cohorts from 15 sites in 8 countries. The response criterion, ALP <1.67×ULN and bilirubin <1×ULN, was studied with Cox regression analyses in different settings, stratified by center and adjusted for age, sex, calendar time and use of ursodeoxycholic acid (UDCA). The endpoint was defined as liver transplantation (LTx) or liver-related death.

Results: Data from 4022 and 4845 PBC patients were included in this analysis. Median follow up time was 6.6 years (IQR, 3.3–11.1) in the UK-PBC cohort and 7.3 (IQR: 3.5–11.5) in the Global PBC cohort. 537 and 747 patients, respectively, reached the endpoint of LTx or liver-related death, in the two cohorts. In both cohorts the response criterion at 1-year follow up was

strongly associated with the endpoints (table), irrespective of sub-population. Especially for the sub-population including patients with an elevated bilirubin >1×ULN or an elevated ALP >1.67 at baseline, but with bilirubin <2×ULN, the HR of non-response versus response was above 3 and strongly significant. The analyses were repeated at different follow-up time points (2–5 years) in the Global PBC cohort and similarly strong associations were found.

Table: Hazard ratio (HR) for the endpoint: LT and liver related death of non-response versus response at 1 year follow-up

Population	UK-PBC				Global PBC			
	N	HR	95%CI	p-value	N	HR	95%CI	p-value
Total study population	4022	7.9	5.9–10.7	<0.0001	4845	4.2	3.3–5.2	<0.0001
UDCA treated	2775	10.7	6.9–16.8	<0.0001	4119	4.3	3.4–5.5	<0.0001
Untreated	712	6.2	4.1–9.3	<0.0001	640	3.3	1.6–6.2	0.0007
Male	335	2.7	1.18–6.3	0.012	497	2.4	1.3–4.6	0.008
Female	3152	8.9	6.5–12.4	<0.0001	4348	4.4	3.4–5.6	<0.0001
Age <55 years	1634	8.9	5.8–13.7	<0.0001	2431	4.7	3.3–6.6	<0.0001

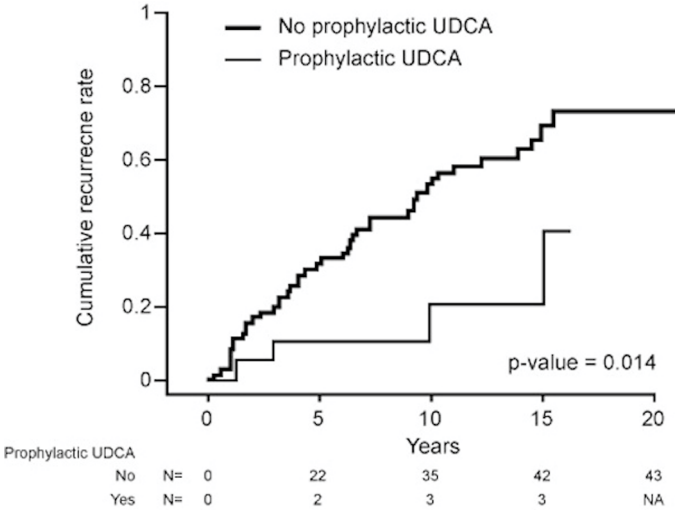
E-mail: christophe.corpechot@sat.aphp.fr

Background and Aims: Recurrence of primary biliary cirrhosis (PBC) after liver transplantation (LT) is not uncommon and can occasionally lead to severe graft dysfunction and retransplantation. Ursodeoxycholic acid (UDCA) is a safe and effective treatment for PBC. The aim of this study was to determine whether routine administration of UDCA after LT could affect the incidence of PBC recurrence.
Methods: All patients who had undergone LT for PBC in 5 French and Swiss centers from 1988 to 2010 were retrospectively studied. A minimal follow-up of one year after LT was required to be included. Recurrences of PBC were biopsy-proven. In all centers, biopsies were routinely performed at 1, 5, 10, 15, 20 and 25 years of follow-up, and at any time when clinically indicated. The patients from a single French center were administered UDCA (13–15 mg/kg/d) in routine as a non-specific protective measure started at the time of LT. The patients from the other centers were treated with UDCA only in case of proven recurrence.
Results: A total of 90 patients (women: 86%; mean age at LT: 54 years) fulfilled inclusion criteria, including 19 (21%) who were receiving UDCA since LT. The mean follow-up was 12 yrs. Recurrence was diagnosed in 48 (53%) patients. The mean number of biopsies and the mean follow-up did not differ according to the recurrence or UDCA statuses. The median time for recurrence was 6 yrs. Cumulative incidence of recurrence was 27%, 47%, 61%, and 68% at 5, 10, 15, and 20 years, respectively. The risk of recurrence differed neither in recipient and donor characteristics nor in calcineurin inhibitor (cyclosporine vs. tacrolimus) regimens. In univariate and multivariate Cox models, routine administration of UDCA was the only factor that significantly affected the risk of recurrence (HR: 0.31; 95% CI: 0.11–0.85; p = 0.014; figure). Although 7 (15%) patients with recurrence progressed to graft cirrhosis, requiring retransplantation in one, neither recurrence nor routine administration of UDCA had a significant impact on survival.
Conclusions: This study strongly suggests that routine administration of UDCA after LT could prevent recurrence of PBC. This supports the extended use of UDCA as prophylaxis for PBC recurrence after LT.



P1149

PURIFIED MESENCHYMAL STROMAL CELLS REDUCE LIVER DAMAGE IN AN ALLO-IMMUNE MODEL OF LIVER DAMAGE (OVA-BIL)

D.D. Houlihan[1], S. Suresh[1], S. Zhang[2], A. Owen[1], L. Hopkins[1], M.C. Strachan[3], S. Dyer[3], K. Attridge[3], L. Walker[3], W. Wei[3], M. Griffiths[3], A. Hollander[2], J. Frampton[3], P.N. Newsome[1]. *[1]Centre for Liver Research, University of Birmingham, Birmingham, [2]University of Bristol, Bristol, [3]University of Birmingham, Birmingham, United Kingdom*
E-mail: P.N.Newsome@bham.ac.uk

Background and Aims: The ability of mesenchymal stromal cells (MSC) to immumomodulate may have clinical relevance in immune-mediated liver damage. Inherent heterogeneity of unsorted MSC populations and impact of prolonged passage in culture may explain varied/reduced function in other settings. We set out to study the biology of a purified MSC population and impact of cytokine priming on their function.
Methods: FACS sorted MSC (PDGFRa Sca-1$^+$; PaS) were isolated from bone marrow (BM) of C57Bl/6 & BALB/c mice and their proliferation, karyotyping and trilineage differentiation studied over passage. This included *in vitro* (suppression of proliferation of co-cultured stimulated CD4$^+$CD25$^-$ T cells) and *in vivo* immunomodulation

studies (Ova-Bil model of allo-immune liver injury). Impact of cytokine priming (FGF2, $TGFb_1$, PDGF-BB) on action of PaS cells was studied.

Results: Medium passage (P3–5) PαS cells cultured in standard media differentiate to bone, cartilage and fat *in vitro* and reduce liver damage in the Ova-Bil model. Cells demonstrated colony forming capacity (CFU-F)/proliferation, although this slowed over passage with expression of senescence-associated β-galactosidase (from <3% to >40%). Simultaneously, late passage cells lost ability of adipogenic/chondrogenic differentiation, ability to suppress T cell proliferation *in vitro* and ability to reduce liver damage in the Ova-Bil model (Figure 1). To overcome this PαS cells were primed with cytokines known to govern MSC proliferation and differentiation (FGF2, PDGF-BB or $TGFβ_1$). Microarray analysis revealed marked differential upregulation of key adipogenic, chondrogenic and osteogenic transcripts between groups. Proliferation of PαS cells was higher with FGF, PDGF, and $TGFb_1$. $TGFb_1$ supplemented cells had attenuated tri-lineage differentiation, but displayed a prolonged ability to immunosuppress *in vitro* and *in vivo* compared with untreated cells (Figure 1). Numbers of liver-infiltrating CD4 and CD8 cells (of both donor derived OT1/OT2 and recipient origin) were reduced after infusion of MSC primed with $TGFb_1$. Detailed karyotypic analyses revealed no significant abnormalities of treated cells.

Conclusions: Purified (PαS) MSC are potent immunomodulators, although in keeping with unsorted MSC, function is lost with passage. Indiscriminate priming with cytokines can reduce immunomodulatory function of MSC, with only $TGFb_1$prolonging their immunosuppressive function in a model of allo-immune liver damage.

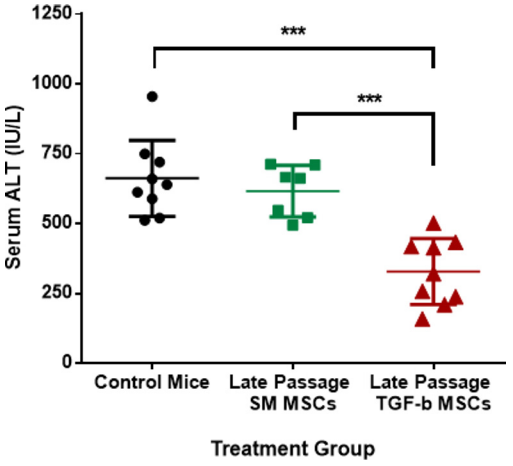


Figure 1.

P1150
CHARACTERIZATION AND OUTCOME OF 93 PATIENTS WITH ISCHEMIC-LIKE CHOLANGIOPATHY WITH SECONDARY SCLEROSING CHOLANGITIS

G.I. Kirchner[1], E. Klingsiek[1], M.N. Scherer[2], M. Loss[2], C. Gelbmann[1], H.-J. Schlitt[2], J. Hartl[1]. *[1]Internal Medicine I, [2]Surgery, University Hospital of Regensburg, Regensburg, Germany*
E-mail: Gabriele.Kirchner@klinik.uni-regensburg.de

Background and Aims: Sclerosing cholangitis in critically ill patients (SC-CIP) with sepsis and ARDS is a cholestatic liver disease, which is characterized by progressive sclerosis of the biliary tree, biliary casts and infection. Until now, little is known about the risk factors and outcome of SC-CIP patients.

Methods: At the University Hospital of Regensburg medical records of 93 patients (f=16, m=77) with SC-CIP were evaluated (between 2002 and 2014). The following parameters were analyzed: cause of sepsis, duration of mechanical ventilation, duration of ICU treatment, age at diagnosis of SC-CIP, microbiology results, time point of diagnosis by ERCP, body weight, survival data, cause of death, and other parameters.

Results: In all patients SC-CIP was diagnosed by ERCP and 81% of patients had Enterococcus in the bile. Age at SC-CIP diagnosis was 56+15 years. Causes of sepsis were polytrauma (28%), post-operative complications (28%) or internal morbidities (44%). The duration on the intensive care unit (ICU) was 48±30 days, and duration of respiratory ventilation was 32±19 days. 46% of patients were temporary on hemodialysis. The mean follow-up was 30±39 months. Twenty-four patients underwent liver transplantation. The 1- and 5-year-survival of all SC-CIP patients was 48% and 34%, respectively. Causes of death were: sepsis (79%), cardiac insufficiency (7%), malignancy (7%), and hemorrhagic shock (7%).

Conclusions: SC-CIP must be kept in mind in icteric patients with sepsis and long-term ICU therapy. ERCP is the gold standard for diagnosis of SC-CIP. The prognosis of SC-CIP is unfavourable. LT is the only curative treatment of SC-CIP.

P1151
GENETIC VARIANTS OF UDP-GLUCURONOSYLTRANSFERASE (UGT) 1A GENES MODIFY THE PRESENTATION AND DISEASE PROGRESSION IN PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS

T.J. Weismüller[1], S. Kalthoff[1], H. Lenzen[2], M.P. Manns[2], C.P. Strassburg[1]. *[1]Department of Internal Medicine 1, University of Bonn, Bonn, [2]Department of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany*
E-mail: tobias.weismueller@gmx.de

Background and Aims: Primary sclerosing cholangitis (PSC) is a chronic progressive cholestatic liver disease with unknown pathogenesis and without a curative medical therapy. The human UDP-glucuronosyltransferases 1A (UGT1A) play a major role in the detoxification and elimination of bilirubin, bile acids and a number of xenobiotics linked to inflammation and tumorigenesis. The relationship between genetic *UGT1A* variants and the course and outcome of PSC has not yet been analyzed.

Methods: A large cohort of German PSC patients with a long-term-follow-up was genotyped for *UGT1A* variants (SNPs) including UGT1A1*28, UGT1A3 −66 T>C, and UGT1A7 p.N129K/p.R131K usingTaqMan-5′-nuclease-assays. The results were correlated with clinical characteristic and the transplant-free survival of the patients.

Results: 328 patients with well characterized and documented PSC were included into the study (70.1% male, mean age at diagnosis 32.6 years, 69.1% with IBD). The mean transplant free survival time was 15.6 years. Patients with wild-type alleles of all three *UGT1A* genes (n = 44) had a significantly longer transplant free survival (19.6 years vs. 14.3 years, p = 0.042, log-rank-test) than patients carrying a homozygous or heterozygous SNP variant in at least one of the *UGT1A1*, *UGT1A3* or *UGT1A7* genes (n = 284). Additionally, we found that the patients carrying wild-type alleles of all three *UGT1A* genes had a lower serum-bilirubin (25 vs. 38 μmol/l, p = 0.023) and serum-cholesterol (195 vs. 223 mg/dl, p = 0.033) at first presentation. Furthermore inflammatory bowel disease was found to be associated with wild-type UGT1A alleles (81.8% vs. 67.1%, p = 0.0499).

Conclusions: This large cohort shows an association with SNP variants of the *UGT1A1, UGT1A3* and *UGT1A7* genes and outcome in PSC. A recently described *UGT1A* variant haplotype, present as a homozygous trait in 10% of the population and leading to impaired glucuronidation of xenobiotics capable of driving inflammatory reactions and carcinogenesis is implicated as a risk factor for the progression of PSC. Higher bilirubin levels may be associated with UGT1A1*28 alleles responsible for Gilbert's syndrome. Thus, *UGT1A*

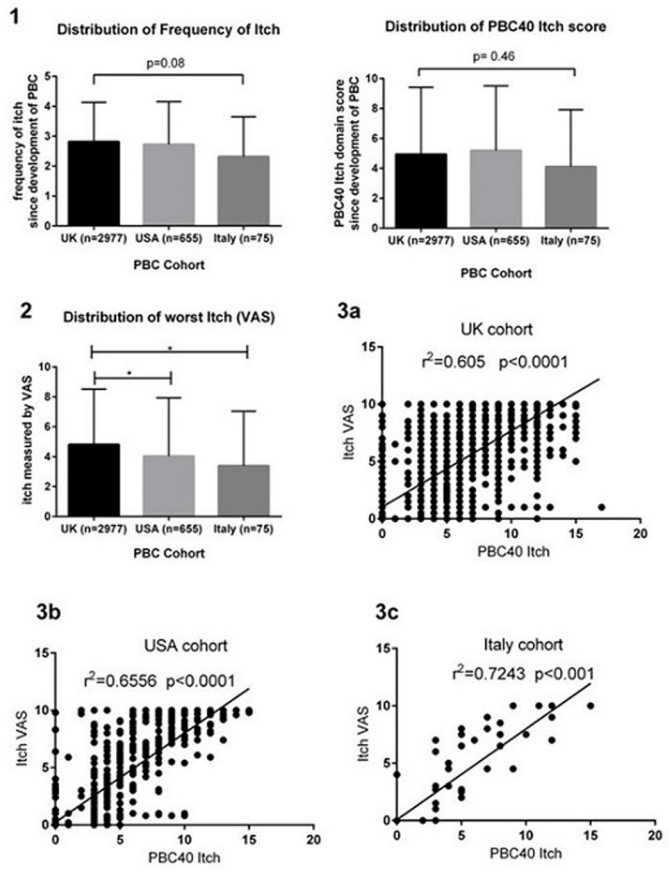
variants may represent a tool for the prognostic stratification of PSC patients and link disease progression in PSC to the regulation of detoxification by glucuronidation.

P1152

A COMPARATIVE STUDY OF PRURITUS IN PBC COHORTS FROM UK, USA AND ITALY

V.S. Hegade[1], G.F. Mells, on behalf of UK-PBC Consortium[2], C. Lammert[3], B. Juran[4], A. Lleo[5], M. Carbone[5], K. Lazaridis[4], P. Invernizzi[5], S. Kendrick[1], R. Sandford[2], G. Hirschfield[6], D.E. Jones[1].
[1]Institute of Cellular Medicine, Newcastle University, Newcastle, [2]Academic Department of Medical Genetics, University of Cambridge, Cambridge, United Kingdom; [3]Division of Gastroenterology and Hepatology, Indiana University, Indianapolis, [4]Mayo Clinic, Rochester, United States; [5]Liver Unit and Center for Autoimmune Liver Diseases, Humanitas Clinical and Research Center, Milan, Italy; [6]Centre for Liver Research, Institute of Biomedical Research, University of Birmingham, Birmingham, United Kingdom
E-mail: vinod.hegade@ncl.ac.uk

Background and Aims: Pruritus (itch) is a common problem in cholestatic liver diseases such as Primary Biliary Cirrhosis (PBC). There are limited studies of 'real-life' experience of cholestatic itch and its treatment in international cohorts. Colestyramine is the recommended first line therapy for cholestatic pruritus. We aimed to compare pruritus experienced by PBC patients from UK, USA and Italy to: (1) understand the prevalence of pruritus in PBC in each cohort, (2) report the frequency of anti-pruritic treatments received by PBC patients from their local health care, (3) study any differences in the frequency and intensity of pruritus between the cohorts and (4) assess the correlation between measures of itch intensity in each cohort.
Methods: This was a cross-sectional study of experience of itch reported by PBC patients without a liver transplant from UK, Mayo clinic (USA) and Italy. Data were collected on frequency of itch (never, rarely, occasionally, frequently, all the time), PBC-40 itch score, intensity of worst itch measured using a 0–10 visual analogue scale (VAS) and treatment received for their itch since diagnosis of PBC. We defined persistent itch as pruritus occurring 'frequently' or 'all the time' and severe itch as persistent itch with a combination of itch score of more than 8 on VAS.
Results: Data were available for 2977 PBC patients from UK, 655 from USA and 75 patients from Italy. 2076 (70%) UK, 445 (68%) USA and 45 (60%) Italy patients had experienced itch at some point in their illness. Of these, persistent itch was reported by 32% (UK), 34% (USA) and 27% (Italy) patients and severe itch by 15% of UK & USA and 13% of Italy patients. Patients with severe itch in UK, USA and Italy reported to have received treatment with colestyramine in 50%, 35% and 30% cases and rifampicin in 16%, 18% and 20% cases respectively. Figures 1 and 2 show the main results of comparison of cohorts ($^*p < 0.05$) and Figures 3a–c show significant correlation between measures of itch intensity in each cohort.
Conclusions: This comparative study of three independent international PBC cohorts suggests prevalence of pruritus in PBC is 60% to 70% of which nearly a third suffer with persistent itch and up to 15% experience severe itch. UK patients had higher scores for severity of worst itch since development of PBC. Treatment of itch in PBC patients appeared unsatisfactory in all three cohorts as more than half of patients with severe itch had not received the first line therapy.



P1153

ACUTE AUTOIMMUNE HEPATITIS INCREASES SECONDARY BILE ACIDS RESULTING IN INTESTINAL APOPTOSIS, INFLAMMATION, AND MUCOSITIS IN GROUP VIA CALCIUM-INDEPENDENT PHOSPHOLIPASE A2 KNOCKOUT MICE

L. Jiao[1], H. Gan-Schreier[1], S. Tuma-Kellner[1], W. Stremmel[1], W. Chamulitrat[1]. *[1]University Heidelberg HospitalInternal Medicine IV, Heidelberg, Germany*
E-mail: walee.chamulitrat@med.uni-heidelberg.de

Background and Aims: Chronic bowel disease can co-exist with severe autoimmune hepatitis (AIH) in the absence of PSC. Genetic background may contribute to these overlap syndromes. We previously have shown that the deficiency of group VIA iPLA2 (iPLA2β) causes an accumulation of hepatocyte apoptosis, and renders the susceptibility for endotoxin acute liver injury. We here tested whether AIH induction in the liver in iPLA2β-deficient mice could result in intestinal injury, and whether bile acid toxicity could be involved.
Methods: Control (WT) and iPLA2$\beta^{-/-}$ female mice at 12 months old were intravenously injected with 10 mg/kg concanavalinA (ConA) or saline for 24 h. A profile of 15 bile acids was measured by LC/MS-MS. Functional assays included liver enzymes, Western blot analysis, qRT-PCR, histology and immunohistochemistry.
Results: Whole-body deficiency of iPLA2β led to a complete absence of this gene in liver and intestine. ConA treatment of iPLA2$\beta^{-/-}$ mice markedly increased liver enzymes, hepatic necrosis, fibrosis with α-smooth muscle actin activation, and biliary ductal reaction in a greater extent than that of treated WT mice. This was concomitant with increases of toxic secondary bile acids including lithocholic, deoxycholic, and chenodeoxycholic acids in liver. Interestingly, the levels of all bile acids were increased and decreased, respectively, in vena cava blood and jejunum of ConA-treated mutants compared with treated WT. While not affecting the duodenum of WT mice, ConA treatment of the mutant mice caused severe villous shortening and atrophy which was associated with increased apoptosis and the proliferation marker Ki67 on periportal lymphocytes. With a greater extent than in WT, ConA treatment of mutant mice increased jejunal expression of pro-inflammatory cytokines TNF-α, IL-6, and SOCS3 as well as chemokines CCL2 and

the receptor of CCL3, CCR5. The observed increased inflammation was concomitant with increased number of mucin-containing goblet cells in the duodenum and ileum, and this was associated with increased expression of a regulator of mucositis Krüppel-like factor 4.

Conclusions: iPLA2β deficiency renders susceptibility for AIH assoicated with increases of hepatic secondary bile acids which could induce intestinal mucosal damage, and hepatic and intestinal damage could in turn lead to an elevation of bile acids in the periphery. Thus, our experimental model demonstrates that AIH in a susceptible host such as with iPLA2β deficiency may lead to enteropathy via bile acid toxicity.

P1154

PRE-TREATMENT SERUM VITAMIN D STATUS IS ASSOCIATED WITH SUBSEQUENT RESPONSE TO UDCA IN PBC

X. Zhou[1], G. Guo[1], Y. Han[1], Y. Shi[1]. [1]*Division of Hepatology, Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Xi'an, China*
E-mail: zhouxmm@fmmu.edu.cn

Background and Aims: Vitamin D is always linked with primary biliary cirrhosis (PBC) for bone complication in the patients. However increasing evidences suggest a non-skeletal role of vitamin D in various autoimmune or liver diseases. We performed this study to investigate the clinical relevance of vitamin D level in PBC, especially the association with therapeutic effects of ursodeoxycholic acid (UDCA).

Methods: Consecutive PBC patients were retrospectively studied. 25-hydroxyvitamin D [25(OH)D] levels were determined by pre-treatment frozen serum samples. Response to UDCA was evaluated by Paris-I and Barcelona criteria respectively. Logistic regressions were performed to identify treatment response associated parameters.

Results: Of 98 patients, the mean serum 25(OH)D concentration was 17.9±7.6 ng/mL. 25(OH)D levels decreased with increasing histological stage ($p = 0.029$) and negatively correlated with bilirubin, alkaline phosphatase and Mayo risk score. After one year of UDCA therapy, 31 patients failed to achieve complete response according to Paris-I criteria. Baseline 25(OH)D level was significantly lower in non-responders (14.8±6.4 vs. 19.3±7.6 ng/mL, $p = 0.005$). In multivariate analysis, vitamin D deficiency at baseline increased the risk of incomplete response, independently from elevated bilirubin and ALP values and advanced stages (OR = 3.93, 95% CI=1.02–15.19, $p = 0.047$). Similar results were obtained when biochemical response was evaluated by Barcelona criteria.

Conclusions: 25(OH)D level is associated with biochemical and histological features in PBC. Pre-treatment vitamin D status independently related to subsequent response to UDCA. Our results suggest adequate 25(OH)D levels may be helpful to improve response to UDCA and supplementation of vitamin D is worth considered, not only for preventing osteoporosis in the patients.

P1155

FXR AGONISM WITH OBETICHOLIC ACID MAY ATTENUATE BONE MINERAL DENSITY DECREASE IN SUBJECTS WITH PRIMARY BILIARY CIRRHOSIS

A. Pares[1], R. Pencek[2], Y. Peters[2], T. Marmon[2], L. MacConell[2], L. Adorini[2], D. Shapiro[2], M. Trauner[3], D. Jones[4]. [1]*Liver Unit, Hospital Clinic, IDIBAPS and CIBERehd, University of Barcelona, Barcelona, Spain;* [2]*Intercept Pharmaceuticals, Inc, San Diego, United States;* [3]*Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria;* [4]*Institute of Cellular Medicine, Newcastle University, Newcastle-upon-Tyne, United Kingdom*
E-mail: pares@ub.edu

Background and Aims: Osteoporosis occurs frequently in subjects with primary biliary cirrhosis (PBC). The farnesoid X receptor (FXR) expressed in bone has been shown to positively regulate bone osteogenesis in mice (Cho 2013). Obeticholic acid (OCA), a farnesoid x receptor agonist being developed for the treatment of PBC, produced significant improvements in indices of hepatic damage and function as well as markers of inflammation and cholestasis in the phase 3 POISE trial. This analysis evaluated the effect of OCA compared to placebo on bone mineral density (BMD).

Methods: Subjects with PBC ± UDCA (if taking UDCA patients were maintained on a stable dose) with ALP ≥1.67×ULN or bilirubin <2×ULN were randomized to PBO, OCA 5 or 10 mg for 12 months. Subjects on 5 mg were titrated to 10 mg after 6 months (OCA Titration) as clinically indicated. Dual-emission X-ray absorptiometry (DEXA) scan was used to assess BMD in a subset of subjects prior to and following 12 months of OCA or placebo treatment. Results of the femoral neck and lumbar spine (using T-score, Z-score, and BMD) were summarized. Changes from baseline at Month 12 were analyzed using an ANCOVA model with baseline values as a covariate. Osteopenia and osteoporosis were based on WHO thresholds: T score −1.0 to −2.5 and ≤−2.5, respectively.

Results: Of 216 subjects enrolled in the trial, 122 had DEXA scans at baseline and Month 12 (85% female; 22% ≥65 years of age; 52% postmenopausal). Baseline ALP was 318±102 U/L and 91% of subjects took concomitant UDCA. At baseline the prevalence of osteopenia and osteoporosis was 7% and 54%, respectively. Placebo subjects had a significant decrease in femoral T-scores ($p = 0.03$) and a reduction was also detected for 10 mg OCA ($p = 0.01$). OCA-treated subjects had significantly smaller decreases in femoral T-scores relative to placebo ($p < 0.05$). No significant differences from baseline or between treatment groups were seen in Lumbar BMD. Results were generally consistent but did not attain statistical significance when assessed based on menopausal status.

Conclusions: Individuals with PBC are at increased risk for osteopenia, osteoporosis and bone fractures. This preliminary analysis of BMD in subjects treated with OCA suggests that OCA may attenuate the deterioration in femoral T scores in subjects with PBC and merits further study of the effects of this drug in preventing bone loss and its complications.

PROGNOSTIC VALUE OF LIVER HISTOLOGY IN AUTOIMMUNE HEPATITIS

L. Puustinen[1], H. Mustonen[2], P. Arkkila[1], S. Boyd[3], J. Arola[3], M. Färkkilä[1]. *[1]Department of Medicine, [2]Department of Surgery, [3]Department of Pathology, Helsinki University Central Hospital, Helsinki, Finland*
E-mail: lauri.puustinen@helsinki.fi

Background and Aims: Liver byopsy is recommended at diagnosis of autoimmune hepatitis and during follow-up. The data on the prognostic value of baseline liver biopsy and the sequential histology is either controversial or scanty.
The aims of the study are to evaluate the prognostic value of liver biopsy at time of diagnosis and during the disease at follow-up of autoimmune hepatitis.
Methods: All 98 patients from our hospital registry, with probable or definite autoimmune hepatitis from years 1995–2012 were studied. 66 percent had multiple liver biopsies and total follow-up was 818 patient years. A multivariate analysis was performed in order to find significant parameters which could predict patient survival, progression of fibrosis, and development of histological or clinical cirrhosis.
Results: At time of diagnosis, only seven percent of patients were cirrhotic. 52 percent of patients had concomitant autoimmune diseases. The only histological findings that predicted fibrosis progression were the total inflammation score (OR 6.22, CI 1.21–31.87, p = 0.028) and eosinophilic infiltration (OR 4.64, CI 1.08–20.01, p = 0.040). Women had an increased risk for fibrosis progression (OR 6.1, CI 1.2–30.8, p = 0.029). Risk for cirrhosis development was lower in men, HR 0.07, CI 0.01–0.42, p = 0.004. Patients with fibrosis stage 3–4 had remarkable greater risk for developing clinical cirrhosis than patients with fibrosis 1 and 2, HR 53.65, CI 7.49–384.18, p = 0.001 vs HR 6.84, CI 1.16–40.32, p = 0.03 and HR 3.39, CI 0.62–18.49, p = 0.018, respectively. Total inflammation (HR 64.2, CI 3.8–1082.7, p = 0.004), rosette formation (HR 8.03, CI 1.89–34.16, p = 0.005), and acute cholestasis (8.74, CI 1.73–44.09, p = 0.009) at baseline liver histology predicted development of cirrhosis. Amount of necrosis had no impact on fibrosis or cirrhosis progression. None of the patients with histological pericholangitis or granulomas developed cirrhosis and only one patient had progressive fibrosis during follow-up.
Conclusions: The baseline liver histology at diagnosis provides important prognostic information of cirrhosis development and fibrosis progression. Female gender, stage of liver fibrosis, degree of inflammation, especially rosette formation, predicted fibrosis progression and cirrhosis. No association was found between follow-up biopsy findings and patients' prognosis or probability of developing cirrhosis.

P1158

DOES A NORMAL IgG INDICATE HISTOLOGICAL REMISSION IN AUTOIMMUNE HEPATITIS (AIH)?

V.M. Gordon[1], A.K. Dube[2], E. Mcfarlane[1], M.A. Karajeh[1], D.C. Gleeson[1]. *[1]Liver Unit, [2]Histopathology, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom*
E-mail: vikki_gordon@hotmail.com

Background and Aims: Response to immunosuppressive treatment in AIH is often monitored by measurement of serum immunoglobulin G (IgG) as well as ALT. It is commonly assumed that serum IgG level correlates with histological activity (or Ishak necroinflammatory score: NIS) on liver biopsy, the historical "gold standard". However, only one group (Luth et al. 2008; J Clin Gastro 42(8): 926–930) have examined this relationship, finding that normalisation of both serum ALT and IgG reliably predicted a NIS of <6 but not a NIS of <4 (corresponding to minimal hepatitis, seen in less than half of the patients presumed to be in remission). Here, we aimed to reassess how well serum IgG correlated with NIS in treated patients with AIH undergoing follow-up biopsy for confirmation of disease remission.
Methods: We assessed 34 follow-up biopsies, performed to confirm histological remission in 28 patients with AIH (International Group criteria; Alvarez J, Hepatol 1999; 31: 929) on immunosuppressive treatment and an accompanying serum IgG (measured within 6 weeks of biopsy).
Results: For 32 of the 34 follow-up biopsies, accompanying serum IgG was in the normal range (≤16 g/L). However, only 13 of these 34 (38%) biopsies showed NIS <4 (minimal hepatitis). On ROC analysis, area under the curve (AUC) for IgG in predicting a NIS of ≥4 (n = 34) was 0.557 (p = 0.583). Sensitivity and specificity of IgG (cut off >16 g/L) in predicting a NIS of ≥4 were 5% and 92% respectively. Corresponding positive (PPV) and negative (NPV) predictive values were only 50% and 38% respectively. AUC for change in IgG (ΔIgG: baseline values minus values accompanying follow up biopsy; n = 33) in predicting NIS ≥4 was 0.571 (p = 0.501). Defining histological remission instead as *minimal or mild* hepatitis – NIS <6 (as Luth's group did because they found that such patients did not develop fibrosis progression), there were still 4/34 patients (12%) with normal serum IgG who were not in histological remission. On ROC analysis, AUC for IgG in prediction of NIS ≥6 on follow-up biopsy (n = 34) was 0.655 (p = 0.274). PPV and NPV for serum IgG (cut off >16 g/L) in predicting NIS ≥6 were 50% and 88% respectively. AUC for ΔIgG in prediction of NIS ≥6 was 0.586 (p = 0.547).
Conclusions: In treated patients with AIH, normalisation of serum IgG is *not* reliably predicative of histological remission. Confirmation of remission still requires a follow-up liver biopsy.

P1159

IDENTIFICATION OF SERUM METABOLITES ASSOCIATED WITH CHOLESTATIC PRURITUS

A. Pares[1], D. Balgoma[2], A. Reig[1], I. Martinez-Arranz[2], A. Castro[2], A. Mas[1]. *[1]Liver Unit, Hospital Clínic, CIBERehd, IDIBAPS, University of Barcelona, Barcelona, [2]OWL Metabolomics, Parque Tecnológico de Bizkaia, Derio, Spain*
E-mail: pares@ub.edu

Background and Aims: The pathogenesis of pruritus, a common and disabling symptom in patients with chronic cholestasis, is unknown but recently itching has been associated with increased levels of lysophosphatidic acid and some bile acids. Moreover, earlier analysis selected a metabolomic profile of itching. Therefore, we have expanded our analyses by measuring the serum concentration of these potential metabolites to better identify those associated with pruritus.
Methods: Serum samples were obtained from 85 patients with primary biliary cirrhosis, 21 with pruritus and 64 without pruritus. All patients received ursodeoxycholic acid (13–16 mg/kg/d) for the duration of the disease which was similar in the two groups (8.3±1.4 years). Methanol serum extracts were analyzed using an ultra performance liquid chromatography-time-of-flight-MS based platform. Then, 45 lipids were quantified according to an appropriate internal standard, including fatty acyls, bile acids, and lysoglycerophospholipids.
Results: Most analytes were elevated in the patients with pruritus as compared with those without. Pamitoyl-L-carnitine, bile acids, particularly primary bile acids (tauro and glycochenodeoxycholic), fatty acids (linoleic, octadecatrienoic, arachidonic, eicosatetraenoic, docosapentaenoic, dodecanoic, myristoleic, 15-HETE-hydroxy-eicosatetraenoic), lysophosphatidyl-cholines (myristoyl, pentadecanoyl, heptadecanoyl, hexadecyl, 1-O-octadecyl), lysophosphoethanolamines (tetradecanoyl and hexadecanoyl), lysophosphoinositol (palmitoyl, and oleoyl), N-acyl ethanolamides (palmitoyl and oleoyl) and pregnenolone sulfate were significantly higher in patients with pruritus. The

multivariate analyses identified, however, taurochenodeoxycholic acid (2.85±0.76 *vs* 0.40±0.29 μM, p < 0.001), 1-myristoyl-2-hydroxy-sn-glycero-3-phosphocholine (2.38±0.31 *vs* 1.33±0.07 μM, p < 0.0001), and docosapentaenoic acid (1.15±0.46 *vs* 0.20±0.02 μM, p < 0.0001), as the analytes independently associated with pruritus.

Conclusions: Pruritus in patients with primary biliary cirrhosis is associated with marked changes in the circulating concentration of different analytes, thus identifying one bile acid, one lysophosphatidylcholine and a free fatty acid as the major potential triggers of itching of cholestasis.

P1160

ANTI-GP210 ANTIBODY IS A SEROLOGICAL MARKER FOR THE PROGRESSION TO END-STAGE ENLARGED LIVER WITH MICRONODULAR CIRRHOSIS IN PRIMARY BILIARY CIRRHOSIS

M. Nakamura[1], A. Mori[2], T. Tanaka[3], N. Yamashiki[3], K. Shirabe[4], Y. Maehara[4], N. Kokudo[5], S. Uemoto[2], S. Aishima[6]. *[1]Clinical Research Center, National Hospital Organization (NHO) Nagasaki Medical Center, Department of Hepatology, Nagasaki University Graduate School of Biomedical Sciences, Omura, [2]Division of Hepato-Biliary-Pancreatic and Transplant Surgery, Graduate School of Medicine, Kyoto University, Kyoto, [3]Organ Transplantation Service, The University of Tokyo, Tokyo, [4]Department of Surgery and Science, Kyushu University Graduate School of Medical Sciences, Fukuoka, [5]Hepatobiliarypancreatic Surgery Division, Artificial Organ and Transplantation Division, The University of Tokyo, Tokyo, [6]Department of Pathology, Medical Department of Saga University, Saga, Japan*
E-mail: nakamuram@nagasaki-mc.com

Background and Aims: We previously reported that explanted livers from patients with primary biliary cirrhosis (PBC) at the time of liver transplantation (LT) were morphologically classified into non-cirrhotic, macronodular, mixed nodular, and micronodular cirrhosis. In addition, we previously reported that positive anti-gp210 antibodies is a strong risk factor for the progression to end-stage hepatic failure in Japanese patients with PBC. However, the association of cirrhotic pattern with anti-gp210 antibodies has not been determined.

Methods: A total of 47 PBC patients (female 45, male 2), in whom the sera before or at the time of LT (age 32–69, median 55 years) were available, were registered from June 2010 to July 2014. Anti-mitochondrial antibodies (AMA), anti-gp210 and anti-centromere antibodies were measured by ELISA. The biochemical and immunological data were compared among 4 different types of cirrhosis.

Results: AMA, anti-gp210 and anti-centromere antibodies were positive in 80.9%, 59.6% and 19.1% of the enrolled 47 patients, respectively. The explanted livers were classified into non-cirrhotic (n = 3), macronodular (n = 9), mixed nodular (n = 9), and micronodular (n = 26) cirrhosis. There were significant differences between micronodular and macronodular cirrhosis in age at liver transplantation (53.5±5.6 vs 59.0±6.1, p = 0.0242), ratio of explanted liver volume to standard liver volume (ELV/SLV) (1.28±0.49 vs 0.79±0.12, p = 0.0097), ALP (743.8±523.5 vs 302.5±73.0 IU/ml, p = 0.017), IgG (2392.0±825.5 vs 1694.7±590.1 mg/dl, p = 0.027) and the positivity of anti-gp210 antibodies (76.9% vs 22.2%, p = 0.0060). The values of these variables in mixed nodular cirrhosis were between those of micronodular and macronodular cirrhosis.

Conclusions: These results indicate that there are two different types of PBC progression to end-stage hepatic failure, enlarged liver with micronodular cirrhosis and atrophic liver with macronodular cirrhosis, and that the former type of progression is represented by positive anti-gp210 antibodies which is a risk factor for more severe bile duct loss, interface hepatitis, and poor biochemical response to treatment. The underlying mechanism for anti-gp210 negative-type progression to end-stage hepatic failure remains to be clarified.

P1161

ROLE OF PNPLA3 FOR CHOLESTATIC LIVER AND BILE DUCT INJURY IN MICE

R. McMahon[1], T. Claudel[1], C. Fuchs[1], E.E. Kershaw[2], M. Trauner[1]. *[1]Hans Popper Laboratory for experimental Hepatology, Division of Gastroenterology and Hepatology, Internal Medicine III, Medical University of Vienna, Vienna, Austria; [2]Division of Endocrinology and Metabolism, Department of Medicine, University of Pittsburgh, Pittsburgh, United States*
E-mail: robert.mcmahon@meduniwien.ac.at

Background and Aims: PNPLA3 belongs to a novel group of nutritional controlled lipid metabolizing enzymes known as the patatin-like phospholipase domain-containing (PNPLA) family. PNPLA3 has triglyceride hydrolase and/or lysophosphatidic acid acyltransferase activities. One genetic variant of PNPLA3, the I148M isoform, is strongly associated with non-alcoholic fatty liver disease (NAFLD) and progression towards fibrosis and cirrhosis in humans. Additionally, recent data indicate that the I148M correlates with susceptibility to progression of cholangiopathies such as PSC. Therefore we endeavoured to test whether the absence of PNPLA3 mitigates or exaggerates cholestatic liver, bile duct injury and biliary fibrosis induced by bile duct ligation (BDL) or 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) feeding as mouse models of sclerosing cholangitis.

Methods: PNPLA3 Knockout (KO) and control mice (WT) were fed either normal chow or 0.1% DDC chow for 12 days. Additionally a cohort of KO and WT mice were subjected to BDL for 7 days.

Results: PNPLA3 is expressed in mouse primary cholangiocytes at levels comparable to hepatocytes (Ct value 29.8 and 27.6 respectively). At baseline WT and KO mice had no changes in bile flow and composition. After BDL both WT and KO mice had similar increases in liver weight/body weight ratios compared to controls whereas DDC feeding induced no liver weight changes. Increases of serum ALT, AST, bile acids, bilirubin and alkaline phosphatase were observed in both WT and KO mice post DDC feeding and BDL, but the differences between the treated groups were not significant. Liver histology/immunohistochemistry illustrated DDC feeding and BDL caused increases of collagen deposition, inflammation and ductular proliferation but no differences were observable between genotypes. Furthermore, DDC feeding significantly induced Cyp2b10, Cyp3a11, OSTβ and MRP3 mRNA expression in WT and KO mice but to similar levels. Additionally, markers of fibrosis, inflammation and biliary damage (i.e. Col1a1, IL6, F4/80, VCAM1, CK19) were increased at both the mRNA and protein levels in response to cholestatic injuries (BDL, DDC) but again differences were not significant between WT and KO mice.

Conclusions: Lack of PNPLA3 in mice does not mitigate or exaggerate DDC feeding or BDL induced cholestasis, hepatic inflammation, ductular proliferation and biliary fibrosis indicating that PNPLA3 may not play a role in cholangiocytes during cholestatic liver and bile duct injury.

P1162

MULTI-CENTRE AUDIT OF MANAGEMENT AND OUTCOME IN AUTOIMMUNE HEPATITIS (AIH) – PRELIMINARY RESULTS

V.M. Gordon[1], on behalf of Autoimmune Hepatitis Audit Group (UK). *[1]Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom*
E-mail: vikki_gordon@hotmail.com

Background and Aims: There are limited data on demographic and presenting features of AIH outside large centres. We are conducting an outcome audit of AIH in 29 UK centres of varying size. We report

demographic, clinical and laboratory features at presentation in this cohort.

Methods: We collected all prevalent (still-attending) cases since 2000 and all incident cases since 2007 by searching electronic patient letters, histology databases and hospital coding. Case validation was by 1999 IAIHG diagnostic criteria. Information was collected and inputted into a web-based data collection system.

Results: Of 957 patients (209 prevalent, 748 incident) with, or treated as AIH, 79% were women. Age at diagnosis was [median (range)] 56 yrs (8–86): 6% were <21 yrs, 17% 21–40 yrs, 39% 41–60 yrs, 36% 61–80 yrs and 2% >80 yrs. Age distribution was similar in women and men. There were 91% Caucasian, 7% Asian, 1% Afro-Caribbean, 0.1% Chinese and 0.3% other groups. 43% had a personal or family history of autoimmune disease, including 15% with thyroiditis/hypothyroidism, 11% PBC, 5% IBD and 3% coeliac disease. HBV and HCV serology was negative in 914 patients (96%) and was undocumented in 39 (4%). Four patients (0.4%) had acute hepatitis IgM antibodies (2 CMV, 1 EBV and CMV, 1 HEV). ANA was present in 49%, ASMA in 41% and Anti-LKM1 in 2%; at least one was present in 78%. AMA was found in 9%. Serum IgG/globulin was raised in 76%. Fifty patients (5%) did not meet IAIHG diagnostic criteria but were treated as AIH.

Presenting symptoms were: none 23%, jaundice/itching 41%, fatigue 32%, nausea, weight loss and abdominal pain each 14%, joint aches 12%, flu-like symptoms 7%, rash 3%, amenorrhoea 0.3%, others 5%. Time from first abnormal liver tests to diagnosis was 3 months (0–167) and was shorter in patients presenting with jaundice/pruritus than in the others: 1 (0–167) vs 5 (0–131) months ($p \leq 0.0001$). At presentation, 4% had ascites, 5% oedema, 1.5% encephalopathy, 0.6% variceal bleeding and 8% had clinical decompensation (defined as ≥1 of these). In an additional 13%, MELD score was >15. 96% of patients had a diagnostic liver biopsy. 21% had cirrhosis (Ishak fibrosis 5/6).

Conclusions: In this large multicentre cohort of AIH patients, 21% had cirrhosis and 21% had liver decompensation at presentation. Delay in diagnosis was often many months, especially in those without jaundice. 4% did not have documented HBV/HCV serology and 5% did not meet IAIHG criteria.

P1163
BASELINE LIVER BIOPSY IN AUTOIMMUNE HEPATITIS (AIH): CONTRIBUTION TO DIAGNOSIS AND PREDICTION OF TREATMENT RESPONSE

V.M. Gordon[1], A.K. Dube[2], E. Mcfarlane[1], M.A. Karajeh[1], D.C. Gleeson[1]. *[1]Liver Unit, [2]Histopathology, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom*
E-mail: vikki_gordon@hotmail.com

Background and Aims: Although recommended in published guidelines, diagnostic liver biopsy is often not performed in patients with suspected AIH: only 62% of UK consultants do so 'routinely' (Dhaliwal Gut 2012:62). Likewise, the uses and the choice of International AIH Group diagnostic criteria (full 1999 or simplified 2008) are not established.

Aims: Assessment, in patients with AIH by 1999 criteria, of the utility of (a) liver histology in diagnosis and prediction of treatment response and (b) the 2008 (simplified) IAIHG diagnostic criteria.

Methods: 90 patients [71 women, median age (range) 61 (14–84) years], presenting since 2006 and undergoing diagnostic liver biopsy for suspected AIH. Histology was assessed (using the 1999 and 2008 criteria and the Ishak scoring system) by one Liver Histopathologist (AKD) without reference to other results.

Results: Interface hepatitis was found in 87 (97%) of biopsies, a mainly plasma-cell infiltrate in 74 (82%), rosettes in 68 (76%), biliary changes in 15% and steatosis in 26%. Prior to biopsy, patients had 11 (8–19) diagnostic points (1999 criteria) and 11 did not have the required 10 points. Biopsy contributed 5 (0–6) more points and all patients then met the 1999 criteria (61 definite, 29 probable). In 49 patients with ≥13 pre-biopsy points, biopsy [contributing 4 (0–5) more points] was not needed for AIH diagnosis but detected biliary changes in 10 patients (resulting in PBC overlap diagnosis and UDCA treatment in 3) and cirrhosis in 9. Histological features did not differ between patients with (n = 68) and without (n = 22) serum antibodies (ANA, ASMA, LKM), between those with (n = 72) and without (n = 10) raised serum IgG, or between treated patients who did (n = 75) and did not (n = 8) achieve normal serum ALT within 6 months. Seventeen of the 90 patients (19%) did not meet the 2008 (simplified) criteria for AIH. In these, necroinflammatory score was 9 (2–16), fibrosis score was 3 (1–6) and, of 14 treated patients, 13 achieved normal serum ALT within 6 months.

Conclusions: Liver biopsy is important for diagnosis of AIH in those with lower, but less so in those with higher, pre-biopsy IAIHG (1999) diagnostic scores. It may also detect cirrhosis or biliary disease. Histological features are not associated with immunological features or treatment response. The 2008 simplified diagnostic criteria will "miss" 19% of patients with AIH by 1999 criteria. Most of these patients have significant disease and respond to treatment.

P1164
IMPAIRED EXPRESSION OF ENZYMES RESPONSIBLE FOR BILE ACID SYNTHESIS AND DETOXIFICATION IN PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS

M. Milkiewicz[1], A. Kempinska-Podhorodecka[1], U. Wasik[1], M. Klak[1], M. Blatkiewicz[1], P. Milkiewicz[2]. *[1]Medical Biology Laboratory, Pomeranian Medical University, Szczecin, [2]Liver and internal Medicine Unit, Medical University of Warsaw, Warsaw, Poland*
E-mail: milkiewm@pum.edu.pl

Background and Aims: Nuclear receptors (NR) coordinate responses aimed at protecting hepatocytes from toxic bile acid (BA). In experimentally induced cholestasis the complex interplay of several pathways under control of FXR, PXR and CAR lead to reduction of BA synthesis and enhanced expression of enzymes responsible for phase I and phase II modification. Whether comparable phenomenon operates in humans requires to be elucidated. The aim of the study was to find out whether self-protective mechanisms against retaining BAs are induced in response to prolonged cholestatic injury in PSC.

Methods: Human tissue specimens were obtained from explanted livers of patients with PSC (n = 11) and primary biliary cirrhosis (PBC, n = 20). Non-cholestatic liver specimens (n = 20) served as controls. Liver protein expressions of FXR, PXR, CAR, SHP alongside with CYP7A1 (BA synthesis), CYP3A4 (phase I hydroxylation), and SULT2A1 (phase II conjugation) were assessed by Western Blot.

Results: The protein levels of FXR and its downstream target gene SHP were significantly enhanced in comparison to controls in both PSC (5.4 fold, $p < 0.0001$ and 2.9 fold, $p < 0.0001$, respectively), and PBC (2.4 fold, $p = 0.03$ and 2.8 fold, $p < 0.0001$, respectively). Hepatocellular expression of FXR-dependent fibroblast growth factor FGF19 and its receptor FGFR4 were highly induced in PSC (45.1 ± 9.1 vs. 1.1 ± 0.1, $p = 0.001$ and 2.6 ± 0.5 vs. 1.0 ± 0.1, $p = 0.03$, respectively). Despite these changes the suppression of a rate limiting enzyme for BA synthesis CYP7A1 was not seen in PSC whereas it was present in PBC (0.54 ± 0.1 vs. 0.96 ± 0.1; $p = 0.006$). PXR and CAR protein levels were increased both in PSC (2.7 fold; $p = 0.04$ and 2.4 fold; $p < 0.0001$, respectively) and PBC (5.9 fold, $p < 0.0001$ and 3.1 fold; $p < 0.0001$, respectively). The expression CYP3A4 enzyme was again not changed in PSC but enhanced in PBC (2.2 ± 0.5 vs. 1.1 ± 0.1, $p = 0.02$). Similarly, the level of SULT2a1 enzyme was unchanged in PSC but upregulated in PBC (2-fold, $p < 0.0001$).

Conclusions: Significant differences between expression of crucial enzymes responsible for bile acids metabolism and hepatoprotection exist between PSC and PBC. Potential impairment

in repression of bile acids synthesis and alterations in detoxification mechanisms in PSC may be accountable for bile acid induced liver injury observed in this cholestatic condition.
This study was supported by the grant no. 2011/02/A/NZ5/00321 from National Science Centre in Poland.

HIGH SEROPREVALENCE OF HEPATITIS E IN PATIENTS WITH AUTOIMMUNE HEPATITIS

M. Eder[1], S. Beinhardt[1], R. Strassl[2], A.F. Stättermayer[1], C. Freissmuth[1], K. Kozbial[1], H. Holzmann[3], P. Ferenci[1], M. Trauner[1], H. Hofer[1]. [1]*Division of Gastroenterology and Hepatology, Department of Internal Medicine III,* [2]*Department of Laboratory Medicine, Division of Clinical Virology,* [3]*Department of Virology, Medical University of Vienna, Vienna, Austria*
E-mail: michael.eder@meduniwien.ac.at

Background and Aims: Incidence of autochthonous hepatitis E virus (HEV) infection is reported to increase in Europe and evolution of chronic hepatitis E has been shown in patients receiving immunosuppressive treatment after solid organ transplantation. HEV infection may mimic autoimmune hepatitis or disease flares during immunosuppressive treatment. Aim of the present study was to investigate the frequency of HEV infection in patients with AIH.
Methods: Sera from seventy-two consecutive patients with AIH (female: 55 [76.4%], age: 42.2±17.5 years [mean±SD]) in a tertiary referral center were retrospectively analyzed at baseline and during treatment. All patients were scored as probable or definite AIH according to the simplified and/or revised scoring system of the IAIHG; prevalence of anti-HEV-antibodies (Beijing Wantai Biological Pharmacy Enterprises Co., Ltd.) and HEV RNA was determined.
Results: 19 (26.4%) patients tested positive for HEV-IgG antibodies, which was more than twice as high as the previously reported sero-prevalence in healthy Austrian individuals (12.4%). No patient tested positive for HEV-RNA. Seropositive patients were older (51±12 vs. 39±18 years, [means±SD], $p < 0.01$) but did not differ significantly in AST levels (14.6 [1.3–121.5] vs. 8.6 [0.7–84.3], ×ULN, median [range]), ALT levels (20.1 [1.6–62.7] vs. 11 [0.8–75.7], ×ULN, median [range]), bilirubin (1.8 [0–32] vs. 1.9 [0–58], mg/dl, median [range]) and IgG-levels (1.3 [0.7–2.7] vs. 1.3 [0.6–3.8], ×ULN, median [range]). Seropositivity did not have an effect on treatment response after 6 or 12 months of immunosuppressive treatment, respectively.
Conclusions: Seroprevalence of HEV-IgG was found to be high in our cohort with AIH patients suggestive that HEV infection might be a possible trigger for development of AIH. Testing for HEV RNA is advisable in patients examined for AIH or not responding to immunosuppressive treatment.

P1166
DECREASED SERUM DNase1 ACTIVITY IN PATIENTS WITH AUTOIMMUNE LIVER DISEASES

N.K. Gatselis[1], A.G. Vakrakou[2], K. Zachou[1], T. Androutsakos[2], K. Azariadi[1], G. Hatzis[2], M.N. Manoussakis[2], G.N. Dalekos[1]. [1]*Department of Medicine and Research Laboratory of Internal Medicine, Medical School, University of Thessaly, Larissa,* [2]*Department of Pathophysiology, School of Medicine, University of Athens, Athens, Greece*
E-mail: ngatselis@gmail.com

Background and Aims: Deoxyribonuclease 1 (DNase1) is an endonuclease involved in chromatin degradation of necrotic cells during programmed cell death, thus its deficiency results in accumulation of DNA from nuclear antigens and may promote susceptibility to immune disorders such as systemic lupus erythematosus and Sjogren's syndrome. The aim of the study was to assess the role of DNase1 serum activity in patients with autoimmune liver diseases as similar data is missing in these groups of patients.
Methods: DNase1 activity was determined by single radial enzyme-diffusion method in serum samples obtained at the time of diagnosis of 224 patients with autoimmune hepatitis (AIH), 249 patients with primary biliary cirrhosis (PBC) and 36 patients with primary sclerosing cholangitis (PSC). Serum samples from 146 patients with chronic viral hepatitis B and C, 140 patients with non-alcoholic fatty liver disease/non-alcoholic steatohepatitis (NAFLD/NASH) and 114 healthy served as the disease control groups and healthy control group, respectively. Serum samples from 50 AIH and 39 PBC patients at least one year after appropriate treatment initiation were also available for paired analyses.
Results: DNase1 activity was significantly lower in AIH, PBC and PSC patients compared either to chronic viral hepatitis ($p < 0.02$, $p < 0.001$, and $p = 0.03$, respectively) or NAFLD/NASH ($p < 0.001$, for each comparison) and healthy control group ($p < 0.001$, for each comparison). No significant difference was found in between each specific autoimmune liver disease. In AIH patients, complete responders to treatment characterized by increased baseline DNase1 serum levels compared to partial responders, responders with relapses and non-responders ($p < 0.05$), while DNase1 activity was significantly increased after achievement of clinical and biochemical remission ($p < 0.001$).
Conclusions: DNase1 serum activity is significantly decreased in autoimmune liver diseases patients, suggesting a potential implication in pathogenesis. In particular, DNase1 activity could be used as a new surrogate biomarker of predicting response to treatment in AIH though further investigation is needed.

P1167
SHARED DISEASE-SUSCEPTIBILITY GENES BETWEEN PRIMARY BILIARY CIRRHOSIS AND CROHN'S DISEASE IN THE JAPANESE POPULATION

Y. Aiba[1], K. Yamazaki[2], N. Nishida[3], M. Kawashima[3], Y. Hitomi[3], A. Komori[1], M. Kubo[2], K. Tokunaga[3], M. Nakamura[1]. [1]*Clinical Research Center, Nagasaki Medical Center, Omura,* [2]*Center for Integrative Medical Science, Institute of Physical and Chemical Research (RIKEN), Yokohama,* [3]*Department of Human Genetics, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan*
E-mail: aiba@nagasaki-mc.com

Background and Aims: We previously identified *TNFSF15* as the most significant susceptibility gene at non-*HLA* loci for both primary biliary cirrhosis (PBC) and Crohn's diseases (CD) in the Japanese population. To further identify shared disease-susceptibility genes between PBC and CD, the associations of PBC and CD were studied with susceptibility genes to CD and PBC, respectively, in the Japanese population.
Methods: We selected 15 and 34 genetic variants which were significantly associated with PBC and CD, respectively, with reference to previously reported genome wide association studies and replication studies in the Japanese population. Association study was independently performed for these genetic variants in CD cohort (1312 CD patients and 3331 healthy controls) and PBC cohort (1279 PBC patients and 1015 healthy controls) in the Japanese population.
Results: Two susceptibility genes to CD, *ICOSLG* (rs2838519, $p = 3.85 \times 10^{-2}$) and *IL12B* (rs6556412, $p = 8.40 \times 10^{-3}$), were significantly associated with PBC, and three susceptibility genes to PBC, *CXCR5* (rs6421571, $p = 2.72 \times 10^{-2}$), *STAT4* (rs7574865, $p = 4.04 \times 10^{-2}$), *NFKB1* (rs230534, $p = 2.16 \times 10^{-2}$), were significantly associated with CD. The risk alleles of *ICOSLG* rs2838519 and *CXCR5* rs6421571 were the same between the two diseases, whereas those of *IL12B* rs6556412, *STAT4* rs7574865, and *NFKB1* rs230534 were opposite.

Conclusions: In addition to *TNFSF15*, *ICOSLG* and *CXCR5* revealed to play an important role in the shared disease-pathways (*ICOSLG-CXCR5* axis) between PBC and CD in the Japanese population. On the other hand, *IL12B*, *STAT4*, *NFKB1* might be involved in oppositely directed manner in the two diseases, indicating the different regulation of Th1/Th17 balance between the two diseases.

PROGNOSTIC CLINICAL BIOMARKERS OF CHOLESTATIC LIVER INJURY: PERTURBATION OF BILE ACID METABOLISM AND REACTIVE OXIDATIVE STRESS MARKER

N. Masubuchi[1], M. Sugihara[2], T. Sugita[3], K. Amano[3], M. Nakano[3], T. Matsuura[4]. *[1]Drug Metabolism & Pharmacokinetics Research Laboratories, [2]Clinical Data & Biostatistics Department, Daiichi Sankyo Co., Ltd., [3]Division of Gastroenterology and Hepatology, [4]Department of Laboratory Medicine, Jikei University School of Medicine, Tokyo, Japan*
E-mail: masubuchi.noriko.wa@daiichisankyo.co.jp

Background and Aims: During the clinical diagnosis of liver injury, clinicians must make an early assessment of the extent of progression from cholestasis in the bile canaliculi to severe hepatocellular injury, and subsequently make an appropriate decision with regard to the therapeutic strategy. In particular, cholestasis is difficult to diagnose by conventional markers at an early stage of disease. The aim of this comprehensive study was to identify definitive biomarkers for distinguishing symptom-based types of liver injury (e.g., hepatocellular injury, cholestasis) using blood samples of patients with liver disease.
Methods: A total 304 blood samples from patients with liver disease (n = 150) and 46 blood samples from healthy volunteers were obtained. The associations between the serum levels with 29 markers of interest such as bile acid components, oxidative stress markers and liver fibrosis markers and the liver injury types were assessed by a multiple logistic regression analysis. Receiver operating characteristic (ROC) analyses were performed to determine the optimal cut-off values of the significant biomarkers for identifying liver injury types.
Results: Multiple logistic regression analysis revealed that reductions in the lithocholic acid (LCA) and deoxycholic acid (DCA) levels, and elevation of the serum sulfated bile acid (SSBA), liver fibrosis marker IV collagen (type IV collagen), hyaluronic acid (HA) and reactive oxygen species (ROS) levels were all significantly associated with cholestasis. On the other hand, elevations in the LCA and type IV collagen levels, and a reduction in the ursodeoxy cholic acid (UDCA) level, were significantly associated with hepatocellular injury. The ROC analyses showed that the largest area under the ROC curve (AUC) was found for ROS, followed by DCA, HA, LCA, SSBA and type IV collagen in the cholestatic-type cases.
Conclusions: The present results of prospective study indicated that reactive oxygen species, lithocholic acid, deoxycholic acid and the sulfated bile acids are promising biomarkers for cholestasis and for distinguishing the types of liver injuries. The proposed diagnostic approach using biomarkers will allow us to accurately diagnose liver injury and to select an appropriate personalized therapy at onset or in the early stage.

OUTCOME INDICATORS IN PRIMARY SCLEROSING CHOLANGITIS: INTERIM ANALYSIS OF THE VALUE-BASED MEDICINE IN HEPATOLOGY STUDY

L. Fabris[1,2], A. Ciaccio[3], S. Okolicsanyi[3], M. Rota[4], P.A. Cortesi[5], M.R. Buonocore[3], M. Gemma[3], P. Giani[6], L.S. Belli[7], S. Fagiuoli[6], L. Scalone[5], M.G. Valsecchi[4], L.G. Mantovani[5], M. Strazzabosco[2,3]. *[1]Department of Molecular Medicine, University of Padova, Padova, Italy; [2]Liver Center & Section of Digestive Diseases, Department of Internal Medicine, Yale University School of Medicine, New Haven, CT, United States; [3]Department of Surgery and Translational Medicine, [4]Department of Health Sciences, Centre of Biostatistics for Clinical Epidemiology, [5]Research Centre on Public Health (CESP), University of Milan-Bicocca, Milan, [6]Department of Gastroenterology, Papa Giovanni XXIII Hospital, Bergamo, [7]Department of Hepatology and Gastroenterology, Liver Unit, Niguarda Hospital, Milan, Italy*
E-mail: mario.strazzabosco@yale.edu

Background and Aims: Primary sclerosing cholangitis (PSC) is an enigmatic disease with scarce therapeutic options, potentially evolving to severe and life-threatening complications, including malignancies like cholangiocarcinoma (CCA) or colon cancer. The clinical management of PSC remains challenging and may benefit from identification of outcome indicators to assess the quality of care.
This study aims to: (A) identify Outcome Indicators (OIs) for PSC, and (B) validate OIs in a clinical context with a preliminary interim analysis.
Methods: (A) A panel of experts generated a list of OIs using a modified version of the Delphi method. (B) OIs with the highest RAND/UCLA score were tested in an ongoing multicentric and prospective study (Value-based Medicine in Hepatology, VBMH).
Results: Five OIs were identified on the basis of the highest rating values and disagreement indexes next to 0. They include: annual rate of acute cholangitis episodes (OI#1); mortality rate for patients not yet listed for liver transplantation (OI#2); rate of quality of life improvement, measured by EQ-VAS (a visual assessment scale ranging from 0 to 100 where the patient points out his present-day health status) and EQ-5D (assessment of 5 domains that measure daily performance according to 3 levels of severity) (OI#3); number of patients died for CCA and CRC (OI#4); incidence and/or worsening of osteoporosis, expressed as T-score differential over a 2-year interval (OI#5). In the validation study, 63 consecutive patients with PSC enrolled in 3 tertiary liver centres in Northern Italy were evaluated for a 24-month follow-up period. For each OI, the following values were reported: OI#1: cumulative incidence of 5.2%, resulting in 0.029 cholangitis/patient; OI#2, OI#4: no patients died without being listed for transplantation or because of cancer during study time; OI#3: 38.9% and 19.4% of patients showed an improvement in EQ-VAS and EQ-5D parameters, respectively; OI#5: 3% of patients developed or worsened osteoporosis.
Conclusions: Five OIs for PSC were identified on a highly shared consensus. Albeit the study population is small (as in the case of rare diseases) and the follow-up time is short as compared to the long natural history of the disease, these OIs have proven to be easy to collect and to work appropriately. Therefore, they are suitable to be extended to specialized centres involved in PSC management to further validate their clinical usefulness.

THE ROLE OF GROWTH HORMONE RECEPTOR IN LIVER FIBROSIS AND CANCER

P. Stiedl[1], R. McMahon[2], L. Blaas[3], V. Stanek[1], J. Svinka[4], B. Grabner[1], G. Zollner[5], S. Kressler[6], T. Claudel[2], M. Müller[7], W. Mikulits[4], H. Esterbauer[8], R. Eferl[4], J. Haybaeck[6], M. Trauner[2], E. Casanova[1,9]. *[1]Ludwig Boltzmann Institute for Cancer Research, [2]Hans Popper Laboratory of Molecular Hepatology, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [3]Department of Biosciences and Nutrition, Karolinska Institute, Huddinge, Sweden; [4]Department of Internal Medicine I, Comprehensive Cancer Center CCC, Institute for Cancer Research, Medical University of Vienna, Vienna, [5]Division of Gastroenterology and Hepatology, Department of Internal Medicine, [6]Institute of Pathology, Medical University of Graz, Graz, [7]Biomodels Austria, Institute of Animal Breeding and Genetics, University of Veterinary Medicine Vienna, [8]Department of Laboratory Medicine, [9]Institute of Pharmacology, Center of Physiology and Pharmacology, Comprehensive Cancer Center, Medical University of Vienna, Vienna, Austria*
E-mail: Patricia.Stiedl@gmail.com

Background and Aims: Growth hormone (GH) resistance and low serum levels of insulin growth factor 1 (IGF-1) have been associated with liver cirrhosis in humans, suggesting an important role for growth hormone receptor (GHR) in this disease. GHR itself controls various cellular functions including the transcription of IGF-1 through signal transducer and activator of transcription 5 (Stat5) signaling. In order to elucidate whether the growth hormone receptor (GHR) plays an active role in the establishment of fibrosis liver diseases or rather happens to be a major consequence of this illness, we crossed mice lacking the *Ghr/bp* gene ($Ghr^{-/-}$) with a mouse model of inflammatory cholestasis and liver fibrosis, the Mdr2 Knockout mouse ($Mdr2^{-/-}$).
Methods: Serum parameters and bile acid contents were analysed. Additionally histological stainings, western blotting and RT-PCRs were conducted to gain mechanistic insights.
Results: Our results indicate that $Ghr^{-/-}$;$Mdr2^{-/-}$ mice show deregulation of bile acid homeostasis and increased serum markers associated with inflammation and fibrosis. Bile duct proliferation and extensive collagen deposition were also observed in $Ghr^{-/-}$;$Mdr2^{-/-}$ compared to $Mdr2^{-/-}$ mice, suggesting that $Ghr^{-/-}$;$Mdr2^{-/-}$ developed a severe liver fibrosis phenotype. Additionally, a greater down regulation of the hepato-protective genes *Hnf6*, *Egfr* and *Igf1* accompanied by increased apoptosis was seen in $Ghr^{-/-}$; $Mdr2^{-/-}$ compared to control mice. Moreover, single knockout mice ($Ghr^{-/-}$) developed bile infarcts when fed with 1% cholic acid compared to Wt controls, indicating that hepatocytes upon loss of GHR become more susceptible to toxic bile acid accumulation. Surprisingly, $Ghr^{-/-}$;$Mdr2^{-/-}$ mice showed a significant decrease in tumor incidence compared to $Mdr2^{-/-}$ mice despite their severe fibrotic phenotype indicating that loss of GHR signaling may slow the progression from fibrosis/cirrhosis to cancer in the liver.
Conclusions: These findings suggest that loss of GHR signaling severely increase liver fibrosis in a mouse model of inflammatory cholestasis, signifying the possible therapeutic value of this pathway in the development of liver fibrosis treatments.

P1171

EPIDEMIOLOGY AND DISEASE BURDEN OF PRIMARY BILIARY CIRRHOSIS IN SOUTH KOREA: A NATIONWIDE, POPULATION-BASED STUDY

K.-A. Kim[1], H.Y. Choi[2], M. Ki[2], S.-H. Jeong[3]. *[1]Internal medicine, Inje University Ilsan Paik Hospital, [2]Department of Cancer Control and Policy, Graduate School of Cancer Science and Policy, National Cancer Center, Goyang, [3]Internal medicine, Seoul National University Bundang Hospital, Seongnam, Korea, South*
E-mail: kakim@paik.ac.kr

Background and Aims: The epidemiology of primary biliary cirrhosis (PBC) has wide geographic variation. There is no data on the prevalence and incidence of PBC in South Korea. The aim of this study was to elucidate the population based nationwide prevalence and incidence of PBC in South Korea.
Methods: We used the data from nationwide population-based Health Insurance Review and Assessment Service claims database and Rare Intractable Disease registration database, which includes physician-certified diagnoses based on uniform criteria for primary biliary cirrhosis from 2008 to 2013. Age-specific incidence and prevalence were calculated, and data on comorbidity and medical costs were also retrieved.
Results: The total number of patients with PBC in South Korea was 2347 in 2013; the prevalence rate in 2013 was 4.61 per 100,000 population, 8.06 in female and 1.16 in male. The incidence rates from 2011 to 2013 were 0.84, 0.92 and 0.87 per 100,000 population, respectively. Female was 87.4% of patients and peak age of new cases was 6th decades. Common comorbidities were hyperlipidemia (17%), hypothyroidism (4.5%) and various extrahepatic autoimmune diseases (2.1%). Common complications were ascites (9.9%), variceal bleeding (4.1%), and hepatocellular carcinoma (1.3%). A total of 71 patients (2.5%) had liver transplantation during the 5 years. The nationwide total direct medical cost was 8.5 million US dollars (USD) per year and the average cost for each patient was 950 USD in 2013.
Conclusions: This is the first report on the nationwide epidemiology of PBC in South Korea. We found the prevalence and incidence of PBC in Korea were lower than those of Western countries, while similar with those in Japan. Further study on the genetic or environmental factors related to the epidemiologic findings are warranted.

P1172

COLECTOMY IS ASSOCIATED WITH DEVELOPMENT OF CHOLANGIOCARCINOMA IN PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS AND INFLAMMATORY BOWEL DISEASE

A. Gulamhusein[1], J.E. Eaton[1], J.H. Tabibian[1], E.J. Atkinson[1], G.J. Gores[1], K.N. Lazaridis[1]. *[1]Mayo Clinic College of Medicine, Rochester, United States*
E-mail: a.gulamhusein@mail.utoronto.ca

Background and Aims: Inflammatory Bowel Disease (IBD) occurs in two-thirds of patients with Primary Sclerosing Cholangitis (PSC) and cholangiocarcinoma (CCA) is estimated to have a lifetime incidence of up to 10% in patients with PSC. Despite these associations, the impact of colectomy in patients with PSC-IBD remains ill defined.
Aim: To identify the association between PSC-IBD and the occurrence of CCA in patients with and without colectomy.
Methods: Adult patients with PSC-IBD at the Mayo Clinic, Rochester from Jan 2005-Dec 2013 were identified. Medical records were retrospectively reviewed for relevant variables including gender, dates of individual diagnoses, occurrence and indication for colectomy, presence of decompensated liver disease, and development of outcomes including CCA, death, and liver transplant. CCA was defined by histologic evidence of malignancy

(biopsy or cytology) or consistent radiographic features. The primary analysis focused on time to development of CCA among those with and without colectomy. Overall rates of CCA within certain age and follow-up periods were determined. Cox proportional hazard models where colectomy was treated as a time-dependent covariate were used to determine the risk of CCA among patients with and without colectomy.

Results: The study cohort consisted of 404 patients with PSC-IBD. The mean age at diagnosis of IBD, PSC, and CCA was 29.4, 40.3 and 56.9 years, respectively. 115 (28%) subjects had a colectomy; 53 (46%) for colonic neoplasia and 38 (33%) for medically refractory disease. Overall the risk of CCA was increased in patients with prior colectomy (HR = 1.8, 95% CI 1.3–2.6, p = 0.002). The risk of CCA increased 40% for every 10 year increase in age (HR = 1.4, 95% CI 1.2–1.6). There was no significant evidence of an increased risk of CCA among those with refractory disease (HR = 0.87 95% CI 0.42–1.83, p = 0.72) or colonic neoplasia (HR = 1.26 95% CI 0.75–2.03) compared to those without colectomy. The rate of CCA per 1000 patient-years in patients 0–29 yrs, 30–39 yrs, 40–49 yrs, 50–64 yrs, and 65+ yrs that did not have a colectomy was 5.9, 16.1, 29.8, 37.7, and 31.9, respectively, compared to 44.0, 39.8, 42.6, 52.4, and 81.6 among those that did have a colectomy.

Conclusions: In this large cohort of patients with PSC-IBD, colectomy was associated with an almost two-fold increased risk of CCA. This association may assist in identifying a subset of patients who are at high risk of this dreadful complication.

P1173

MAIT CELLS ARE ENRICHED IN PORTAL TRACTS AND RESPOND TO BILIARY EPITHELIAL CELLS PRESENTING BACTERIAL LIGANDS DURING LIVER INFLAMMATION

H. Jeffery[1], B. van Wilgenburg[2], S. Hunter[1], A. Kurioka[2], K. Parekh[1], K. Stirling[1], S. Roberts[1], D. Adams[1], P. Klenerman[2], Y.H. Oo[1].
[1]Centre for Liver Research and NIHR BRU, University of Birmingham, Birmingham, [2]Peter Medawar Building for Pathogen Research, University of Oxford, Oxford, United Kingdom
E-mail: Jefferhc@bham.ac.uk

Background and Aims: Mucosal-Associated Invariant T (MAIT) cells are unconventional T-cells characterised by the invariant T-cell antigen receptor α-chain, Vα7.2, high expression of CD161 and restriction by the MHC class 1-related molecule, MR1. They are important for antibacterial immunity at mucosal sites; however, their role in the pathogenesis of hepatic inflammation remains unclear. Here we investigated the frequency, phenotype, localisation and function of liver infiltrating (LI) MAIT cells.

Methods: Blood and LI MAIT cells were phenotyped by flow cytometry. Intrahepatic localisation was examined by immunohistochemistry. MAIT cell activation in response to *E. coli*-exposed biliary epithelial cells (BEC) was assessed in a co-culture study ± anti-MR1.

Results: MAIT cells were enriched in liver vs. blood in normal (9% vs. 3% of T-cells, p < 0.01) and diseased (4% vs. 0.3%, p < 0.01) tissues. However, frequencies were lower in diseased vs. normal livers (4% vs. 9%, p < 0.01). In blood and normal livers most were $CD8^+$; however, the $CD4^+$ subset was increased in diseased livers (11% vs. 3% of $CD3^+$MAIT cells, p < 0.05). LI MAIT cells had a $CD45RA^-CCR7^-$ (88%) $CD69^+$ (80%) phenotype and expressed the serine exopeptidase CD26 (91%) as well as adenosine pathway markers CD39 (45%) and CD73 (21%). Human intrahepatic Vα7.2 cells resided in hepatic sinusoids and around bile ducts. Consistent with this distribution they expressed the sinusoid recruitment receptor CXCR3 (80%), integrins LFA-1 (91%) and VLA-4 (58%) and biliary homing chemokine receptors CCR6 (53%), CXCR6 (21%), CCR10 (4%) and integrin αEβ7 (23%). Gut homing integrin α4β7 (20%) and cytokine receptors IL-18Rα (84%) and IL23R (20%) were also detected. MAIT cells from diseased livers possessed mixed lineage phenotypes expressing RORc and Tbet and cytokines IL17, IL22, IFNγ and TNFα. They also produced cytolytic granzyme B. In response to *E. coli*-exposed BEC, MAIT cells expressed IFNγ and CD40L. These responses were inhibited by blocking with anti-MR1.

Conclusions: We provide first evidence that activated effector memory $CD3^+CD161^{++}Va7.2^+$ MAIT cells are enriched in human livers with an altered CD4/CD8 profile in disease. High expression of CXCR3/LFA-1/VLA-4 indicates recruitment via hepatic sinusoids and CCR6/CXCR6/αEβ7 suggest homing to the peri-biliary region where LI MAIT cells are activated in response to bacteria-exposed BEC in an MR1 dependent manner, leading to liver injury through their release of cytolytic enzymes and inflammatory cytokines.

P1174

MICROBIOTA-DEPENDENT MARKER TRIMETHYLAMINE-N-OXIDE (TMAO) IS ASSOCIATED WITH THE SEVERITY OF PRIMARY SCLEROSING CHOLANGITIS

M. Kummen[1,2,3,4], M. Vesterhus[1,5], M. Trøseid[1,2,6], B. Moum[3,7], A. Svardal[8], K.M. Boberg[1,3,9], P. Aukrust[2,3,4,6], T.H. Karlsen[1,2,3,4,9,10], R.K. Berge[8,11], J.R. Hov[1,2,3,4,9].

Jebsen Inflammation Research Centre, [3]Institute of Clinical Medicine, University of Oslo, [4]Research Institute of Internal Medicine, Oslo University Hospital Rikshospitalet, Oslo, [5]Department of Medicine, National Centre for Ultrasound in Gastroenterology, Haukeland University Hospital, Bergen, [6]Section of Clinical Immunology and Infectious Diseases, Oslo University Hospital Rikshospitalet, [7]Division of Medicine, Department of Gastroenterology, Oslo University Hospital Ullevål, Oslo, [8]Department of Clinical Science, University of Bergen, Bergen, [9]Section of Gastroenterology, Department of Transplantation Medicine, Oslo University Hospital Rikshospitalet, Oslo, [10]Department of Clinical Medicine, University of Bergen, [11]Department of Heart Disease, Haukeland University Hospital, Bergen, Norway
E-mail: martin.kummen@medisin.uio.no

Background and Aims: Trimethylamine-N-oxide (TMAO) is produced in the liver from trimethylamine, which is exclusively generated by gut bacteria from dietary choline and carnitine found in e.g. red meat and dairy products. TMAO influences bile acid levels, metabolism and potentially also inflammation. Given the production in the liver, link to the gut microbiota and bile acid homeostasis, we aimed to investigate the regulation of TMAO in primary sclerosing cholangitis (PSC).

Methods: We measured serum TMAO in 305 PSC patients, 90 ulcerative colitis (UC) patients and 99 healthy controls (HC), with a median age (male %) of 41 (76), 38 (51) and 40 (60), respectively. Reduced liver function was defined by increased prothrombin time (International Normalized Ratio >1.2 or Normotest <70).

Results: TMAO level was lower in PSC patients than in UC and HC (medians 3.1, 4.0 and 3.5, respectively, p < 0.05 versus HC and UC). We hypothesized that this could be explained by reduced liver function affecting TMAO production. In line with this, TMAO in PSC with reduced liver function, but not TMAO in those with normal liver function, was lower than in HC (p < 0.05). The TMAO level in UC was higher than in PSC irrespective of liver function (p < 0.05), while TMAO was similar in PSC patients with and without inflammatory bowel disease. Focusing on PSC patients with normal liver function, the TMAO level was higher in patients reaching an end-point during follow-up (liver transplantation, n = 70, or all-cause death, n = 21) than those without (median 4.6 versus 2.7, p = 0.001). AUROC-analysis yielded an AUC of 0.64 (p < 0.001) with a suggested optimal TMAO cut-off of 4.1μM. When stratified by this value, PSC patients with high TMAO exhibited shorter transplantation-free survival than patients with low TMAO (median 3.0 versus 16.2 years, p < 0.001, Figure 1). In Cox regressions, TMAO

>4.1μM and Mayo risk score were independently associated with transplantation-free survival, with HR 2.0 (95% CI 1.2–3.1, p = 0.005) and 1.5 (95% CI 1.2–1.8, p < 0.001), respectively.
Conclusions: PSC patients with impaired liver function had decreased TMAO level, suggesting that TMAO may be influenced by reduced liver function. On the other hand, in PSC patients with normal liver function, elevated TMAO was associated with a shorter liver transplantation-free survival, suggesting that dietary factors and gut microbiota profile may be relevant for the disease prognosis in PSC.

	0	3	5	10	15
Number at risk

P1175
ABILITY OF A SIMPLE RADIOLOGIC SCORE, ASSESSED BY THREE-DIMENSIONAL MAGNETIC RESONANCE CHOLANGIOGRAPHY (MRC), TO PREDICT CLINICAL OUTCOME OF PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS (PSC)

S. Lemoinne[1], L. Arrivé[2], A. Donald Kemgang Fankem[1], C. Housset[1], C. Corpechot[1], O. Chazouillères[1]. *[1]Service d'hépatologie, [2]Service de radiologie, Hôpital Saint-Antoine APHP, Paris, France*
E-mail: sara_lemoinne@yahoo.fr

Background and Aims: The natural course of PSC is highly variable and the use of current prognostic models is not recommended in an individual patient. The prognostic value of cholangiographic features assessed by endoscopic retrograde cholangiography has been suggested but cholangiography by magnetic resonance imaging (MRI) has become the radiologic standard for diagnosis of PSC. We have previously shown that 2 MRI risk scores can predict radiologic progression in PSC patients. The aim of this study was to evaluate the ability of these scores to predict clinical outcome of PSC patients.
Methods: This retrospective single center study included PSC patients who had not been studied in our previous work. Time of inclusion was defined by the date of the first three-dimensional MRC. Primary endpoint was transplantation free survival. Predictive value of clinical, biological and radiologic features [including the 2 MRI scores: MRI score without gadolinium = 1·(dilatation of intrahepatic bile ducts) + 2·(dysmorphy) + 1·(portal hypertension); MRI score with gadolinium = 1·(dysmorphy) + 1·(parenchymal enhancement heterogeneity)] were analyzed by Cox regression models.
Results: 67 patients were included. Their characteristics at baseline were (median [extremes]): age 36.8 years [14.2–76], male 63%, IBD 67%, ursodesoxycholic acid treatment 82%. Gadolinium administration was performed in 61% of patients. Median duration of follow-up was 3.62 years. 8 patients underwent liver transplantation and 2 patients died. In univariate analysis, factors associated with transplantation free survival were: bilirubin, ASAT, albumin and MRI score without gadolinium. Prognostic factors identified by multivariate analysis adjusted on age at entry were ASAT and MRI score without gadolinium. The performance of the MRI score without gadolinium for predicting clinical outcome was assessed by ROC analysis showing an AUC of 0.818 [0.691–0.946] ($p < 10^{-6}$). With a threshold at 2, this score had a sensitivity of 90% and a specificity of 56%.
Conclusions: A MRI risk score, that we have previously identified as associated with radiologic progression, appears also able to predict clinical outcome in PSC patients. Further steps include study of larger populations as well as external validation.

P1176
SERUM AUTOTAXIN IS ASSOCIATED WITH SIGNIFICANT IMPAIRMENT OF HEALTH RELATED QUALITY OF LIFE, CLINICAL AND BIOCHEMICAL FACTORS IN PRIMARY BILIARY CIRRHOSIS

E. Wunsch[1], A.E. Kremer[2], J. Trottier[3], M. Krawczyk[4], O. Barbier[3], F. Lammert[5], P. Milkiewicz[1,6]. *[1]Department of Clinical and Molecular Biochemistry, Pomeranian Medical University in Szczecin, Szczecin, Poland; [2]Translational Research Center Department of Medicine 1, Friedrich-Alexander-University Erlangen, Erlangen, Germany; [3]Laboratory of Molecular Pharmacology, CHU-de-Québec & Faculty of Pharmacy, Laval University, Québec, Canada; [4]Department of Medicine II, Saarland University Hospital Saarland University, [5]Department of Medicine II, Saarland University Hospital Saarland University, Homburg, Germany; [6]Liver and Internal Medicine Unit, Department of General, Transplant and Liver Surgery of the Medical University of Warsaw, Medical University of Warsaw, Warsaw, Poland*

Background and Aims: Autotaxin (ATX) is involved in the synthesis of lysophoshatidic acid (LPA), a robust neuronal activator. Both parameters were recently linked to pruritus in cholestasis (Hepatology 2012;56:1391–1400), and it was hypothesized that ATX inhibitors could be useful for the treatment of cholestatic itch. The potential association between ATX and other relevant factors related to chronic cholestatic conditions has not been studied yet.
Methods: This study involved a group of 116 well characterized patients with PBC (M/F-9/107; mean age 58±12 years). PBC-40, PBC-27 and SF-36 questionnaires were used in the assessment of health related quality of life (HRQoL). Fifty-two patients had liver cirrhosis on histology or imaging. Total fasting serum bile salts (BS) and 27 BS metabolites were analyzed in 47 patients. ATX activity was quantified enzymatically.
Results: Serum ATX activity showed a significant correlation with pruritus assessed with the itch-specific domains of PBC-40 and PBC-27 questionnaires (r = 0.305; p = 0.001). It also correlated with serum AST (r = 0.234; p = 0.02) and ALP activities (r = 0.323; p = 0.0007). ATX was significantly higher in patients with cirrhosis (11.6±3.5 vs 9.3±4.7; p = 0.004) and correlated with the Mayo risk score (r = 0.451; p = 0.004). It also correlated with total fasting serum BS concentrations (r = 0.493; p = 0.0005). In multivariate analysis, glycine conjugates of lithocholate (LCA-Gly) and cholate (CA-Gly)

were independent variables related to ATX activity. In terms of HRQoL, serum ATX was associated with *fatigue* (r = 0.218; p = 0.02) in PBC-40 as well as *fatigue* (r = 0.217; p = 0.02), *cognitive* (r = 0.207; p = 0.03) and *emotional* (r = 0.202; p = 0.03) domains of the PBC-27 questionnaire. No correlations were found with generic SF-36 domains, except for *physical functioning* (r = 0.204; p = 0.03).

Conclusions: In patients with PBC, serum ATX is not only associated with pruritus but may also be involved in impairment of further aspects of patients' quality of life and liver dysfunction. Thus, ATX inhibitors could be of potential benefit not only in the treatment of pruritus but also other incapacitating symptoms related to chronic cholestasis.

E-mail: m.h.harms@erasmusmc.nl

Background and Aims: Hepatic decompensation is an important complication in primary biliary cirrhosis (PBC). However, it remains unclear which factors best predict decompensation. Therefore we aimed to identify baseline factors predicting decompensation to support risk stratification purposes.

Methods: Long-term follow-up (FU) data of ursodeoxycholic acid (UDCA) treated patients was derived from 11 North American and European centers. Decompensation was defined as a first event of ascites, variceal bleeding, or encephalopathy. Patients with decompensation prior to baseline or within the first year of FU were excluded. Risk factor analysis was performed using Cox proportional hazard models. Biochemical non-response was defined by the Paris I criteria. Survival was defined as liver transplantation free survival.

Results: The study population consisted of 2326 UDCA treated PBC patients. 413 patients (18%) were excluded because of missing data, and 78 (3%) because of decompensation before baseline or within first year of FU. Of 1835 included patients (median FU 9.1 years, IQR 5.0–14.3), 163 developed decompensation [ascites: 70 (42.9%), variceal bleeding: 25 (15.3%), encephalopathy: 11 (6.7%), multiple events: 57 (35%)]. On multivariable analysis, the following baseline factors were independently predictive of occurrence of decompensation (Table): year of diagnosis (p = 0.007), moderate disease stage (abnormal bilirubin and/or albumin) (p < 0.001), advanced disease stage (abnormal bilirubin and albumin) (p = 0.013), higher serum alkaline phosphatase levels (p < 0.001), lower platelet count (p < 0.001), higher AST/ALT ratio (p < 0.001) and biochemical non-response after one year (p < 0.001). Among biochemical non-responders 3-, 5-, and 10-year decompensation rates were 8.2%, 15.1% and 24.8%, versus 0.7%, 1.3%, and 3.8% in biochemical responders. One-year survival of decompensated vs. non-decompensated patients was 65.6% vs. 99.7% respectively and 5-year survival was 26.2% vs. 93.6% (time dependent HR 33.9; 95% CI 22.3–51.7). Survival after decompensation did not significantly differ between ascites, variceal bleeding and encephalopathy.

Table: Univariable and multivariable analysis on associations with decompensation

	Univariable analysis		Multivariable analysis	
	HR	95% CI	HR	95% CI
Baseline				
Male gender	1.38	0.86–2.23		
AMA	0.95	0.58–1.57		
Age at start FU	1.01	0.99–1.02		
Year of diagnosis	0.93	0.92–0.95	0.97	0.95–0.99
Moderate disease stage [a]	5.29	3.82–7.34	2.40	1.68–3.42
Advanced disease stage [b]	5.61	3.14–10.03	2.22	1.19–4.16
Albumin	0.15	0.05–0.42		
Platelets (per 10 units)	0.91	0.90–0.93	0.93	0.91–0.95
LN bilirubin	3.55	3.00–4.20		
LN alkaline phosphatase	2.39	1.90–3.01	1.68	1.29–2.18
LN AST	2.68	2.11–3.42		
LN ALT	1.58	1.26–1.97		
LN AST/ALT ratio	2.24	1.63–3.07	2.23	1.55–3.21
LN APRI [c]	2.85	2.41–3.36		
After one year				
Biochemical non-response [d]	6.12	4.42–8.47	2.97	2.04–4.33

[a] Abnormal albumin or bilirubin; [b] Abnormal albumin and bilirubin; [c] AST/platelets ratio index; [d] Paris I Criteria.

Conclusions: Earlier year of diagnosis, advancing disease stage, higher alkaline phosphatase, lower platelet count, higher AST/ALT ratio, and biochemical nonresponse are independently associated with hepatic decompensation in PBC. Since survival following decompensation is poor, these factors might be useful for risk stratification.

P1178

MICRORNAS IN SERUM AND BILE OF PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS AND/OR CHOLANGIOCARCINOMA

T. Voigtländer[1], S.K. Gupta[2], S. Thum[2], J. Fendrich[2], M.P. Manns[1], T. Thum[2], T.O. Lankisch[1]. *[1]Gastroenterology, Hepatology, Endocrinology, [2]Institute of Molecular and Translational Therapeutic Strategies, Medical School Hannover, Hannover, Germany*
E-mail: voigtlaender.torsten@mh-hannover.de

Background and Aims: Patients with primary sclerosing cholangitis (PSC) are at high risk for the development of cholangiocarcinoma (CC). Analysis of micro ribonucleic acid (MiRNA) patterns is an evolving research field in biliary pathophysiology with potential value in diagnosis and therapy. Our aim was to evaluate miRNA patterns in serum and bile of patients with PSC and/or CC.

Methods: Serum and bile from consecutive patients with PSC [n = 40 (serum), n = 52 (bile)], CC [n = 31 (serum), n = 19 (bile)] and patients with CC complicating PSC (PSC/CC) [n = 12 (bile)] were analyzed in a cross-sectional study between 2009 and 2012. The miRNA levels in serum and bile were determined with global miRNA profiling and subsequent miRNA-specific polymerase chain reaction-mediated validation.

Results: Serum analysis revealed significant differences for miR-1281 (p = 0.001), miR-126 (p = 0.001), miR-26a (p = 0.001), miR-30b (p = 0.001) and miR-122 (p = 0.034) between patients with PSC and patients with CC. MiR-412 (p = 0.001), miR-640 (p = 0.001), miR-1537 (p = 0.003) and miR-3189 (p = 0.001) were significantly different between patients with PSC and PSC/CC in bile.
Conclusions: Patients with PSC and/or CC have distinct miRNA profiles in serum and bile. Furthermore, miRNAs are differentially expressed in bile of patients with CC on top of PSC indicating the potential diagnostic value of these miRNAs.

P1179
CONNECTING THE LIVER AND GUT IN PSC: INTESTINAL CCL25 IS INCREASED IN COLITIS, CORRELATES WITH INFLAMMATORY ACTIVITY AND FACILITATES EFFECTOR CCR9+ LYMPHOCYTE RECRUITMENT

P.J. Trivedi[1,2], T. Bruns[1,3], S.T. Ward[4,5], E. Liaskou[1], M. Mai[3], C. Schmidt[3], G.M. Hirschfield[1,2], C.J. Weston[1], D.H. Adams[1,2].

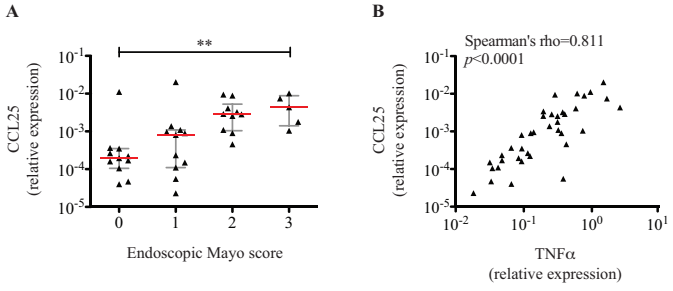
E-mail: p.j.trivedi@bham.ac.uk

Background and Aims: Recruitment of mucosal T-cells to the liver in response to aberrantly expressed homing signals drives hepatobiliary inflammation in primary sclerosing cholangitis (PSC). This is exemplified by the 'gut-homing' chemokine CCL25, which recruits intestinal CCR9$^+$ effector cells to the PSC liver. However, previous studies report CCL25 expression as being confined to the small bowel whereas PSC is typically associated with colonic inflammation. Our aim was to determine whether CCL25 and CCR9 are expressed in the inflamed human colon in patients with ulcerative colitis.
Methods: Mucosal biopsies were obtained during surveillance colonoscopy (n = 40) and colonic tissue from patients undergoing surgical resection for refractory colitis (n = 6), or non-colitis-associated cancer (n = 5). CCL25 mRNA (relative to GUSB) was evaluated by qRT-PCR and protein expression confirmed using western blotting (relative to β-actin) and tissue-ELISA. Lymphocyte CCR9 expression was quantified by flow cytometry, and the ability of sorted $\alpha4\beta7^+CCR9^+$ and $\alpha4\beta7^+CCR9^-$ T-cells to transmigrate across hepatic sinusoidal endothelium (HSEC) investigated in flow-based adhesion assays.
Results: CCL25 mRNA and protein were absent from normal colon but present in ulcerative colitis. CCL25 mRNA expression correlated with endoscopic Mayo score (0.0029 vs. 0.00023; p = 0.0001) and tissue levels of TNFα (Spearman's rho 0.811; p < 0.0001) as indices of inflammatory activity (Figure 1). In colitis, 93% of CD4$^+$ and 16% of CD8$^+$ T-cells expressed CCR9 (6% and 2% in normal colon; p = 0.01 and 0.03) and were predominantly CD127$^+$ effector lymphocytes. $\alpha4\beta7^+CCR9^+$ T-cells showed enhanced transendothelial migration across HSEC compared with $\alpha4\beta7^+CCR9^-$ T-cells (60 vs. 30 cells/10^6 perfused; p = 0.045).



Conclusions: CCL25 is expressed in the inflamed human colon, correlates with inflammatory activity and is associated with high frequencies of CCR9$^+$ tissue-infiltrating lymphocytes. These findings lend further support to the mucosal lymphocyte homing hypothesis of PSC and show how it can be applied to colitis.

E-mail: w.lammers@erasmusmc.nl

Background and Aims: In primary biliary cirrhosis (PBC) several biochemical criteria have been proposed to evaluate response to ursodeoxycholic acid (UDCA) after 1 year of therapy. All criteria are predictive of transplant-free survival, but with varying performance. We aimed to develop a prediction model identifying patients in need of additional therapy after 1 year and also during the course of therapy.
Methods: Data from 4119 UDCA-treated patients of the international Global PBC Study Group platform were included. The database was randomly split in a derivation (n = 2488, 60%) and validation cohort (n = 1631, 40%). Cox proportional hazard regression model was used to develop a model predicting transplantation-free survival based on a combination of biochemical and clinical variables after 1 year of UDCA therapy. Usefulness was tested up to 5 years follow-up. Predictive ability was tested with AIC and C statistic and compared with existing criteria. Finally, patients were sex-, age- and calendar time matched with the general Dutch population to identify patients with a significantly worse survival than the general population; hence most in need of additional therapy.

Results: In the derivation set 558 patients underwent liver transplantation or died during a median follow-up of 7.8 years and in the validation set 328 patients during a follow-up of 7.5 years. Variables included in our final model were: age at entry (HR 1.05, P < 0.0001), bilirubin (HR 2.56, P < 0.0001), albumin (HR 0.10, P < 0.0001), alkaline phosphatase (HR 1.40, P = 0.0002) and platelet count (HR 0.97, P < 0.0001) and a prognostic index was calculated based on the beta coefficients. The model at 1 year follow-up had a good performance in both the derivation (C statistic 0.81, 95% CI 0.79–0.83) and validation cohort (0.82, 0.79–0.84) and was better compared with Barcelona (0.58, 0.55–0.60), Paris-1 (0.69, 0.66–0.71), Rotterdam (0.69, 0.66–0.71), Toronto (0.61, 0.58–0.63) and Paris-2 criteria (0.63, 0.61–0.65). The model had a comparable performance after 2, 3, 4 and 5 years of UDCA therapy and did not lose predictive power. 50% of patients were identified with a survival significantly deviating from that of a matched population.
Conclusions: We showed and validated that during UDCA therapy liver transplant-free survival can accurately be predicted with a model comprising age, bilirubin, albumin, alkaline phosphatase and platelet count. The model is useful up to 5 years UDCA therapy. 50% of patients could potentially benefit of additional therapies to UDCA.

P1181
MICROBIOTAL PRODUCT ACTIVATION OF NLRP3 INDUCES IL-18 SYNTHESIS AND IMPAIRS THE EPITHELIAL BARRIER FUNCTION IN REACTIVE CHOLANGIOCYTES

M. Marzioni[1], L. Agostinelli[1], L. Maroni[1], S. Saccomanno[1], E. Mingarelli[1], C. Rychlicki[1], S. De Minicis[2], J.M. Banales[3], A. Benedetti[4], G. Svegliati-Baroni[1]. *[1]Università Politecnica delle Marche, Ospedali Riuniti University Hospital, Ancona, [2]A. Murri Hospital, Fermo, Italy; [3]Biodonostia Research Institute – Donostia University Hospital, San Sebastian, Spain; [4]Biodonostia Research Institute – Donostia University Hospital, Ancona, Italy*
E-mail: luca.maroni@live.it

Background and Aims: Microbiobial products are hypothesized to be able to affect cholangiocyte biological response to injury and to participate to the development of cholangiopathies, in particular of Primary Sclerosing Cholangitis (PSC). Microbiotal products activate a signalling cascade defined as inflammasome, being NLRP3 one of the key molecules. NLRP3 induces IL-1β and IL-18 synthesis and release, thus modulating cell biology and eliciting pro-inflammatory signals. We aimed to verify whether NLRP3 inflammasome is activated in sclerosing cholangitis and which are its effects in reactive cholangiocytes.
Methods: NLRP3 expression was tested in cholangiocytes from normal and cholestatic livers. NLRP3 was knocked down *in vitro* by siRNA. *In vivo*, wild type (WT) and *Nlrp3*^{A350VneoR} (*Nlrp3*$^{-/-}$) mice were fed with 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC, a model of sclerosing cholangitis) for 4 weeks.
Results: NLRP3 is overexpressed in cholangiocytes of mice subjected to DDC and of patients affected by PSC, but not in normal conditions. *In vitro*, exposure of cultured cholangiocytes to LPS/ATP induced NLRP3 and interleukin (IL)-18 expression but not IL-6 or IL-1β expression and release. LPS/ATP also significantly decreased Zonluin-1 expression and did not affect cell proliferation. Knock down of NLRP3 expression by siRNA neutralized the effects of LPS/ATP on IL-18 synthesis and re-established Zonulin-1 expression. *In vivo*, the increases in the liver CK-19-positive parenchyma induced by 4 week DDC in WT animals were reduced in *Nlrp3*$^{-/-}$ mice.
Conclusions: NLRP3 is expressed in reactive cholangiocytes and its activation leads to IL-18 synthesis, Zonulin-1 downregulation and to impaired biological response to injury. These findings suggest that microbiotal products may participate to the development of certain cholangiopathies by activating the inflammasome in cholangiocytes and impairing the barrier function of the biliary epithelium.

E-mail: oihane.erice@biodonostia.org

Background and Aims: Primary biliary cirrhosis (PBC) is a chronic cholestatic liver disease associated with autoimmune phenomena targeting the intrahepatic bile duct cells (ie. cholangiocytes). Changes in the expression of miRNAs (miRs) were reported in livers from PBC patients compared to normal controls. We recently reported that the overexpression of miR-506 in PBC livers is preferentially located in the bile duct cells, where it promotes cholestasis through the direct targeting of both the Cl^-/HCO_3^- anion exchanger 2 (AE2) [Banales JM, *et al. Hepatology* 2012; 56(2): 687–697] and the inositol 1,4,5-trisphosphate receptor ($InsP_3R3$) [Ananthanarayanan M, *et al. J Biol Chem.* 2014; *in press*]. Here, we investigated the mechanisms of miR-506 overexpression and its direct role in the regulation of cholangiocyte pathophysiology.
Methods: Different sizes of miR-506 promoter (3000, 2000 or 1000 bp) were cloned in a luciferase expression vector, which were transfected in human cholangiocytes (H69 cells). The role of pro-inflammatory cytokines, bile acids, estrogens and glucocorticoids was evaluated on the promoter activities. MiR-506 or a negative controls miRNA sequence were also cloned in an expression vector under the regulation of the CMV promoter; these constructs were stably transfected in H69 human cholangiocytes, and the cell proliferation and adhesion were evaluated. Proteomic analysis of H69, H69-CMV-miR(−) and H69-CMV-miR506 were carried out.
Results: The 3000 bp miR-506 promoter (Z1) showed higher basal luciferase activity compared to the 2000 (Z2) and 1000-bp (Z3) constructs in H69 human cholangiocytes. The presence of pro-inflammatory cytokines found overexpressed PBC livers (ie, IL8, IL12, IL17 and IL18) upregulated the Z1 promoter activity but not the Z2 and Z3 activities. On the other hand, bile acids, estrogens and glucocorticoids did not alter the miR-506 promoter activities. Overexpression of miR-506 decreased cholangiocyte proliferation and adhesion. These functional alterations were linked to changes in the expression of proteins involved in the mitochondrial energetic metabolism and the cytoskeleton.
Conclusions: Upregulation of miR-506 in PBC cholangiocytes may be promoted by pro-inflammatory cytokines. MiR-506 inhibits the proliferation and adhesion of human cholangiocytes by regulating different metabolic and cytoskeletal proteins. MiR-506 represents a potential therapeutic target for PBC patients.

P1183

URSODEOXYCHOLIC ACID INHIBITS HEPATIC CYSTOGENESIS IN EXPERIMENTAL MODELS OF POLYCYSTIC LIVER DISEASE

P. Muñoz[1,2], J.J. Garcia Marín[2,3], M.J. Perugorria[1,2,4], A.D. Urribarri[5], E. Saez[5], M. Uriz[5], S. Sarvide[5], A. Portu[5], A. Concepción[5], M. Rodriguez Romero[2,3], M.J. Monte[2,3], A. E-mail: patricia.munoz@biodonostia.org

Background and Aims: Polycystic liver diseases (PCLDs) are genetic disorders characterized by progressive biliary cystogenesis, which is the main cause of morbidity. Current therapeutic strategies show short-term and/or modest beneficial effects. We and others have recently reported that the hyperproliferation of polycystic cholangiocytes is dependent on the persistent downregulation of the intracellular calcium levels $[Ca^{2+}]_i$ (Perugorria MJ, et al. *Nat Rev Gastroenterol Hepatol*. 2014; *in press*). Thus, pharmacological approaches aimed to normalize the $[Ca^{2+}]_i$ in cystic cholangiocytes have been suggested as potentially beneficial. Here, we investigated the therapeutic value of ursodeoxycholic acid (UDCA) in this condition and the molecular mechanisms of action.
Methods: UDCA was examined *in vitro* and in polycystic (PCK) rats. Hepatic cystogenesis, fibrosis, inflammation and the bile acid content were analyzed in PCK rats treated with UDCA for 5 months. Likewise, the animal motor behavior was evaluated by using the *Open field* test with infrared rays.
Results: Chronic treatment of PCK rats with UDCA for 5 months halts hepatic cystogenesis, fibrosis and inflammation, and improves their motor behavior. As compared to normal animals, PCK rats show increased intrahepatic concentration of bile acids. The *Cyp7a1* mRNA is not different between normal and PCK rat livers and the bile acid concentrations are lower in bile samples collected from PCK than in normal rats. These data suggest that the increased intrahepatic bile acid concentration in PCK rats may be preferentially accumulated in biliary cysts. We found that UDCA decreases the intrahepatic accumulation of cytotoxic bile acids in PCK rats and normalizes the diminished bile acid concentration in bile collected from PCK rats. *In vitro*, UDCA inhibits the hyperproliferation of polycystic human cholangiocytes in a dose-dependent manner without affecting apoptosis rate; this event was associated with increased $[Ca^{2+}]_i$, AKT phosphorylation and diminished ERK1/2 phosphorylation.
Conclusions: UDCA inhibits the hyperproliferation of polycystic human cholangiocytes by raising intracellular $[Ca^{2+}]_i$ that may increase AKT phosphorylation and subsequently inhibits the MAP kinases pathway. UDCA halts the liver disease of an animal model of PCLD, representing a potential therapeutic tool that is currently being evaluated in an international multicenter phase II clinical trial (http://clinicaltrials.gov/show/NCT02021110).

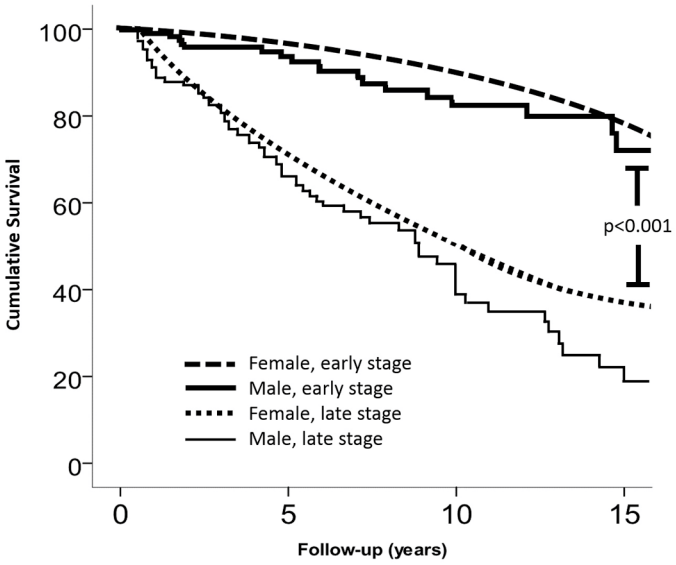
E-mail: angelac.cheung@utoronto.ca

Background and Aims: Primary biliary cirrhosis (PBC) largely affects middle-aged females, thus disease epidemiology in young and male patients is limited. The primary aim was to identify age and sex differences in biochemical response and transplant-free survival using the Global PBC Study Group database.
Methods: A longitudinal study was performed from a well-defined cohort of 4117 patients treated with ursodeoxycholic acid (UDCA). Logistic regression and Cox proportional hazard models were applied, adjusted by center. Biochemical response to UDCA was defined by Paris-1 criteria.
Results: 413 males and 3704 females were included. At diagnosis, males were older (52.9±11.8 vs 56.7±12.6, $p < 0.0001$), with more advanced disease (higher bilirubin, 0.65×ULN vs 0.82×ULN, $p = 0.034$, and more portal hypertension, 22% vs 14%, $p = 0.001$). On univariate analysis, males were less likely to respond than females (60% vs 70%, $p < 0.0001$). After adjusting for age, era of diagnosis, disease stage, log bilirubin, log alkaline phosphatase (ALP) and platelets, sex was no longer an independent predictor of response ($p = 0.852$). Similarly, on univariate analysis for death or liver transplantation, male sex was significant (HR 1.65, 95% CI 1.39–1.95), but this association disappeared after adjusting for age, disease stage, year of diagnosis, log bilirubin, log ALP and response.

Younger patients with early stage disease had a significantly lower response than their older counterparts, regardless of sex (30–39 years: OR 2.24 95% CI 0.99–5.09 vs 70–79 years: 5.92 95% CI 2.44–14.32); patients with moderate/late disease had uniformly poor response to treatment across all age groups.

Conclusions: After adjusting for disease severity, males appear to have comparable response and transplant-free survival as females with PBC. Younger patients with early disease have significantly diminished response compared with older patients at the same stage. Our study suggests that age and disease severity at diagnosis are the most significant independent predictors of response and prognosis in patients with PBC. Early diagnosis and therapeutic intervention is key in these rare subgroups. Young patients with poor UDCA response, particularly with early disease, should be targeted for newer therapies as they have the potential to derive the greatest benefit.



P1185

EFFECTIVENESS OF ADALIMUMAB FOR PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS ASSOCIATED WITH INFLAMMATORY BOWEL DISEASE

I. Franceschet[1], N. Cazzagon[1], A. Floreani[1]. [1]*Dept. of Surgery, Oncology and Gastroenterology, University of Padova, Padova, Italy*
E-mail: irene.franceschet@gmail.com

Background and Aims: Primary sclerosing cholangitis (PSC) is a chronic biliary disease with a marked comorbidity with extra-hepatic conditions, mainly inflammatory bowel disease (IBD). The medical treatment for PSC is still disappointing, whereas immunomodulators and biologics have been able to demonstrate efficacy in IBD. *Aim:* To analyse: (1) the natural history of patients with PSC ± associated with IBD; (2) the long-term efficacy of biologics in patients with PSC and concomitant IBD.

Methods: 92 consecutive PSC patients (seen from 1987 to 2014) were included in the study: 50 (54.3%) were males, and 42 (45.7%) females. The mean age at diagnosis was 32.0±14.3 years, and the mean follow-up was 103.8±86 months. Forty-nine patients (53.3%) had associated IBD (38 ulcerative colitis, 10 Crohn's disease, 1 indeterminate colitis). Clinical activity and endoscopic severity were scored according to the CD activity index and Mayo subscore for endoscopy.

Results: Table 1 shows the major events occurred during the follow-up. Three patients with IBD experienced, as second-line treatment, Adalimumab (ADA), an anti-TNFa monoclonal antibody, previous written consensus. Patients were assessed before starting treatment, at month 6 and 12. ADA induction was 160 mg at week 0, and then 80 mg at week 2, while ADA maintenance treatment was 40 mg every 2 weeks. After 6 and 12 months of ADA, a sustained clinical remission of IBD was obtained; a reduction in ALT, GGT, alkaline phosphatase and Mayo PSC score was obtained.

Event	PSC + IBD (N = 49)	PSC − IBD (N = 43)	p
OLTx	7 (14.3%)	7 (16.3%)	0.79
CCA	0	2 (4.6%)	0.13
HCC	2 (4.1%)	0	0.18
Gallbladder cancer	1 (2.0%)	0	0.35
Colorectal cancer	4 (8.2%)	0	0.05
Death	5 (10.2%)	5 (11.6%)	0.83

Conclusions: This is the first study evaluating the efficacy of biologic agents in PSC. Promising results come from ADA for PSC+IBD during a 12 months follow-up. Furthers studies are warranted to investigate the long-term tolerability and efficacy in such patients.

P1186

CHOLESTASIS AND BILE ACIDS INDUCE EXPRESSION OF THE ONCOFETAL MARKER Nope IN ADULT MURINE HEPATOCYTES INDEPENDENT OF FXR

A. Bowe[1], V. Hoffmann[1], H. Morton Curth[1], P. Fickert[2], D. Nierhoff[1]. [1]*Gastroenterology and Hepatology, University hospital cologne, Cologne, Germany;* [2]*Research Unit for Experimental and Molecular Hepatology, Division of Gastroenterology and Hepatology, Medical University of Graz, Graz, Austria*
E-mail: AndreaBowe@gmx.de

Background and Aims: Neighbor of Punc E11 (Nope) is strongly expressed in hepatic stem/progenitor cells and in hepatocellular carcinoma but not in terminally differentiated hepatocytes. We here investigated the expression pattern of Nope in adult mice after biliary liver injury.

Methods: Liver tissue was extracted from adult C57Bl/6 mice and $Fxr^{-/-}$ mice 24 hours up to 4 weeks after bile duct ligation (BDL) or after a 1 week diet containing cholic (0.5%) or ursodeoxycholic acid (0.5%). Liver tissue was tested for expression levels of Nope via quantitative RT-PCR. Costainings were performed for Nope in combination with CK19 (biliary), E-cadherin (epithelial) or the canalicular marker dipeptidylpeptidase (DPP) IV.

Results: Bile duct ligation leads to a significantly increasing expression level of Nope (after 1 week 87-fold vs. adult liver, p = 0.00016). Costainings with E-cadherin and DPPIV demonstrate a sinusoidal expression pattern of Nope on hepatocytes, but no expression on CK19-positive cholangiocytes (after 4 weeks 676-fold vs. adult liver). At later stages after BDL, almost all of the hepatocytes stain positive for Nope. In $Fxr^{-/-}$ mice, Nope is expressed without additional biliary injury (28-fold vs. adult liver, p < 0.0007) and shows a further and significant increase after BDL (440- vs. 28-fold, p = 0.03). A diet with cholic (26-fold vs. adult liver, p = 0.002) or ursodeoxycholic acid (8-fold vs. adult liver, p = 0.004) also leads to a significant expression of Nope with a membranous staining pattern on hepatocytes. A diet with hydrophobic acids results in a significantly higher expression of Nope (p = 0.04).

Conclusions: We here report the bile acid-induced expression of the oncofetal marker Nope on adult hepatocytes probably indicating their dedifferentiation. The induction of Nope is not mediated through Fxr but a lack of the receptor leads to a higher expression level probably due to limited compensatory mechanisms of bile acid homeostasis in hepatocytes.

P1187

CD4+ T CELLS FROM PATIENTS WITH PSC EXHIBIT A REDUCED APOPTOTIC SENSITIVITY AND DOWNREGULATION OF PROAPOPTOTIC Bim IN PERIPHERAL BLOOD

T. Schoknecht[1], D. Schwinge[1], C. Weiler-Normann[1], N. Pannicke[1], M. Sebode[1], J. Herkel[1], A.W. Lohse[1], C. Schramm[1]. [1]*I. Department of Internal Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*
E-mail: t.schoknecht@uke.de

Background and Aims: The immunopathogenesis of the chronic liver disease primary sclerosing cholangitis (PSC) remains largely elusive. Recently, genetic studies indicated that PSC is associated with polymorphisms in the locus encoding for proapoptotic Bim. Bim is crucial for immunological tolerance through induction of apoptosis of activated T cells in response to T cell receptor (TCR) restimulation-induced cell death (RICD) as well as cytokine withdrawal-induced cell death (CWID). We therefore aimed to investigate, whether a defective apoptosis of T cells might contribute to the pathogenesis of PSC.
Methods: A total of 34 patients with PSC, 26 patients with PBC and 32 healthy donors were included in the study. T cells were freshly isolated from peripheral blood and were activated with anti-CD3 and anti-CD28. Induction of apoptosis was triggered by TCR restimulation with anti-CD3 in the presence of IL-2 (RICD) or by IL-2 withdrawal (CWID) for 24 h. Cell loss of CD4+ and CD8+ T cells was quantified by Annexin V staining using flow cytometry. Expression of proapoptotic and antiapoptotic molecules after RICD or CWID was quantified by qRT-PCR.
Results: CD4+ T cells from patients with PSC showed, compared to control groups, a significantly reduced cell loss after induction of apoptosis by RICD (PSC: 20.9% vs healthy: 30.1% vs PBC: 33.6%, $p = 0.0002$) as well as by CWID (PSC: 7.1% vs healthy: 12.1% vs PBC: 12.3%, $p = 0.003$). Cell loss of CD8+ T cells showed no significant differences after RICD or CWID between analysed groups. We next investigated the expression of proapoptotic (Bim, Fas-ligand, Bak) and antiapoptotic molecules (Bcl-2) in T cells. Whereas there was no difference in the expression of Fas-ligand, Bak or Bcl-2, the expression of proapoptotic Bim in T cells from PSC patients was significantly decreased after RICD as compared to control groups (fold induction: PSC: 6.8 vs healthy: 12.9 vs PBC: 12.8, $p = 0.0098$).
Conclusions: Our findings indicate that CD4+ T cells from patients with PSC exhibit a significantly reduced apoptosis sensitivity. A diminished up-regulation of proapoptotic Bim may contribute to this phenotype. Thus, defective apoptosis of activated CD4+ T cells may be part of the immune dysregulation observed in patients with PSC. Future studies must show whether these findings relate to the genetic associations recently described.

P1188

AUTOIMMUNE HEPATITIS (AIH) AND PRIMARY BILIARY CIRRHOSIS (PBC) ALTER THE N-LINKED GLYCOSYLATION PATHWAY

A. Lee[1,2], M.N. Christiansen[3], N.H. Packer[3], S.V. McLennan[2,4], N.A. Shackel[1,2,5]. [1]*Liver Injury and Cancer, Centenary Institute of Cancer Medicine and Cell Biology,* [2]*Sydney Medical School, The University of Sydney, Camperdown,* [3]*Department of Chemistry and Biomolecular Sciences, Macquarie University, North Ryde,* [4]*Department of Endocrinology,* [5]*A.W. Morrow Gastroenterology and Liver Centre, Royal Prince Alfred Hospital, Camperdown, Australia*
E-mail: alee6991@uni.sydney.edu.au

Background and Aims: Proteins undergo post-translational modifications which can alter their structure and function. *N*-linked glycosylation is one such method of modification. Alterations to glycosylation pathways are involved in diseases such as tumour formation and metastasis. However, not much is known about glycosylation changes in liver disease and injury. The aim of this study was to determine if AIH or PBC alters the *N*-linked protein glycosylation profile of the liver and expression profile of glycosylation-associated genes.
Methods: Liver tissue from non-diseased donors ($n = 10$), AIH patients ($n = 7$) and PBC patients ($n = 7$) was treated with peptide:*N*-glycosidase F to obtain membrane protein *N*-linked glycans which were then analysed using liquid chromatography-electrospray ionization tandem mass spectrometry. Real-time PCR was used to analyse the expression of glycosylation-associated genes involved in the formation of these glycans.
Results: The membrane protein *N*-linked glycan profile of the diseased livers showed that there were less hybrid and complex type glycans and more high mannose type glycans compared to the donor tissue. There was also more fucosylation and less sialylation of the glycan structures in the diseased tissue. The expression of genes known to be involved in the formation of these structures were also dysregulated in the same pattern in which the proteins were affected. MAN1A1 involved in removing mannose residues was downregulated ($P < 0.001$), fucosylation genes FUT4 and FUT8 were upregulated ($P < 0.001$), and sialylation genes ST3GAL2 and ST3GAL6 were downregulated ($P < 0.05$).
Conclusions: Liver cell membrane protein *N*-linked glycan structures were found to be altered in both AIH and PBC compared to donor tissue. This was also reflected in the gene expression data which indicates that the post-translational changes are occurring due to irregularities at the transcriptional level. The pattern of glycosylation also indicates that there is an aberration in the *N*-linked glycosylation pathway where proteins are being processed through the Golgi apparatus to become fucosylated and expressed at the cell surface, but the high mannose type glycan structures indicate that distal changes to the glycan structure are not occurring.

P1189

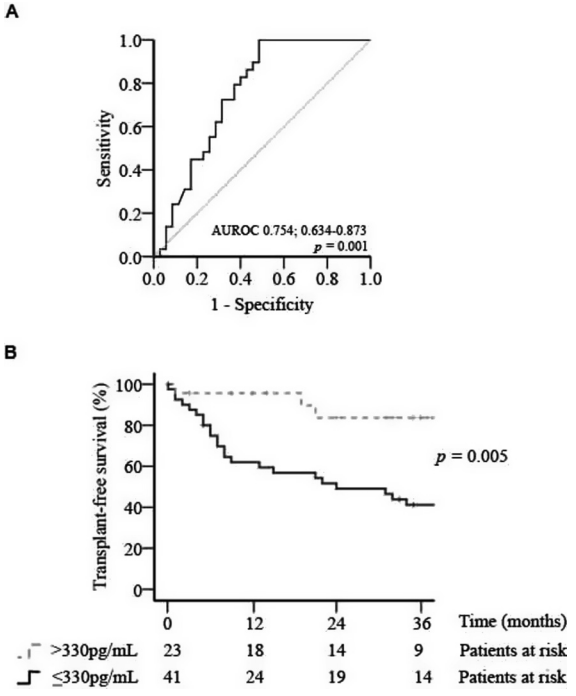
DECREASED SERUM TWEAK LEVELS ARE PREDICTIVE OF ADVERSE OUTCOME IN PRIMARY SCLEROSING CHOLANGITIS

A. Wilhelm[1], P.J. Trivedi[1], G.M. Hirschfield[1], J.D. Widmer[1], C.J. Weston[1], S.C. Afford[1]. [1]*Centre For Liver Research and NIHR Biomedical Research Unit, University of Birmingham, Birmingham, United Kingdom*
E-mail: wilhelm_annika@yahoo.co.uk

Background and Aims: Primary sclerosing cholangitis (PSC) is a progressive inflammatory cholangiopathy. TNF-like weak inducer of apoptosis (TWEAK) is a mediator of inflammation and a mitogen for ductular reactive cells both of which are prominent features in PSC. Given that robust biomarkers reflective of disease activity and prognosis are lacking in PSC, our aim was to prospectively evaluate circulating soluble (s)TWEAK titre with regard to outcome prediction across a cohort of UK PSC patients.
Methods: Serum samples were obtained from 64 individuals newly diagnosed with PSC between 2010–3 (median age 36; 62.5% male), 24 ulcerative colitis patients and 24 healthy control subjects. sTWEAK was quantified using ELISA and correlated with clinical outcome. Risk-analysis was performed using Cox proportional hazards modelling, logistic regression and Kaplan–Meier survivorship estimates (SPSS v21).
Results: sTWEAK titre was significantly lower in patients with PSC (275 pg/mL, IQR 111–410) compared to healthy controls (942, 885–1044; $p < 0.01$) and individuals with ulcerative colitis alone (1130, 959–1429; $p < 0.0001$). Lower sTWEAK levels when applied as a continuous variable was predictive of rapid progression to liver transplantation/death with high accuracy (AUROC 0.754; Figure 1A). Stratification through a cut point of 330 pg/mL (sensitivity 86%) predicted poorer transplant-free survival in PSC patients with lower titres (unadjusted HR: 4.013; $p < 0.01$; Figure 1B). Additional predictors of poor outcome were elevated

baseline ALP (HR: 1.136), hypoalbuminaemia (HR: 1.164), elevated bilirubin (HR: 1.004), INR >1.2 (HR: 3.497), hyponatraemia (HR: 1.176) and immunosuppression (HR: 3.501) (all $p < 0.05$). However, sTWEAK retained predictive value on multivariable analysis independent of all tested covariates (adjusted HR: 3.628, $p = 0.044$).

Conclusions: Lower sTWEAK levels distinguish patients with PSC compared to those with colitis alone and healthy subjects. Moreover, sTWEAK represents a robust prognostic marker of rapid disease progression. This observation contributes to ongoing efforts serving to refine risk-stratification tools in PSC.



P1190

THE ROLE OF NKT CELLS IN A MOUSE MODEL (NOD.C3C4) WITH SPONTANEOUS BILE DUCT INFLAMMATION

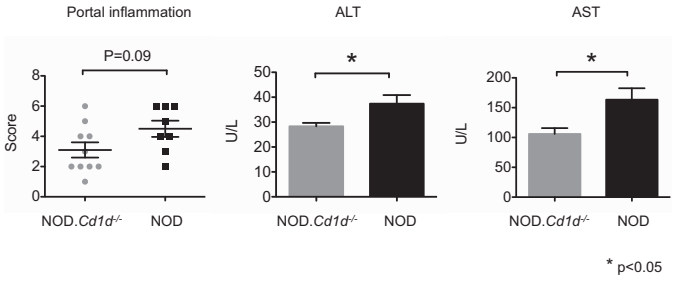
E. Schrumpf[1,2,3], X. Jiang[1,2], S. Zeissig[4], M.J. Pollheimer[5,6], J.A. Anmarkrud[1], C. Tan[1], M.A. Exley[7,8], T.H. Karlsen[1,2,3], R.S. Blumberg[8], E. Melum[1,2]. *[1]Norwegian PSC Research Center, Division of Cancer, Surgery and Transplantation, [2]K.G. Jebsen Inflammation Research Centre, Research Institute of Internal Medicine, Oslo University Hospital, Rikshospitalet, [3]Institute of Clinical Medicine, University of Oslo, Oslo, Norway; [4]Department of Internal Medicine, University Hospital Schleswig-Holstein, Kiel, Germany; [5]Research Unit for Experimental and Molecular Hepatology, Division of Gastroenterology and Hepatology, Department of Internal Medicine, [6]Institute of Pathology, Medical University of Graz, Graz, Austria; [7]Manchester Collaborative Centre for Inflammation Research (MCCIR) Faculty of Medical & Human Sciences, University of Manchester, Manchester, United Kingdom; [8]Division of Gastroenterology, Hepatology and Endoscopy, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, United States*
E-mail: elisabeth.schrumpf@medisin.uio.no

Background and Aims: Natural killer T (NKT) cells are activated by lipid antigens presented by CD1d molecules and represent an important regulatory lymphocyte subset of the liver. The NOD.c3c4 mouse was developed on a NOD background and spontaneously develops biliary inflammation both in extra- and intra-hepatic bile ducts. NOD mice are known to have systemic NKT cell defects (Baxter et al., 1997). We aimed to clarify if NKT cells contribute to disease development in the NOD.c3c4 model.

Methods: The lymphocyte populations from spleens, thymii and livers of NOD.c3c4 mice (n = 3–5) and NOD control mice (n = 3–5) were investigated. Lymphocytes were stained *ex vivo* for NKT cell and activation markers and analyzed by flow cytometry. NOD mice (n = 10) and NOD.*Cd1d*$^{-/-}$ mice (n = 10) were irradiated and injected with NOD.c3c4 bone marrow to create bone marrow chimeras. Three months after bone marrow transfer, liver histology and serum samples were analyzed.

Results: NKT cells were twice as abundant in all three tissues of NOD.c3c4 mice compared to NOD control mice. The NKT cells in the NOD.c3c4 mice displayed an activated phenotype indicated by up-regulation of CD122 in thymus, spleen and liver. Transfer of NOD.c3c4 bone marrow led to a more severe biliary disease in the NOD than in the NOD.*Cd1d*$^{-/-}$ mice. The NOD mice had a trend towards larger biliary inflammatory infiltrates (p = 0.09) and significantly higher serum alanine transferase and aspartate transferase levels compared to *Cd1d*$^{-/-}$mice (p < 0.05 for both comparisons, see figure).

Conclusions: The present study demonstrates that NKT cells are more abundant and show an activated phenotype in liver, spleen and thymus in the NOD.c3c4 model. NOD.c3c4 bone-marrow transfer suggested that CD1d plays a role in development of bile duct inflammation in this model.



P1191

INCREASED IgG4 RESPONSES TO MULTIPLE ENVIRONMENTAL ANTIGENS INDICATE A POLYCLONAL EXPANSION AND DIFFERENTIATION OF PRE-EXISTING B CELLS IN AUTOIMMUNE PANCREATITIS AND IgG4-RELATED CHOLANGITIS

E.L. Culver[1], M. Makuch[2], E. Vermeulen[2], A. van Leeuwen[2], R. Sadler[3], T. Cargill[1], P. Klenerman[1], R.C. Aalberse[2], S.M. Van Ham[2], E. Barnes[1], T. Rispens[2]. *[1]Peter Medawar Building, Oxford University, Oxford, United Kingdom; [2]Immunopathology, Sanquin Research, Amsterdam, Netherlands; [3]Clinical Immunology, Churchill Hospital, Oxford, United Kingdom*
E-mail: emmaculver@yahoo.co.uk

Background and Aims: Autoimmune pancreatitis and IgG4-related sclerosing cholangitis are the pancreatic and biliary manifestations of a systemic fibro-inflammatory condition (IgG4-related disease; IgG4-RD), characterized by an elevated serum IgG4 concentration and abundant IgG4-positive plasma cells in the involved organs. An important question is whether the elevated IgG4 response is causal, or a mere reflection of immune-regulatory mechanisms of the disease. We sought to investigate if the IgG4 response represents a generalised polyclonal amplification by examining the response to common environmental antigens.

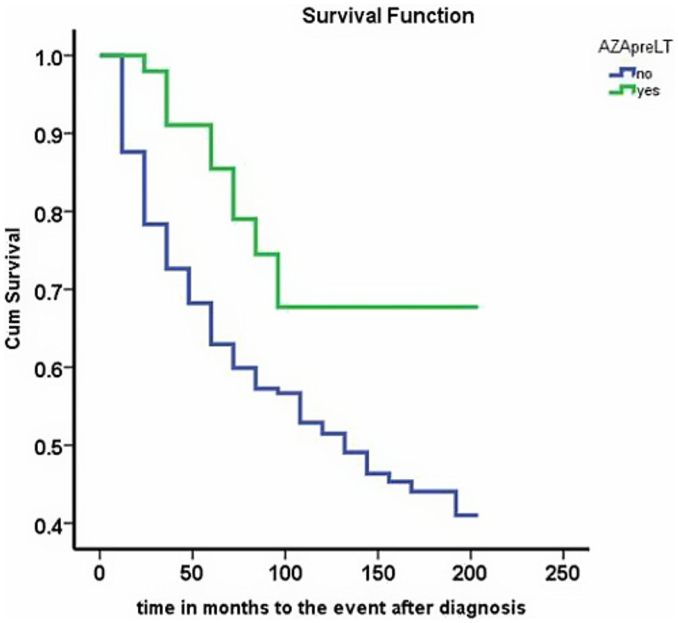
Methods: Serum from 24 patients with IgG4-RD (14 treatment-naïve, 10 treatment-experienced), 9 patients with primary sclerosing cholangitis and an elevated serum IgG4 (PSC-high IgG4), and 18 healthy controls were tested against egg white and yolk, milk, banana, cat dander and serum, peanut, rice and wheat antigens by radioimmunoassay. Serum levels of IgG subclasses and IgE were measured and serum electrophoresis and immunofixation performed.

Results: The concentration of serum total IgG, IgG4, IgE, and to a lesser extent IgG1, was higher in IgG4-RD patients versus healthy controls, as well as in the PSC-high IgG4 patients versus healthy controls. We demonstrated an elevated polyclonal IgG4 response to multiple antigens in patients with IgG4-RD [egg (p = 0.004); milk (p = 0.04); peanut (p = 0.0003); cat dander and serum (p = 0.012); rice and wheat (p = 0.006)] and in PSC-high IgG4 [egg (p = 0.03); cat dander and serum (p = 0.04); rice and wheat (p = 0.01)], compared to healthy controls. There was a strong positive correlation between serum IgG4 and multiple antigen-specific responses. Responses to antigens [banana (p = 0.001), egg (p = 0.039), peanut (p = 0.003), and cat (p = 0.006)] were higher in treatment-naïve compared to treatment-experienced IgG4-RD patients, as were serum total IgG (p = 0.017) and IgG4 (p = 0.001). Serum electrophoresis and immunofixation demonstrated polyclonality in all patients.
Conclusions: This is the first study to show enhanced levels of polyclonal IgG4 to multiple antigens in patients with IgG4-RD. This supports that elevated IgG4 levels reflect an aberrant immunological regulation of the overall IgG4 response, but does not exclude that causality of disease could be antigen-driven.

P1192
AZATHIOPRINE, STEROIDS AND THE PRESENCE OF INFLAMMATORY BOWEL DISEASE BEFORE LIVER TRANSPLANTATION INFLUENCE TRANSPLANT FREE SURVIVAL IN PRIMARY SCLEROSING CHOLANGITIS

F. Saffioti[1], P. Manousou[1], S. Aspite[1], D. Chatzidis[1], A. Marshall[1], M. Pinzani[1], D. Thorburn[1]. [1]*UCL Institute for Liver and Digestive Health, The Royal Free Sheila Sherlock Liver Centre, Royal Free Hospital, London, United Kingdom*
E-mail: fsaffioti.83@gmail.com

Background and Aims: Primary Sclerosing Cholangitis (PSC) is a chronic, cholestatic liver disease, progressive in the majority of cases. Currently the only therapeutic option is liver transplantation (LT).
Our aim was to assess whether there are any factors affecting the severity of PSC, comparing the course of disease in patients not needing LT and those who died or were transplanted.
Methods: Between 1990 and 2013, 370 consecutive patients with PSC have been diagnosed and followed up. Data was collected retrospectively and Cox regression analysis was used to evaluate all the factors known to affect disease severity: demographics (sex and age at diagnosis), Inflammatory Bowel Diseases (IBD) type [ulcerative colitis (UC), Crohn's disease (CD), indeterminate (IC)] and duration from diagnosis, colonic extent of UC, IBD activity in the last 5 years of follow-up (FUP), IBD treatment during the whole FUP period [steroid, azathioprine (AZA), surgery], severity of disease at last colonoscopy (before last FUP or before LT), prevalence of colorectal dysplasia/carcinoma, PSC duration from diagnosis, PSC severity at last FUP before LT (serum albumin, bilirubin and decompensation), UDCA treatment, cholangiocarcinoma, outcome. FUP was censored at time of LT, death or last FUP.
Results: 234 (63%) male, median age at diagnosis 41 years: 333 patients were diagnosed with PSC, 16 with small duct PSC, 21 with autoimmune overlap. 138 (41%) were transplanted at a median of 40 months from diagnosis. 62 (17%) died at a median of 94 mo from diagnosis. 246 (67%) were diagnosed with IBD: 208 UC, 30 CD, 8 IC. 20 had colon cancer, 13 dysplasia. 66 underwent colectomy.
Cox regression analysis revealed that factors associated with transplant free survival were: AZA use pre-LT (p = 0.012, OR 2.3, 95% CI 1.2–4.4), steroids pre-LT (p = 0.001, OR 4.7, 95% CI 2.2–10.1) and concomitant IBD (p = 0.023, OR 2.11, 95% CI 1.11–3.4). A total of 53 patients were on AZA pre-LT: 7 were transplanted at a median of 62 mo and 5 died at a median of 105 mo from diagnosis. Of 318 not on AZA: 131 underwent LT and 57 died at a median of 44 mo and 82 mo after the diagnosis.
The only factors associated with survival, however, were age at diagnosis <40 years (p = 0.01, OR 1.03, 95% CI 1.01–0.03) and the absence of hepatobiliary malignancy (p = 0.03, OR 0.7, 95% CI 0.5–0.99).
Conclusions: In our cohort of PSC patients, pre-LT use of AZA and steroids significantly prolonged transplant free survival. Patients with concomitant IBD had an increased transplant free survival compared to those without IBD.



P1193
NECROPTOSIS CONTRIBUTES TO THE PATHOGENESIS OF CHOLESTATIC LIVER INJURY

M.B. Afonso[1], P.M. Rodrigues[1], A.L. Simão[1], H. Cortez-Pinto[2,3], D. Ofengeim[4], J. Amaral[1], R.E. Castro[1], J. Yuan[4], C.M.P. Rodrigues[1]. [1]*Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Universidade de Lisboa,* [2]*Gastrenterology, Hospital Santa Maria,* [3]*IMM, Faculty of Medicine, Universidade de Lisboa, Lisbon, Portugal;* [4]*Department of Cell Biology, Harvard Medical School, Boston, United States*
E-mail: mbafonso@ff.ulisboa.pt

Background and Aims: Cholestasis is associated with hepatic toxicity and inflammation. In addition, regulated necrosis may be involved in the pathogenesis of inflammatory liver diseases, and kinase activity of receptor interacting protein 3 (RIP3) is key for necroptic signalling. Thus, we aimed to evaluate the role of necroptosis after common bile duct ligation (BDL), a classic experimental model for acute cholestasis and secondary biliary fibrosis, and in human primary biliary cirrhosis (PBC), a cholestatic chronic liver disease.
Methods: BDL or sham surgery was performed in 6–9 animals per group of C57BL/6 wild-type (WT) or RIP3 knockout (KO) mice. Serum and livers were collected 3 and 14 days after BDL. Histology, serum liver enzymes and bilirubin were evaluated. Liver RIP3 and proinflammatory cytokines mRNA were determined by qRT-PCR. Total and soluble/insoluble liver proteins were analysed by Western blot. RIP3 kinase activity was determined *in vitro*. Finally, RIP3 was evaluated in liver specimens of 5 patients with PBC and 5 healthy controls by immunohistochemistry.
Results: BDL resulted in bile duct hyperplasia, multifocal necrosis, fibrosis and inflammatory cell infiltration in mouse liver.

Concomitantly, RIP3 and mixed lineage kinase domain-like (MLKL) were strongly retained in the insoluble protein fraction ($p < 0.05$), which is consistent with the known insoluble amyloid structure of the necrosome. RIP3 mRNA and protein expression, and RIP3 kinase activity were significantly increased ($p < 0.05$), suggesting necroptosis activation. Remarkably, BDL in RIP3 KO mice resulted in a significant decrease in circulating levels of hepatic enzymes and bilirubin (at least, $p < 0.05$), together with decreased expression of proinflammatory cytokines in liver (at least, $p < 0.05$), both at 3 and 14 days. Histological analysis revealed that RIP3 deficiency strongly abrogated liver necrosis and fibrosis induced by BDL. In addition, RIP3 KO decreased RIP1 phosphorylation and caspase-1 activation ($p < 0.05$), with no change in caspase-3/7 activity. Finally, PBC patients showed augmented liver RIP3 expression, when compared with controls ($p < 0.05$).

Conclusions: In conclusion, RIP3-dependent signalling is activated in human PBC and mediates hepatic necroinflammation and fibrosis in BDL mice. As such, RIP3-dependent signalling should be regarded as a potential therapeutic target in cholestatic liver disease.

DELAYED BILE ACID UPTAKE WITH METABOLIC CONSEQUENCES IN NA+-TAUROCHOLATE COTRANSPORTING POLYPEPTIDE KNOCKOUT MICE

D. Slijepcevic[1], J.M. Donkers[1], C. Kaufman[1], C.G.K. Wichers[1], E.H. Gilglioni[1], F.A. Lempp[1], S. Duijst[1], D.R. de Waart[1], R.P.J. Oude Elferink[1], W. Mier[1], B. Stieger[1], U. Beuers[1], S. Urban[1], S.F.J. van de Graaf[1]. *[1]Tytgat Institute for Liver and Intestinal Research & Department of Gastroenterology & Hepatology, AMC Amsterdam, Amsterdam, Netherlands*

E-mail: d.slijepcevic@amc.uva.nl

Background and Aims: Bile acids (BAs) are metabolic signaling molecules that improve glucose handling and decrease inflammation. We hypothesize that reduced hepatic BA uptake could lead to BA spillover into the circulation, thereby stimulating systemic BA signaling. The Na^+-taurocholate cotransporting polypeptide (NTCP) mediates uptake of conjugated BAs, implying a central function of this basolateral transporter in the enterohepatic circulation of BAs. Here, we investigated conjugated BA dynamics *in vivo* in the first NTCP-knockout mouse model. NTCP was recently also identified as the Hepatitis B Virus (HBV) entry receptor. The HBV entry inhibitor Myrcludex B is described as a potent NTCP inhibitory peptide. Therefore, we tested the specificity of this inhibitory peptide for NTCP *in vivo*.

Methods: We generated a conventional knock-out mouse by deletion of NTCP exon 1. BA kinetics were assessed using tritium-labelled taurocholate (TCA). Mice were fed 0.1% UDCA to challenge the hepatic BA uptake machinery. Bile flow was determined after cannulation of the gall bladder. Expression levels of BA transporters was analyzed by qPCR and Western blot. Mice were imaged by positron emission tomography (PET) to assess binding of gadolinium-labelled Myrcludex B.

Results: NTCP-knockout mice have markedly elevated serum total BA concentrations, mainly composed of conjugated BAs. The body weights of NTCP-knockout mice were significantly reduced directly post-weaning. A subset of knockout mice normalized serum total BA concentrations during maturation, although serum TCA clearance was reduced. The hypercholanemic phenotype was rapidly triggered by UDCA-feeding. Bile flow was slightly reduced, but biliary BA output remained intact. Fecal BA excretion was reduced in hypercholanemic NTCP-knockout mice. However, NTCP-knockout mice showed increased renal BA excretion and reduced *Asbt* expression in kidney. Hepatic uptake of conjugated BAs was potentially affected by downregulation of OATP1A1 and upregulation of OATP1A4. Finally, PET imaging showed a complete abrogation of hepatic binding of Myrcludex B in NTCP-knockout mice.

Conclusions: Chronic NTCP-deficiency causes (episodic) conjugated hypercholanemia, associated with a reduced hepatic BA uptake capacity and renal BA excretion. Finally, Myrcludex B is a specific tool to pharmacologically inhibit NTCP and the NTCP-knockout mouse is an interesting model to study the metabolic effects of conjugated BAs.

CHARACTERISTIC CHANGES IN BILE ACIDS SYNTHESIS REGULATORY MECHANISMS IN PRIMARY BILIARY CIRRHOSIS. UDCA NON-RESPONSE IS ASSOCIATED WITH HIGHER EXPRESSION OF FGF19

E. Wunsch[1], M. Milkiewicz[2], J. Trottier[3], A. Kempinska-Podhorodecka[2], U. Wasik[2], E. Elias[4], O. Barbier[3], P. Milkiewicz[1,5]. *[1]Department of Clinical and Molecular Biochemistry, [2]Medical Biology Laboratory, Pomeranian Medical University in Szczecin, Szczecin, Poland; [3]Laboratory of Molecular Pharmacology, CHU-de-Québec & Faculty of Pharmacy, Laval University, Québec, Canada; [4]University of Birmingham, Birmingham, United Kingdom; [5]Liver and Internal Medicine Unit, Department of General, Transplant and Liver Surgery of the Medical University of Warsaw, Medical University of Warsaw, Warsaw, Poland*

E-mail: ewa.wunsch@gmail.com

Background and Aims: Primary biliary cirrhosis (PBC) affects small bile ducts, leading to hepatocellular accumulation of bile acids (BA) and cholestatic injury of the liver. Cholestasis induces adaptive mechanisms protecting the liver against bile salt toxicity. These include regulatory mechanisms of BA synthesis – fibroblast growth factor 19 (FGF19) and farnesoid X receptor (FXR)/orphan nuclear receptor small heterodimer partner (SHP) signaling pathways. Their expression has not yet been studied in PBC. We analyzed expression of FGF19, FGFR4, FXR, SHP, CYP7A1 and phosphorylation of extracellular signal-regulated kinase (P-ERK/ERK) in patients with PBC and searched for their potential relationship with clinical/laboratory findings.

Methods: In total 96 patients with PBC were studied. Serum FGF19, liver biochemistry, Mayo Risk score, health-related quality of life (HRQoL) and 29 bile acids metabolites were analyzed in 51 patients. Liver tissues from non-cirrhotic (n = 24) and cirrhotic (n = 21) patients were used for molecular analysis.

Results: FGF19 mRNA expression was enhanced in non-cirrhotic and cirrhotic tissues (9 fold; $p < 0.0001$ and 69 fold, $p < 0.0001$, respectively) and correlated with fibrosis stage, indicators of cholestasis, Mayo Risk Score and worse HRQoL. Serum levels of FGF19 correlated with worse liver biochemistry, Mayo Risk Score, UDCA non-response and concentration of several bile acids species. Expression of FXR mRNA was increased in non-cirrhotics compared to controls ($p = 0.0001$). Protein levels of FGF19, FGFR4, FXR and SHP were increased in cirrhotic tissue *vs* controls (9 fold, $p < 0.001$; 2 fold, $p = 0.007$; 2 fold, $p = 0.04$; 2 fold, $p < 0.0001$, respectively). This was accompanied by downregulation of CYP7A1 (almost 50% reduction *vs* control, $p = 0.006$). Similar P-Erk/Erk expression levels in PBC and controls were seen, indicating that repression of Cyp7A1 is not modified in MAPK/ERK dependent manner.

Conclusions: PBC induces characteristic changes in liver expression of BA synthesis regulatory molecules. FXR, SHP, FGF19, FGFR4 are increased in PBC, what is accompanied by downregulation of CYP7A1. Lack of response to UDCA is associated with higher expression of FGF19. Whether up-regulation of FGF19 reflects its contribution to compensatory mechanisms in PBC requires further investigation.

AUTOIMMUNE HEPATITIS WITH T-REGULATORY CELL DEFICIENCY IN THE CONTEXT OF GATA-2 DYSFUNCTION: A NOVEL SINGLE GENE ASSOCIATION

G.J. Webb[1], A.G. Richter[2], M. Blahova[1], S.M. Curbishley[1], K.-K. Li[1], D.A.H. Neil[3], Y.H. Oo[1], D.H. Adams[1], V.H. Bigley[4], M.P. Collin[4], G.M. Hirschfield[1]. *[1]NIHR Centre for Liver Research, University of Birmingham, [2]Department of Immunology, [3]Department of Pathology, Queen Elizabeth Hospital, Birmingham, [4]Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom*
E-mail: gwilym.webb@gmail.com

Background and Aims: To date, only one monogenic disease (AIRE dysfunction) has been associated with autoimmune hepatitis (AIH). We sought to characterise a young woman with AIH as part of a spectrum of immunodeficiency and myelodysplasia.
Methods: Our patient presented to our service aged 27 with hepatitis and ascites. She had a background of lymphoedema in her teens, recurrent superficial skin infections and trilineage cytopaenias requiring repeated transfusion. Investigations revealed IgG at 41.05 g/l, ANA 1:100 and negative viral studies, other than EBV (stable at 10^4-10^5 copies/ml). Liver biopsy showed plasma cells and interface hepatitis consistent with AIH. There was also peribiliary inflammation with granulomata but no mycobacteria, mild steatosis, moderate iron deposition and mild-moderate fibrosis. Staining for other aetiologies including viruses was negative. The International Autoimmune Hepatitis Group score was 21. Corticosteroid treatment induced resolution of ascites and a fall in transaminases, but the patient developed progressive multifocal leukoencephalopathy. Immunosuppression was reduced and transaminses rose again. Peripheral lymphocyte subsets were quantified by flow cytometry, serum Fms-like tyrosine kinase ligand by ELISA and DNA extracted and sequenced.
Results: Sequencing confirmed a novel 1081C>T, R361C mutation in exon 7 of *GATA2*. Monocytes, dendritic, B- and natural killer cells were markedly reduced. Total T-cell numbers were maintained (343.3×10^4/ml; 92–202) but with near absence of $FoxP3^+$ T-regulatory cells (Treg). Serum Flt-3L was elevated (1267 pg/ml; 48–174) consistent with GATA2 dysfunction. The patient was maintained on low dose tacrolimus and steroids but had biochemical evidence of ongoing hepatitis, with worsening anaemia and infections. Stem cell allograft was attempted but failed. Vulval cancer developed secondary to human papilloma virus, and she died from its complications.
Conclusions: Until now, the only monogenic association with AIH has been AIRE dysfunction, although abnormalities in Treg function are proposed. We demonstrate a syndrome consistent with AIH, with near absence of Treg in *GATA2* dysfunction. This is in the context of abnormalities in antigen-presenting and effector cells, and possibly other regulatory mechanisms. Our findings support the hypothesis that deficiencies in regulation, together with unknown environmental triggers (including possible viral infection), may result in an AIH-like illness.

P1197

NATURAL HISTORY OF FATIGUE AND PRURITUS IN PRIMARY BILIARY CIRRHOSIS: IMPLICATIONS FOR THE ROLE OF PRURITUS IN THE AETIOLOGY AND TREATMENT OF FATIGUE

L. Jopson[1], V. Hegade[1], G. Mells[2], R. Sandford[2], D.E. Jones[1]. *[1]Institute of Cellular Medicine, Newcastle University, Newcastle, [2]Academic Department of Medical Genetics, University of Cambridge, Cambridge, United Kingdom*
E-mail: laura.jopson@ncl.ac.uk

Background and Aims: Fatigue and pruritus are the most common symptoms associated with Primary Biliary Cirrhosis (PBC) and both can have a significant impact on quality of life. Effective treatments are available for pruritus but not, as yet, for fatigue. It is postulated that pruritus can worsen fatigue, and that itch should be adequately managed prior to assessing fatigue severity however it is not well understood whether an improvement in pruritus is associated with an improvement in fatigue and the degree to which it has an effect. The aim of this study was to investigate whether fatigue and pruritus are stable over time and whether an improvement in pruritus results in an improvement in fatigue.
Methods: 1000 randomly selected patients from the UK-PBC cohort with baseline and follow-up symptom data were used for this study. Symptom data for fatigue was captured using the PBC-40 and intensity of pruritus in the last seven days on a visual analogue scale (VAS). Longitudinal data was captured at entry into the Cambridge genetics study (2009–2011) and follow-up in 2014.
Results: Severity of symptoms at the two time points was not meaningfully different (Figure 1). Scores at the two time points correlated strongly for both symptoms (Figure 2), however there was significantly more variation in the scores for pruritus. A statistically significant association was seen between the delta pruritus scores and the delta fatigue scores at the two time points for an individual (Figure 3) suggesting a change in pruritus (main variable symptom) has a linked effect on fatigue. Of 179 patients who showed a clinically significant worsening in fatigue score, 56 (31%) had worsening of their itch and only 34 (19%) had a worsening of 2 or more VAS units.
Conclusions: Over the follow-up period mean fatigue and pruritus severity remained stable. Baseline and follow-up fatigue and pruritus severity scores showed strong correlations. In the majority of patients fatigue remained static over time, however in contrast, despite pruritus staying the same in net terms there were a significantly greater number of patients whose symptom severity changed (worsening or improving). This is likely to reflect the effects of biological deterioration, development of itch and response to therapy. Fatigue severity change is linked to pruritus severity change in a significant minority of patients suggesting that targeting pruritus is a potentially valuable first step in treating fatigue and should be incorporated into clinical guidelines.

E-mail: mc767@medschl.cam.ac.uk

Background and Aims: Risk-stratification in PBC is currently based on the biochemical response to treatment with ursodeoxycholic acid (UDCA) and does not take the stage of the liver disease into account. However, it has been shown that fibrosis and interface hepatitis predict outcome in PBC, independent of the UDCA response. We studied the UK-PBC Research Cohort with the following aims: (1) to identify pre-treatment histological variables that are independently associated with outcome in PBC and (2) to determine whether these variables might improve the accuracy of prognostic models based on UDCA response.
Methods: We analysed liver biopsy reports from PBC patients in the UK-PBC Research Cohort. We classified fibrosis, portal inflammation, interface hepatitis, lobular inflammation, ductopenia, copper-associated protein and steatosis according to their severity. We also classified the reports by Ludwig stage. We defined UDCA response according to the Paris 1 criteria. We defined outcome as liver transplant or liver-related death. Survival curves for each variable were estimated using the Kaplan–Meier method. Cox's proportional hazards models were used to estimate the coefficients for each variable. Akaike's Information Criterion (AIC) was used for variable selection. Correlation coefficient between all continuous variables and fibrosis stage was calculated.
Results: In multivariate analysis, fibrosis [bridging vs. none HR = 3.6 (1.5–8.4), p = 0.004; cirrhosis vs. none HR = 9.5 (3.4–26.8), p < 0.001] and interface hepatitis [focal vs. none HR = 2.6 (1.2–5.7), p = 0.014; widespread vs. none HR = 2.37 (1.0–5.6), p < 0.001] were associated with outcome, independent of UDCA response. The prognostic model consisting of fibrosis, interface hepatitis and UDCA response was more accurate than the model consisting of UDCA response alone (AIC changes from 477.24 to 404.07). Figure 1 shows the plot of survivor function for responder and non-responder to UDCA therapy stratified by the Ludwig stage. Correlation coefficient between platelet count and fibrosis stage was significant but weak (−0.025, p < 0.001).
Conclusions: Fibrosis and interface hepatitis are independently associated with long-term outcome in PBC and improve the accuracy of prognostic models. Liver biopsies may therefore inform risk stratification in PBC. Platelet count correlates to stage of fibrosis – but the correlation may be too weak for platelet count to be used as a surrogate marker. Current recommendations for liver biopsy in PBC should be reviewed.

TACROLIMUS IS SAFE AND EFFECTIVE IN PATIENTS WITH RESISTANT TYPE 1 AUTOIMMUNE HEPATITIS

N.N. Than[1], C. Wiegard[2], J. Mann[1], K. Fussel[2], G. Hirschfield[3], A.W. Lohse[2], D. Adams[3], C. Schramm[2], Y.H. Oo[3]. *[1]Liver Unit, University Hospital Birmingham NHS Trust, Birmingham, United Kingdom; [2]Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Centre for Liver research and NIHR Biomedical Research Unit for Liver Disease, University of Birmingham, Birmingham, United Kingdom*
E-mail: nwenithan@gmail.com

Background and Aims: Autoimmune hepatitis (AIH) is an immune mediated liver injury related to loss in self-tolerance requiring long term immunosuppressive therapy. Most patients respond to treatment with prednisolone and azathioprine but second line immunosuppressive therapy may be required in those who fail to respond. Tacrolimus is a potent inhibitor of T cell activation used to prevent graft rejection in organ transplantation.
Aims: To investigate the clinical efficacy and safety of tacrolimus in patients with refractory AIH.
Methods: Data were collected retrospectively between 1997 and 2014 from 19 patients being treated in two tertiary referral liver units' centres in the United Kingdom and Germany. Biochemical, immunological and MELD scoring improvement was assessed.
Results: The majority of patients were Caucasian (84%) and female (63%); median simplified AIH score was 7 (range: 4–8) and 16% were cirrhotic at presentation. The median age at diagnosis was 30 years (Range: 16–70). Most (95%) were treated with prednisolone and azathioprine [AZA] as first line treatment prior to tacrolimus therapy. The median time of starting tacrolimus from diagnosis was 2.5 years. 63% of patients were started on tacrolimus due to incomplete remission or flare of AIH despite apparent adherence

to therapy; 21% were intolerant of first line treatment with AZA and 11% were started at initial diagnosis of AIH. Median duration of treatment was 24 months and median dose of tacrolimus was 2 mg per day. The majority of patients were on prednisolone (58%) and azathioprine (42%) in addition to tacrolimus. There was a significant improvement in aspartate transaminase levels ($p < 0.05$) at 6, 12 months and at the latest follow up. Bilirubin fell significantly at 12 months and latest follow up ($p < 0.05$) and IgG at the latest follow up. The median model for end stage liver disease score (MELD) pre treatment was 8 which was stable at 12 months (median 7). No significant side effects or renal dysfunction were reported during the treatment period. All patients are alive during the follow up although one underwent liver transplantation. Tacrolimus treatment was discontinued in 9 patients because of a failure to respond and of these, 4 patients had developed PSC/AIH overlap on follow up liver biopsies and magnetic resonance cholangiopancreatography (MRCP).

Conclusions: Tacrolimus therapy in patients with resistant type 1 AIH is safe, generally effective and improves biochemical and MELD score.

P1200
THE EFFECT OF AZATHIOPRINE ON THE RISK OF MALIGNANCY IN PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS: A LONG-TERM MULTICENTER STUDY

R. Zenouzi[1], T.J. Weismüller[2], K.K. Jorgensen[3], H. Lenzen[4], P. Hübener[1], K. Schulze[1], M. Bubenheim[5], T.H. Karlsen[3], K.M. Boberg[3], M.P. Manns[4], A.W. Lohse[1], C. Schramm[1]. *[1]1st Department of Medicine, University Clinic Hamburg-Eppendorf, Hamburg, [2]Department of Internal Medicine 1, University of Bonn, Bonn, Germany; [3]Section for Gastroenterology and Norwegian PSC Research Center, Division of Cancer Medicine, Surgery and Transplantation, Oslo University Hospital, Rikshospitalet, Oslo, Norway; [4]Dept. of Gastroenterology, Hannover Medical School, Hannover, Germany; [5]Biostatistics Department, Rouen University Hospital-Charles Nicolle, Rouen, France*
E-mail: rzenouzi@uke.de

Background and Aims: Primary sclerosing cholangitis (PSC) is a chronic progressive liver disease of unknown etiology. One of the major clinical challenges in PSC is the development of hepatobiliary malignancy. Approximately 15% of patients develop cholangiocarcinoma (CCA), which is associated with a poor prognosis. In addition, the risk of colon carcinoma and gall bladder cancer is increased. Many patients are treated with azathioprine. The effect of azathioprine, however, on the risk of hepatobiliary malignancy has not been evaluated so far. Both an enhanced as well as a lower risk for CCA development under immunosuppressive treatment could be expected. We therefore investigated the risk of hepatobiliary malignancy in a large multicenter cohort of patients with PSC with respect to azathioprine treatment.

Methods: We performed a retrospective study in a cohort with well-defined PSC from three large tertiary care centers from Germany and Norway. With respect to risk calculation, we only analyzed malignancy development, which was observed after the first diagnosis of PSC, and considered azathioprine treatment, when administered between PSC diagnosis and one of the endpoints: malignancy development, liver transplantation, death or lost to follow-up. Statistical analysis was performed using an univariate Cox proportional hazard model under the assumption of competing risks of different endpoints.

Results: 683 patients (472 male) were included into the study. 484 (71%) patients had concomitant inflammatory bowel disease, 89 (13%) an overlap syndrome with autoimmune hepatitis. Within a median observation time of 9.4 years, in 41/683 patients (6%) a CCA was diagnosed. CCA developed in 3/118 (2.5%) of patients who had been treated with azathioprine as compared to 38/565 (6.7%) of patients not treated with azathioprine. Using the univariate hazard model this difference was not statistically significant. Also, azathioprine treatment did not seem to affect the risk of gallbladder (0.6% in the whole group) or colorectal cancer (1% in the whole group).

Conclusions: Based on this retrospective multicenter cohort including a large number of patients and a long observation period, treatment with azathioprine did not significantly affect the risk of hepatobiliary malignancy in patients with PSC. Therefore, in patients with PSC and concomitant inflammatory bowel disease or autoimmune hepatitis, the treatment with azathioprine should not be withheld.

P1201
LONG-TERM THERAPY WITH BEZAFIBRATE AND URSODEOXYCHOLIC ACID IS INSUFFICIENT FOR PREVENTING DISEASE PROGRESSION IN PATIENTS WITH ADVANCED PRIMARY BILIARY CIRRHOSIS

A. Reig[1], P. Sesé[1], A. Pares[1]. *[1]Liver Unit, Hospital Clínic, IDIBAPS, CIBERehd, University of Barcelona, Barcelona, Spain*
E-mail: pares@ub.edu

Background and Aims: It has been observed that treatment with fibrates is effective to normalize liver biochemistries in patients with primary biliary cirrhosis (PBC) and suboptimal response to ursodeoxycholic acid (UDCA). However, there are no consistent data regarding the long-term course and outcome in these patients, and therefore, we have assessed the effects of the combined treatment with UDCA and bezafibrate for a long period of time.

Methods: 48 patients (45 female) with PBC treated with UDCA for a mean 9 years and alkaline phosphatase (AP) levels (>1.5 xUNL). Patients were treated with bezafibrate (400 mg/d) plus UDCA (13–16 mg/kg/d), and therapeutic response and baseline characteristics, clinical and biochemical changes and prognosis after long-lasting therapy was assessed. The full therapeutic response was defined as AP normalization.

Results: After a median of 38 months of treatment, patients were divided into two groups according to AP normalization. 26 patients (54%) normalized AP (median 4 months). In these patients, baseline jaundice (0% vs 18%, $p = 0.03$), pruritus (19% vs 67%, $p = 0.007$) and liver stiffness (6.9 ± 0.5 vs 13.2 ± 2.5 kPa, $p = 0.007$) was lower, and age was higher (57.2 ± 1.7 vs 49.8 ± 2.4 years, $p = 0.01$) than in patients who remained with elevated AP. These patients also had lower transaminase (ALT), AP, gamma glutamyl transferase (GGT), bilirubin, albumin and cholesterol and higher than patients without complete response. During the assessment period, partial or complete itching relieve was observed in all cases, regardless of the biochemical AP response. Moreover, improvement in all biochemical parameters was observed in the patients who normalized AP, while these effects were less prominent in the patients without full AP response. During follow-up, 5 patients, all of them without AP normalization (23%) developed events of disease progression (one patient died, 3 were transplanted or fulfilled criteria for transplant, and one patient developed a hepatocellular carcinoma).

Conclusions: The long-term treatment with UDCA and bezafibrate results in excellent response in more than half of the cases, and it is associated with a complete or partial itching relieve. The absence of complete response was observed in patients with advanced disease who remain at risk of developing severe events. Consequently, the combined treatment is especially effective in patients with lower fibrosis and severity of cholestasis.

P1202

DEFINITION AND COMPARATIVE ANALYSIS OF THE T CELL RECEPTOR REPERTOIRE IN PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS

E. Liaskou[1], E.K. Klemsdal Henriksen[2,3,4], K. Holm[2,3,4], D. Hamm[5], J. Fear[1], M.K. Viken[6], J. Roksund Hov[2,3,4], E. Melum[2,3,4], H. Robins[7], J. Olweus[4,8,9], T.H. E-mail: e.liaskou@bham.ac.uk

Background and Aims: Primary sclerosing cholangitis (PSC) is a chronic liver disease characterized by immune-mediated biliary injury and a clear HLA association. T cell infiltration is characteristic of the PSC lesions, but their target antigen specificity is still unknown. We aimed to characterize the T cell receptor (TCR) beta chain complementarity-determining region 3 (CDR3) of liver-infiltrating T cells to assess if disease-specific TCR repertoires could be identified in the livers of patients with PSC relative to controls with primary biliary cirrhosis (PBC) or alcoholic liver disease (ALD).
Methods: Genomic DNA (400 ng) from PSC (n = 20), PBC (n = 10) and ALD (n = 10) was extracted from liver tissue sampled at liver transplantation and subjected to high-throughput sequencing by ImmunoSEQ pipeline (Adaptive Biotechnologies Corp, Seattle, WA). Genomic DNA from the same samples was used for *HLA-DRB1* and *HLA-B* typing.
Results: In PSC cases a higher number of productive unique TCR beta sequences (clones in which the entire TCR gene is expected to translate to a functional protein) was detected (16,544±1,000) (mean±SEM), compared to PBC (14,264±1,754, $P = 0.4$) and ALD (8,123±1,451, $P = 0.0002$). Assessment of TCR clonal frequency distribution revealed an overall lower clonality of PSC samples (0.134±0.007), compared to PBC (0.153±0.013) and ALD (0.146±0.013), further suggesting a higher T cell diversity in PSC. Nevertheless, eight TCR beta sequences were uniquely shared in 30–40% of PSC cases (Table 1), in frequencies ranging from 2×10^{-4}% to 4×10^{-2}%, and were completely absent from PBC and ALD disease control groups. Different V family genes were used to create these eight amino acid sequences, supporting antigen-driven selection.
Conclusions: Our data suggest the presence of a highly diverse TCR repertoire in PSC patients, however, also demonstrate eight clones uniquely found in PSC but not in liver disease control groups. Refined assessments are needed to distinguish non-specific phenomena (e.g. end-stage liver disease and biliary bacterial colonization) from potentially antigen-specific T cell expansions.

P1203

EFFECT OF IMMUNOSUPPRESSIVE DRUGS ON THE KINETICS OF CO-INHIBITORY MOLECULE EXPRESSION AND PRO-INFLAMMATORY CYTOKINE PRODUCTION BY EFFECTOR T CELLS IN AUTOIMMUNE HEPATITIS

C.R. Grant[1], R. Liberal[1], B.S. Holder[1], G. Mieli-Vergani[1], D. Vergani[1], S. Longhi[1]. *[1]Institute of Liver Studies, King's College London School of Medicine, King's College Hospital, London, United Kingdom*
E-mail: charlotte.grant@warwick.ac.uk

Background and Aims: Immunosuppressive drugs (ISDs) are the mainstay of treatment for autoimmune diseases, including autoimmune hepatitis (AIH). Little is known about the effects that ISDs have on the kinetics of effector T cell (Teff) inhibitory molecule expression or pro-inflammatory cytokine production in the context of autoimmunity. We aimed to investigate the effect of ISDs on Teff activation-induced expression of co-inhibitory molecules and pro-inflammatory cytokines.
Methods: $CD4^{pos}CD25^{neg}$ Teff cells were isolated immunomagnetically from the peripheral blood of eight healthy subjects (HS) and six newly-diagnosed ANA/SMA^{pos} treatment-naïve AIH patients. Teff cells were stimulated polyclonally with or without rapamycin, prednisolone, FK-506, mycophenolic acid, 6-mercaptopurine or cyclosporine. Expression of the co-inhibitory molecules TIM3, PD1 and CTLA4 and of the pro-inflammatory cytokines IL17, IFNγ, and TNFα was assessed by flow-cytometry.
Results: In HS and AIH, TIM3 expression increased over 96 hrs, without ISDs exerting a significant effect ($p < 0.01$ for all comparisons). TIM3 expression peaked more quickly in AIH compared to HS, with higher levels present at 48 hrs ($p < 0.001$ by two-way ANOVA). PD1 expression was higher in AIH compared

to HS (at 48 hours; $p < 0.0001$ and 96 hrs; $p = 0.0026$ by two-way ANOVA). In AIH patients, PD1 continued to increase between 48 and 96 hrs ($p < 0.05$) but this was prevented by ISDs. CTLA4 expression increased over time to similar extents in AIH and health, with little effect of ISDs.
Cytokine expression tended to increase rapidly by 48 hrs, falling again by 96 hrs. In contrast to HS, IFNγ production continued to increase between 48 and 96 hrs in AIH patients ($p < 0.05$). ISDs prevented this increase, with cyclosporine significantly lowering IFNγ expression ($p < 0.01$).
Conclusions: Co-inhibitory molecules and pro-inflammatory cytokines display distinct patterns of activation-induced expression. PD1 and IFNγ increases are restrained by ISDs in AIH, suggesting a novel mechanism of action of these drugs.

E-mail: evklem@rr-research.no

Background and Aims: Primary sclerosing cholangitis (PSC) is a chronic liver disease of unknown etiology where the majority of patients have concurrent inflammatory bowel disease (IBD). Previous studies have reported that gut-specific addressins and chemokines are also involved in the recruitment of mucosal T cells to the liver of PSC patients. We hypothesized that common antigenic determinants form the basis of this shared T cell response and aimed herein to assess if T cell receptor (TCR) beta sequences previously detected in liver tissue of PSC patients are also detected in matched gut and blood samples.
Methods: Genomic DNA was isolated from liver tissue obtained at liver transplantation, gut biopsies and blood from ten Norwegian PSC patients. All PSC patients had a concurrent diagnosis of IBD (nine had ulcerative colitis, one had Crohn's disease). Sequencing of the TCR beta chain complementarity-determining region 3 (CDR3) of all specimens was performed using the ImmunoSEQ pipeline (Adaptive Biotechnologies Corp, Seattle, WA).
Results: Detection rates in liver tissue, gut biopsies and blood for each of the previously reported PSC specific TCR beta sequences are given in Table 1. All previously reported PSC specific TCR beta sequences were detected in the present patient panel, mostly at lower rates in liver (0–5 patients) and gut (0–4 patients) than in blood (2–9 patients). Assessment of the general overlap between paired liver and gut samples for the 200 most frequent sequences in the TCR repertoire of each sample revealed a mean of 17.3% TCR beta sequences shared between the liver and gut of each patient (with a range from 4.0% to 34.0%).
Conclusions: Previously reported PSC specific TCR beta sequences were detected in blood, liver and gut of the present independently sampled patient panel. The relationship between the observed overlap of T cell specificities and the shared mechanisms of liver and gut T cell recruitment mechanisms warrants further study.

COMPREHENSIVE ANALYSES OF AUTOIMMUNE HEPATITIS TYPE 1 ASSOCIATED mRNA, lncRNA, AND miRNA IN CD4+ T CELLS TARGETED BY PREDNISOLONE TREATMENT

R. Nakagawa[1,2], R. Muroyama[2], S. Ito[2], K. Takano[1], K. Goto[2], M. Nakano[1], C. Saeki[1], Y. Matsubara[2], N. Kato[2], M. Zeniya[1]. *[1]Department of Gastroenterology and Hepatology, The Jikei University School of Medicine, [2]Division of Advanced Genome Medicine, The Institute of Medical Science, The University of Tokyo, Tokyo, Japan*
E-mail: lake.vic30@gmail.com

Background and Aims: Prednisolone (PSL) is commonly used to treat autoimmune hepatitis (AIH) type 1. Although the progression of disease becomes mild in almost all patients treated with PSL, some patients resist the treatment and require additional immunosuppressors. Mechanism of PSL treatment for AIH is still not fully understood. Thus, we analyzed the dynamics of gene expression by PSL treatment including messengerRNA (mRNA), long non-codingRNA (lncRNA), and microRNA (miRNA) in CD4+ T cells to reveal the mechanism of PSL treatment for AIH.
Methods: Clinically and pathologically diagnosed 2 naïve AIHs (nAIH), 7 AIHs in remission with PSL (rAIH), and 7 healthy controls, who agreed to provide samples with written informed consent, were enrolled in this study. This study was approved by the institutional review board. Total RNA was extracted from CD4+ T cells purified from peripheral blood. The comprehensive analysis of the genes was undergone using microarrays. Differentially expressed genes were compared among 3 groups using the fold change (FC) cut-off and the ANOVA. The data were classified by hierarchical clustering to extract the PSL targeted genes. Then correlation analysis was performed to extract the genes correlating with the liver injury.
Results: Microarray study showed that 1,072 mRNAs, 128 lncRNAs ($p < 0.05$, FC >1.5), and 17 miRNAs ($p < 0.05$, FC >1.2) were differentially expressed among 3 groups. By the hierarchical clustering, each group was clearly distinguished by mRNA and lncRNA expression, and their expression profiles were classified into 8 clusters. One mRNA cluster consisted of differentially expressed mRNAs, which decreased from nAIH to rAIH and became close to healthy control by PSL treatment. Inflammation associated 6 cytokines and 3 chemokines were extracted from this cluster. The expression of cytokine/chemokine was strongly correlated with each other and the value of ALT. Moreover, also 7 lncRNA and 7 miRNA were correlated with cytokine/chemokine expression and the value of ALT.
Conclusions: PSL treatment changed the mRNA/lncRNA/miRNA expression profile of CD4+ T cell in AIH. Certain differentially expressed mRNAs/lncRNAs/miRNAs were identified to be key players in the pathogenesis of AIH targeted by PSL treatment.

P1206

ANTI-INFLAMMATORY AND DIRECT ANTIFIBROTIC EFFECT OF ORAL HEPATOTROPIC DPP4 INHIBITORS IN MODELS OF NASH AND BILIARY FIBROSIS

X.-Y. Wang[1], S.-Y. Weng[1], T. Klein[2], Y.O. Kim[1], D. Schuppan[1,3]. *[1]Institute of Translational Immunology and Research Center for Immunotherapy, University Medical Center, Mainz, Germany, Mainz, [2]Boehringer Ingelheim Pharma, Biberach an der Riss, Germany; [3]Division of Gastroenterology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States*
E-mail: wang@uni-mainz.de

Background and Aims: Non-alcoholic steatohepatitis (NASH) is characterized by steatosis, lobular inflammation and progressive parenchymal fibrosis. Anti-inflammatory and especially antifibrotic therapies for NASH are urgently needed. Glucagon like peptide 1 (GLP-1) is an attractive molecule for the treatment of insulin resistance. GLP-1 is rapidly inactivated by cell surface dipeptidyl peptidase-4 (DPP-4). Therefore we studied the effect of two indirect GLP-1 agonists, hepatotropic DPP4-inhibitors, on liver inflammation and fibrosis in models of NASH and biliary fibrosis.
Methods: Linagliptin and Sitagliptin were administered daily by oral gavage to Mdr2KO mice and to C57BL/6mice fed a methionine and choline deficient (MCD) diet for 4 and 6 weeks. Hepatic fibrosis was assessed by morphometric analysis of Sirius red stained collagen and measurement of hydroxyproline content. Serum biochemistries were determined by an autoanalyzer, and hepatic inflammation and fibrosis were assessed by semiquantitative immunohistochemistry. Fibrosis and inflammation related transcript levels were measured by quantitative real-time polymerase chain reaction (qPCR). Ex vivo analysis of hepatic inflammatory cells was done by FACS.
Results: In the 4 week treatment group only 50 mg/kg/day of Linagliptin lowered serum ALT, AST, ALP and LDH and also decreased fibrosis and inflammation related gene expression (aSMA, TIMP-1, TGFβ1, MMP-13, CD68 and TNF α) compared to vehicle-treated controls. However, after 6 weeks' treatment, both Linagliptin and Sitagliptin reduced hepatic collagen accumulation, and also decreased fibrosis and inflammation related gene expression (aSMA, TGFβ1, TNF α). The expression of CD68, F4/80, Caspase 3, as determined by semiquantitive immunohistochemistry, was significantly suppressed. There was a decrease of hepatic $CD11b^{+}Ly6C^{+}$high (proinflammatory monocytes/macrophages) and of total F4/80+ cells (macrophages, Kupffer cells) when compared to mice that received the MCD diet without treatment. In Mdr2KO mice 10 and 50 mg/kg/day of Linagliptin significantly decreased procollagen α1(I), TGFβ1, TIMP-1, MMP-8 transcript levels, but increased putatively anti-fibrotic MMP-9 and -13.
Conclusions: In mice fed the MCD diet for 6 weeks, the DPPIV inhibitors Linagliptin and Sitagliptin significantly decreased inflammation and apoptosis. Linagliptin and Sitagliptin attenuated liver injury and fibrosis through inhibition of inflammatory and apoptosis pathways that are prevalent in human NASH.

P1207

FATIGUE IN PRIMARY BILIARY CIRRHOSIS: SIMILAR PREVALENCE TO THE POPULATION FROM THE SAME GEOGRAPHIC AREA, AND ASSOCIATION WITH COMORBIDITIES AND SEVERITY OF CHOLESTASIS

A. Reig[1], P. Sesé[1], S. Lens[1], L. Caballeria[1], A. Pares[1]. *[1]Liver Unit, Hospital Clínic, IDIBAPS, CIBERehd, University of Barcelona, Barcelona, Spain*
E-mail: pares@ub.edu

Background and Aims: The pathogenesis of fatigue in patients with primary biliary cirrhosis (PBC) is unknown, and previous studies are uncertain regarding the specificity of this symptom and the association with comorbidities. It has also been suggested that the prevalence of this symptom varies by geographic area. Therefore, we have assessed the prevalence, severity and potential risk factors in a series of patients with primary biliary cirrhosis as compared with a age-matched control group of the same geographical area.
Methods: A multidomain disease-specific quality of life responses and clinical findings questionnaire for PBC (PBC-40) was distributed to a consecutive series of 182 patients and in an age mactched group of 48 women of similar age group. Clinical, laboratory, histological, duration and biochemical response to ursodeoxycholic acid (UDCA), and comorbidities were recorded in 108 PBC patients.
Results: PBC-40 scores were significantly different between patients and controls for symptom (18.7±4.9 vs 16.4±4.2. $p = 0.003$), itching (4.5±2.4 vs 3.3±0.6, $p < 0.0001$), cognitive (11.9±5.9 vs 9.4±4.2, $p = 0.007$) and social (18.9±7.4 vs 16.7±4.0, $p = 0.05$) domains, but were similar for fatigue (23.3±11 vs 23.3±8.8, p:ns) and emotional (7.2±3.5 vs 6.8±2.4 p: ns) domains. Depending on the fatigue severity patients were divided into two groups: severe/moderate fatigue and no/mild fatigue. There were no significant differences in age, sex, biochemical variables, duration of UDCA treatment and histology at diagnosis between the two groups. Patients with severe/moderate fatigue had lower hemoglobin levels (12.4±1.9 vs 13.1±1.3 g/l, $p = 0.002$), higher levels of total bilirubin (1.1±0.5 vs. 0.3±0.5 mg/dl, $p = 0.001$) and (gGT 210±45 vs 129±20 U/ml, $p = 0.005$) as compared with patients with no/mild fatigue. There was no relationship between fatigue and hypothyroidism, sicca syndrome or with response to UDCA. Diagnosis or therapeutic intervention for depression was found in 18 of 78 patients (23%), and depression was significantly associated with fatigue (OR: 5.8, 95% CI: 1.9–17.9, $p = 0.003$).
Conclusions: Fatigue is a common manifestation in but similar to the control population of the same area. Fatigue is related to the severity of the disease, and comorbidities such as depression and anemia, but it is independent of the disease duration and therapeutic response to ursodeoxycholic acid.

P1208

ANALYSIS OF HUMORAL IMMUNE RESPONSE IN A NEW ANIMAL MODEL OF AUTOIMMUNE HEPATITIS: NEW ANTIGENS IDENTIFICATION

M. Blasi[1,2], I. Gil-Fariña[2], M. Di Scala[2], J. Prieto[2,3], M. González[4], P. Díez[4], M. Fuentes[4], G. González-Aseguinolaza[2]. *[1]Internal Medicine and Hepatology, Clínica Universidad de Navarra, [2]Hepatology and Gene therapy, Centro de Investigación de Medicina Aplicada, [3]Hepatology and Internal Medicine, Clínica Universidad de Navarra, Pamplona, [4]Medicine, Proteomics Unit, Cancer Research Centre (CIC), Salamanca, Spain*
E-mail: mercedes.blasi@gmail.com

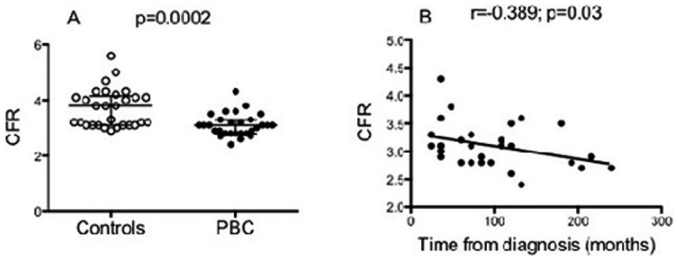
Background and Aims: Autoimmune Hepatitis (AIH) is a chronic disease characterized by the immuno-dependent destruction of hepatocytes, because of the loss of immunologic tolerance to autoantigens. Therapeutic alternatives are limited to control inflammation with immunosupressive and immunomodulatory drugs. The molecular mechanism of the trigger of the immune attack is poorly understood. The progress in this field is critical to develop new treatments, being necessary animal models that represent clinical, histological and serological manifestations of human AIH. In our laboratory, we have developed an animal model that mimics main characteristics seen in humans. One of our aims has been to look forward new antigens in this new model.
Methods: The model of AIH has been established through the administration of an adeno-associated virus (AAV) that express hepato-specifically IL-12 (AAV-IL12), triggering an immune response against hepatic antigens, harming liver parenchyma. Vectors AAV-IL12 and AAV-Luc (as control) were injected intravenously in C57BL/6 mice, that were sacrificed at day 60. Histopatological analysis was done, certifying the disease

development. Reactivity of serum auto-antigens was done by using a protein array, NAPPA (Nucleic Acids Programmable Protein Arrays), containing >4000 proteins and its corresponding controls, being identified different serum profiles between both situations.
Results: At 60 days, livers coming from IL-12 mice showed a mononuclear infiltrate, piecemeal necrosis, apoptotic hepatocytes and liver fibrosis whether controls were normal. IL-12 mice serum recognised many proteins that weren't recognised by control mice serum. Proteins that reacted more and were expressed in the liver in AIH mice were selected and are being validated individually.
Conclusions: The identification of new hepatic antigens involved in AIH, can open doors in the development of new and specific therapeutic strategies as the induction of tolerance against these antigens.

P1209
CORONARY MICROVASCULAR DYSFUNCTION IN PATIENTS WITH PRIMARY BILIARY CIRRHOSIS WITHOUT METABOLIC SYNDROME: A HINT FOR THEIR INCREASED CARDIOVASCULAR RISK

N. Cazzagon[1], C. Dal Lin[2], G. Famoso[2], I. Franceschet[1], A. Floreani[1], F. Tona[2]. *[1]Dept. of Surgery, Oncology and Gastroenterology, [2]Dept. of Cardiac, Thoracic and Vascular Sciences, University of Padova, Padova, Italy*
E-mail: nora.cazzagon@gmail.com

Background and Aims: Primary biliary cirrhosis (PBC) is characterized by a long natural history and a low incidence of cardiovascular events despite high serum cholesterol levels. Metabolic syndrome may increase the cardiovascular risk, however. Coronary flow reserve (CFR) is widely used to examine the integrity of coronary microvascular circulation and it is well recognized as a predictor of cardiovascular outcome. *Aim:* To evaluate the risk of coronary microvascular dysfunction in patients with PBC without metabolic syndrome.
Methods: 29 PBC patients (27 F, aged 56±11 years) without clinical evidence of heart disease and without metabolic syndrome, and 29 sex- and age-matched healthy controls underwent CFR by transthoracic Doppler echocardiography (TDE). Coronary flow velocity in the left anterior descending coronary artery was detected by TDE at rest and during iv. adenosine infusion. CFR was the ratio of hyperaemic diastolic flow velocity (DFV) to resting DFV.
Results: The median time between the onset of symptoms and CFR assessment was 7 years (interquartile range 3–10.5 years). In PBC patients CFR was significantly lower than in controls (3.1±0.3 vs 3.8±0.4, $p < 0.0002$) (Fig. A). CFR was inversely related to the time from diagnosis ($r = -0.389$, $p = 0.03$) (Fig. B) and age ($r = -0.370$, $p = 0.04$), and positively correlated with TSH ($r = 0.411$, $p = 0.03$). No relationship was found between CFR and LDL-cholesterol.
Conclusions: CFR is impaired in PBC patients and is correlated with the length of disease, suggesting a negative effect of PBC on coronary microcirculation that may contribute to the increased cardiovascular risk, even in patients without metabolic syndrome.



P1210
IMPACT OF SPECIALIST PATHOLOGY REVIEW OF LIVER BIOPSIES ON THE FINAL DIAGNOSIS AND PATIENT MANAGEMENT

A. Paterson[1], M. Allison[2], R. Brais[1], S. Davies[1]. *[1]Histopathology, [2]Hepatology, Addenbrooke's Hospital, Cambridge University NHS Foundation Trust, Cambridge, United Kingdom*
E-mail: alp37@cam.ac.uk

Background and Aims: It is standard UK practice for all patients with a malignant diagnosis to be discussed at multidisciplinary team (MDT) meetings, which includes histopathological review, prior to planning treatment. Studies have shown a discrepancy rate of 7–15% between the original diagnosis and specialist centre review. Few studies have explored the potential impact on patient management of such a review for non-malignant pathologies.
This study reviewed all liver biopsies referred to our centre, a university teaching hospital and transplant centre, to determine (a) the extent of agreement with the original report; (b) the predicted impact on patient management; (c) the main areas of diagnostic discrepancy.
Methods: All native and transplant liver biopsies for focal lesions and non-lesional assessments referred for review from 2010 to 2013 were included. The extent of agreement with the original diagnosis and probable impact on clinical management were obtained from the histopathology report, with discussion with Consultant Hepatologists as required.
Results: A total of 1333 liver biopsies met inclusion criteria. The majority, 65%, were referred for specialist advice; 24% were reviewed due to transfer of care or joint clinical management, including transplant assessment; and 11% for MDT discussion. In 786 cases, 59%, there was a difference in interpretation compared with the original report, 67% of which were predicted to result in some change in patient management. This was most frequent in cases referred specifically for second opinions, although 28% cases reviewed for a MDT meeting and/or transfer of care showed differences likely to change treatment.
In 64% with a final diagnosis of chronic biliary disease, and over half where the major pathology was autoimmune hepatitis, acute hepatitis, vascular/architectural abnormalities, or a benign lesion, specialist review was associated with a potential alteration of management. Although agreement was better for chronic viral hepatitis, fatty liver disease and malignant lesions, in 24–36% of cases altered management was still likely after the biopsy review.
Conclusions: A specialist pathology review of liver biopsies may result in changed patient management in almost 40% of cases. Although relevant to all disease groups, chronic biliary disease is highlighted as a particular diagnostic challenge.

Genetic and pediatric liver diseases

Background and Aims: Lysosomal Acid Lipase (LAL) Deficiency is a progressive multisystem disease that is an underappreciated cause of cirrhosis, severe dyslipidemia and early onset atherosclerosis.
Methods: A phase 3, double-blind, placebo (PBO) controlled trial (NCT01757184) randomized affected children and adults (N = 66) to pbo or sebelipase alfa (SA) 1 mg/kg every other week for 20 weeks. Primary endpoint was ALT normalization. Secondary endpoints included additional important efficacy assessments, safety and immunogenicity. Medically important abnormalities were common at baseline including fibrosis (100%), bridging fibrosis (Ishak score 3 or 4; 47%) and cirrhosis (31%) in biopsied patients (n = 32) and a median LDL-C of 204.0 mg/dL (range 70–378 mg/dl). Mean age of biopsied patients was 12 yr. LDL-C was ≥190 mg/dL in 58% [38 of 66 of patients, including 24% (9 of 38) who were on lipid lowering medications].
Results: After 20 weeks, ALT normalization (ULN range 34–43 U/L) was achieved in 31% of the SA group and 7% of the PBO group. Multiple secondary efficacy endpoints were also met including relative reduction in LDL-C, non-HDL-c, and triglycerides and relative increase in HDL-C. 65 subjects continue in the open label part of the study with data availability to week 36. PBO subjects when transitioned to SA demonstrated effects consistent with the results of the double blind period. Further reductions were observed in those who remained on SA non-HDL-C (−39% vs −28%) and LDL-C (−44% vs −29%) for week 36 versus last double blind visit respectively. Over 350 infusions of SA were given during the double-blind period. The number of patients with AEs was similar in each arm. During the double-blind period, most AEs were mild and unrelated to SA; 6 patients experienced infusion-associated reactions (4 PBO; 2 SA). Dosing was paused in 1 patient after an atypical infusion-related reaction following SA treatment. Safety profile in the open-label period was consistent with the double-blind period. One additional, unrelated SAE was reported (gastroenteritis) in the open-label period.
Conclusions: Sebelipase alfa for 20 weeks demonstrated statistically significant improvements in ALT normalization and in a number of other important disease related abnormalities including marked reductions in LDL. Additionally, open label data show further reductions noted with longer term exposure. The safety profile appears favorable and infusions were generally well tolerated.

P1212
IMPACT OF SEBELIPASE ALFA ON SURVIVAL AND LIVER FUNCTION IN INFANTS WITH RAPIDLY PROGRESSIVE LYSOSOMAL ACID LIPASE DEFICIENCY

S. Jones[1], D. Plantaz[2], R. Vara[3], J.J. Gargus[4], J. Hughes[5], S. Rojas-Caro[6], A.G. Quinn[6], V. Valayannopoulos[7]. *[1]University of Manchester, Manchester, United Kingdom; [2]Hôpital Couple Enfant CHU Grenoble, Grenoble, France; [3]Evelina Children's Hospital, London, United Kingdom; [4]University of California Irvine, Irvine, United States; [5]The Children's University Hospital, Dublin, Ireland; [6]Synageva BioPharma Corp., Lexington, United States; [7]Hôpital Necker-Enfants Malades, Paris, France*
E-mail: sandra.rojas-caro@synageva.com

Background and Aims: Lysosomal Acid Lipase Deficiency (LAL D) in infants, historically known as Wolman Disease, is a medical emergency with rapid disease progression and death occurring within the first 6 months (mo) of life. In a natural history study, failure to thrive, liver complications, massive hepatomegaly, and mortality were confirmed in LAL D infants. Disease progression was frequently accompanied by rapidly progressive liver failure. In addition to steatosis and foamy histiocytes, fibrosis was prominent and seen in 4 infants before 6 mo of age and in 1 infant as early as 1.5 mo of age. In infants with evidence of growth failure who did not undergo transplant, the K-M estimate (95% CI) of survival past 1 year of age was 0 (0, 0). Those treated with HSCT or liver transplant survived slightly longer but still died before 1 year of age (median age 8.6 mo).
Methods: A phase 2/3 trial (LAL-CL03) assesses the safety and efficacy of sebelipase alfa (SA) in 9 LAL deficient infants with growth failure in the first 6 mo of life. Median baseline liver function tests reveal significant underlying liver dysfunction with a median ALT and AST of 145 IU/L and 125 IU/L respectively. At symptom onset, subjects had diarrhea/vomiting (n = 6), hepatomegaly (n = 9), splenomegaly (n = 8), or adrenal calcification (n = 6).
Results: As of November 1, 2014, 6 subjects have met the primary endpoint of survival at 12 mo of age with a mean age of 22 mo and 5 continue to receive SA. Deaths (n = 4) were unrelated to SA and were deemed to be either related to underlying disease or, in 1 subject, due to complications of an abdominal paracentesis. 3 subjects died after receiving ≤4 doses. In addition to improved survival relative to the historical cohort, all subjects demonstrated improved weight gain, improvement of GI symptoms, and reductions in hepatosplenomegaly. Rapid improvements in biochemical and hematological markers including ALT, AST, hemoglobin, and bilirubin were observed. One SA-related SAE occurred: an infusion reaction of malaise with tachycardia and fever. The majority of the infusion associated reactions were reported as fever, diarrhea, or vomiting. To date, 4 subjects tested positive to anti-SA antibodies and all 4 continue weekly infusions of SA.
Conclusions: Analysis suggests that SA rapidly improves weight gain and many of the disease activity parameters observed in infants with LAL D. These improvements appear to be accompanied by a substantial survival benefit compared to a matched historical control group.

P1213

ADENO-ASSOCIATED VIRUS VECTOR-MEDIATED LIVER GENE THERAPY FOR CRIGLER–NAJJAR SYNDROME

P. Bosma[1], P. Labrune[2], N. Brunetti-Pierri[3], L. D'Antiga[4], M. Ott[5], M. Beinat[6], F. Ronchi[7], F. Mavilio[8], U. Beuers[9], A. Muro[10], U. Baumann[5], F. Mingozzi[8]. *[1]Liver Center, Academic Medical Center, Amsterdam, Netherlands; [2]Assistance Publique – Hôpitaux de Paris, Paris, France; [3]Translational Medicine, Federico II University, Naples, [4]Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy; [5]Hannover Medical School, Hannover, Germany; [6]Patient Association France, Paris, France; [7]CIAMI Onlus, Rimini, Italy; [8]Genethon, Evry, France; [9]Academic Medical Center, Amsterdam, Netherlands; [10]International Centre for Genetic Engineering and Biotechnology, Trieste, Italy*
E-mail: fmingozzi@genethon.fr

Background and Aims: Crigler–Najjar syndrome (CN) is an autosomal recessive rare disorder caused by mutations in the UDP-glucuronosyltransferase 1 isotype A1 (UGT1A1) gene. In severe CN, lack or reduced activity of UGT1A1 results in high levels of serum unconjugated bilirubin (UCB), which can lead to brain damage and death. Treatment of CN consists of phototherapy for 10–12 hours per day, which presents several limitations and has a major impact on the quality of life of patients. Liver transplantation is the only curative option for CN. The limited therapeutic options available prompted us to develop a new therapy for CN based on the transfer of a corrected copy of the UGT1A1 gene to hepatocytes.
Methods: Adeno-associated virus (AAV) vectors are one of the most attractive vectors for in vivo gene transfer. Clinical trial results demonstrate long-term correction of inherited diseases with AAV vectors, particularly for liver-directed gene therapy.
An AAV vector optimized for the liver expression of the UGT1A1 transgene was developed (AAV-UGT1A1). Safety and efficacy of correction of CN with AAV-UGT1A1 were assessed in mouse and rat models of CN.
Results: We demonstrated that a single intravenous administration of AAV-UGT1A1 resulted in efficient targeting of the liver and was sufficient for the long-term correction of CN in affected rats and mice, resulting in UCB levels undistinguishable from wild-type animals. Correction of CN was documented for at least 6 months post-gene transfer (observation ongoing) with no need for immunosuppression or additional interventions.
Conclusions: Long-term correction of the pathological accumulation of UCB in animal models of CN can be achieved at AAV-UGT1A1 vector doses similar to those safely tested in human gene therapy trials. Based on these encouraging results, efforts towards a multicenter clinical trial for AAV-UGT1A1 vector-mediated gene transfer to the liver in severe CN patients have been initiated. Orphan Drug Designation was obtained, and vector manufacturing in GMP and mandatory GLP toxicity studies are ongoing. Screening of CN patients to identify subjects potentially eligible for enrollment in the proposed trial has started in four European countries.

DIET HIGHLY INFLUENCES THE DEVELOPMENT OF HEPATOCELLULAR ADENOMAS AND CARCINOMAS IN MICE WITH GLYCOGEN STORAGE DISEASE TYPE IA

J. Clar[1], M. Raffin[1], S. Gaillard[2], O. Beuf[2], G. Mithieux[1], F. Rajas[1]. *[1]Inserm U855/Université Lyon1, LYON, [2]CREATIS, CNRS UMR 5220, Inserm U1044, INSA-Lyon, Villeurbanne, France*
E-mail: fabienne.rajas@univ-lyon1.fr

Background and Aims: Glycogen storage disease type Ia (GSDIa) is an inherited disorder in which the catalytic enzyme of glucose-6-phosphatase is deficient. GSDIa patients are prone to severe hypoglycaemia and present hepatomegaly and steatosis caused by a large accumulation of glycogen and triglycerides in the liver. In despite of intensive dietary treatment, most patients exhibit hepatocellular adenomas (HCA), which may undergo malignant transformation into hepatocellular carcinoma (HCC) at the third decade of life. Some nutrients such as sucrose, fructose or galactose are restricted or excluded but none specific recommendations about lipid consumption are available. In this study, we propose to determine the effect of junk food on hepatic tumour development in liver-specific G6pc knock-out (L-G6pc$^{-/-}$) mice, which present all hepatic symptoms of the human pathology of GSDIa, including the late development of HCA.
Methods: After the induction of G6pc deletion at adulthood, L-G6pc$^{-/-}$ mice were fed either a STD, or a high fat and high sucrose (HF/HS), or a high fat (HF) diet. After 5, 7 and 9 months of diet, tumour development was followed by in vivo magnetic resonance imaging (MRI). Livers were histologically analysed and liver weight, glycogen and triglycerides stores were measured.
Results: The glycogen and triglycerides storage in livers of L-G6pc$^{-/-}$ mice were not affected by the different diets. Spectacularly, the development of hepatic tumours in L-G6pc$^{-/-}$ mice was highly enhanced on HF/HS and HF diets. Indeed, only 20% of L-G6pc$^{-/-}$ mice have developed millimetric HCA after 9 months of STD diet, whereas first nodules were detected earlier (at 5 months) in 10–30% of L-G6pc$^{-/-}$ mice fed a HF/HS or HF diets, respectively. After 9 months of HF/HS and HF diets, more than 80% of L-G6pc$^{-/-}$ mice developed multiple tumours about 5–15 mm in diameter. Interestingly, about 50% of nodules were proven to be HCC in L-G6pc$^{-/-}$ mice fed a HF/HS diet while most tumours corresponded to HCA in mice fed a STD or HF diet.
Conclusions: These results suggest that tumour development is hugely accelerated with a HF diet. In addition, HF/HS diet induced the malignant transformation of hepatic tumour in mice with GSDIa. Thus the consumption of junk food (fast food) could rapidly damage the liver of patients with GSDIa. Molecular analysis of these tumours would permit us to characterize crucial pathways involved in hepatocarcinogenesis.

IN VITRO EVALUATION OF ANTISENSE DRUGS IN METABOLIC LIVER DISEASE-SPECIFIC HEPATOCYTE-LIKE CELLS USING IPS-CELL TECHNOLOGY

V. Sauer[1], C. Niemietz[1], G. Chandhok[1], A. Zibert[1], H.H.-J. Schmidt[1]. *[1]Uniklinik Münster, Klinik für Transplantationsmedizin, Münster, Germany*
E-mail: vanessa.sauer@ukmuenster.de

Background and Aims: Amyloidoses represent a group of diseases in which a misfolded protein conformation leads to an extracellular tissue deposition, followed by dysfunctions of tissues or organs. Transthyretin (TTR) belongs to this group of about 25 human proteins with amyloid potency that is mainly secreted by the liver. Currently, more than 100 TTR mutations have been discovered in patients with familial amyloidosis (ATTR) with different clinical manifestation. Drug therapy of ATTR is partially possible on a protein level. However, a full silencing of the mutated TTR gene would enormously increase therapeutic outcome. Antisense oligonucleotides (ASOs) and small interfering RNAs (siRNA) are the most commonly used gene-silencing strategies. These artificial nucleotides bind complementary to the target gene mRNA, hence inactivating the translation of the protein. In this study, ATTR patient-specific hepatocyte-like cells (iHeps) were generated from induced pluripotent stem (iPS) cells, followed by a broad *in vitro* analysis of ASOs and siRNA effects on TTR expression.
Methods: Fresh urine (250–500 ml) from ATTR patients was processed for isolation of renal epithelial cells, followed by reprogramming into iPS cells by using integration-free vectors, such as nucleofection of episomal (EBNA) plasmids. After characterization of iPS colonies, a 3-step differentiation protocol toward hepatocytes was performed. Briefly, iPS cells encountered a treatment with specific growth factors (activin A, Wnt3a, FGF2,

HGF) for 14 days. iHeps were then characterized by analysis of typical hepatic markers, e.g. albumin and TTR via RT-PCR, immunocytochemistry and hepatocyte-specific functional assays. For TTR gene silencing, ASOs or siRNAs were introduced into iHeps using cationic lipids with or without electroporation. The phenotype of TTR knockdowns in iHeps was examined *in vitro*.
Results: After 2 weeks of cultivation of urinary cells, 4–6 stable cell populations emerged. Episomal vectors yielded iPSCs with characteristic features and normal karyotype. The iHeps indicated a high similarity to primary human hepatocytes. ASOs or siRNA treatment generated TTR depleted ATTR iHeps.
Conclusions: Urine cell-derived iPSCs can be reprogrammed and efficiently differentiated to iHeps. Antisense drugs are suitable tools for TTR knockout in ATTR iHeps. As a result, ASOs or siRNA could be potentially useful for pharmacological development and regenerative medicine.

P1216
ADVANCED LIVER DISEASE CORRELATES WITH LOW SERUM LYSOSOMAL ACID LIPASE ACTIVITY

E. Shteyer[1,2], R. Villenchik[1], M. Mahamid[1,2,3], N. Nator[1], R. Safadi[1,3].
[1]*The Liver Unit, Gastroenterology Institute, Hadassah Medical Center,* [2]*Gastroenterology Institute, Shaare Zedek Medical Center, Jerusalem,* [3]*Liver Unit, Holy Family Hospital, Nazareth, Israel*
E-mail: johnnyamer@hotmail.com

Background and Aims: Deficiency of lysosomal acid lipase (LAL) causes Wolman disease (WD) and cholesteryl ester storage disease (CESD) due to organ infiltration by macrophages filled with cholesteryl esters and triglycerides. Decreased LAL in various degrees may be asymptomatic, cause fatty liver or even cirrhosis. Replacement enzyme therapy is currently available in clinical trialsto study LAL levels in patients with Non Alcoholic Fatty Liver Disease (NAFLD) and idiopathic cirrhosis.
Methods: Medical records of patients aged 1 year to 65 years that underwent liver biopsy from the years 2006 to 2012 were screened. Patients with biopsies showing cryptogenic cirrhosis, microvesicular steatosis or metabolic syndrome related macrovesicular steatosis, were screened for LAL activity using the new method of dried blood spots specific assay (Synageva Inc.). Clinical, laboratory, imaging and pathological data was collected and analyzed.
Results: Of those patients screened 4 had cryptogenic cirrhosis, 9 had microvesicular steatosis and 9 had macrovesicular steatosis. The mean age was 32.4±23.3 (ranges 2.9–71.8) years. Mean LAL activity was 0.74 (median 0.8, ±0.28) nmol/punch/hour. Three cases had LAL <0.37 (carriers) but none of the 22 cases had LAL <0.03 (diagnostic for WD & CESD). However, threshold of LAL activity <0.6 (as compared to 0.4 and 0.5), in seven of the 22 cases allocated severity markers of liver disease: low serum calcium, hypoalbuminemia, low total protein and prolonged INR due to synthetic dysfunction, low platelets due to hypersplenism and portal hypertension, high serum uric acid a result of low blood volume, and impaired glucose and HbA1c levels suggesting insulin resistance.
Conclusions: LAL activity <0.6 is associated with severe liver injury in patients with fatty liver and cirrhosis. Although our pilot study is small and had biases the results are in-line with other reports suggesting lysosomal alterations in NAFLD. Further larger studies are warranted to define the relation of LAL levels to the severity of liver disease and the need for replacement therapy in those cases.

P1217
DYNAMICS OF HUMAN LIVER PROGENITOR CELLS IN THE PERINATAL PERIOD

M.H. Schoots[1], A. Timmer[1], M.L. Bulthuis[1], A.S. Gouw[1]. [1]*Pathology and Medical Biology, UMCG, University of Groningen, Groningen, Netherlands*
E-mail: m.h.schoots@umcg.nl

Background and Aims: In humans, insufficiency of hepatocytes to contribute adequately to liver regeneration will activate the normally quiescent liver progenitor cells (LPC) which is recognizable as ductular reaction. Results of several studies suggest parallels between fetal development and adult liver regeneration but little is known about LPC behaviour in the human liver in the perinatal period. We investigated the patterns of LPC in livers of children who died after 28 weeks of gestation, either in utero or within 1-week postpartum.
Methods: 52 cases were selected based on absence of liver diseases. All samples were stained with CK7 to highlight the LPC. Portal CK7+ cells were scored as number of quadrants per portal tract (PT) in which CK7+ cells are present (1 to 4) and 10 PT per sample were scored. Strings of small parenchymal CK7+ cells, phenotypically matching LPC were counted as LPC-complexes (LPCcx) in 10 hotspots per sample. CK7+ intermediate hepatobiliary cells (IHBC) were counted separately in 10 hotspots per sample.
Results: Based on the staining pattern of the portal CK7+ cells, cases can be divided in 2 groups: one with a ductal plate pattern (DP, n = 14) and a group showing mature PT (MPT, n = 38) containing ductular reaction. There were no significant differences in gestational age, clinical condition and time of death between the 2 groups. Also no differences in LPCcx and IHBC presence was seen, suggesting that there is a variable pattern of PT maturation regardless of gestational age.
We subdivided the cases in those with and without IHBC to assess parenchymal regeneration. In the DP group a borderline difference in LPCcx was found ($p = 0.06$) showing higher numbers of LPCcx in the IHBC positive group. In the MPT group a higher number of LPCcx was seen in the IHBC positive cases ($p = 0.04$) whereas no difference was seen in the scoring of ductular reaction. Increase of LPCcx parallels the presence of IHBC regardless the PT pattern.
Conclusions: In perinatal livers there is a variable pattern of PT maturation unrelated to gestational age. Regardless the PT maturation pattern, parenchymal LPC activation can be present indicating parenchymal regeneration. The latter does not parallel the portal regenerative activity expressed as ductular reaction.

P1218
ALPHA-1 ANTITRYPSIN DEFICIENCY AND LIVER DISEASE IN CHILDHOOD

P. Cardoso[1], S. Nobre[1], S. Ferreira[1], I. Gonçalves[1]. [1]*Liver Transplant Unit, Hospital Pediátrico, Coimbra, Portugal*
E-mail: patricia_neves_cardoso@hotmail.com

Background and Aims: Alpha-1 antitrypsin deficiency (A1ATD) is a genetic disease, relatively common in individuals of Northern European and Iberian descent. The most common abnormal alleles are Z and S, and majority of individuals with severe A1ATD have ZZ phenotype (PiZZ). It is known that about 10% of affected infants will develop some form of liver disease. After biliary atresia (BA), A1ATD is the second cause of liver transplantation (LT) in childhood, in our country. We aim to characterize pediatric population with A1ATD and liver disease followed in the liver unit, and those who were referred for LT, of a tertiary pediatric hospital.
Methods: A retrospective review of the medical records of patients diagnosed with A1ATD was made (December 1994 to October 2014). Demographic, clinical and laboratorial parameters were studied. Two groups were considered: those who underwent LT and those

who did not. Statistical analysis used *SPSS*® 18.0 ($p < 0.05$ statistically significant).
Results: The study included 41 patients, 24 (58.5%) boys. Median age at diagnosis was 2 months (15 days to 16.8 years; 1 with prenatal diagnosis). Median follow up was 7.9 years. Majority (82.9%) of patients were from northern and central regions of our country. There was 33 PiZZ, 5 PiSZ, 1 PiSS, 1 PiMZ and 1 PiMS. Enlarged liver and/or spleen (29) and neonatal cholestasis (28) were the most common clinical presentations. Five patients had intrauterine growth restriction (2 premature), 12 had failure to thrive at presentation. From the 21 patients who underwent liver biopsy, 13 had abnormalities consistent with A1ATD. Regarding comorbidities, 4 patients had asthma (1 PiZZ, 1 PiSZ, 1 PiMZ, 1 PiMS), 4 had BA (3 PiSZ, 1 PiZZ), and 1 had mitochondrial disease (PiZZ). Twenty-five patients (61%) progressed to end-stage liver disease and underwent LT (23 PiZZ, 2 PiSZ with BA) and 2 required retransplant. Median age at first LT was 4.3 years. Infection (25%) was the most common complication after LT. Statistical significance ($p = 0.016$) was found for AST level at presentation (mean AST in LT group 227 U/L *versus* no LT group 129 U/L). Three patients died, 1 following LT (primary non function), 2 due to comorbidities (primary immunodeficiency; mitochondrial disease).
Conclusions: It is highlighted that other severe diseases involving liver could be present. A1ATD can be a severe disease as nearly two thirds of the patients had progressed to end-stage liver disease requiring LT. AST level at presentation was shown to be a marker of disease severity.

P1219
HEPATIC HEDGEHOG SIGNALING AND STEROIDOGENESIS – AN EVIL PARTNERSHIP?
C. Rennert[1], M. Matz-Soja[1], F. Eplinius[1], A. Ricken[2], R. Gebhardt[1].
[1]*Institut Für Biochemie,* [2]*Institut für Anatomie, University of Leipzig, Leipzig, Germany*
E-mail: rgebhardt@medizin.uni-leipzig.de

Background and Aims: The liver has multiple anabolic and catabolic functions. Novel results showed that Hedgehog (Hh) signaling, a pathway commonly associated with embryogenesis, development and cancer, is active in hepatocytes and acts as a master regulator of zonation in the adult liver (Gebhardt and Matz-Soja, WJG, 2014). We are interested in how this signaling pathway is connected to sex-specific regulation of gene expression.
Methods: For these investigations we bred a transgenic mouse with an inactivated Hh signaling, by a hepatocyte-specific knockout (KO) of Smoothened, a key protein of Hh signaling (SAC mice). Homozygous female SAC KO mice are unable to reproduce whereas syngeneic male littermates were fertile. To explain these observations we performed histological and molecular biological analyses of liver and ovary.
Results: The results showed an infantile reproductive system and no histological features of oestrus cycle activity. These manifestations were associated with alterations in the gene expressions of hepatic insulin like growth factor 1 and binding protein 1 (*Igf1, Igfbp1*; Matz-Soja et al., CCS, 2014). Surprisingly we observed alterations in steroidogenic gene expression as well; yet it was assumed that steroidogenesis occurs in the liver only during embryogenesis and is down-regulated afterwards. We found changes in expression of several steroidogenesis associated genes, like cytochromes (e.g. *Cyp17a1, Cyp11A1*, *Cyp19a1*) and hydroxysteroid dehydrogenases (*Hsd3b1*, *Hsd17b2*). In SAC KO mice the expression of *Cyp17a1* was dramatically increased in both genders relative to wild type mice with an even higher expression in males. No such changes were found in the ovaries. Furthermore we observed an up-regulation of estrogen receptor (*Esr1*) gene expression, relevant for steroid hormone mediated signaling and a clear correlation to the also up-regulated *Cyp17a1* expression. Most of these changes could likewise be induced by transfection of cultured hepatocytes with Gli3 siRNA.
Conclusions: Collectively, the experiments showed a clear influence of the morphogenic Hh pathway on the reproductive system and the regulation of steroidogenesis. Apparently, these effects reflect just an example of the general effect of this morphogenic pathway on gene expression rather than an altered hepatic steroidogenesis feed-back through different levels of sex hormones. These unexpected findings are promising for future studies to improve our understanding of the gender dimorphism of regulation in liver.

P1220
INTERACTION OF TLR-IFN AND HLA POLYMORPHISMS ON SUSCEPTIBILITY OF CHRONIC HBV INFECTION IN SOUTHWEST HAN CHINESE
D. He[1], S. Tao[2], S. Guo[2], M. Li[2], J. Wu[2], H. Huang[2], X. Guo[2], Y. Wang[2]. [1]*The 88th hospital of PLA, Tai'an,* [2]*The third military medical university, Chongqing, China*
E-mail: hedengming@gmail.com

Background and Aims: The innate immunity represented by TLR-IFN signal pathway plays a crucial role in HBV infection. HLA polymorphisms are associated with chronic HBV infection. We aimed to explore TLR-IFN gene polymorphisms association with chronic HBV infection and interaction between TLR-IFN and HLA gene polymorphisms.
Methods: In Chinese Southwest Han population, 1191 chronic HBV infection and 273 HBV clearance were selected as case and control, respectively. A total 39 SNP loci for 23 TLR-IFN gene (TLR3 rs3775296, TLR4 rs11536889 and rs1927907, TLR5 rs5744174, TLR9 rs352140, MYD88 rs7744, IRAK1 rs1059702 and rs1059703, IFNG rs2069705, IFNGR1 rs3799488 and rs10457655, IFNGR2 rs1059293 and rs2834211, IL15 rs10519613 and rs10833, IL28B rs12979860 and rs8099917, IL29 rs30461, IL6 rs1800796, EBI3 rs4905 and rs6613, IL12B rs3212227, NFKB1 rs4648068, NFKB2 rs7897947, IL1B rs1143623, rs1143627, and rs16944, IL2 rs2069772, IL10 rs1800872 and rs1800896, IL12A rs2243115 and rs568408, CXCL10 rs4256246, rs4508917, and rs8878, MX1 rs1557370, rs2070229, rs467960, and rs469390) were selected for genotyping. Four HLA SNP loci associated with chronic HBV infection by GWAS, rs3077, rs2856718, rs9277535, and rs7453920 were selected to explore the gene-gene interaction between HLA and TNF-IFN. SNPStats and MDR were used for statistical analysis.
Results: Significant association was seen in rs352140 (OR = 0.70, p = 0.0088), rs16944 (OR = 0.67, p = 0.016), rs3212227 (OR = 1.38, p = 0.021), rs3799488 (OR = 1.48, p = 0.0048), rs1059293 (OR = 0.27, p = 0.011), rs467960 (OR = 0.68, p = 0.022), as well as four SNP loci in HLA. A synergistic relationship was seen between rs9277535 and rs16944 (0.13%), rs1143623 and rs6613 (0.10%). The combination of rs9277535 and rs16944 was the best model to predict chronic HBV infection (TA = 0.6040, p = 0.0010, CVC = 10/10).
Conclusions: TLR-IFN gene polymorphisms are associated with chronic HBV infection. Interacted with TLR-IFN polymorphisms may be one mechanism for HLA polymorphism to influence the susceptibility of chronic HBV infection. The combination of rs9277535 and rs16944 is better than rs9277535 to predict chronic HBV infection.

P1221

IL12A GENE POLYMORPHISM IS CLOSELY CORRELATED WITH HBeAg SEROCONVERSION IN ENTECAVIR TREATED CHRONIC HEPATITIS B PATIENTS

J. Wu[1], Y. Wang[1]. [1]*The Chongqing Key Laboratory For Research of Infectious Diseases, Chongqing, 400038, China*
E-mail: 499902269@qq.com

Background and Aims: Host genetic factor is one of important reasons for different response of antiviral treatment in chronic hepatitis B. IL-12A play an important role in immune to HBV. IL12A rs568408 is association with many diseases. The study aimed to observe the association between IL12A gene polymorphism and HBeAg seroconversion in chronic hepatitis B patients who received entecavir treatment.
Methods: IL12A rs568408 was genotyped using the MGB-TaqMan SNP genotyping assay in 109 HBeAg-positive chronic hepatitis B patients who had received entecavir treatment. After 24 months, 29 cases achieved HBeAg seroconversion (response) were assigned as the case and the remaining 80 cases were assigned as the control. SNPstats was applied to analyze the association between IL12A rs568408 and HBeAg seroconversion.
Results: IL-12A rs568408 was associated with HBeAg seroconversion (OR 3.72, 95% CI 1.34–10.32, p = 0.012). GA genotype achieved higher HBeAg seroconversion rate than GG genotype.
Conclusions: IL-12A rs568408 was significantly associated with HBeAg seroconversion in HBeAg-positive chronic hepatitis B patients who received entecavir treatment.

P1222

CIRRHOSIS AND CARCINOMA IN COURSE OF CHRONIC HEPATITIS C IN CHILDREN

M. Figlerowicz[1], A. Mania[1], K. Mazur-Melewska[1], P. Kemnitz[1], W. Sluzewski[1]. [1]*Department of Infectious Diseases and Child Neurology, Poznan University of Medical Sciences, Poland, Poznan, Poland*
E-mail: mfiglerowicz@gmail.com

Background and Aims: Chronic hepatitis C (CHC) can lead to cirrhosis, cancer and finally hepatic failure. These serious complications are observed after years of HCV infection, and therefore by far more frequently in adults patients than in children. Retrospective analysis of the frequency of serious complications: cirrhosis and cancer in course of CHC in children, as well as clinical characteristic of patients with these complications.
Methods: The research included 146 children with CHC who were subject to treatment in our Department from 1991 to 2013. The diagnosis of CHC was established based on clinical symptoms, the detection of HCV antibodies (enzyme immunoassay), and/or HCV RNA (RT-PCR method), and by histological changes, grading the activity (G0–G4) and histological progression – staging (F0–F4) in the liver.
Results: Cirrhosis (F3/F4) was diagnosed in 7 children (4.79%) with CHC caused by genotype 1 of HCV (1a and 1 b in 4 and 3 patients respectively). All these children were infected during hospitalization, 6 of them under previous oncological therapy. Symptoms of hepatic failure were observed in 3 children (2.05% of whole group, 42.85% of children with cirrhosis). Cancer was diagnosed in 1 patient, ten years old boy with Down syndrome and cirrhosis in course CHC, caused by genotype 1b of HCV. Among symptoms of cirrhosis were observed: edema, ascites, splenomegaly, signs of portal hypertension, coagulation defects, weakness, asitia, abdominal pain, icterus, ginecomastia. In 4 children with cirrhosis coexistence of others chronic illnesses were found: in 2 children Down syndrome, in 1 common variable immunodeficiency, in 1 coeliac disease.
Conclusions: The parameter which increases the risk of cirrhosis and hepatic failure in course of CHC in children is congenital immunodeficiency including Down syndrome.

P1223

FRAILTY IN CHILDREN: A NOVEL TOOL THAT MEASURES THE MORBIDITY ASSOCIATED WITH END-STAGE LIVER DISEASE

B.M. Kamath[1], C. Quammie[1], J.F. Daniel[2], E.M. Alonso[3], E. Hsu[4], K. Furuya[5], N. Gupta[6], G.W. Telega[7], L. Book[8], H. Lin[9], S. Sundaram[10], J. Yap[11], T. Miloh[12], M. Englesbe[13], C. Sonneday[13], V. Ng[1]. [1]*Hospital for Sick Children, Toronto, Canada;* [2]*Children's Mercy, Kansas City,* [3]*Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago,* [4]*University of Washington – Seattle Children's Hospital, Seattle,* [5]*Alfred I. DuPont Hospital for Children, Delaware,* [6]*Children's Healthcare of Atlanta, Atlanta,* [7]*Children's Hospital of Wisconsin, Milwaukee,* [8]*Primary Children's Medical Center/University of Utah, Salt Lake City,* [9]*Children's Hospital of Philadlephia, Philadelphia,* [10]*Children's Hospital Colorado, Denver, United States;* [11]*Edmonton Clinic Health Academy, Edmonton, Canada;* [12]*Phoenix Children's Hospital, Phoenix,* [13]*University of Michigan, Ann Arbor, United States*
E-mail: binita.kamath@sickkids.ca

Background and Aims: Frailty is a syndrome of decreased reserve and resistance to stressors, resulting from cumulative declines and causing vulnerability to adverse outcomes. Frailty (composed of 5 classic Fried criteria) can be reliably and reproducibly measured in adults and is a powerful predictor of mortality. A large study of adults listed for liver transplantation (LT) demonstrated that 17% were frail and that frailty scores strongly predicted wait list mortality. To-date, frailty has not been investigated in children with liver disease. We hypothesized that (i) frailty can be measured in children; and (ii) frailty assessments can identify morbidity in children with end-stage liver disease that is not captured by available scoring systems.
Methods: This was a prospective multi-center study of children (5–17 years) with chronic liver disease listed for LT (Listed) or with chronic liver disease without evidence of decompensation (Control). Fried frailty elements were assessed with either the same adult tools (i) weakness (grip strength with hand-held dynamometer) & (ii) slowness (6-minute walk distance) or with validated paediatric tools (iii) shrinkage (triceps skinfold thickness), (iv) exhaustion (PedsQL™ Multidimensional Fatigue Scale) & (v) physical activity (modified Physical Activity Questionnaire). In adults each element is scored as abnormal (1) or normal (0) leading to a 5-point scale with 5 representing the most frail patients. This was adapted in children to abnormal (2), suboptimal (1) and normal (0) resulting in a 10-point scale. Each score was assigned based on standard deviations (sd) of the mean in validated norms (2: <2sd, 1: ≥−2sd to ≤−1sd, 0: >−1sd).
Results: 46 frailty assessments were completed in 14 Listed and 32 Control subjects at 12 sites. Median age was 11.9 yrs. Median time to complete the assessments was 76.9 min in Listed and 58.4 min in Controls. Using a cut-off of 6/10 defining frailty (comparable to a validated threshold of 3/5 in adults), 7/14 (50%) Listed children were frail compared to 0/32 Controls (p < 0.0001). There was no association between frailty and MELD/PELD scores.
Conclusions: Frailty assessments in children are feasible. In our cohort, frailty was present in 50% of children listed for LT. Frailty and MELD/PELD scores are independent and therefore frailty captures an under-appreciated aspect of morbidity in end-stage liver disease. Frailty assessments may be useful to optimize the selection and timing of paediatric LT.

P1224

NEXT-GENERATION SEQUENCING FOR THE DIAGNOSIS OF WILSON'S DISEASE

D. Németh[1], J. Pál Kósa[1,2], K. Árvai[2], P. Horváth[1], B. Tobiás[1], B. Balla[1], A. Folhoffer[1], A. Krolopp[1], P. András Lakatos[1], F. Szalay[1]. [1]*1 st Department of Internal Medicine, Semmelweis University,* [2]*PentaCore Laboratory, Budapest, Hungary*
E-mail: neemethd@gmail.com

Background and Aims: Wilson's disease (WD) is an autosomal recessive disorder of copper metabolism with ATP7B gene mutation at chromosome 13 in the background. More than 550 disease-causing mutations have been identified. The appearance of the next-generation sequencing (NGS) opened a new era making possible quick, one-step detection of all mutations.
Methods: Ion Torrent Personal Genome Machine was used for detecting ATP7B mutations in clinically diagnosed Wilson patients with 4 or higher score according to the international diagnostic system. 3 known homozygous, 5 compound heterozygous patients with only one known mutation and 1 patient without any known mutation were involved. The mutations detected by NGS were validated by the traditional Sanger sequencing.
Results: The average time of sequencing was 8 hours. In each 9 patients (7–51 years; 4 with liver disease, 1 with only neurological symptoms and 3 with both hepatic and neurological manifestations and 1 symptomless sibling) the mutations on both alleles have been identified strengthening the Wilson's disease diagnosis. All the formerly known mutations have been confirmed by NGS and the other mutations have been identified in the heterozygous patients. One missense mutation (R969Q) have been detected in 2 non family member patients, 5 other mutations (M769L, A1063V, P1134P-fs, L1305P and Q1351X) were identified in single patients. The H1069Q mutation was present in 8 out of 9 patients (3 homozygous and 5 heterozygous).
Conclusions: Although the international score system helps to set-up the diagnosis of WD, in some cases it still remains a challenge. The next-generation sequencing is a fast and relatively cheap method for detecting the wide spectrum of disease-causing mutations of ATP7B gene.

P1225

LIVER STIFFNESS MEASUREMENT IN PATIENTS WITH WILSON DISEASE

D. Gancheva[1], I. Kotzev[1]. [1]*Clinic of gastroenterology, hepatology and nutrition, St. Marina University hospital of Varna, Varna, Bulgaria*
E-mail: gancheva_vn@abv.bg

Background and Aims: Liver stiffness measurement (LSM) using transient elastography (TE) is non-invasive method for fibrosis assessment in chronic liver diseases. Its performance in patients with Wilson disease (WD) is incompletely specified yet. The aim of our study was to evaluate the LSM in WD patients.
Methods: Liver stiffness in 38 WD patients was measured by FibroScan®402 (Echosens, Paris, France, M probe). We compared the sonographic evaluation of the normal and reduced elasticity. In 13 patients, liver biopsy was available for comparison.
Results: The patients with liver disease only (n = 17) had a mean value of 12 kPa. The patients with a mixed WD form (n = 17) presented with a mean value of 16.8 kPa. Purely neurological patients (n = 2) had a value of 6.15 kPa while two presymptomatic individuals had a value of 4.9 kPa. Ten patients had normal elasticity (mean of 5.21 kPa, F0). Sonographic assessment of slightly reduced liver elasticity corresponded to the mean value of 7.77 kPa. The patients with moderately reduced elasticity received a mean value of 11 kPa. Rigid liver coincided with a high value of 29.9 kPa (F4). Ultrasound evaluation of advanced fibrosis corresponded to the value ≥11 kPa (F3) in 17 patients. Twelve of them were with liver cirrhosis and with a mean value of 45.39 kPa (11.5–69.1 kPa, F4). Seven patients had histologically proved fibrosis. There was liver stiffness of F3–F4 in four of them while the other three presented with F0–F1. Six individuals with liver biopsy had no fibrosis at all. All the patients except one were with F0 Fibroscan score.
Conclusions: TE is non-invasive, rapid and helpful method for LSM. More investigations are needed to validate LSM in WD. Our experience shows that Fibroscan assessment correlates with clinical and ultrasound evaluation of the liver stiffness. Our preliminary results indicate that it is a reliable diagnostic tool in clinical practice when managing WD patients.

P1226

SERUM BILE ACIDS IN NEONATES: DETERMINATION OF NORMAL VALUES IN FED AND FASTENED CONDITION

E. Zöhrer[1], B. Resch[1], G. Fauler[2], H. Scharnagl[2], T. Stojakovic[2], J. Jahnel[1]. [1]*Department of Pediatrics,* [2]*Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University Graz, Graz, Austria*
E-mail: e.zoehrer@medunigraz.at

Background and Aims: Serum bile acids (BA) are high in neonates and gradually fall, reaching adult values by age 11 (Jahnel et al. 2014, unpublished data). BA are mostly conjugated to glycine; however – since taurine is abundant in breast milk and supplemented in infant formulas – in neonates BA are mostly conjugated to taurine. We aimed to measure BA composition in healthy neonates to determine standard values for this age group.
Methods: Serum total BA (tBA) concentrations were measured in 16 healthy term neonates without cholestasis on the third day after birth. Neonates were divided into two groups: Fasted (n = 5) and fed (n = 11). Using high-performance liquid chromatography–high-resolution mass spectrometry to analyse 10 µl of serum, we created 15-BA profiles including unconjugated and taurine- or glycine-conjugated BA.
Results: In fed neonates tBA values (16.3±5.8 µmol/l) were higher than in fasted neonates (5.4±3.3 µmol/l). In fed vs. fasted neonates taurine-conjugated BA (10.2±2.8 µmol/l vs. 2.3±0.6 µmol/l) were clearly more abundant than glycine-conjugated BA (5.8±0.5 µmol/l vs. 2.1±0.5 µmol/l). Primary taurocholic acid, taurochenodeoxycholic acid, and glycocholic acid were the most abundant BA, whereas levels of all secondary BA were <0.1 µmol/l. No differences in tBA profiles were visible between breast-milk-fed and formula-fed neonates.
Conclusions: This study confirms that taurine-conjugated BA are the predominant BA species in neonates. Since BA may serve as non-invasive biomarkers in hepatic and gastrointestinal disorders, to determine age-specific normal fed and fasted BA value ranges in neonates is essential.

P1227

INTRA-HEPATIC CHOLESTASIS OF PREGNANCY (ICP): PREVENTION OF RECURRENCE OF ICP AND INTRA-UTERINE FETAL DEATH BY PRE-PRURITUS ADMINISTRATION OF URSODEOXYCHOLIC ACID

J.R. Bernuau[1], P. Millot[2], D.C. Valla[3], A.-M. Bernard[4], E. Sauvanet[5], D. Luton[6], D. Dhumeaux[7], Hepatology and Obstetrics Departments, Hospital Beaujon, 92118 Clichy, France. [1]*Hepatology Department, Hospital Beaujon, 92118 Clichy,* [2]*Hépato-Gastroentérologie, Hôpital Mamoudzou, Mayotte,* [3]*Hepatology, Hospital Beaujon, 92118 Clichy,* [4]*Obstetrics and Gynecology, Institut Hospitalier Franco-Britannique, 92300 Levallois,* [5]*Obstétrique, Hôpital Saint-Joseph, 75014 Paris,* [6]*Obstétrique and Gynecologie, Hospital Beaujon, 92118 Clichy,* [7]*Hepatology, Hospital Henri-Mondor, Créteil, France*
E-mail: jrbernuau@yahoo.fr

Background and Aims: Ursodeoxycholic acid (UDCA) is a recognized efficient treatment of established generalized pruritus (GP) and biochemical abnormalities of intra-hepatic cholestasis of pregnancy (ICP), a disorder associated with possible fetal death

and a 70% rate of recurrence in the following pregnancies. However, UDCA is not always effective and whether it may obviate recurrence of ICP and in utero fetal death has not been demonstrated. The aim of this study was to show that, in some women who sustained ICP at their initial pregnancy, early administration of UDCA during a further pregnancy may prevent the recurrence of ICP and also in utero fetal death.

Methods: Pregnant women with a previous history of ICP agreed to ingest UDCA in the absence of pruritus in the 2nd trimester of a new singleton pregnancy. The daily dose of UDCA ranged between 12 and 16 mg/kg/day up to delivery.

Results: Four women (22–31 year-old) developed GP and abnormal liver blood tests between the 26th and 36th week (wk) of their 1st singleton pregnancy. In one woman with a familial history of symptomatic gallstones, UDCA was not administered during her 1st pregnancy (associated with *in utero* fetal death at 33 wks of gestation) and during her 2nd (twin) pregnancy (associated with GP from the 18th wk of gestation and death of the twin neonates after 5 days following delivery at the 24th wk of gestation). During the 3rd and 4th pregnancies, UDCA (15 mg/kg/day) was given before the occurrence of pruritus, from the 15th and the 17th wks and up to the end of gestation. Both pregnancies were not complicated by pruritus and ended by delivery of normal neonates at 35 wks of gestation. In the 1st pregnancy of the 3 other women, pruritus occurred for 10 days to 4 wks, 2 women were given low dose of UDCA for less than 4 wks successfully, and all were delivered at 35–36 wk of gestation (one cesarean delivery; one low-weight neonate with respiratory distress). The all 3 women had another singleton pregnancy during which UDCA was given before the occurrence of pruritus, between 17 and 24 wks of gestation; pruritus was not observed, normal delivery took place at 35–37 weeks of gestation and the 3 neonates were normal.

Conclusions: in some women with a history of ICP, pre-pruritus administration of UDCA from the 2nd trimester to the end of a further pregnancy may prevent the recurrence of ICP and, even, intra-uterine fetal death.

P1228

CHANGED SERUM BILE ACID LEVELS IN CHILDREN AND ADOLESCENTS WITH ACUTE INFECTIOUS ENTERITIS OR INFLAMMATORY BOWEL DISEASE

J. Jahnel[1], E. Zöhrer[2]. [1]*Departement of pediatrics, Medical university of Graz,* [2]*Departement of pediatrics, Medical University Graz, Graz, Austria*
E-mail: joerg.jahnel@medunigraz.at

Background and Aims: Bile acids (BA) undergo highly efficient enterohepatic circulation which is impaired in acute infectious diarrhea (AID) and in inflammatory bowel disease (IBD) due to disturbed reabsorption of BA in the terminal ileum and colon. Decreased portal-venous concentrations of BA lead to an upregulation of *de novo* BA synthesis in hepatocytes, resulting in increased peripheral-blood BA levels. We aimed to quantitate the impact of inflammation of the gastrointestinal tract on BA metabolism.

Methods: Serum BA levels were measured in patients with AID (n = 57) due to viral infection or in IBD patients with active disease (n = 28; 85 overall, ages 0–18 years). Patients with IBD were further divided into two groups: ulcerative colitis (n = 15) with acute colitis and Crohn's disease with terminal ileitis (n = 13). Healthy children and adolescents (n = 197) served as controls. IBD patients with primary sclerosing cholangitis served as positive controls. 10 µl of serum was required for creating a 15-BA profile including unconjugated and taurine- or glycine-conjugated BA by high performance liquid chromatography–tandem-mass spectrometry.

Results: In the AID group BA levels were significantly decreased (2.9±3.8 µmol/L) compared to normal ranges (4.3–6.4 µmol/L; $p < 0.01$). In IBD patients BA levels were significantly decreased in Crohn's disease patients (3.1±1.9 µmol/L; $p < 0.01$ vs. controls) as well as in the ulcerative colitis group (3.2±2.0 µmol/L; $p < 0.01$). Glycine- and taurine-conjugated BA were both elevated in this group, especially glyco-ursodeoxycholic acid Interestingly, patients suffering from IBD and primary sclerosing cholangitis (n = 5) had highly elevated serum BA levels (95.8±89.8 µmol/L).

Conclusions: This study shows that an acute viral enteritis as well as chronic intestinal inflammation impairs BA re-uptake leading to significantly reduced serum BA levels. Whether medical manipulation of the intestinal BA transport in IBD or acute enteritis favorably affects symptoms like diarrhea requires further investigation.

P1229

LIVER TRANSPLANTATION FOR PROGRESSIVE FAMILIAL INTRAHEPATIC CHOLESTASIS TYPE 3 (MDR3 DISEASE) PRESENTING IN THE 5TH DECADE OF LIFE

H. Elsiesy[1], F. Abaalkhail[1], S. Yousif[1], M. Al Sebayel[1], H. Alhussaini[2], M. Alquaiz[3], D. Broring[1], W. Alhamoudi[1], M. Shagrani[1], King Faisal Liver Group. [1]*Liver transplantation,* [2]*Pathology,* [3]*Gastroenterology, King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia*
E-mail: helsiesy@gmail.com

Background and Aims: PFIC a rare heterogeneous group of autosomal-recessive disorders that presents during the neonatal period or within the first year of life resulting in intra-hepatic cholestasis during childhood. PFIC3 generally occurs later presenting either in late infancy, childhood, or even early adulthood [The Multiple Facets of ABCB4 (MDR3) Deficiency].

Case report: 44-year old gentleman with history of DM and jaundice since childhood due to Dubin–Johnson syndrome without itching, he developed progressive jaundice and intractable itching associated with dark urine and pale stools, over the past 2 years, his total bilirubin was 563umol/L with high GGT and very high serum bile acid. Serology for viral hepatitis, autoimmune hepatitis, Wilson, alpha 1 antitrypsin and hemochromatosis were negative. Abdominal US showed no bile duct dilatation. MRCP showed Moderate splenomegaly without evidence of primary sclerosing cholangitis (PSC), liver biopsy showed Chronic liver disease (stage II/IV) with finding suggestive of small duct PSC, and Dubin-Johnson syndrome.

He was started on hemodialysis for biopsy proven diabetic nephropathy 1 year ago.

Results: Progressive familial intrahepatic cholestasis (PFIC3) was considered and liver biopsy stained negative for MDR3 by immunostaining and total absence of MRP2 (Dubin Johnson protein), and genetic testing revealed a combination of Dubin-Johnson mutations and MDR3 mutations. He received Living related liver transplantation from his daughter on September 16, 2014 and he has an excellent graft function, awaiting for kidney transplant.

Conclusions: PFIC 3 may present in adults leading to progressive liver disease requiring liver transplantation.

P1230

CHANGED SERUM BILE ACID LEVELS IN CYSTIC FIBROSIS

E. Zöhrer[1], J. Jahnel[2]. [1]*Departement of pediatrics, Medical University Graz,* [2]*Departement of pediatrics, Medical university of Graz, Graz, Austria*
E-mail: joerg.jahnel@medunigraz.at

Background and Aims: Cystic fibrosis (CF) may affect the liver. We investigated changes in serum bile acid (BA) levels in different ages in CF patients with the aim to evaluate BA as a serum marker for CF associated liver disease.

Methods: The concentrations of BA were measured by the liquid-chromatography-tandem mass spectrometry in patients suffering from CF, divided into 3 age groups and in groups with and without ursodeoxycholic acid (UDCA) treatment. BA levels were correlated

with laboratory values like bilirubin, the alkaline phosphatase activity (AP), and elevated gamma-glutamyl transferase activity (GGT), and serum transaminase activity (AST, ALT).
Results: BA levels were measured in 49 patients. Most patients had continually UDCA-treatment (n = 36) and showed BA values significantly above the reference ranges: <11 years: 11.7±6.2 μmol/l (3.61–6.41 μmol/l, p < 0.01; n = 7), 12–19 years: 6.3±7.8 (3.09–4.12; p < 0.01; n = 15), >19 years: 7.9±4 (3.09–4.12; n = 14). The group without UDCA treatment also showed higher serum BA concentrations without reaching significant values: <11 years: 5.1±4.8 (n = 2), 12–19 years: 5.77±0.96 (n = 3) and >19 years: 4.4±4 (n = 8). No group had significant changes of routine liver serum parameters (AP, GGT, AST and ALT levels) compared to healthy controls; however the average values of AST, ALT and GGT in the group without UDCA treatment were higher than the average values in the group with UDCA treatment.
Conclusions: BA values are mostly increased in CF patients due to UDCA treatment. BA in serum seems not to be early marker for progredient liver disease in CF, sonography the liver seems to be indispensable. However, BA measurements could be used to test the compliance of the CF patients concerning regularly UDCA intake.

P1231
POTENTIAL OF INDUCED PLURIPOTENT STEM CELLS FOR THE TREATMENT OF CRIGLER–NAJJAR LIVER DISEASE

C. Unzu[1], M. Friedli[2], E. Planet[2], S. Offner[2], D. Trono[2], B. Wildhaber[1].
[1]Pathology and Immunology, University of Geneva, Geneva, [2]Life sciences SV, EPFL, Lausanne, Switzerland
E-mail: carmen.unzu@unige.ch

Background and Aims: Combination of gene therapy and hepatocyte (HEP) transplantation is a promising alternative to liver transplantation for many inherited metabolic liver diseases, such as Crigler–Najjar (CNI). Nevertheless, the major obstacle that remains is the insufficient amount of corrected HEP available for transplantation. Induced pluripotent stem cells (iPS) are endowed with intrinsic self-renewal ability and the potential to differentiate into any of the three germ layers, allowing cell amplification before differentiation. As such, iPS are heralded as the most promising avenue for cell-based therapeutics. However, recent evidence indicates that genetic and epigenetic features of iPS are heterogeneous and could affect the safety of the approach.
Methods: Several iPS clones from CNI patient-specific HEP were generated and efficiently differentiated to HEP-like cells (HLC). In order to show the potential of these cells for gene therapy, CNI-HLC were transduced with a lentiviral vector expressing the UDPGT protein, missing in CNI disease, under the control of a hepatic promoter. Then, transcriptomes of parental CNI-HEP, CNI-iPS and CNI-HLC at different time-points were analyzed by RNA-sequencing.
Results: The heat-map revealed sample clustering according to their potency level. Interestingly, many differences appeared between CNI-HEP and CNI-HLC, with higher expression of many transcripts in the latter. Also, many endogenous retroelements, which are known targets of epigenetic silencing upon embryonic stem cell differentation, were induced by the reprogramming of the CNI-HEP to iPSC. However, most returned to basal levels upon differentiation to CNI-HLC, indicating that this phenomenon was largely reversible.
Conclusions: Hepatocyte-derived iPS cells display epigenetic anomalies translating in the upregulation of many endogenous retroelements. While expression of these elements seemed largely suppressed upon ex vivo differentiation of these iPS into HLC, our results warrant further examination of the epigenetic features of iPS-derived hepatocytes before these can be considered for clinical application.

P1232
FUNCTIONAL CHARACTERIZATION AND DRUG RESPONSE TO ZINC AND D-PENICILLAMINE OF DISEASE-CAUSING ATP7B MUTATIONS IN A HUMAN HEPATOMA CELL LINE

G. Chandhok[1], V. Sauer[1], C. Niemietz[1], A. Zibert[1], H.H.-J. Schmidt[1].
[1]Klinik für Transplantationsmedizin, Uniklinik Münster, Münster, Germany
E-mail: gursimran.chandhok@gmail.com

Background and Aims: In Wilson disease (WD) hepatocyte survival is significantly affected by toxic copper (Cu) overload due to mutation of the liver copper transporter ATP7B. More than 600 mutations of ATP7B are described. Copper toxicity in WD is reversed commonly by D-penicillamine (DPA) and/or zinc (Zn). The impact of the individual ATP7B mutation expressed in WD patients for efficacy of standard treatment is not known.
Methods: ATP7B mutations that are frequent in Europe/USA and Asia as well as various frequent homozygous genotypes observed in India were selected. Stable cell lines were established expressing the mutations in a human hepatoma HepG2 ATP7B knockout cell line that was established recently by our group (PLoS ONE, 9: e98809, 2014). Cell survival as well as induction of apoptosis was determined in mutant cell lines following Cu exposure and Zn/DPA treatment.
Results: In the mutant cell lines ATP7B protein expression varied while mRNA expression was on similar levels as compared to wild type. Co-localization studies with late endosome-lysosome marker lamp2 suggested impairment of trafficking in various mutant cell lines. Mutant cell lines showed different grades of activity to escape toxic Cu with mutation p.H1069Q displaying a moderate activity. No activity was observed for mutant cell lines encoding incomplete reading frames. Characteristic responses to treatment were observed after Zn, DPA and Zn+DPA combined treatment for individual cell lines. Overall, DPA treatment was more efficient as compared to Zn treatment. Of note, only Zn+DPA treatment could fully restore ATP7B activity as compared to ATP7B wild type.
Conclusions: Individual ATP7B mutations differ in their capacity to escape toxic Cu and show genotype-specific response to treatment. The type of ATP7B mutation may modulate the efficacy of Zn and DPA treatment suggesting that current regimens might further improve using the knowledge of functional parameters exerted by ATP7B.

E-mail: varma.sharat@yahoo.com

Background and Aims: To investigate predictors of clinical evolution in PFIC-II patients and their relationship to BSEP expression and (re)targeting.
Methods: 23 children with established PFIC-II were retrospectively included. Clinical, biochemical and histological characteristics were reviewed at presentation and following treatment with Ursodeoxycholic acid (UCDA) only (10 mg/kg TDS) (n = 20) or UCDA and Partial Biliary Diversion (PBD) (n = 3). BSEP immunostaining was obtained in 20/23 patients. Response to treatment was defined as normalization of pruritus, disappearance of jaundice, and normalisation of alanine amino transferases (ALT) (<1.5 upper limit of normal – ULN). The duration of remission was also recorded.

Six responders had a paired biopsy with BSEP immunostaining, 2 after PBD.

Results: Twelve of 23 patients were non-responders, 1 partial responder and 10 responded to treatment. Non-responders had earlier onset of jaundice (<9 months), neonatal cholestasis and higher ALT levels. ALT >165 IU/L had sensitivity of 72% and specificity of 55% to predict non-response.

Eight of 12 non-responders had no BSEP expression, 1 cytoplasmic, 1 canalicular, 2 not done. Amongst 10 responders, 5 had cytoplasmic BSEP expression and 5 absent. Paired biopsies were obtained after treatment in 6/10: De novo canalicular expression of BSEP occurred in 4/6, 2 with baseline cytoplasmic expression and 2 with no baseline expression.

Seven patients were still responders at last follow up (median 20 months, range 5–67 months), one of them died from unrelated cause, and 3 did relapse after 56, 72 and 82 months. Amongst the 9 living responders a median relapse free survival time of 72 months (95% CI 48 to 96 months) was observed and the five years Kaplan–Meier relapse free survival was 75% (95% CI 33–100%).

Conclusions: PFICII children with late onset presentation, ALT <165 IU/L and cytoplasmic BSEP are likely to respond at least transiently to non-transplant treatment while patients with neonatal cholestasis do not. All but one PFIC II patients had abnormal or no BSEP expression. De novo or retargeted canalicular expression of BSEP can occur under treatment amongst the responders.

P1234

LOW HEPCIDIN/FERRITIN RATIO IN C282Y HOMOZYGOTES CORRELATES INVERSELY WITH TRANSFERRIN SATURATION AND NON-TRANSFERRIN BOUND IRON LEVELS

J.D. Ryan[1], E. Ryan[2], J. Russell[2], B. Coughlan[2], H. Tjalsma[3], D.W. Swinkels[3], S. Stewart[2], J. Crowe[2]. *[1]Translational Gastroenterology Unit, University of Oxford, Oxford, United Kingdom; [2]Liver Centre, Mater Misericordiae University Hospital, Dublin, Ireland; [3]Department of Laboratory Medicine, Radboud University Medical Centre, Nijmegen, Netherlands*

E-mail: johnryan@physicians.ie

Background and Aims: HFE Hereditary Haemochromatosis (HFE-HH) is characterised by deficient hepcidin production, a high serum ferritin and transferrin saturation, and subsequent formation of toxic non-transferrin bound iron (NTBI) with parenchymal iron overload. The purpose of this study was to determine the serum hepcidin:ferritin ratio across a cohort of different HFE genotypes presenting with raised ferritin levels, and to examine the relationship of this ratio with transferrin saturation, NTBI and LFTs.

Methods: Fasting blood samples were collected from 77 individuals referred with suspected iron overload to our centre. Transferrin saturation, ferritin and liver function tests were measured using standard laboratory methods. Serum hepcidin levels were measured using a combination of weak cation exchange chromatography and time of flight spectrometry, while NTBI levels were measured using a one step fluorescence-based assay. Data was analysed using SPSS version 18.

Results: The table depicts the study results. The hepcidin:ferritin ratio was significantly lower in C282Y homozygotes compared to compound heterozygotes and controls, despite similar ferritin levels across the groups. Transferrin saturation levels were significantly higher in C282Y homozygotes compared to compound heterozygotes and controls, and C282Y homozygotes had significantly higher NBTI levels compared to controls. ALT levels and age were not significantly different between groups. Within the C282Y homozygous cohort, the hepcidin:ferritin ratio strongly correlated with transferrin saturation ($r = -0.639$, $p = 0.001$) and NTBI ($r = -0.647$, $p = 0.001$), while ALT showed a moderate correlation with NTBI ($r = 0.431$, $p = 0.035$) and with the hepcidin:ferritin ratio (−0.405, $p = 0.049$).

	C282Y (1) n = 29	Compound heterozygote (2) n = 22	Controls (3)* n = 26	ANOVA/post hoc Tukey HSD (1) vs (2); (1) vs (3)
Hepcidin, nM	3.2 (2.2–3.7)	5.1 (3.1–7.2)	6.0 (4.6–10.6)	**<0.001**; **<0.001**
NTBI, μM	5.9 (4.7–7.1)	4.63 (4.1–5.69)	3.9 (3.1–4.8)	0.115; **<0.001**
Ferritin, μg/L	594 (364–1028)	405 (320–696)	470 (379–730)	0.273; 0.774
Trans Sat, %	72.4 (19.2)	47 (10)	38.9 (14.6)	**<0.001**; **<0.001**
ALT, IU/L	37 (25–51)	41 (28–56)	44 (20–59)	0.424; 0.285
Age, years	48.3 (10.3)	47.1 (12.1)	54 (11.2)	0.925; 0.150
Hepcidin:ferritin ratio	4.96 (3.7–6.3)	11.5 (7.1–18.5)	12.5 (9.4–21.2)	**<0.001**; **<0.001**

*6 H63D homozygotes, 6 C282Y heterozygotes, 7 H63D heterozygotes and 7 normal genotypes.

Conclusions: Low hepcidin:ferritin ratios are associated with high transferrin saturation and NTBI levels. The serum hepcidin/ferritin ratio may serve as a useful clinical tool to reflect the inadequate hepcidin response to increased iron loading. Moreover, increased NTBI levels may play a role in the suppression of hepcidin underlying the pathogenesis of HFE-HH.

P1235

HEREDITARY HEMOCHROMATOSIS: ROLE OF H63D HOMOZYGOSITY IN HEPATIC IRON OVERLOAD

R.M. Martin Mateos[1], J. Graus Morales[1], D. Rey Zamora[2], V.F. Moreira Vicente[1], A. Albillos[1], D. Boixeda de Miquel[1]. *[1]Gastroenterology, [2]Genética, Hospital Universitario Ramón y Cajal, Madrid, Spain*

E-mail: rosamartinmat@hotmail.com

Background and Aims: Hereditary hemochromatosis (HH) is the leading genetic cause of iron overload. C282Y homozygotes account for 80–85% of patients with HH, however, H63D mutation may also play an important role. Current data argue both for and against the association between H63D homozygosity and hemosiderosis. Our aim is to analyse the effect of this polymorphism on iron metabolism and to determine if it predisposes carriers to develop a significant liver disease.

Methods: Retrospective analysis including 445 subjects studied from 1994 to 2012 who presented iron overload or family history of hemochromatosis. Genetic analyses were performed using allele-specific polymerase chain reaction amplification and data were obtained from medical records and laboratory database.

Results: We included 192 homozygous H63D, 109 homozygous C282Y, and 144 wild-type HFE subjects (without H63D nor C282Y mutations).

Mean ferritin and IST values for homozygous H63D were 372.1±385 mg/dl and 42.4±19.1%, respectively. Older patients had higher ferritin levels, indicating a trend towards gradual increase over time. Serum iron, AST, ALT, bilirubin, and GGT values were all within normal ranges in this group. Twenty-one H63D patients (10.94%) showed parenchymal iron overload (measured by biopsy or magnetic resonance), and seven (3.65%), signs of cirrhosis with portal hypertension. Only 11 cases (5.72%) showed iron overload in absence of other factors associated with hyperferritinemia.

C282Y homozygotes had significantly higher levels of ferritin (980.9 ng/mL) and IST (82.7%) than H63D group, and presented higher percentages of parenchymal iron overload (48.6%).

Subjects with wild-type alleles showed higher ferritin levels (595.6 ng/mL) than H63D homozygotes, but similar IST values, iron deposition, and portal hypertension prevalence.

Regarding possible confounding variables, wild-type subjects had the highest prevalence of non-inherited hyperferritinemia-related factors, confirming a secondary origin of iron overload in this group.

Conclusions: H63D homozygosity is related to increased levels of ferritin. Hepatic iron overload is present in 5.72% of these patients in the absence of other conditions associated to hyperferritinemia. However, H63D homozygosity doesn't determine

clinically significant iron overload in most cases. When these patients present analytical and/or histological evidence of iron overload, other hyperferritinemia-related factors should be investigated first.

P1236

IMPACT OF HIGH PORTAL PRESSURE ON RENAL HEMODYNAMICS IN CHILDREN WITH PORTAL HYPERTENSION

R.Z. Yuldashev[1], M.M. Aliev[1], G.S. Adilova[1]. [1]*Pediatric Surgery, The Republic Specialized Scientific Practical medical centre of pediatrics, Tashkent, Uzbekistan*
E-mail: rustam0511@yahoo.com

Background and Aims: Hemorrhage from gastroesophageal varices in children with prehepatic portal hypertension is best controlled by various types of portosystemic shunt, but long-term follow up of children who have had splenorenal shunt surgery due to portal hypertension gave evidence for assuming the risk of renal venous hypertension (RVH).
The purpose of this study was to investigate the impact of portosystemic shunt surgery on renal blood
Methods: The results of 170 portosystemic shunt operations were followed from 2005 to 2014. 12 patients applied side to side splenorenal shunt, 12 children assessed the distal splenorenal shunt (DSRSh), 82 had central splenorenal shunt (CSRSh) with splenectomy. 44 iliacomesenterial anastomosis (IMA) and in 20 cases performed mesocaval anastomosis (MCA). Patients had a standard pre and postoperative work up including gastrointestinal endoscopy, Doppler ultrasonography (US), angiography, multislice computed tomography and MR imaging.
Results: On Doppler US at early and late postoperative periods PI and RI of left renal artery remained at high numbers (PI = 1.48±0.17 and RI = 0.72±0.19, $p \leq 0.05$ respectively) after the CSRSh with splenectomy. After DSRSh, these signs haven't been detected. 11 (13.4%) patients after CSRSh on Doppler US revealed signs of impeded venous outflow on the left renal vein (LRV). 8 patients after IMA on US Doppler and CT and MRI angiography revealed dilated left testicular and ovarian veins (Figure 1), with retrograde blood flow in them, which clinically manifested as left flank pain, macro- and microhematuria, varicocele and ovaricocele
Conclusions: Portosystemic shunt surgery is highly effective treatment for children with prehepatic portal hypertension. But study shows that total shunts such as central splenorenal shunt with splenectomy and iliacomesenterial anastomosis more negatively effect on hemodynamics of left kidney. Shunting the large amounts of blood from a system of high pressure to a low manifests as clinical signs of renal venous hypertension.

Figure 1. Fourteen-year-old boy with extrahepatic portal hypertension, after IMA. MSCT angiogram reveals enlarged and tortuous spermatic vein (arrow) draining to inferior cava through left renal vein.

P1237

THE MODIFIED IRON AVIDITY INDEX: A PROMISING PHENOTYPICAL PREDICTOR IN HFE-HAEMOCHROMATOSIS

P. Verhaegh[1], W. Moris[1], C. van Deursen[2], G. Koek[1].
[1]*Gastroenterology, Maastricht University Medical Centre, Maastricht,* [2]*Gastroenterology, Atrium Medical Centre, Heerlen, Netherlands*
E-mail: p.verhaegh@maastrichtuniversity.nl

Background and Aims: Phenotypes of the HFE-related haemochromatosis vary considerably, which makes it difficult to identify which patients need maintenance phlebotomy therapy, and if so, how often. Besides phlebotomy therapy has side effects; therefore, it would be of great value to have a tool to predict the phenotype, to be able to individualize therapy. The aim of this retrospective study is to determine if the iron avidity index (IAI) is a good phenotypical predictor of the number of phlebotomies during maintenance treatment (NPDMT) needed per year in patients with C282Y homozygous haemochromatosis.
Methods: Patients with hereditary haemochromatosis homozygous for C282Y on maintenance treatment, in the Atrium Medical Centre, Heerlen, the Netherlands, for at least one year, were included. The IAI was calculated by dividing ferritin level at diagnosis by age at diagnosis. Due to skewed distribution, IAI was natural logarithmic (LN) transformed.
Linear regression analysis was used to assess the association between the IAI and NPDMT and to assess influence of current age, age at diagnosis, sex and PPI use on this association.
Furthermore, Pearson correlation was used to analyse the correlation between the modified IAI and NPDMT per year. The results were analysed using IBM SPSS Statistics 22 software (IBM Inc., Armonk, NY, USA).
Results: In total, 95 patients (60% men) with a mean age of 62 (±10.7) years, were included in the analysis. The IAI is showing a significant positive relation with NPDMT per year ($r = 0.299$, $p = 0.002$). Linear regression analysis showed the confounding effect of sex on the relationship between IAI and NPDMT per year. PPI use was independently associated with NPDMT. A modified Iron Avidity Index, adjusted for sex, was calculated and showed a significant positive correlation with NPDMT ($r = 0.343$, $p = 0.000$) (see Figure 1).

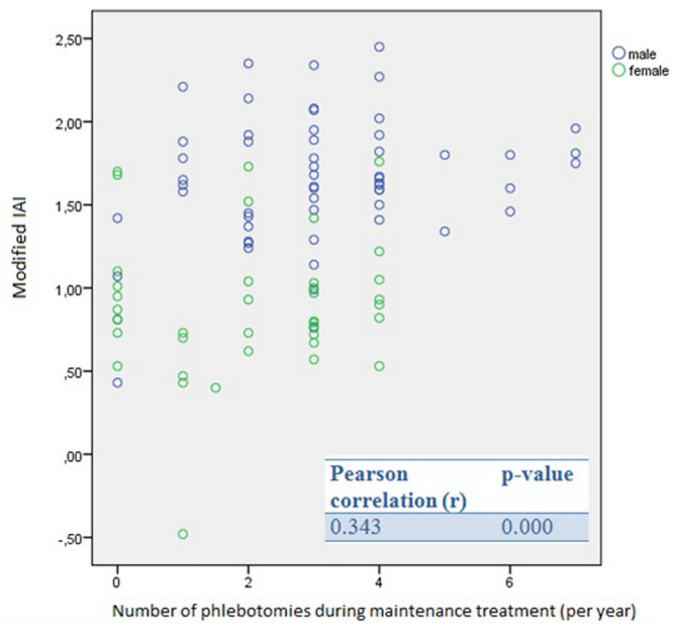

Figure 1. Scatterplot of the modified IAI vs. number of phlebotomies during maintenance treatment, with a Pearson correlation of 0.343; showing that women need less phlebotomies per year during maintenance treatment.

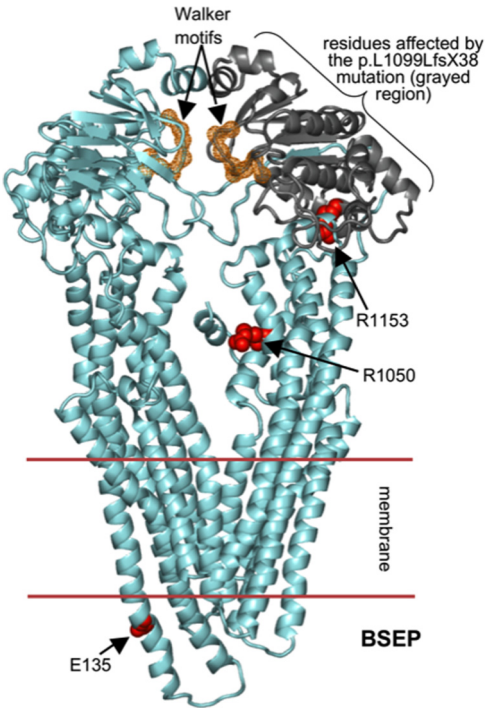
Conclusions: The modified IAI, adjusted for sex, is a promising index for predicting the yearly number of phlebotomies during maintenance treatment as an expression of the phenotype of patients with hereditary haemochromatosis homozygous for C282Y. Due to the retrospective design of the study, information on factors, such as weight, BMI and diet, were lacking and are probably of importance because of the fact that HFE related haemochromatosis is a heterogeneous disorder. Future studies should be performed to refine this index to make it into a useful tool to predict the number of phlebotomies in maintenance therapy more accurately.

P1238

INTERMEDIATE FAMILIAL INTRAHEPATIC CHOLESTASIS (IFIC): PHENOTYPIC SPECTRUM WITHIN THE BRIC–PFIC SPECTRUM

I. Giovannoni[1], F. Callea[1], E. Bellacchio[2], G. Torre[3], V. Nobili[4], J. De Ville De Goyet[5], G. Maggiore[6], R. Boldrini[1], P. Francalanci[1].
[1]Pathology and Molecular Histopathology, [2]Research Laboratories, [3]Hepatology, Gastroenterology and Nutrition Unit, [4]Hepato-Metabolic Disease Unit, [5]Paediatric Surgery and Transplantation, Bambino Gesù Children's Hospital, IRCCS, Rome, [6]Clinical and Experimental Medicine Pediatric Gastroenterology, University Hospital of Pisa, Pisa, Italy
E-mail: isabella.g@fastwebnet.it

Background and Aims: Benign recurrent intrahepatic cholestasis (BRIC) and progressive familial intrahepatic cholestasis (PFIC) belong to a *spectrum* of autosomal liver disorders: familial intrahepatic cholestases (FIC). Their differentiation is based on genetic and phenotypic presentation. Clinical transition between BRIC and PFIC is rarely reported. We hypothesize that patients with a compound heterozygosity for BRIC and PFIC mutations belong to an intermediate form of familial intrahepatic cholestasis (IFIC).
Methods: Two cases, a male (case 1), 11 year-old, with intermittent jaundice since 1 month-old and a female (case 2), 5 year-old, with intractable pruritus and jaundice, since 5 months old, underwent liver biopsies, which were analyzed by histology and immunohistochemistry (IHC) with an anti-BSEP antibody. *ABCB11* gene was sequenced. To define the mutation pathogenicity, the homology modeling was done (Figure).



Results: In case 1, liver biopsy showed preserved architecture and mild signs of intrahepatic cholestasis. Genetic analysis showed p.E135K (BRIC mutation) and p.L1099LfsX38 (new mutation). The homology modeling revealed that p.E135K has an effect on the N-glycosylation interfering with stability, function and intracellular trafficking. Conversely, the p.L1099LfsX38 causes the loss of most of the residues forming the 2nd ABC transporter domain, abolishing the protein function (PFIC mutation). In case 2, three liver biopsies displayed progression of cholestasis and IHC revealed persistent preserved BSEP canalicular staining. Genotyping showed p.R1050C (BRIC mutation) and p.R1153H (PFIC mutation). The p.R1153H should impair the protein function influencing the structure of the Walker motif in the 2nd ABC transporter domain of BSEP. The p.R1050C, interacting with a site of ubiquitination, will increased BSEP degradation.
Conclusions: Familial intrahepatic cholestasis is distinguished into BRIC and PFIC. A clinical progression from benign to severe form is rarely described. Our cases suggest the existence of a *de novo* form of Intermediate FIC, with an intermediate phenotype between the benign phenotype (BRIC) and the more severe (PFIC), genetically supported by a compound heterozygosity (BRIC-PFIC). Absence of phenotype-genotype correlation, at least in our cases, would suggest the possibility of a IFIC *spectrum,* depending on mutation severity.

P1239

ASSESSMENT OF DIET AND PHYSICAL ACTIVITY IN PAEDIATRIC NON-ALCOHOLIC FATTY LIVER DISEASE PATIENTS: A UK CASE CONTROL STUDY

P.S. Gibson[1], E. Fitzpatrick[2], D. Kamat[2], A. Dhawan[2], M.E. Ford-Adams[3], A. Desai[3], K. Hart[1], J.B. Moore[1]. *[1]Nutritional Sciences, Faculty of Health and Medical Sciences, University of Surrey, Guildford, [2]Paediatric Liver Centre, [3]Multidisciplinary Obesity Clinic, Department of Child Health, King's College Hospital, London, United Kingdom*
E-mail: p.s.gibson@surrey.ac.uk

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is now the most common cause of chronic liver disease in children with an estimated prevalence of 10% in the general paediatric population increasing to 80% in obese children. The aim of this study was to characterise the habitual diet and activity behaviors of children with biopsy-confirmed NAFLD compared to obese children without liver disease.
Methods: Biopsy proven paediatric NAFLD cases and ultrasound clear obese controls (OC), recruited from King's College Hospital specialist paediatric liver and obesity clinics respectively completed 24-hour dietary recall, a Physical Activity Questionnaire (PAQ), a Dutch Eating Behavior Questionnaire (DEBQ) and a 7-day food and activity diary (FAD) in conjunction with wearing a pedometer. Personal diet and lifestyle feedback was provided with the goal of weight reduction at 6-month follow-up.
Results: 21 NAFLD and 8 OC have completed the study to date. Groups were well matched for age, gender and baseline anthropometrics with the majority of patients having a BMI over the 99.6th\ centile. The NAFLD group were predominantly Caucasian (80%) while OC group were largely Black (78%) ($p < 0.01$). 24-hour recall data highlighted NAFLD patients had higher intakes of saturated fatty acids (SFA) and iron when comparing dietary recommended values ($p = 0.048$ and $p = 0.021$ respectively), while the 7-day FAD demonstrated higher dietary intakes of vitamin D in the OC compared to NAFLD (3.7 μg/d versus 2.1 μg/d; $p = 0.05$). No significant differences in absolute intakes of fructose, or Vitamins C or E were identified. Under-reporting was prevalent within the sample (NAFLD: 65%, OC: 75%; $p = 0.61$). In addition, NAFLD patients showed a greater number of steps taken (NAFLD: 8,414, OC: 5,965; $p = 0.02$) despite both groups not meeting the recommended 10,000 steps a day.

Conclusions: This is the first study to assess dietary and lifestyle activity in a UK paediatric NAFLD population. While clear differences were not identified between groups, issues of sample size, under reporting and confounding by ethnicity have impacted on the findings and are being addressed in the ongoing study. Development of NAFLD-specific diet and lifestyle guidelines are currently not supported. The current study demonstrates that the paediatric population is failing to conform to standard recommendations for both diet and physical activity, and should therefore remain the focus of clinical management.

P1240
CLINICAL, BIOCHEMICAL AND HISTOPATHOLOGIC PROFILE OF SUBJECTS WITH GLYCOGENIC HEPATOPATHY (MAURIAC SYNDROME)

S. Mukewar[1], P. Kamath[1], L. Roberts[1], Y. Kudva[2]. *[1]Gatsroenterology and Hepatology, [2]Endocrinology, Mayo Clinic, Rochester, MN, United States*
E-mail: mukewar.saurabh@mayo.edu

Background and Aims: Glycogenic hepatopathy is a syndrome of elevated transaminases and liver enlargement in type-1 diabetes patients. Since its description, there have been mostly case reports discussing this condition. We aimed to conduct a case series to describe clinical, biochemical and histo-pathologic profile of these patients.

	Overall (n = 36)	Adults (n = 24)	Pediatric (n = 12)
Male	8 (22.2%)	5 (20.8%)	3 (25%)
Age at presentation (years) [a]	20.9±5.8	23.3±5.7	16.3±1.76
Height (cm) [b]	166.8 (161.8, 169.5)	168 (162.4, 171.6)	161.5 (148.8, 164.9)
Weight (kg) [a]	64.4±13.3	66±9.7	61.1±18.8
Body mass index (BMI; kg/m^2) [a]	23.5±3.5	23.4±2.7	23.8±4.8
Percentile height for age [b]	30 (8.5, 49)	n/a	30 (8.5, 49)
Percentile weight for age [b]	78.5 (43.5, 83.8)	n/a	77 (62.5, 80.8)
BMI for age [b]	76 (53, 84)	n/a	81.5 (72.3, 89.8)
Clinical features			
Abdominal pain	23 (63.9%)	14 (58.3%)	9 (75%)

Follow up			
Resolved transaminases	18 (50%)	9 (37.5%)	9 (75%)
Resolving transaminases	3 (8.3%)	2 (8.3%)	1 (8.3%)
No follow up	15 (41.6%)	13 (54.2%)	2 (16.7%)

[a] Mean ± standard deviation. [b] Median (interquartile range).

Methods: Electronic medical records at Mayo Clinic, Rochester were searched from January 1, 1998 to January 1, 2014 using the term "Mauriac syndrome" and "Glycogenic hepatopathy" and reviewed in detail. Demographic, clinical, biochemical and histopathologic data was abstracted.
Results: Results are described in the table. 36 patients were diagnosed with glycogenic hepatopathy – 24 adults and 12 pediatric patients. 20 had liver biopsy and 16 were clinically diagnosed. 28 (77.8%) cases were female. Only 2 out of 12 (16.7%) pediatric patients, both from the clinically diagnosed group, had percentile height, weight and BMI for age below the third percentile. Abdominal pain was the most common symptom [23 (63.9%)] and hepatomegaly was seen in 28 (77.8%) cases on imaging. All patients had poor control of diabetes (HBA1c – 11.2±2.4). Transaminases were elevated from 3 to 20 times the upper limit of normal.
Conclusions:
- Growth retardation is uncommon in glycogenic hepatopathy.
- Majority of cases present with abdominal pain, hepatomegaly, transaminase elevation, hypertriglyceridemia, without any synthetic liver dysfunction.
- Liver biopsy rarely shows fibrosis, inflammation or megamitochondria.
- On follow up, majority of individuals with follow up data had resolution of transaminases with improved glycemic control.

P1241
JAK/STAT PATHWAY AND SUSCEPTIBILITY TO HEPATITIS B VIRUS INFECTION AND RELATED LIVER DISEASES

T.V. Hoang[1], N.X. Hoan[1], A. Clark[1], F. Gerlach[1], N.L. Toan[2], L.H. Song[3], C.-T. Bock[4], P.G. Kremsner[1], T.P. Velavan[1]. *[1]Institute of Tropical Medicine, University of Tübingen, Tübingen, Germany; [2]Department of Pathophysiology, Vietnam Military Medical University, [3]Institute of Clinical Infectious Diseases, Tran Hung Dao Hospital, Hanoi, Vietnam, [4]Department of Infectious Diseases, Robert Koch Institute, Berlin, Germany*
E-mail: tong.van-hoang@uni-tuebingen.de

Background and Aims: Hepatitis B virus (HBV) infects approximately 350 million people worldwide and is the leading cause for chronic hepatitis, liver cirrhosis and hepatocellular carcinoma. The activation of JAK/STAT pathway by cytokines and growth factors is related to different processes such as cell proliferation, differentiation and apoptosis. Several protein members of JAK/STAT pathway including SOCS1, SOCS3, STAT1, STAT3, and STAT5 have been demonstrated to associate with the HBV infection and modulate the outcomes of liver diseases. We investigated the influence of polymorphisms in the JAK/STAT pathway gene members including Cytokine-inducible SRC homology 2 (SH2) domain protein (*CISH*), the signal transducers and activators of transcription 4 (*STAT4*) and the suppressors of cytokine signalling 3 (*SOCS3*) on HBV infection and HBV-related liver diseases.
Methods: We utilized a Vietnamese cohort (n = 1084) clinically classified into different subgroups including chronic hepatitis B carriers, liver cirrhosis, hepatocellular carcinoma and healthy controls to investigate the effect of the reported variants. The genotyping of investigated variants was performed by FRET real-time PCR and sequencing. A multivariate regression analysis was performed to investigate potential effect of studied variants and to exclude the confounding effects of other factors such as age and gender. We also analyzed the influence of studied variants on the disease outcomes represented by different clinical parameters.
Results: The first results showed that *CISH* variants −292A/T were significantly associated to HBV infection (Allelic: OR: 1.22, 95% CI 1–1.49; $P = 0.04$; Recessive: OR: 1.69, 95% CI 1.23–2.54; $P = 0.007$). A gene dose effect for the risk allele *−292T* was also observed ($P = 0.04$). In addition, the *STAT4* variant (rs7574865) was marginally

associated with HCC susceptibility in CHB carriers in allelic and recessive genetic models (OR = 0.84, 95% CI 0.7–0.99, P = 0.048 and OR = 0.7, 95% CI 0.5–0.99, P = 0.047).
Conclusions: Our findings significantly contribute to understand the functional roles of JAK/STAT pathway member proteins during HBV infection, pathogenesis and progression of liver diseases.

P1242
ETHNIC DIFFERENCES IN PAEDIATRIC NON-ALCOHOLIC FATTY LIVER DISEASE

J.P. Mann[1], M.J. Armstrong[2], P. Sewel[3], S. Rajwal[3], P. McClean[3].
[1]Paediatrics, University of Cambridge, Cambridge, [2]NIHR Centre for Liver Research, University of Birmingham, Birmingham, [3]Liver Unit, Leeds General Infirmary, Leeds, United Kingdom
E-mail: jakemann@doctors.org.uk

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is now the most common cause of liver disease in children, with an estimated prevalence of 5–10%. The majority of published data has involved Caucasians. Data is lacking regarding the phenotypic differences of NAFLD in children of Asian origin.
Methods: We performed a retrospective review of children consecutively diagnosed with NAFLD at a tertiary referral hepatology service in the UK, between 2003 and 2014. Patients had been referred from either primary care physicians or general paediatricians with incidental asymptomatic abnormal liver function tests (LFTs) and/or fatty liver on ultrasound scan (USS). Patients with inadequate data or with secondary fatty liver disease were excluded. Patients were divided by ethnicity into Asian and Caucasian. All values are (±SD), unless stated.
Results: 100 patients with primary NAFLD were identified. 59/100 were Caucasian and 41/100 were of Asian origin, of whom, 73% (30/41) were Pakistani. There was male predominance in both groups, 73% (43/59) in Caucasian and 78% (32/41) in Asians. Mean ages at presentation were 12.6±2.5 and 11.7±2.8 years in Caucasian and Asian groups, respectively.
Asian patients had a significantly lower body mass index (BMI) centile than Caucasian (91.2±9.5 vs. 96.1±5.1, $p < 0.05$). There were no differences in LFTs between Asian and Caucasian patients, ALT (87.8±60.9 vs. 94.3±84.5 IU/L) and bilirubin (9.4±7.6 vs. 9±6.5 μmol/L). 61% (25/41) Asian patients had an elevated gamma glutamyl transferase, compared to 60% (35/59) Caucasian patients. Markers of the metabolic syndrome were similar in both groups: total cholesterol 4.4±1 vs. 4.4±1 mg/L, triglycerides 2.0±1.4 vs. 2.2±1.4 mg/L, and HbA1c 38.6 vs. 39.1±7.4 mmol/mol.
20 patients had undergone biopsy. 33% (2/6) demonstrated moderate-severe fibrosis in Asian patients, compared to 21% (3/14) Caucasian patients ($p = 0.61$).
Conclusions: Asian children with NAFLD have similar disease severity as their Caucasian counterparts, despite a significantly lower BMI centile at presentation. Referring clinicians and risk stratification scores require a greater awareness of ethnic differences in adiposity in paediatric NAFLD.

EU Public health

P1243
BIRTH COHORT DISTRIBUTION AND SCREENING OF VIREMIC HCV INFECTIONS IN LUXEMBOURG

C. Seguin-Devaux[1], V. Arendt[2,3], S. Blach[4], P. Hoffmann[5], H. Razavi[4], T. Staub[3], D. Struck[2], J. Mossong[6]. *[1]Laboratory of Retrovirology, [2]Centre de Recherche Public de la Santé, Strassen, [3]Centre Hospitalier de Luxembourg, Luxembourg, Luxembourg; [4]Center for Disease Analysis, Louisville, United States; [5]Health Directorate Luxembourg, Luxembourg; [6]Laboratoire National de Santé, Dudelange, Luxembourg*
E-mail: sarah.blach@centerforda.com

Background and Aims: In Luxembourg, the majority of viremic hepatitis C virus (HCV) infected individuals are thought to have already been diagnosed (85%). Additionally, nearly 100 viremic cases are newly diagnosed annually. As the undiagnosed population dwindles, identifying new cases becomes increasingly difficult (Wedemeyer 2014). This analysis seeks to understand if targeted birth cohort screening strategies can improve detection rates.
Methods: A previously described HCV disease burden model was populated with Luxembourgish assumptions regarding HCV prevalence, viremic rate and age distribution (Razavi 2014). The viremic population was aged to 2013 accounting for mortality and cure rates, and was stratified according to birth cohort. The number of screenings required to identify one viremic case was calculated as follows:
1/[(viremic HCV prevalence)·(1 − diagnosis rate)].
Costs (expressed in €) associated with diagnosing (anti-HCV serology and HCV RNA qualitative) and informing treatment (genotype and viral load) for one viremic case were estimated as follows:
€8·(anti HCV tests administered) + €65·(HCV RNA tests administered for anti HCV positive cases) + €228·(treatment informing tests administered for HCV RNA positive cases).
Results: More than 50% of the viremic HCV infected population was estimated to be born between 1965 and 1984, with 75% born between 1960 and 1989. Random screening of the general population would require 1,120 anti-HCV tests (in addition to further confirmatory tests) to diagnose one new HCV case, while targeted screening in the 1960–1989 cohort (25–50 years of age) could diagnose one new case per 671 persons screened. Targeted screening in the 1960–1989 cohort would cost about €8,170 per positive diagnosis, as compared with a €13,460 cost for random screening. Screening within 5-year age cohorts could find anywhere from one case per 569 persons screened (1975–1979 cohort, 15% of the viremic population) to one case per 236,680 persons screened (2010–2014 cohort, <1% of the viremic population).
Conclusions: Considering only the direct cost of diagnosis, the most efficient birth-year screening strategy would particularly target persons born between 1960 and 1984 (25–50 years of age), as this cohort accounts for 75% of viremic cases and requires screening of only 671 individuals to identify one viremic HCV infected case. Targeted birth cohort screening is more efficient and cost effective than random screening.

P1244

PREVALENCE AND CLINICAL OUTCOME OF POST TRANSFUSION HEPATITIS C IN YOUNG AND ADULTS

C. Millbourn[1,2], A. Psaros-Einberg[3,4], G. Lindh[2], I. Hökeberg[5], B. Fischler[3,4], K. Lindahl[1,2]. *[1]Department of Medicine Huddinge, Unit of Infectious diseases Karolinska Institutet, [2]Department of Infectious Diseases, Karolinska University Hospital Huddinge, [3]Department of Pediatrics, Karolinska University Hospital, [4]CLINTEC, [5]Department of Communicable Disease Prevention and Control, Karolinska Institutet, Stockholm, Sweden*
E-mail: charlotta.millbourn@karolinska.se

Background and Aims: The prevalence of chronic hepatitis C in Sweden is estimated to 0.5%. Before 1991 blood transfusion was a common route of transmission. The primary aim of this study was to estimate anti HCV prevalence in individuals receiving blood transfusions in an urban area during that period. The secondary aim was to study the effect of age at transfusion on liver disease and treatment outcome.
Methods: This is a single centre retrospective analysis of anti HCV tested individuals during a national screening campaign in 2008–2010 of recipients of blood transfusions 1965–91 in an urban area. Subjects were informed through media and encouraged to perform anti HCV testing by their general physician. All anti HCV positive subjects were referred to Karolinska University Hospital for further investigation. Inclusion criterion for this study was blood transfusion as the most likely mode of transmission. Subjects with ongoing or a history of drug abuse were excluded. Data on age at transfusion, age at diagnosis, HCV genotype, IL28B genotype, viral load, fibrosis score, liver histology and antiviral treatment was recorded.
Results: 134 of 7473 (1.8%) tested individuals were anti HCV positive and of those 102 were HCV RNA positive resulting in a prevalence of chronic hepatitis C infection of 1.4%. In 99 patients data was retrieved showing that 71% were female, 45% of the patients were older than 61 y at diagnosis. Obstetric or gynecological intervention were the most common causes of transfusion. The rate of advanced liver damage was 18% (n = 56). Patients younger than 19 y of age at transfusion (group1, 23% of the cohort) were significantly more often started on antiviral treatment compared to adult patients (group 2), 65% vs 29% $p < 0.001$. No significant correlation was found between treatment outcome and gender, age at transfusion or IL28B gt.
Conclusions: This study found an anti HCV prevalence of 1.8% which is considerably higher than previous estimations. Most patients acquiring HCV through transfusions are female, but mostly elderly patients were identified in a national campaign. In this study, patients infected during childhood were more likely to receive antiviral treatment than individuals with post transfusion hepatitis C contracted later in life. Additional data on the hepatitis C epidemic in Sweden are needed regarding prevalence and age distribution. If treatment coverage is higher in younger individuals this population should be targeted for general screening.

P1245

PUBLIC HEALTH IMPACT OF HCV SCREENING AND TREATMENT IN THE FRENCH BABY-BOOMER POPULATION

O. Ethgen[1,2], Y. Sanchez Gonzalez[3], G. Jeanblanc[4], D. Misurski[3], T. Juday[3]. *[1]SERFAN Innovation, Namur, [2]EMIR, University of Liège, Liège, Belgium; [3]AbbVie Inc., North Chicago, United States; [4]AbbVie, Rungis, France*
E-mail: o.ethgen@serfan.eu

Background and Aims: Because of the high prevalence of chronic hepatitis C in baby-boomers (born between 1945 and 1965) in many developed countries, screening and treatment of this population is of public health importance. This study examined the projected impact of screening a French baby-boomer (FBB) population for hepatitis C virus (HCV), followed by one of four treatment strategies for naïve genotype (GT) 1 patients: (1) no treatment; (2) interferon (IFN)-based direct-acting antiviral (DAA) regimens in fibrosis stages F2–F4 (current standard of care); (3) IFN-free all-oral DAA regimens in stages F2–F4 or (4) IFN-free all-oral DAA regimens in stages F0–F4.
Methods: A sequential, multi-cohort, health-state-transition model projected the number of FBBs with HCV achieving a sustained virologic response 12 weeks after treatment (SVR_{12}) or progressing to decompensated cirrhosis (DCC), hepatocellular carcinoma (HCC), liver transplant (LT) and liver-related death (LrD) from 2015 to 2035. Epidemiology and mortality data were extracted from the median population projection by the French National Demographic Institute. The proportion of FBBs screened for HCV was projected to increase from 57% in 2015 to 72%/78%/85% (low/medium/high screening scenarios) in 2035, with a new cohort of patients being diagnosed each year. SVR_{12} rates were extracted from clinical trials. A HCV prevalence estimate of 0.5% (61% GT 1) and transition probabilities across health states were obtained from published literature.

Table: Projected public health impact (medium HCV screening scenario 2015–2035)

	Time period				
	2015–2019	2020–2024	2025–2029	2030–2035	Overall
Number of newly diagnosed patients from screening					
F0–F1	727	525	331	160	1,743
F2–F3	306	319	271	169	1,066
CC	66	59	51	35	212
Total	1,099	904	653	364	3,020
Total, low scenario	770	655	501	324	2,250
Total, high scenario	1,428	1,153	804	405	3,790
Number of life years					
No treatment					
SVR_{12}	0	0	0	0	0
DCC	9	42	84	153	288
HCC	7	36	76	143	262
LT	0	3	10	24	38
LrD [a]	3	17	35	65	120
IFN-based DAAs for F2–F4					
SVR_{12}	725	2,891	5,131	8,158	16,906
DCC	1	2	2	2	7
HCC	1	2	2	2	6
LT	0	0	0	1	1
LrD [a]	0	1	1	1	3
IFN-free DAAs for F2–F4					
SVR_{12}	743	2,921	5,164	8,193	17,020
DCC	0	0	0	0	2
HCC	0	0	0	0	2
LT	0	0	0	0	0
LrD [a]	0	0	0	0	1
IFN-free DAAs for F0–F4					
SVR_{12}	2,194	7,053	10,447	14,241	33,935
DCC	0	0	0	0	2
HCC	0	0	0	0	2
LT	0	0	0	0	0
LrD [a]	0	0	0	0	1

DCC, Decompensated cirrhosis; F, Fibrosis stage; HCC, Hepatocellular carcinoma; LT, Liver transplantation; LrD, Number of liver-related deaths; SVR_{12}, Sustained virologic response 12 weeks after treatment.
[a] Measured as number of cases.

Results: The low, medium and high HCV screening scenarios demonstrated that 2,250, 3,020 and 3,790 new FBBs would be diagnosed with HCV from 2015 to 2035 (see Table). In the medium screening scenario, the number of life years lived with SVR_{12} (and patients achieving SVR_{12}) during 2015–2035 would be 16,906 (1,740) with the current standard of care, 17,020 (1,747) with all-oral, IFN-free DAAs for F2–F4, and 33,935 (2,952) with all-oral, IFN-free DAAs for F0–F4. The number of patient-years lived in DCC, HCC or LT during 2015–2035 would be 587 (120 LrDs) without treatment, 14 (3 LrDs) with the current standard of care, and 4 (1 LrD) with IFN-free, all-oral DAAs for F2–F4 or F0–F4.
Conclusions: An enhanced screening policy coupled with broader access to IFN-free, all-oral DAAs will diminish the future burden of HCV in the FBB population. Our analysis suggests that IFN-free, all-oral DAAs for F0–F4 could double the number of years FBBs live with SVR_{12} compared to the current standard of care.

P1246

ABDOMINAL ULTRASONOGRAPHY GUIDANCE REDUCES THE RISK OF COMPLICATIONS AND IMPROVES SUCCESS RATE AFTER LIVER BIOPSY: RESULTS OF A META-ANALYSIS COMPARING THE USE OF ULTRASOUND GUIDANCE TO THE "BLIND METHOD"

A. Garioud[1], J.-F. Cadranel[1], J.-B. Nousbaum[2], A. Smaïl[3], H. Lison[1], T. Thévenot[4], M. Medmoun[1], D. Belloula[1], F. Kazerouni[5], K. Hadj-Nacer[5], A. Cazier[6], V. Di Martino[4]. *[1]Service d'Hépato-gastroentérologie, de Nutrition et d'Alcoologie, GHPSO, Creil, [2]Service d'Hépato-gastroentérologie, CHRU La Cavale Blanche, Brest, [3]Service de Chirurgie digestive, GHPSO, Creil, [4]Université de Franche-Comté, CHRU Jean Minjoz, Besançon, [5]Service d'Imagerie médicale, [6]Service d'Anatomopathologie, GHPSO, Creil, France*
E-mail: armand.garioud@ghpso.fr

Background and Aims: Percutaneous liver biopsy (LB) remains essential for histological diagnosis of many diffuse liver diseases. Two techniques can be used: "blind" liver biopsy (B-LB) and ultrasound-guided liver biopsy (US-LB). Reports on usefulness of US guidance are conflicting. The present meta-analysis aims to assess whether ultrasonography guidance effectively reduces the occurrence of complications and improve the quality of the material harvested.
Methods: Studies comparing the two techniques were selected by 3 independent searchers on PubMed. 24 pooled analyzes were conducted regarding the following endpoints: pain, complications (including anxiety, hypotension, bleeding and injury of the biliary tract), mortality, sample size, number of portal tracts and failure rate as assessed by histologic examination. Statistical analyses were performed according to the random effect model (Der Simonian and Laird) with determination of weight-adjusted odds ratios (ORs).
Results: 17 publications published as full paper in peer review journals including three randomized controlled studies were included. Data from 24,630 biopsies (14,603 B-LB and 10,027 US-LB) in 24,180 patients were analysed. Compared with B-LB, US-LB was significantly associated with lower failure rates (OR = 0.32; 95% CI: 0.16–0.62; $p < 0.0001$), less pain (OR = 0.55; 95% CI: 0.44–0.70; $p < 0.0001$) and fewer complications (all events combined) (OR = 0.54; 95% CI: 0.37–0.79; $p < 0.0001$). When restricting the analyses to randomized controlled trials, the benefit of ultrasound guidance was maintained for pain (OR = 0.51; 95% CI: 0.34–0.77; $p < 0.0001$) and for overall complications (OR = 0.37; 95% CI: 0.20–0.72; $p = 0.003$). The low number of events did not allow powerful analyses for each complication or mortality. The analyses regarding sample size and number of portal tracts provided heterogeneous results.
Conclusions: This meta-analysis indicates the superiority of LB with ultrasound guidance compared with "blind" LB. The risk of pain and complications are reduced by 50% and the success rate is improved by 68%. These results support the recommendation of a systematic ultrasound-guidance for all percutaneous LB.

P1247

UNEXPECTED HIGH PREVALENCE OF HCV-VIRAEMIA (HCV RNA+) IN THE EMERGENCY DEPARTMENT (ED) OF A LONDON HOSPITAL – SHOULD WE BE SCREENING FOR HCV IN ED ATTENDEES?

C. Orkin[1], E. Leach[2], S. Flanagan[1], E. Wallis[1], G.R. Foster[3], M. Ruf[4], C Y. Tong[5]. *[1]Infection and Immunity, [2]Biochemistry, [3]Hepatology, Barts Health NHS Trust, [4]Public Health, Gilead Sciences, [5]Virology, Barts Health NHS Trust, London, United Kingdom*
E-mail: chloe.orkin@bartshealth.nhs.uk

Background and Aims: The UK national public health authority, Public Health England, recently recommended a rapid scale-up in diagnosis and treatment of hepatitis C virus (HCV) infection in order to reduce the substantial HCV-related healthcare burden. It is estimated that up to 50% of HCV infected individuals in the UK remain undiagnosed. While excellent treatments now exist, making the diagnosis is the key to curing HCV, both for individuals and for public health. 1 in 4 people in the UK attend an Emergency department (ED) each year. However, HCV testing is not routine and data on HCV prevalence in ED settings are sparse. Local prevalence data are crucial in informing public health strategy for HCV.
Aim: To estimate the HCV RNA+ prevalence and cost per diagnosis per viraemic infection in ED attendees.
Methods: We conducted an unlinked anonymous HCV seroprevalence study using residual biochemistry samples from 997 Royal London hospital ED attendees over 18 years during a 12 day period between 4/9/14 and 16/9/14. Samples were anonymised except for age, gender and ethnicity and tested for HCV antibody (Ab) using an automated EIA (Architect, Abbott). Reactive samples were further tested for HCV RNA (COBAS Amplicor, Roche). Anonymisation of samples and HCV testing were double blinded.
Results: 997 samples were tested for HCV Ab, overall HCV seroprevalence was 2.6% (26/997) with 1.2% (12/997) HCV RNA+. Median age of RNA+ was 47 y (age unknown in 80). 66.7% (8/12) of RNA+ were male. 75% (9/12) RNA+ individuals were aged 25–54 y (RNA+ 9/441; 2.0%). There was a substantial variation in age–sex specific RNA+ prevalence peaking at 48% (3/63) in males 35–44 y, compared to 0% (0/136) <35y ($p = 0.0614$) and 1.4% (4/278) ≥45 y ($p = 0.2415$). Despite ethnic diversity within ED attendees with 30% being Asian (300/997) and 31% white British (311/997), 58% (7/12) of RNA+ were in white British attendees (2.3% RNA+ in white British vs 0.3% in Asians; $p = 0.0766$). Assuming cost for HCV Ab is £6 and HCV-RNA is £40/test, screening ED attendees aged 25–54 could identify 75% of RNA+ at a cost of £360 per viraemic infection. This would likely yield the most favourable benefit/cost ratio.
Conclusions: We found unexpectedly high levels of active HCV infection in screening ED attendees in this ethnically diverse large urban London hospital. The distinct local epidemiological profile of RNA+ attendees suggests that routine screening of ED attendees aged 25–54 years could be an effective strategy.

P1248

SUCCESSFUL MANAGEMENT OF PRECARIOUS POPULATION AFTER SYSTEMATIC HBV TESTING IN FRANCE: A PROSPECTIVE COHORT STUDY

F. Roudot-Thoraval[1], I. Rosa-Hézode[2], M. Trompette[2], L. Costes[2], M. Chousterman[3,4], the PRECAVIR Study Group. *[1]Public Health and Clinical Research, Hôpital H Mondor, Université Paris-Est Val de Marne, [2]Hepatology and Gastroenterology, [3]Access to Care Unit, [4]Health Networks, Centre Hospitalier Intercommunal, Créteil, France*
E-mail: michel.chousterman@gmail.com

Background and Aims: In France, HBV infection is two to six times more prevalent among precarious individuals, especially migrants. However, their conditions of life make them unlikely to have access to screening and care. *Aims:* To offer precarious individuals HBV testing and access to care when positive.
Methods: Between May 2007 and May 2014, 149 (6.7%) out of 2,223 consecutive precarious adults attending two primary healthcare settings in Créteil, France, were tested HBsAg+. 95% were unaware of their status. 66% were male, mean age was 32 years (±9). Two were French, and 152 were migrants (sub-Saharan African 139, Asian 5, Eastern European 5, Latin American 2, Mediterranean area 1). Sixty-eight were asylum seekers and 72 illegal immigrants. All were offered referral to specialist.
Results: 140 HBsAg+ patients (91%) kept their appointment with a specialist, within a median of 33 days after testing, and 134 of them (96%) underwent biological and virological evaluations: 7 were HBeAg+, 57 had HBV DNA level >2,000 IU, 21 had >20,000 IU, and 26 had ALT > upper limit of normal. Co-infections were observed in 9 cases (HIV 5, HCV 2, HDV 2). Chronic active hepatitis was diagnosed in 27 patients, among which 1 cirrhosis and 2 patients were immune-tolerant. When needed, 14 out of 19

patients had access to antiviral therapy. The median follow-up was 14 months and currently, 83 patients (59%) are still followed-up.
Conclusions: Testing and referral were well accepted among this precarious population, in the context of a coordinated program that enables them to have access to optimized care.

P1249
ALCOHOLIC LIVER DISEASE AND LIVER CANCER AS PUBLIC HEALTH ISSUES IN THE BURDEN OF LIVER-RELATED MORTALITY IN THE LAST 15 YEARS IN BRAZIL

H. Perazzo[1], P.M. Luz[1], R. De Boni[1], J. Fittipaldi[1], S.W. Cardoso[1], B. Grinsztejn[1], V. Veloso[1]. *[1]Fundação Oswaldo Cruz (FIOCRUZ), Rio de Janeiro, Brazil*
E-mail: perazzohugo@gmail.com

Background and Aims: Liver-related mortality (LRM) has been increasing in the last decades worldwide. The aims of this study were to evaluate the global and specific LRM rates in the last 15 years in Brazil.
Methods: We analyzed mortality data in the Brazilian Unified Health System Information Technology Department (DATASUS) database from 1998 to 2012. Death causes were classified according to the 10th revision of the International Classification of Diseases (ICD-10). The ICD-10 codes for LRM were: viral hepatitis [B15-B19]; liver cancer [C22]; alcoholic liver disease [K70]; liver fibrosis and cirrhosis [I85, K73, K74] and others liver diseases [K72, K75, K76]. Population habitants' statistics were also available by the Brazilian Institute of Geography and Statistics (IBGE). Mortality rates were calculated by the ratio between absolute number of deaths and current estimated population and were expressed as death rates per 1,000 or 100,000 inhabitants.
Results: Overall mortality rates ranged from 5.76 to 6.09 deaths per 1,000 persons from 1998 to 2012. Cardiovascular disease, non-liver cancer and external causes were the top ranking death causes. A total of 482,238 people died due to liver diseases in the last 15 years, representing the 7th known cause of death. LRM rates [per 100,000 habitants] has been increasing from 15.7 to 19.7 from 1998 to 2012 and it was higher in males compared to females (26.1 vs 9.7) and higher in the South-East region compared to the North region (20.3 vs 11.3) in the last 15 years. Liver fibrosis and cirrhosis (31%), alcoholic liver disease (23%) and liver cancer (22%) were the most frequent liver-related death causes in this period. In individuals older than 40 years, 23,304 people died from liver cancer (10.5 per 100,000) from 1998 to 2002 compared to 29,969 (11.7 per 100,000) from 2003 to 2007 and 37,759 (12.0 per 100,000) from 2008 to 2012. Following the same trend, in people older than 40 years, deaths [per 100,000 habitants] due to alcoholic liver disease has been increasing: 10.6 (23,641 deaths) from 1998 to 2002; 12.5 (32,037 deaths) from 2003 to 2007 and 13.3 (41,721 deaths) from 2008 to 2012. On the other hand, death rates [per 100,000 habitants] from liver fibrosis and cirrhosis have been decreasing in Brazil in the last 15 years [18.3 (1998–2002); 16.9 (2003–2007); 14.5 (2008–2012)].
Conclusions: Liver-related death rates, especially due to liver cancer and alcoholic liver disease, have been increasing in the last 15 years in Brazil.

P1250
LOW INCIDENCE OF REINFECTION WITH HEPATITIS C VIRUS AFTER SUCCESSFUL TREATMENT IN MONTREAL

N. Machouf[1], B. Trottier[1], C. Galanakis[2], E. Huchet[2], M. Poliquin[2], S. Vézina[2], S. Lavoie[2], D. Longpré[2], D. Legault[2], R. Thomas[2]. *[1]Clinique médicale l'Actuel, Montreal, [2]Clinique médicale l'Actuel, Montréal, Canada*
E-mail: nima.machouf@lactuel.ca

Background and Aims: In Montreal the incidence rate of HCV infection is estimated at 26/100 py among the IDU population. Though treatment uptake among HCV infected patients remains low, the latter is likely to change given the recent development of promising INF-free treatments. HCV reinfection has been reported both in UDI and MSM patients but the extent to which reinfection occurs is unknown. The aim of this study was to evaluate the incidence of reinfection in a clinical cohort of HCV treated patients.
Methods: HEPVIRAC's (Hepatite Viral – l'Actuel's Cohort) patients with sustained virological response (SVR) to HCV treatment were included in this study. Censoring date was either the date of HCV reinfection or the date of the last negative HCV RNA test. Reinfection was defined as detectable HCV RNA with or without ALT elevation. Date of reinfection was estimated as the midpoint between the last negative and first positive HCV RNA tests. The rate of reinfection was calculated using the number of person-years of observation after the end of HCV treatment. Time from SVR to reinfection was estimated using Kaplan–Meier analyses.
Results: 338 patients cured from HCV were included. Men represent 77% and women 23% of the sample; mean age was 46 years; major risk factor for HCV infection was IDU for 275 (82%) patients, sexual transmission for 30 (9%) and the remaining patients were infected from tattoos (n = 9), transfusion/contaminated liquid (n = 11), sharing of non IDU material (n = 4) or were from endemic regions (n = 5). Patients were followed up (FU) for a median of 2.7 years after the end of treatment (IQR, 1.7–4.8), for a total of 1175 person-years of FU. 316 (94%) patients remained persistently negative, while 22 (6%) became reinfected during FU period with an overall reinfection rate of 1.7/100py [95% CI 1.07–2.58]. Median time from cure to reinfection was estimated at 14.7 years (95% CI 13.6–15.7). Cumulative incidence of seroconversion within 2 years of SVR was 4% (9/210) and 11% (10/88) within 5 years of SVR. Following adjustment for past or present drug use, the incidence rate of HCV reinfection was 0.43/100py [95% CI 0.02–0.11] for non drug users; 1.90/100py [95% CI 1.13–3.14] for past IDU and 3.60/100py [95% CI 1.44–7.39] for present IDU.
Conclusions: HEPVIRAC shows a relative low risk of HCV reinfection after successful treatment. Although the rate of HCV reinfection is higher in IDU than non IDU, it remains much lower than the overall incidence rate of the first HCV infection in drug users in Montreal.

P1251
HEPATITIS B AND C: KNOWLEDGE, ATTITUDES AND PREVENTIVE PRACTICES OF THE GREEK GENERAL ADULT POPULATION. PRELIMINARY RESULTS OF THE GREEK NATIONAL HEALTH EXAMINATION SURVEY "HPROLIPSIS"

A. Karakosta[1], V. Sypsa[1], G. Papatheodoridis[2], G. Vourli[1], O. Anagnostou[1], M. Kantzanou[1], M. Gavana[3], A. Vantarakis[4], G. Chlouverakis[5], P. Voulgari[6], Y. Alamanos[7], G. Rachiotis[8], G. Trypsianis[9], G. Touloumi[1]. *[1]Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, [2]Academic Department of Gastroenterology, Laiko General Hospital, National and Kapodistrian University of Athens, Athens, [3]Laboratory of Hygiene and Social Medicine, Medical School, Aristotle University of Thessaloniki, Thessaloniki, [4]Department of Public Health, Medical School, University of Patras, Patras, [5]Laboratory of Biostatistics, School of Medicine, University of Crete, Heraklion, [6]Rheumatology Clinic, Medical School, University of Ioannina, Ioannina, [7]Institute of Epidemiology, Preventive Medicine and Public Health, Corfu, [8]Department of Hygiene and Epidemiology, Department of Medicine, University of Thessaly, Larissa, [9]Laboratory of Medical Statistics, Medical School, Democritus University of Thrace, Alexandroupolis, Greece*
E-mail: akarakosta@med.uoa.gr

Background and Aims: Awareness, standpoints and practices of the general population are of major importance for planning prevention and treatment programmes. We aimed to investigate knowledge level, attitudes and preventive measures for hepatitis B (HBV) and C viruses (HCV) infection in the general Greek adult population (≥18 years).

Methods: Data from the ongoing Greek study Hprolipsis, the first Health Examination Survey of HBV, HCV and HIV in the general population and in vulnerable populations (immigrants and Roma), were analyzed. Multistage stratified random sampling based on 2011 census was applied to select the sample. A standardized questionnaire was administered by trained interviewers. Questionnaire data collected during the period March-August 2014 were analyzed.
Results: In total 2074 subjects were included in this analysis, 923/1151 male/female, median age 56.2 years (IQR: 40.4–68.8). Only 29.6% and 19.5% of the participants had a good knowledge level of HBV and HCV, respectively. These low percentages were mainly attributed to the high levels of misunderstandings regarding transmission modes. 34.1% and 37.2% believed that HBV and HCV are transmitted by daily social contact and 45.7% and 48.3% by insect bites, respectively. Results from multivariable analysis revealed a trend for lower knowledge scores with older age, lower education level and lower family income. 44.2% did not usually use condom. More frequent condom use was associated with age <40 years and higher educational level. The majority (58.4%) of the population was not aware of HBV vaccine. Awareness of HBV vaccine was higher in females (43.9% vs 36.8% for males, p = 0.011). The majority of the participants were not aware of the possibility of treatment (HBV: 67.3%, HCV: 75.3%). Testing history for HBV and HCV has been reported by 25% and 18.8% of subjects, respectively. Age >40 years and lower educational level were associated with lack of HBV/HCV testing history. Among those tested, positive results for HBV and HCV infections were reported by 5.9% and 1.5%, respectively.
Conclusions: There are significant knowledge gaps in the Greek general population regarding modes of transmission, preventive measures and treatment availability for both HBV and HCV. There is an urgent need for large scale awareness activities to fill the gap of knowledge and to increase population engagement in preventive measures.

P1252
PREVALENCE OF HBV SEROLOGICAL MARKER IN GENERAL HEALTHY POPULATION

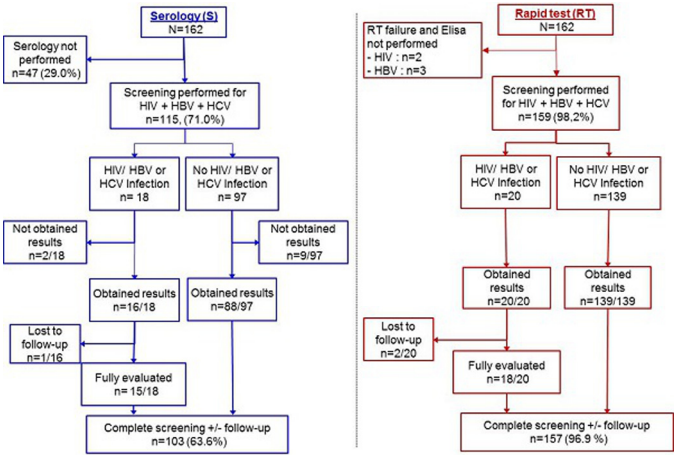
D. Li[1], T. Wang[1]. [1]*Lab Med, West China Hospital, Chengdu, China*
E-mail: jiangxili1219@163.com

Background and Aims: Hepatitis B virus (HBV) infection is a serious global public health problem affecting billions of people globally. In China, HbsAg, was used to determine the prevalence HBV instead of HBcAb. Furthermore, HBcAb was in ELISA assays diluted 1:30 in ELISA assays. The lack of information of HBcAb seroprevalence without diilution among the general healthy population is an obstacle for evaluating the prevalence of HBV. Therefore, this population based serological survey was conducted in Sichuan province, China, where no large epidemiological data was available.
Methods: 7603 healthy subjects were selected in west China. The subjects' age ranged from 6 to100 years old. Serum samples were tested for HBcAb, HBeAg, HBeAb, HBsAg and its antibody. Screening tests were carried out by Elecsys assays
Results: The prevalence of HBsAg and HBcAb in our district was before 0.57% and 57.6%, respectively. The prevalence of HBcAb were more seen in males (P < 0.05) and in 40–50 age groups. We found 3194 of 3511 HBcAb negative individuals were HBsAb positive alone. What's more, the distribution of HBsAb positive rate was associated with the age distribution, in other words, the young people has less exposure to HBV suggesting the HBV vaccine plan helps to control HBV spread.
Conclusions: Approximately 57.6% of general healthy population has prior exposure to HBV and less than 1% is HBsAg carriers. HBV vaccine plan should be emphasized and successful in China.

P1253
SIMULTANEOUS HIV–HBV–HCV POINT-OF-CARE TESTS IMPROVE THE SCREENING OUTCOMES

J. Bottero[1,2,3], A. Boyd[1], J. Gozlan[4], J. Nau[5], M.-D. Pauti[6], P.-M. Girard[1,2,3], K. Lacombe[1,2,3]. [1]*UMR_S 1136, INSERM,* [2]*Sorbonne Universités, UPMC,* [3]*Infectious Diseases, Hôpital St Antoine,* [4]*Virology, Hôpital St Antoine, AP-HP,* [5]*CASO,* [6]*Médecins du Monde, PARIS, France*
E-mail: julie.bottero@sat.aphp.fr

Background and Aims: In France, more than 55% of people infected with HBV, 45% of those infected with HCV, and 17% of HIV-positive persons are unaware of their status. The study objective was to evaluate the usefulness of simultaneous HIV-, HBV- and HCV-rapid tests on improving infection awareness in a population of predominately immigrants.
Methods: The OptiScreen III study was a randomized, prospective study in an urban clinic for persons without healthcare coverage ("Medecins du Monde"). Participants were randomized 1:1 to receive: standard HIV, HBV and HCV serology (S), where participants received a prescription to perform veinopuncture at an outside laboratory and then return to the clinic to obtain their results, or combined rapid tests (RT) (VIKIA® HIV, VIKIA® HBsAg and Oraquick® HCV), where participants received testing at the clinic and could opt to obtain results 30mn latter. Study endpoints were the proportion obtaining test results and, among those with positive serology for any test, seeking further care within four months.
Results: Of the 162 participants randomized to receive standard, only 104 (64.2%) returned to retrieve their test result. In comparison, 159/162 (98.2%) of those randomized to the RT arm obtained their results ($p < 0.001$). Thirty-eight (11.7%) tested positive for HIV (n = 7), HBV (n = 23), or HCV (n = 8) and no co- or tri-infection was observed. There were no significant difference between RT and S arms ($p = 0.7$). In the RT and S arms respectively, 20/20 (100%) and 16/18 (88.9%) of infected participants received their screening result ($p = 0.2$) and 18/20 (90.0%) and 15/18 (83.3%) received specialized care ($p = 0.7$). Overall, 157 (96.9%) in the RT arm were appropriately linked to screening and further linked to care, if necessary, versus 103 (63.6%) in the S arm (p < 0.001).
Conclusions: The simultaneous use of HIV-, HBV- and HCV-rapid tests improved the proportion screened. However, seeking further care might be influenced by the individual's motivation.



P1254

HEPATITIS C SPONTANEOUS CLEARANCE MAY INDUCE PARTIAL PROTECTION AGAINST REINFECTION AMONG PERSONS WHO INJECT DRUGS: RESULTS FROM A COHORT STUDY

J. Bruneau[1,2], G. Zang[2], D. Jutras-Aswad[2,3], N. Bédard[2], M.-E. Turcotte[2], R. Bouchard[2], N. Shoukry[2,4], E. Roy[5,6]. [1]*Department of Family Medicine, Université de Montréal,* [2]*CRCHUM, Université de Montréal,* [3]*Department of Psychiatry,* [4]*Department of Medicine, Université de Montréal, Montreal,* [5]*Université de Sherbrooke, Longueuil,* [6]*Institut National de Santé Publique du Québec, Montreal, Canada*
E-mail: julie.bruneau@umontreal.ca

Background and Aims: In Montréal, Canada, HCV transmission has remained high over the past decade among people who inject drugs (PWID). However, HCV reinfection has not been estimated. A related key question is whether the nature of the initial immune response during primary infection confers partial immunity against reinfection, and whether this potential effect may differ according to the clearance mechanism, i.e., spontaneous vs. treatment induced. Our aims were to estimate the incidence rate of HCV reinfection among PWID in Montreal, and to examine the association between HCV reinfection and the clearance mechanism, adjusted for associated behavioural factors.
Methods: PWID were recruited into a prospective cohort study between 2004 and 2013. HCV reinfection rate was estimated among anti-HCV-positive/HCV-RNA-negative participants well characterised for previous HCV clearance mechanism (spontaneous vs. treatment-induced). At each semi-annual visit, data were collected by validated interviewer-administered questionnaire and blood samples were tested for HCV-RNA to detect new infections. Time-to-event methods were used to estimate incidence rates (IR). Time-updated Cox regression models were conducted to examine factors associated with HCV incidence.
Results: Of 226 participants included in analyses [76% males, mean age 38.7 years (SD: 9.9)], 128 (57%) had previously cleared their infection spontaneously. Overall, 33 participants became reinfected with HCV [IR = 4.8 per 100 p-year (95% CI: 3.36, 6.65)]. Reinfection IR were 4.07 per 100 p-year (95% CI: 2.5, 6.2) among the 128 spontaneous resolvers, and 6.33 (95% CI: 3.60, 10.37) among the 98 participants who cleared their infection through treatment, respectively. In multivariate analysis, participants who cleared their infection through treatment were 2.5 times more likely to become reinfected compared to spontaneous resolvers, after adjusting for risk behaviours. Prescription opioid injection and cocaine injection were the main behavioural characteristics associated with reinfection (Table 1).

Table 1. Factors associated with HCV reinfection

Variable	Crude HR (95% CI)	Adjusted HR (95% CI)
HCV initial clearance		
Spontaneous clearance (ref)	1	
Clearance through treatment	1.79 (0.9, 3.7)	2.49 (1.2, 5.3)
Less than 30 years of age	1.70 (0.8, 3.6)	1.34 (0.6, 3.1)
Gender (female vs. male)	0.88 (0.4, 2.2)	0.78 (0.3, 2.0)
Incarceration past 3 months	0.94 (0.3, 3.1)	0.95 (0.3, 3.3)
Injection cocaine past month	1.77 (0.8, 3.7)	1.93 (1.0, 4.2)
Injection heroin past month	1.19 (0.5, 2.6)	0.91 (0.4, 2.1)
Injection prescription opioid past month	3.52 (1.7, 7.1)	4.05 (1.9, 8.7)
Sharing syringes or injection paraphernalia past 6 months	1.67 (0.8, 3.5)	1.48 (0.7, 3.3)

Conclusions: Our results support the hypothesis that the initial immune response induced during HCV spontaneous clearance is likely associated with long-lived, highly efficient memory immune responses that can partially protect against re-infection, relative to treatment-induced clearance. Injection prescription opioid and injection cocaine are the main drivers of HCV reinfection among PWID, calling for targeted prevention strategies.

P1255

ACCESSING HEPATITIS C TESTING: WHO, WHAT, WHERE, AND WHEN?

R. Simmons[1], L. Cieply[1], S. Mandal[1], S. Lattimore[1]. [1]*Immunisation, Hepatitis and Blood Safety, Public Health England, London, United Kingdom*
E-mail: ruth.simmons@phe.gov.uk

Background and Aims: Clinical pathways for persons with Hepatitis C (HCV) are important to quantify, to understand and manage factors that influence the uptake of healthcare interventions, continuity in care and outcomes in persons with HCV, with the overall aim to reduce onward transmission. We describe the distribution of persons testing for HCV and diagnosis rates by health care services.
Methods: Data were extracted from the sentinel surveillance programme of blood born viruses which include all testing undertaken by a network of 24 sentinel laboratories within England irrespective of test result. Data for persons who were first reported to the sentinel surveillance programme during 2013 were analysed. Data were excluded if persons were aged less than one year, or the samples were dried blood spot, oral fluid, reference testing, and testing from hospitals referring all samples.
Results: During 2013, 188, 364 persons were tested for HCV, with three out of five tests conducted in primary care settings. Overall, the highest proportion of HCV testing was conducted within GP surgeries (29.9% of all tests) followed by GUM clinics (18.4%), with the lowest proportion within drug dependency services and HIV clinics both 0.8%. The distribution of persons testing positive for anti-HCV by service type was similar to that of tests with 70% of persons with a positive result testing within primary care settings. A third of positive tests were among those requested at GP surgeries, and 17.1% from GUM clinics, with little change in the distribution of tests over the past three years. Despite differences in the proportion of tests and diagnoses between primary and secondary care settings the diagnosis rate was similar with 2.2% and 1.3% respectively. While, drug dependency services represented the lowest proportion of tests in 2013, the diagnosis rate was the highest at 10.1%, followed by prisons with 9.4%. Diagnosis rates for both these testing services have fallen over the past 3 years, falling from 18.0% to 10.1% for drug dependency units and 11.9% to 9.4% in prisons.
Conclusions: Overall a higher proportion of persons are accessing testing in primary care settings, in particular GP surgeries and GUM clinics suggesting persons are presenting earlier within the course of their infection, and a suitable setting through which undiagnosed infections can be detected. However, positivity rates are still associated with services accessed by high risk individuals such as drug users.

P1256

THE GLOBAL AND REGIONAL BURDEN OF LIVER DISEASE, 2013

B.C. Cowie[1,2,3], N. Allard[1,3,4], J.H. MacLachlan[1,3], N. Bhala[5]. [1]*Epidemiology, Doherty Institute,* [2]*Victorian Infectious Diseases Service, Royal Melbourne Hospital,* [3]*Medicine, University of Melbourne,* [4]*Joslin Clinic, Cohealth, Melbourne, Australia;* [5]*Queen Elizabeth Hospital Birmingham, Edgbaston, United Kingdom*
E-mail: benjamin.cowie@mh.org.au

Background and Aims: The Global Burden of Disease Study 2013 (GBD 2013) is a collaboration of more than 1000 researchers in over 100 countries, which provides comprehensive morbidity and mortality estimates for 291 diseases and injuries for the global population between 1990 and 2013.
Methods: Estimates for the annual number of deaths attributable to incident viral hepatitis, and for cirrhosis and liver cancer

attributable to hepatitis B, hepatitis C, alcohol and other causes were obtained for the years 1990 to 2013 by region and for the global population. These estimates were compared with all cause mortality to explore changing trends in the relative burden of liver diseases over time.
Results: Global deaths related to liver disease increased from 1.5 million in 1990 to 2.1 million in 2013, with those attributable to viral hepatitis increasing from 895,000 to 1.4 million over this period. Deaths from liver cancer due to hepatitis B infection increased by 50%, while liver cancer deaths causes by hepatitis C were estimated to have more than tripled between 1990 and 2013. Cirrhosis deaths for all causes increased steadily over time. Deaths due to incident hepatitis A and hepatitis B decreased, particularly after 2000, but those from hepatitis E were estimated to remain stable.
Conclusions: Chronic liver disease, particularly due to viral hepatitis, is responsible for a significant and increasing proportion of human deaths and ranks among the leading contributors to global mortality. The ability of GBD 2013 and future GBD studies to systematically compare trends in liver disease burden between populations and over time allows for local prioritisation of policy and public health interventions, and the capacity to monitor the impact of these responses into the future.

P1257
EARLY IDENTIFICATION OF PATIENTS AT RISK FOR CHRONIC HEPATITIS B AND C IN ARNHEM REGION, THE NETHERLANDS

G. Ter Beest[1], J. Gisolf[1], M. Belgers[2], T. Waegemaeckers[3], C. Swanink[4], M. Spanier[5], J.M. Vrolijk[5], P. Van Bentum[1], L. Roovers[6], C. Richter[1]. *[1]Infectious Diseases, Rijnstate Hospital, [2]Addiction Care, Iriszorg, [3]Infectious Diseases, Municipal Health Service, [4]Microbiology, [5]Gastroenterology and Hepatology, [6]Clinical Research, Rijnstate Hospital, Arnhem, Netherlands*
E-mail: gterbeest@rijnstate.nl

Background and Aims: Hepatitis B virus (HBV) and Hepatitis C virus (HCV) infections are often asymptomatic and therefore diagnosed late at a stage when liver damage such as fibrosis, cirrhosis or hepatocellular carcinoma (HCC) has already occurred. The challenge is to identify patients early. Between 2009 and 2014 we conducted five screening projects in Arnhem region to identify patients at risk who are not yet aware of their HBV- and HCV infection. All participants were offered free screening on HBV and/or HCV.
Methods: In order to reach our target group we used different approaches. We organized educational meetings about HBV and HCV, and developed brochures, posters, video's and websites (community based). In two screening projects the target group received a personal invitation and a flyer with information on the educational meetings offering free onsite testing for HBV and HCV (personal invitation). We approached volunteers from the respective target groups and trained them to be 'ambassadors' of the project (key persons). We mainly focused on first generation migrants (FGM) from seven middle and high endemic countries, but also did a HCV screening project among (ex) intravenous drug users (IDU) who had never been tested before. We also performed a hepatitis awareness campaign 'Heptember', offering free HBV and HCV testing for all persons considering themselves to belong to the risk group for HBV of HCV.
Results: We found that only screening projects combining community approach, use of key persons with personal invitation could achieve high participation rates up to 36%. In total we tested 2710 participants and identified 68 persons with hepatitis B (positive HBsAg) and nine with hepatitis C (positive HCV-RNA) (2.5% and 0.3% respectively). Clinical evaluation revealed that four patients had liver cirrhosis, two with HBV and two with HCV.
Conclusions: Personal invitation of FGM, seems to be very promising. In the future it should be integrated into daily practice of primary health care. To target the risk groups for HCV infection, such as (ex) IDU, seems to be more complicated. Many (ex) IDU are not in care and are difficult to reach. Therefore, also community base programs like "Heptember" (revealing two ex IDU with chronic hepatitis C) seem to be an effective method to identify these patients at risk and need to be continued.

P1258
PREVALENCE OF SIGNIFICANT HEPATIC FIBROSIS AND CIRRHOSIS ASSESSED BY THE NAFLD FIBROSIS SCORE IN PATIENTS ATTENDING THE DIABETIC CLINIC

J.L. Chin[1], G. Chan[1], P.S.-P. Sin[1], Z. Siddiqui[1], E. O'Rathallaigh[1], A. Rahman Aftab[1], G. Courtney[1], C. McGurk[2]. *[1]Hepatology, [2]Endocrine, St. Luke's General Hospital, Kilkenny, Kilkenny, Ireland*
E-mail: junliong@hotmail.com

Background and Aims: Non-alcohol fatty liver disease (NAFLD) is common in diabetic patients with metabolic syndrome. NAFLD fibrosis score (NFS) is a validated non-invasive scoring system that helps to identify patients with significant fibrosis and cirrhosis. This score can help to determine high risk patients warranting hepatology assessment and hence, applying NFS to routine diabetic care appears useful. The aim of this study is to apply the NFS to patients attending the diabetic clinic to assess the prevalence of significant fibrosis and cirrhosis.
Methods: We retrospectively examined all patients attending the diabetic clinic from March to June 2014 and included patients with type II diabetes and impaired glucose tolerance. Patients with type 1 diabetes and gestational diabetes were excluded. Data were obtained from laboratory database and electronic diabetic patient record (Cellma).
Results: Of the 521 patients screened, only 29.4% (153) of patients with complete laboratory data were studied. In our cohort of 153 patients, the median age was 63 (IQR 56.0, 71.5) years and 64.1% (98) of patients were male. More than half of our patients (56.2%; n = 86) had a BMI >30 kg/m^2. Of these, 14.4% (22) of patients had a BMI >40 kg/m^2, 14.4% (22) had a BMI of 35–40 kg/m^2 and 27.5% (42) had a BMI of 30–35 kg/m^2. The median HBa1c reading was 53 (44, 61) mmol/mol. Using the NAFLD fibrosis score, almost a quarter of our patients (24.2%, n = 37) had significant fibrosis with a median score of 1.169 (0.898, 1.563). The majority of our diabetic patients (66.0%, n = 101) had an indeterminate score of −0.224 (−0.744, 0.302). Only 15 (9.8%) patients had no significant fibrosis with a score of −1.820 (−2.500, −1.550).
Conclusions: Using the NFS in routine diabetic care, the prevalence of NAFLD with significant fibrosis was estimated to be close to a quarter of all patients. Only a small proportion of patients were assessed to have no significant fibrosis.

P1259
HEPATITIS B IN PREGNANCY IN UKRAINE: WASTED CHANCE

I. Kravchuk[1], N.F. Chumak[2], R.R. Schade[3], I.S. Hepburn[3]. *[1]Obstetrics, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, [2]Obstetrics, Territorial Medical Amalgamation, Novograd-Volynsk, Novograd-Volynsk, Ukraine; [3]Medicine, Good Samaritan Hospital, Lebanon, PA, United States*
E-mail: rschade@live.com

Background and Aims: Limited data regarding the prevalence of HBV in countries of the former USSR suggest that it is much more common than in Western Europe (3–14.4%). Since perinatal transmission is associated with a higher rate of viral chronicity, vertical transmission could be an important contributor to the epidemic of HBV in countries with high prevalence.
Methods: To assess the prevalence of HBV in a subset of young female patients and practices of care for pregnant woman with HBV, we performed a retrospective review of delivery records at 2 centers serving an area with a population of 105,000 in Central

Ukraine and 250,000 in Western Ukaine. Comparison was made to EASL Guidelines for HBV in pregnancy. All pregnant women in Ukraine are offered free prenatal care and HBsAg testing is a part of routine screening. The number of deliveries, presence of HBsAg, attitudes toward HBV infant vaccination among women post partum, and treatment offered were studied.

Results: The results are outlined in the table. HBsAg was detected in 0.72% of pregnant women. None had additional testing for HBeAg or viral load. None were receiving anti-viral therapy and none were offered consultation for HBV post-partum. Although many children were vaccinated for HBV, those at risk for vertical transmission did not receive HBIG even though it is manufactured in Ukraine. Attitudes toward vaccination are positive in the majority of these mothers, however, distrust and worry about potential side effects precluded achievement of 100% vaccination of newborns for HBV. Internal turmoil and trouble with vaccine purchase and distribution may have led to the recent observed decrease in vaccination rates.

Conclusions: HBsAg was detected in 0.72% of pregnant Ukranian women. No treatment was offered to these mothers with HBV. Prophylaxis of vertical transmission of HBV was not carried out effectively, however, vaccine is available and was given to most newborns. Education of health care providers regarding EASL Guidelines, available treatment options and prevention of vertical transmission with HBIG would greatly improve care for these mothers and infants. Despite constitutional guarantees of access to health care in Ukraine, limited resources were allocated to these patients with HBV. With the new government and development of closer ties to the European Union it is hoped that such change will occur.

Year	No. of births	% HBsAg+	% vaccinated
2008	3907	0.87%	79.5%
2009	3967	0.91%	74.4%
2010	3827	0.89%	66.4%
2011	3715	0.62%	47.8%
2012	3828	0.57%	61.7%
2013	3821	0.47%	14.1%

P1260
PERCEPTIONS OF VIRAL HEPATITIS TESTING IN MIGRANT COMMUNITIES AND THE PRIMARY CARE PHYSICIANS THAT SERVE THEM

S. Mathew[1,2], M. Petrova[1], J. Hendy[2], S. de Lusignan[2], J. Zamani[1], R. Tiwari[3], M. Nicholls[4], P. Kennedy[5], G. Foster[5], A. Ala[1,6].
[1]Department of Gastroenterology and Hepatology, Frimley Park Hospital, Surrey, [2]Department of Health Care Management and Policy, University of Surrey, Guildford, [3]Rushmoor Healthy Living, Rushmoor Council, Hampshire, [4]Surrey and Sussex Health Protection Team, Public Health England, Surrey and Sussex, [5]Centre for Digestive Diseases, Queen Mary University, London, [6]Faculty of Health and Medical Sciences, University of Surrey, Guildford, United Kingdom
E-mail: banju78@hotmail.com

Background and Aims: Migrant groups are disproportionately affected by hepatitis B and C (CVH). Effective community testing must be culturally-appropriate, and ideally include informed testing in primary care. General Practitioners (GPs) offer a direct and effective route for community testing, but participation is thought to be poor, with little study into the awareness, understanding and perception of GPs towards CVH case-finding. We conducted focus group sessions among members of the Nepali community; a new and unique community to the UK, as well as GPs to study and contrast the awareness and perception of both groups to CVH and CVH testing.

Methods: We conducted 4 focus group sessions in the Nepali community; divided by age (greater/less than 30 years) and sex. We explored the understanding and perception of liver disease and viral hepatitis, including developing new testing strategies. We also conducted focus group sessions among GPs from 2 large General Practices in South East England that serve this growing Nepali community. We explored the understanding and perception of viral hepatitis case-finding, including recent national testing guidance.

Results: 32 members of the Nepali community took part in focus group sessions. A strong extrinsic association was seen related to most concepts of liver disease, including spiritual causes/cures and food pollution. Younger groups associated a greater degree of stigmatisation towards liver disease from alcohol or prostitution. However all groups wanted to engage with liver disease education and testing, and universally so via primary care services.

9 GPs of varying seniority, from military and civilian backgrounds took part in the focus group session. Overall CVH testing was viewed as a low priority, with one senior GP expressing that they had not seen a single case in the past 20 years. No GP was aware of national case-finding guidance, despite its recent release and community focus. Migrant testing was not offered by any GP, with the feeling that this would be viewed as "racial profiling" by members of the migrant community.

Conclusions: Members of the Nepali community expressed universal interest in engaging with primary care to learn more about liver disease and testing. However, the GPs in the same area viewed CVH case-finding as a low priority, with little awareness of national or international guidance for migrant testing. Stigmatisation was raised by some younger members of the migrant focus group, but was almost a universal concern to GPs.

P1261
SPECIFIC PATTERNS OF DRUG CO-USE INCREASE RISK FOR HEPATITIS C VIRUS INFECTION IN PEOPLE WHO INJECT DRUGS

S. Puzhko[1,2], É. Roy[3,4], D. Jutras-Aswad[1,5], G. Zang[1], A.A. Artenie[1], J. Bruneau[1,2,6]. *[1]Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CRCHUM), [2]Family Medicine, McGill University, Montreal, [3]Université de Sherbrooke, Longueuil, [4]Institut national de santé publique du Québec, Quebec, [5]Psychiatry, [6]Family Medicine, Université de Montréal, Montreal, Canada*
E-mail: svetlana.puzhko2@mail.mcgill.ca

Background and Aims: Prescription opioid injection (PO) and poly-substance use were shown to be associated with hepatitis C virus (HCV) transmission among people who inject drugs (PWID). Little is known, however, about the role of specific drug use patterns in the risk of HCV infection. The aim of this study was to examine the association between HCV seroincidence and use of specific drugs and their combination among PWID, with a focus on PO injection.

Methods: Data from a prospective cohort in Montreal (HEPCO) were used. PWID who were HCV and human immunodeficiency virus (HIV)-seronegative at baseline and completed ≥1 visit between 2004 and 2013 were included. At each visit, data were collected by validated interviewer-administered questionnaire and blood sample was tested for HCV-RNA and antibodies to detect new infections. Kaplan–Meier survival analysis and time-varying Cox regression models were conducted.

Results: Of the 356 participants (81.2% males; mean age: 34.7 years), 123 participants (34.6%) reported PO injection. Overall, 115 seroconverted to HCV (incidence rate: 14.51/100 person-years [95% CI: 12.0, 17.4]). In univariate analyses, use of the following drugs was associated with HCV incidence: injecting PO (crude hazard ratio [cHR]: 3.14 [95% CI: 2.2, 4.6]), cocaine (cHR: 4.04 [95% CI: 2.6, 6.4]), or heroin (cHR: 1.63 [95% CI: 1.1, 2.4]); using non-injection tranquilizers (cHR: 1.75 [95% CI: 1.2, 2.5]), or smoking crack/cocaine (cHR: 1.54 [95% CI: 1.1, 2.2]). Co-use patterns involving PO injection (compared to no use of either drugs) associated with HCV included: PO with tranquilizers (cHR: 4.12 [95% CI: 2.5, 6.7]), PO with cocaine injection (cHR: 10.86 [95% CI: 5.8, 20.3]), PO with crack/cocaine smoking (cHR: 4.14 [95% CI: 2.5, 6.7]). In multivariate analysis, PO injection was independently associated with HCV infection compared to non PO injection. Further, PWID who co-used

all three drugs with PO injection had the highest risk of HCV acquisition (Table 1).

Table 1. Unadjusted and covariate-adjusted associations

Variable	Crude HR (95% CI)	Adjusted HR (95% CI)
Drug use past month		
No injection PO (ref)	1	1
Injection PO + 0–2 of the 3 drugs [a]	2.54 (1.7, 3.9)	1.94 (1.2, 3.0)
Injection PO + 3 drugs	6.01 (3.6, 10.1)	4.94 (2.9, 8.5)
Age (5-year increment)	0.91 (0.8, 1.0)	0.97 (0.9, 1.1)
Male	0.97 (0.6, 1.5)	0.79 (0.5, 1.3)
Unstable housing conditions past month	2.13 (1.5, 3.1)	1.96 (1.3, 2.9)
Incarceration past 3 months	1.82 (1.2, 2.9)	1.90 (1.2, 3.0)
Sharing syringes or injection equipment past 6 months	2.10 (1.4, 3.0)	1.83 (1.2, 2.7)

HR, hazard ratio.
[a] Injection cocaine, crack/cocaine smoking, non-injection tranquilizers.

Conclusions: Our results suggest that PO injection and its co-use with cocaine injection, non-injection tranquilizers, or smoked crack/cocaine increases the risk of HCV infection for PWID. In addition, our data point to the importance of polysubstance use as major driver of HCV transmission for PO injectors. These findings suggest that comprehensive HCV prevention strategies should address polysubstance abuse. Specifically, PO injectors using multiple drugs should be identified as high priority targets for interventions.

P1262

AN ACCURATE SCORE FOR THE PREDICTION OF SUSTAINED VIRAL RESPONSE UNDER PROTEASE INHIBITOR-BASED TRIPLE THERAPY IN CIRRHOTIC PATIENTS: THE CUPIC ALGORITHM – THE ANRS CO20 CUPIC STUDY

E-mail: JeBoursier@chu-angers.fr

Background and Aims: Antiviral therapy is highly required in patients with chronic hepatitis C (CHC)-induced cirrhosis, to decrease liver-related complications or death. New drugs allow for high rates of sustained viral response (SVR) in genotype 1 CHC with very few side effects, but these treatments are not yet widely available. As a consequence the standard of care for cirrhotic patients in many countries currently remains the triple therapy using protease inhibitors (PI) Boceprevir (BOC) or Telaprevir (TEL). We aimed to develop an algorithm for the prediction of SVR after PI-based triple therapy in cirrhotic patients.

Methods: 484 patients from the ANRS CO20 CUPIC cohort were included and randomly divided in a derivation and a validation sets. All patients had genotype 1 CHC-induced cirrhosis and were treated by triple therapy using BOC or TEL according to standard of care.

Results: 52.1% of patients achieved SVR. In the derivation set, independent predictors of SVR among data collected at day0 were: treatment history (previous response to dual therapy by PEG-interferon + ribavirin), TEL treatment, gammaGT, platelets, and viral load. These 5 easy-to-collect variables were combined in the d0-score to predict SVR before treatment initiation. When data collected at w4 of triple therapy were introduced in the model, independent predictors of SVR were: treatment history, gammaGT, platelets, and w4 viral load. These 4 variables were combined in the w4-score to predict SVR since 4 weeks of triple therapy. Thresholds for very low (≤10%) or very high (≥90%) chance of SVR were calculated for both scores. The sequential use of the d0-score and then the w4-score, called the CUPIC algorithm, predicted SVR in the validation population with 85% accuracy in 54% of patients. The 46% remaining patients had 50% SVR rate (grey zone). As "treatment history" is not available in naïve patients, we used the same methodology to develop 2 others scores without this variable (independent predictors: genotype 1a, IL28B, gammaGT, platelets, TEL treatment, d0 and w4 viral load). The sequential use of these 2 scores predicted SVR with 84% accuracy in 48% of patients of the validation population.

Conclusions: By using simple variables, the CUPIC algorithm predicts PI-based triple therapy success or failure before or since week4 of treatment. This algorithm will help physicians to balance between treating now patients having CHC-induced cirrhosis with PI-based triple therapy or waiting for new drugs.

P1263

GLOBAL ESTIMATE OF HCV INFECTION IN THE PEDIATRIC AND ADOLESCENT POPULATION

M.H. El-Sayed[1], H. Razavi[2]. *[1]Department of Pediatrics, Ain Shams University, Cairo, Egypt; [2]Center for Disease Analysis, Louisville, Colorado, United States*
E-mail: manalhelsayed@yahoo.co.uk

Background and Aims: A number of studies have reported global estimates of HCV infections, but little attention has been paid to HCV infection among pediatric and adolescent (Ped) populations aged 15 years old or younger. The aim of this study was to develop a global estimate of anti-HCV and viremic prevalence in this population using extrapolations from published studies.

Methods: A comprehensive literature search was conducted to identify studies reporting HCV infections that were representative of the general Ped population. Analyses in high risk populations (e.g., patients on dialysis, chemotherapy, and hemophiliacs) were excluded. Data were available in 24 countries (Egypt, Pakistan, Ethiopia, Cameroon, Thailand, Tunisia, …). A ratio of HCV infection in Ped to adult population was calculated for each country and the results were grouped by country income classification. These ratios were then applied to HCV prevalence estimates in adults in all countries in the same income classification. Given the high spontaneous clearance in the Ped populations, a viremic rate of 50–75% was applied to the anti-HCV estimates based on published studies in the Ped population.

Results: The Ped to Adult anti-HCV prevalence ratio was 4% (3%>5%, 90% uncertainty interval) in high income countries, 21% (19%>25%) in upper middle income countries, 28% (20%>43%) in lower middle income countries and 54% (38%>106%) in low income courtiers. Globally, 13.2 (11.5–21.2) million Peds are estimated to be anti-HCV positive, corresponding to an anti-HCV prevalence of 0.7% (0.2–1.3%). There are 6.6 (6.1–11.6) million viremic infections corresponding to a viremic prevalence of 0.4% (0.1–0.8%). Viremic prevalence was lowest in high income countries at 0.3% (0.03–0.5%) and highest in low income countries at 0.6% (0.1–1.0%). Over 85% of all HCV infections are in low income and low middle income

countries with Nigeria, Egypt, Pakistan, India, China, Ethiopia and the Republic of Congo accounting for over 50% of all HCV infections in the Ped population.

Conclusions: HCV infection in the pediatric and adolescent populations is highest in low income and low middle income countries where access to care is already limited. Clinical and epidemiological studies in this population are needed as soon as possible to tackle HCV infection. This would ensure early access of the Ped population to care and inclusion in clinical trials with novel safer therapies.

P1264

ADDRESSING THE HCV PUBLIC HEALTH BURDEN: SURVEILLANCE OF SOFOSBUVIR'S IMPACT ON EU5 MARKETS AND HOW, IF AT ALL, TREATMENT RATES, DRUG SHARES AND PRESCRIBING HABITS CHANGED

S. Fernando[1], A. Wilson[1], M. Frantsen[1], S. Brown[1]. [1]*Ipsos Mori, London, United Kingdom*
E-mail: samantha.fernando@ipsos.com

Background and Aims: Despite the HCV therapeutic market evolving at speed, access constraints across the EU5 (France, Germany, Italy, Spain, UK) mean HCV remains a major public health burden. Focusing on genotype 1 (G1) HCV patients we explore – at a country level – HCV treatment rates, uptake of sofosbuvir, and specific differences between patients treated with sofosbuvir-based regimens (i.e. + RBV / + IFN / + other DAAs) and those untreated.

Methods: Ipsos Healthcare's HCV Therapy Monitor, running since 2006 in the EU5, reports on >240 physicians per quarter across the EU5. Physicians provide patient demographic, disease and treatment data on HCV patients seen within each study period.

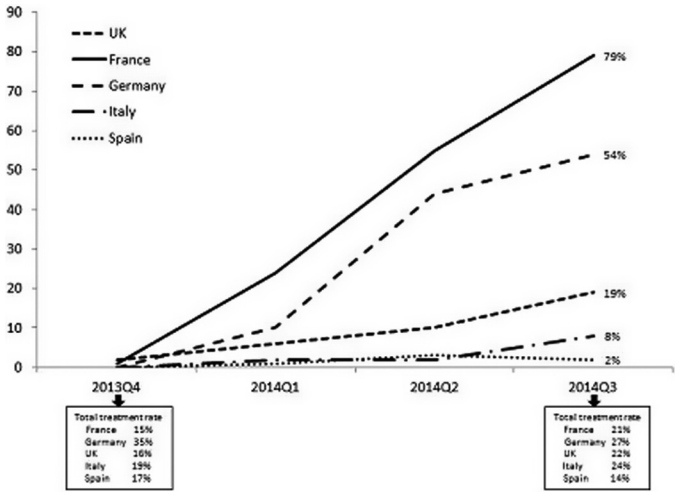

Figure: Percentage of genotype 1 patients treated with a sofosvubir-containing regimen over time.

Results: Overall, treatment of HCV patients in the EU5 is low – below 30%. Germany has the highest proportion of treated patients and Spain the lowest (2014 Q3 data) (Figure 1). Rates are static, apart from in France where significant increases are seen (2014 Q3 data). The EMA approval of sofosbuvir in January 2014 led to accelerated uptake of the drug in France and Germany – reaching 79% and 54%, respectively, of all treated G1 patients (Figure 1). This was not replicated in the other EU5 markets, where local price negotiations meant sofosbuvir only became widely available in October 2014; uptake among treated patients in the UK is below 20% and, in Spain and Italy, below 10%. 98% of UK physicians (and comparable numbers in Spain and Italy) cited cost and access as barriers to sofosbuvir use. Looking at characteristics of sofosbuvir-treated patients, those in France are more likely to have F3 or F4 (compensated) liver damage than those in Germany. In both countries, physicians treat fewer substance abusers and patients with concomitant conditions.

Conclusions: As our results show, the rapid evolution of HCV treatment is not matched by increasing treatment rates. The approval of curative sofosbuvir-based regimens was highly anticipated; however, price and access, alongside long-term warehousing, have clearly impeded higher proportions of patients being treated – especially in UK, Spain and Italy where drugs take longer to be approved. Country-specific disparities are also seen in physicians' selection of patients for treatment; it appears they are having to prioritise treatment for certain patient types. With G1 patients representing the largest proportion of EU5 HCV patients, timely access to new regimens and a uniform consensus to treatment is essential to curb the spread of HCV.

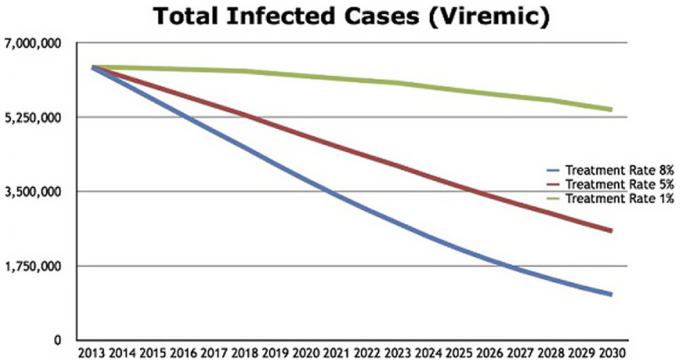
P1265

ESTIMATING THE EPIDEMIOLOGIC AND ECONOMIC IMPACT OF DIFFERENT TREATMENT RATES FOR HEPATITIS C VIRUS (HCV) IN EGYPT

A. Shelbaya[1], A. Kuznik[2], M. Salem[3], W. Mankola[4], K. Sadik[5].
[1]*Columbia School of Public Health, Brooklyn, United States;* [2]*Abuja University, Abuja, Nigeria;* [3]*Save The Children,* [4]*Egyptian Ministry of Health,* [5]*Sustainable Health Initiative, Cairo, Egypt*
E-mail: ams2283@cumc.columbia.edu

Background and Aims: The burden of HCV infection in Egypt is one of the highest globally (est viremic cases at 6.5 mill). New promising Hep C antiviral agents are more efficacious, but more costly, posing challenging policy questions related to rates of treatment and budget allocations. This analysis attempts to quantify the epidemiologic and economic impact of different treatment rates in Egypt.

Methods: The analysis was based on a 17-year Markov state transition cohort with annual cycle lengths. At baseline, viremic patients were divided into 5-year age increments. Disease severity at baseline was modelled on the basis of data in the US [i], subsequently calibrated to data severity for Egypt [ii]. In the model, patients would then progress through the various HCV stages from F0 to F3, based on international transition probabilities [iii] and were also at general population risk of death. Following the state of F3, patients could progress to hepatocellular carcinoma or cirrhosis. Following cirrhosis to other progressive stages up to hepatocellular carcinoma and liver related death. Patients could be cured spontaneously in state F0 or with antiviral therapy in any state from F0 to cirrhosis at a cure rate of 92% in stages F0–F3 and a cure rate of 80% in the stage of cirrhosis. Cured patients would transition to the mortality risk of the age-matched general population. In each cycle, new incident patients were introduced at a rate of approximately 128,000 or 2%.



Results: The model indicates significant gains using the new antivirals when following a treatment rate of 8% (450k viremic cases/year) relative to a policy of 1% (65k cases/yr) or 5% (300k cases/yr). By 2030 viremic cases would go down from

5.5 to 2.5 to 1 million cases in the 1%, 5% and 8% treatment rate scenarios. Liver related deaths from 41,000 to 24,000 to 14,000 cases by 2030 respectively. Total annual costs would start at $1.3 billion on the first year of treatment in the 8% treatment rate pattern but decreases reaching an annual budget of $580 million by 2030. Respectively 5% and 1% rates would start at $900 million and $550 million to go down to $600 million and $500 million by 2030.

Conclusions: Treating patterns using the new antiviral Hep C agents from 300k/yr to 450k/yr would have a substantial clinical benefit. It would cost the society (government and private) more, in the short run, but eventually they would start running out of patients, so costs would go down. With 450k/year, you can get to around 1% prevalence by 2030.

P1266

HUMAN ALBUMIN USE IN CIRRHOTIC PATIENTS IN FRANCE: RESULTS OF THE NATIONAL "ALBU-LIVE" SURVEY

E-mail: armand.garioud@ghpso.fr

Background and Aims: Use of human albumin (Alb) in the management of complications of cirrhosis has increased in recent years. Three indications are validated: therapeutic paracenteses (TP), spontaneous bacterial peritonitis (SBP) and hepatorenal syndrome type 1 (HRS); in these 3 indications EASL recommendations have been published [*J Hepatol.* 2010 Sep; 53(3)]. Aims of this survey were to assess prescription practices of French hepato-gastroenterologists in validated indications and to seek for differences according to experience and work location of practitioners (P).

Methods: All P working in Hepato-Gastroenterology units of general and university hospitals (GH and UH) and private clinics were individually contacted. A pre-established questionnaire evaluated: (1) use of albumin in validated indications and (2) prescription for other clinical situations for which albumin use is not validated. The survey was conducted between April 1 and August 10, 2014.

Results: 451 answers were obtained and analysed. The mean age of P was 40 [20–67] years. Location of exercise was UH (47.7%), GH (45.8%), liberal activity (3.3%). 56.7% were senior-P, 6.5% attached physicians, 12.4% assistants and 24.4% residents.

TP: 99.6% of P compensate for paracentesis. 87.8% of P compensate only with Alb; 12% use other volume expanders. When Alb is used, 84.6% use a fixed dose: 20 g for 3 liters in 2/3 of cases. The infusion begins during (52.6%) or after (32.3%) the paracentesis.

SBP: 94% use albumin infusion concomitantly with antibiotic treatment. The EASL-protocol (1.5 g/kg D1–1 g/kg D3) is respected by 56.2%, more often by senior-UH than by senior-GH (60.3% vs 42.1%; $p = 0.015$).

HRS: 66.5% of P use Alb infusion to confirm the diagnosis of HRS; senior-SH more often than senior-PH (81.2% vs 57.8%; $p = 0.0006$). For treatment, 84% of P use Alb concomitantly with vasopressor treatment but the dose and the duration are very heterogeneous.

Other clinical situations: 23.5% use Alb for severe bacterial infections (except SBP), 47.9% for severe hyponatremia, 43.9% for severe hypoalbumemia and 65.9% after thoracocentesis for hydrothorax. 19.1% of P use Alb in other circumstances.

Conclusions: In this large French survey, albumin prescription is in accordance with EASL-recommendations only for TP. The EASL-schedule in SBP is followed only by 56%. The use of albumin for diagnosis and treatment of HRS is not adapted with EASL-guidelines and very heterogeneous. Finally, Alb in cirrhotic patients is beyond the scope of the approved indications in many cases.

P1267

RETRIEVAL OF PATIENTS WITH CHRONIC HEPATITIS B AND C BY INTENSIFYING REGIONAL COLLABORATION, ARNHEM REGION, THE NETHERLANDS

C. Richter[1], T. Waegemaeckers[2], I. Polling[3], L. de Graaf[3], C. Swanink[4], M. Roelofs[5], C. Poorterman[6], M. Spanier[7], J.M. Vrolijk[7], J. Gisolf[1], G. ter Beest[1]. *[1]Infectious Diseases, Rijnstate Hospital, [2]Infectious Diseases, Municipal Health Service, [3]General Practitioner, [4]Microbiology, Rijnstate Hospital, [5]Laboratory for General Practitioners, [6]Association of Midwives, [7]Gastroenterology and Hepatology, Rijnstate Hospital, Arnhem, Netherlands*
E-mail: crichter@rijnstate.nl

Background and Aims: Excellent treatment is available for chronic hepatitis B virus (HBV) and hepatitis C virus (HCV). However, many patients once diagnosed for HBV of HCV have been lost to follow-up in primary care and/or hospital care. The challenge is to retrieve these patients and bring them back into care.

Methods: We organized two meetings at the hepatitis centre of Rijnstate hospital with participation of the municipal health service (MHS), general practitioners (GP), centre for drug addicts, health service in prisons, midwives in primary care and two microbiological laboratories in the region. In the first meeting we formulated problems, in the second meeting we made a definite plan to retrieve patients who have been lost to follow-up.

Results: 1. In the hospital we checked hospital records of all patients been seen with HBV since 2007 at the department infectious diseases. We found that 72 out of 242 patients were lost to follow

up or had no advised control of ALAT in primary care. All these patients are being traced.
2. In a pilot study of two general primary care practices (2300 patients each) 30 patients (21 with HBV and nine with HCV) were retrieved by a laboratory search 2000–2014. We identified ten patients in need for re-evaluation and if necessary referral to our hepatitis centre.
3. All pregnant women are screened for HBV in primary care, with the main purpose of prevention of mother to child transmission. These women are often lost to follow-up after delivery, without adequate evaluation for potential need for therapy. We established a plan for retrieval of these women with a major role for the laboratories and the municipal health service.
4. All patients with a positive HBsAg test are automatically being reported by the laboratories to the MHS. The MHS compared their registration list with all patients being in specialist care in the hospital and found that 64 out of 230 (28%) referred patients never arrived at the hospital. These patients are being traced.
Conclusions: Regional retrieval of patients with HBV and HCV infection is possible with close collaboration of all regional health providers for hepatitis. At the same time the organisation of regional hepatitis care can be optimized, in order to avoid unnecessary loss to follow-up of patients in the future. However, it is time consuming and will need extra budgeting for extending the project to other regions in the Netherlands.

P1268
THE CORRELATION BETWEEN DEPRESSION AND CHRONIC HEPATIC CONDITIONS AS MEASURED BY THE PHQ-9 DEPRESSION ASSESSMENT ACCOUNTING FOR SOCIAL CHARACTERISTICS

J.-M. Hermes[1], G. Mann-Deibert[1], A.M. Hefner[1], T.A. Couturier[1], C. Hill[1], R. Pozza[1], P.A. Reshamwala[1], T.I. Hassanein[1]. [1]*Southern California Liver Centers, Coronado, United States*
E-mail: kbiando@livercenters.com

Background and Aims: Most insurance payors in the United States are requiring the results of a standardized depression assessment prior to initiating treatments for chronic liver diseases. Existing research shows that depression rates among patient populations who are experiencing viral hepatitis are more than twice as high as the general US population. What is less known are the social factors including class, gender, and race/ethnicity impact the relationship between depression and viral hepatitis. Our aim is to review the utility of knowing patient depression scores in the treatment of liver diseases as a whole-body approach to medicine. We ask: how do social factors statistically moderate the correlation between depression and viral hepatitis and other chronic liver conditions? Does knowing the social circumstances of patients contribute to the treatment design for patients with any chronic hepatic condition?
Methods: We assessed 274 consecutive patients with one or more chronic hepatic conditions including viral hepatitis, liver cancer, non-alcoholic steatohepatitis. The patients have an average depression score of 11.5±8.6 out of a possible 27 points. The data contains 112 female patients and 159 male patients with a mean age of 53.2±13.9. We further measured SES indicators including zip code (proxy measure for income), race/ethnicity to measure if these factors impacted the relationship between depression and chronic hepatic conditions.
Results: Based on logistic regression models, the findings show patients with high depression scores (>15) are 35% more likely to be Hispanic compared to other ethnic groups, 61.7% more likely to be women than men and 64.7% more likely to be from impoverished communities when compared to more affluent communities. Patients with 3 or more comorbidities experience depression at nearly double the rates of patients with only one chronic hepatic condition.
Conclusions: While research has consistently shown that patients with chronic liver disease are likely to have higher than average depression rates, our analysis of social factors shows: depression rates are higher for (1) Hispanics; (2) women; (3) patients who live in impoverished communities; and (4) patients with comorbidities. Future research should consider socioeconomic and demographic characteristics and control of comorbidities as they impact depression and progression of chronic liver disease.

P1269
"YOU'RE BETTER OFF WAITING": KNOWLEDGE AND AWARENESS OF HEPATITIS C DIRECT-ACTING ANTIVIRALS IN A COHORT OF PEOPLE WHO INJECT DRUGS

P. Higgs[1], K. Hsieh[2], M. Hellard[2]. [1]*National Drug Research Institute, Curtin University,* [2]*Centre for Population Health, The Burnet Institute, Melbourne, Australia*
E-mail: peter.higgs@curtin.edu.au

Background and Aims: People who inject drugs (PWID) are the group at greatest risk of hepatitis C (HCV) infection. They are also the group most likely to transmit the infection, and should be a priority population for treatment as a public health initiative. Although few currently receive treatment, the advent of new direct-acting antiviral (DAA) treatment provides hope for increased uptake of therapy. The Burnet Institute and St Vincent's Hospital in Melbourne Australia will commence recruitment for the Hepatitis C *Treatment and Prevention* (TAP) Study in December 2014, The TAP Study will examine the feasibility of treating PWID in the community using directly acting antiviral therapy (DAAs) and evaluate a network-based approach to treatment and its impact on HCV prevalence and incidence. To inform recruitment of the TAP Study we interviewed PWIDs to better understand their knowledge of the DAAs and identify their perceptions on the best methods to include them in HCV care and treatment.
Methods: Participants were recruited from the SuperMIX cohort comprising over 700 PWID followed since 2008 and included eligible TAP study participants. In-depth interviews were conducted with twenty-three HCV RNA positive participants. Interviews were transcribed, coded, and then analysed for emerging themes and similarities between participants. General descriptions and critical interpretation of themes were generated and selective quotes extracted verbatim to best illustrate the critical themes. The analysis of the interviews was shaped by the knowledge of the data and the existing literature.
Results: Whilst most PWID had a basic understanding of HCV, for many it was limited. The majority of participants had limited knowledge of HCV treatment, with most being unaware that DAAs would soon be available. Once the researcher explained that DAAs would have high efficacy and a low side effect profile the majority were very interested in undergoing treatment and also having their injecting partners treated for their HCV.
Conclusions: This study found that limited knowledge and understanding of HCV restricted participants ability to make a well-informed decisions about their HCV management. However when presented with accurate information, most were enthusiastic about accessing DAA treatment. It is important that we engage and work with PWID if we are to successfully implement HCV treatment programs that benefit both the individual infected with HCV and prevent the ongoing transmission of the virus.

P1270

HEPATITIS C AND B TESTING AMONG PEOPLE LIVING WITH HIV IN ENGLAND

S. Lattimore[1], L. Cieply[1], S. Mandal[1]. [1]*Immunistation, Hepatitis and Blood Safety Department, Public Health England, London, United Kingdom*
E-mail: sam.lattimore@phe.gov.uk

Background and Aims: The British HIV Association guidelines for the management of hepatitis viruses in HIV-positive adults, recommends testing for hepatitis, B and C at HIV diagnosis, and annually thereafter. The sentinel surveillance of blood-borne viruses collects laboratory data irrespective of test result; providing information on the population undergoing HIV and hepatitis testing at 16 sentinel laboratories.

Methods: Demographic information and HBV and HCV testing histories for persons newly diagnosed with HIV between 2008 and 2013 were extracted from the laboratory information systems of 16 sentinel laboratories in England. Where self reported ethnicity was unavailable, it was assigned using name analysis software. Duplicate records, reference testing and individuals aged <16 years at HIV diagnosis were excluded. Characteristics of individuals tested and testing positive for HIV, HBV and HCV were described. Data were managed in MS Access and analysed in R (CRAN).

Results: In total, 1,936,792 persons were tested for HIV across all settings, of whom 17,962 (0.9%) tested positive. Two thirds of all HIV positive persons were male (12,228/17,691) and where known, three quarters were white ethnic origin (75.9%; 6426/8463). Overall, 75.8% (13,412) of HIV positive persons were tested for anti-HCV, of whom 5.9% (797) tested positive. Of anti-HCV positive persons, 86.3% (688) were tested for HCV-RNA, of whom 75.9% (522) were positive indicating an active infection.

HCV genotype information was available for 73.3% (383) of all HCV-RNA positive persons. Genotype 1 infections were the most prevalent (61.8%; 237), followed by genotype 3, genotype 4 and genotype 2, representing 23.7%, 12.0% and 2.5%, respectively. HCV genotype distribution did not vary significantly by gender ($\chi^2 = 1.64$; $p = 0.57$), or by age group, but did vary by ethnic group ($\chi^2 = 19.84$; $p = 0.02$).

Overall 72.4% (13,011) of HIV positive persons were tested for HBsAg, of whom 4.5% (591) tested positive. Of these, 62% (372) were tested for HBV DNA, of whom 84.9% (315) tested positive.

Conclusions: Approximately three-quarters of persons newly diagnosed with HIV were tested for HCV and HBV. Of these 522 and 591 persons were identified as being HIV/HCV and HIV/HBV co-infected, respectively. These findings suggest that while screening rates for HCV and HBV are high, further work is necessary to monitor and improve testing rates, and reduce the significant contribution of HCV and HBV towards hepatic morbidity and mortality in HIV infected individuals.

P1271

HOW SHOULD SCALE UP OF HCV ANTIVIRAL TREATMENT BE PRIORITIZED? A COST-EFFECTIVENESS ANALYSIS INCLUDING INDIVIDUAL AND POPULATION PREVENTION BENEFITS

M. Hickman[1], N. Martin[1], P. Vickerman[1], G. David[2], S. Hutchinson[2], T. Martin[3], G. Dore[4], J. Grebeley[4], A. Miners[5], G. Foster[6]. [1]*School of Social and Community Medicine, University of Bristol, Bristol,* [2]*Health Protection Scotland, Glasgow,* [3]*St Thomas' Hospital, London, United Kingdom;* [4]*University of New South Wales, Sydney, Australia;* [5]*London School of Hygiene & Tropical Medicine,* [6]*Queen Marys University, London, United Kingdom*
E-mail: matthew.hickman@bristol.ac.uk

Background and Aims: New HCV direct-acting antivirals (DAAs) will dramatically improve cure rates but are associated with high costs. European guidelines recommend prioritizing DAAs for severe liver disease for individual benefit, but earlier treatment of those at risk of transmission such as people who inject drugs (PWID) may be more cost-effective. We determine the most cost-effective HCV treatment prioritization strategy by disease stage and risk status.

Methods: We use a previously developed dynamic HCV transmission and disease progression cost-effectiveness model to compare prioritization of HCV treatment using interferon-free DAAs. We evaluate providing treatment at earlier disease stages (mild or moderate fibrosis) and by risk status (PWID or ex-PWID) compared to delaying treatment until compensated cirrhosis. We assume 12 week treatment duration (£3200/wk) and 90–95% SVR, depending on disease stage. We explore settings with populations with chronic HCV prevalence among PWID at 20, 40, or 60%. We perform a probabilistic cost-utility analysis estimating long-term costs (in £UK=€1.25) and outcomes as quality adjusted life-years gained (QALYs) discounted 3.5%/yr. We rank strategies by calculating Net Monetary Benefit (NMB) = (mean incremental QALYs × Willingness to pay [WTP] threshold) − mean incremental costs. We use a WTP threshold of £30,000 (~€37,500) per QALY gained. Highest NMB has highest rank.

Results: After treating people with cirrhosis, in populations with 20% or 40% chronic prevalence among People Who Inject Drugs (PWID), which is consistent with most sites in Europe, it is more cost-effective to prioritize treatment to PWID at earlier disease stages because of substantial prevention benefits (Table 1) – rather than delay treatment. Only in populations with very high (60%) chronic HCV prevalence among PWID is it more cost-effective to prioritize DAAs to non-PWID with moderate disease (Table 1).

Table 1. Net monetary benefit of treating People Who Inject Drugs (PWID) or non-injectors with mild or moderate disease compared to delaying treatment until development of severe disease

Rank	Group	Net monetary benefit (£30,000 WTP)
20% baseline chronic prevalence among PWID		
1	PWID, mild	£13,267,319
2	PWID, moderate	£7,365,353
3	Ex/non-PWID, moderate	£2,796,417
4	Ex/non PWID, mild	£919,001
40% baseline chronic prevalence among PWID		
1	PWID, moderate	£5,894,771
2	PWID, mild	£5,581,928
3	Ex/non-PWID, moderate	£2,796,417
4	Ex/non PWID, mild	£919,001
60% baseline chronic prevalence among PWID		
1	PWID, mild	£2,796,417
2	PWID, moderate	£1,562,238
3	Ex/non PWID, mild	£919,998
4	Ex/non-PWID, moderate	£919,001

Conclusions: In many European settings it will be more cost effective to treat People Who Inject Drugs at earlier disease stages rather than delaying treatment. Guidance on treatment allocation and prioritisation when scaling up HCV treatment needs to take account of disease stage and potential prevention benefit.

P1272

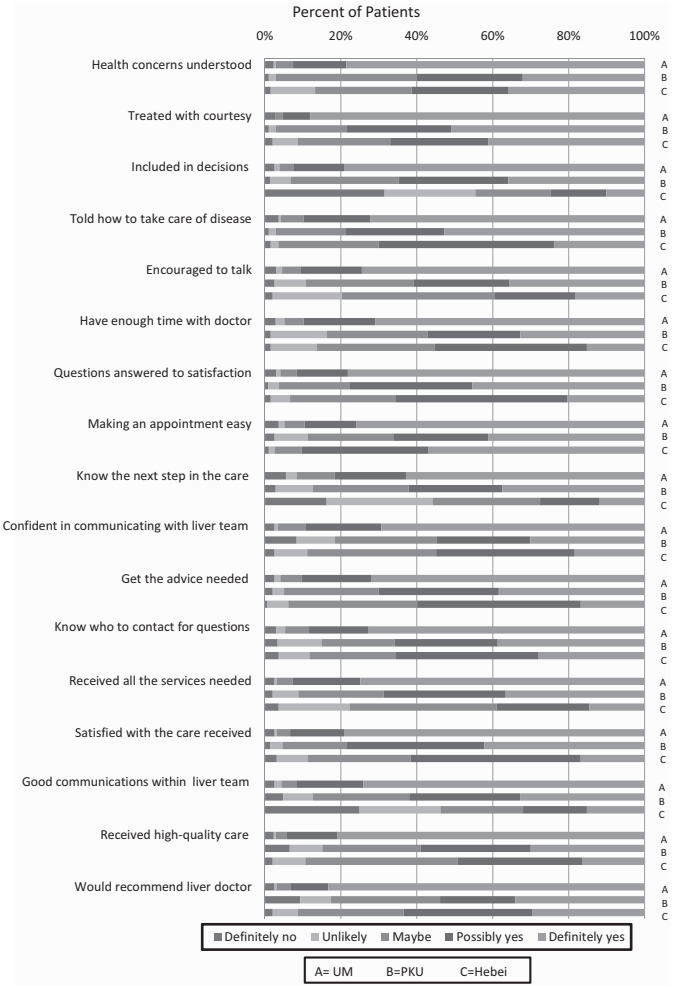
A COMPARATIVE STUDY OF PATIENT SATISFACTION WITH LIVER DISEASE CARE IN THE UNITED STATES AND URBAN AND RURAL CHINA

M. Yang[1], E. Wu[2], F. Du[3], A. Xie[2], C. Rodd[2], S. Cheng[2], H. Rao[1], A. Lin[4], C. Zhang[5], L. Wei[1], A.S. Lok[2]. [1]*Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Diseases, Beijing, China;* [2]*Division of Gastroenterology and Hepatology,* [3]*Medical School,* [4]*The Molecular and Behavioral Neuroscience Institute, University of Michigan, Ann Arbor, United States;* [5]*Clinical Epidemiology & Biostatistics, Peking University People's Hospital, Beijing, China*
E-mail: ymicecream@163.com

Background and Aims: Patient satisfaction is an important measure of quality of care and may be different for different

diseases and different clinical settings. There is no validated tool to measure patient satisfaction with liver disease care. Aims of this study were: (1) To validate an 18-item survey for patient satisfaction with cancer care in patients with liver disease. (2) To compare satisfaction with care among patients attending liver clinics in the United States (U.S.) and in urban and rural China and to determine factors associated with satisfaction with liver disease care.

Methods: Established adult patients with liver disease seen in the liver clinics at University of Michigan (UM), Peking University (PKU) and Hebei clinic were invited to participate in this study. The "Patient Satisfaction with Cancer Care" questionnaire (Jean-Pierre P, et al. Cancer. 2011; 117: 854–61) was tested for validity in patients with liver disease and for internal consistency. Results from UM, PKU and Hebei patients were compared.



Results: A total of 990 patients were analyzed between 6/2014 and 9/2014, 395 UM, 398 PKU and 197 Hebei. Median age was 53 years and 59.8% were men. Most common liver disease was HCV at UM (43.5%) and HBV at PKU (67.8%) and Hebei (49.2%). 40.3% of patients at UM, 43.2% at PKU and 15.2% at Hebei had been seen at the liver clinics for >5 years. Exploratory factor analysis revealed a 1-dimensional measure with 17 of 18 items forming a coherent set explaining 73% of the variance in patient satisfaction at UM, 62% at PKU and 68% in Hebei. Reliability assessment revealed high internal consistency (0.97 at UM, 0.94 at PKU and 0.95 in Hebei). Mean total satisfaction score (maximum = 85) of patients at UM was higher than at PKU (78 vs. 66, $P < 0.001$); which in turn was higher than in Hebei (66 vs. 60, $P < 0.001$). Univariate analyses revealed that site, age, education, type of liver disease, liver disease knowledge, and duration of follow up at liver clinic were associated with satisfaction with liver disease care. Multivariate logistic regression analysis revealed that site was the only factor associated with satisfaction with liver disease care.

Conclusions: The Patient Satisfaction with Cancer Care survey is a valid tool for assessing satisfaction with liver disease care. Patient satisfaction with liver disease care in the U.S. is better than in urban China, which in turn is better than in rural China. Understanding these differences may improve patient satisfaction and outcomes.

P1273
ACUTE PORTAL VEIN THROMBOSIS: CLINICAL FEATURES, DIAGNOSIS AND OUTCOMES AFTER 5 YEARS OF FOLLOW-UP

A. Peixoto[1], M. Silva[1], P. Pereira[1], G. Macedo[1]. [1]*Gastroenterology, Centro Hospitalar de São João, Oporto, Portugal*
E-mail: armandoafp5@gmail.com

Background and Aims: Acute portal vein thrombosis (APVT) is a rare thrombotic obstruction of extrahepatic/intrahepatic portal venous system, associated with local and systemic risk factors. The clinical features APVT are poorly defined in the literature. The proportion that progress to chronic PVT and the influences of various treatments are unknown. The aim was to summarize the clinical features of APVT in a Portuguese reference center as well as their evolution over five years of follow-up.

Methods: A total of 5 APVT patients admitted in our hospital from 2008 to 2009 were analyzed retrospectively.

Results: APVT was diagnosed in 1 female and 4 males, with a mean age of 47 years old. Most patients (n = 4) presented with abdominal pain and tenderness. Only one patient had cirrhosis by the time of diagnosis. A hereditary thrombofilia was detected in 2 cases, an intra-abdominal infection in 1, a mieloproliferative disease in 1, and nocturnal paroxistic hemoglobinuria in another one. Diagnosis was confirmed by angio-CT in 3 patients (60%) and MRI in another 3 (40%). None of the patients underwent thrombolysis nor thrombectomy. Four patients (80%) were anticoagulated after diagnosis (warfarin). The one patient with cirrhosis was not anticoagulated because of previous hemorrhagic events, and died soon after. The mean duration time of anticoagulation was 39 months, and was effective in half of the patients (n = 4). Intestinal infarction was the solo complication reported in one patient. No other patient died within the period of follow-up.

Conclusions: Our data reveals to be similar to that found in the literature, showing the value of following the available recommendations regarding diagnosis and therapeutics. It also confirms that anticoagulation therapy is the treatment of choice in this rare disease, with real impact on long time survival.

P1274
SUPPORTIVE AND PALLIATIVE CARE IN ADVANCED LIVER DISEASE: PATIENTS' NEEDS AND PRIORITIES

B.M. Kimbell[1], M. Kendall[1], K. Boyd[1], S.A. Murray[1]. [1]*Primary Palliative Care Research Team, University of Edinburgh, Edinburgh, United Kingdom*
E-mail: barbara.kimbell@ed.ac.uk

Background and Aims: The number of people dying with advanced liver disease is rising rapidly, yet little is known about the support needs and priorities of patients and their families as they approach the last year of life. Palliative care services are increasingly recognising the needs of non-cancer patients, but liver disease remains relatively neglected. This study aimed to illuminate the needs and experiences of people with advanced liver disease and those of their lay and professional carers to inform their appropriate supportive and palliative care. Specifically, it explored the dynamic physical, psychosocial, existential and information needs of patients and their lay and professional carers, and their use and perceptions of health, social and voluntary services.

Methods: Multi-perspective, serial in-depth interviews. Patients with advanced liver disease of different aetiologies were recruited in hospital. Patients and their lay carers were interviewed up to 3 times over one year. Case-linked professionals were interviewed once. Interviews were recorded, transcribed and analysed using grounded theory techniques and NVivo 9 software.
Results: 15 patients and their lay and professional carers were recruited, and 53 interviews conducted. Uncertainty emerged as the central factor dominating experiences across all dimensions of need, at all stages of the illness, and for all participants: patients, lay carers and professionals. This uncertainty related to the nature of the illness, the unpredictability of physical deterioration and prognosis, poor communication and information-sharing, and complexities of care. Current care arrangements were a poor fit with the high levels of physical and psychosocial need identified. The pervasive uncertainty meant that planning for deterioration and death was largely neglected.
Conclusions: Uncertainty lies at the heart of the experiences of patients, lay and professional carers. As a result, the needs of this patient group are currently poorly met from diagnosis to bereavement. Uncertainty makes it especially important to plan ahead to help people live and, in due course, die as well as possible. Professionals must acknowledge and actively manage this uncertainty to improve liver patients' quality of life and facilitate their appropriate and timely supportive and palliative care.

P1275
STIGMA AND DISCRIMINATION IN VIRAL HEPATITIS – THE VOICE OF THE PATIENT

C.N. Varaldo[1], J. Costa[2], A.R. Pascom[3], V.M. Postigo[4]. *[1]Director, Grupo Otimismo de Apoio a Portadores de Hepatite, Rio de Janeiro, [2]Departamento DST/AIDS/Hepatitis, [3]Departamento DAST/AIDES/Hepatites, Ministerio da Saude – Brazil, Brasilia, [4]Doutora em Teoria Psicanalítica, Private, Rio de Janeiro, Brazil*
E-mail: varaldo@hepato.com

Background and Aims: Stigma and discrimination affect the quality of life of those infected with viral hepatitis. Few studies have evaluated the circumstances and the degree to which stigma and discrimination are present, but these studies are based on the view of health professionals. In the present study, we have tried to listen to the voice of the patient in order to find out from the own infected in what contexts, and with what intensity stigma and discrimination affect their quality of life.
Methods: A questionnaire with 12 items was used to evaluate how the carrier of hepatitis feels stigmatized and discriminated against. 1,217 people infected with hepatitis B or C in Europe and Americas were interviewed, by the electronic system SurveyMonkey®. Participation was voluntary, anonymous, and each participant has accepted a term of consent.
Results: The results show that 49.6% of those infected have suffered some kind of discrimination. Of the 94.1% who reported the infection to the family, 24.6% said that relatives started to avoid physical contact. Of the 73.7% who reported their condition to friends, 46.9% claims to have suffered discrimination and 23.8% were no longer invited to social events. Of the 57.4% who reported their condition to their partners, 33.3% had their relationships affected. 42.7% of infected had their sexual life affected. Of the 46.1% who reported their condition to work colleagues, 10.1% lost their jobs. Their self-image was affected in 55.8% of the cases and 41.4% felt ashamed of their condition. Although the survey indicates that 70% of health professionals attended carriers properly, 24.6% of those professionals have maintained a certain distance from the patient and 6.9% denied care to people infected with hepatitis. 21.2% also claim to have suffered some kind of discrimination at the dentists, 10.8% when they were taking tests at a laboratory and 17.1% claim to have been discriminated against in the beauty segment (manicure / pedicure). Thus, 38.7% of respondents said that the population has some degree of rejection in the face of illness and that 33.5% of people do not show solidarity and understanding.
Conclusions: The results are extremely important because they allow us to identify the situations and population segments where discriminatory behavior and stigma are more frequent, enabling the design of strategies and action plans to fight these adverse situations that much impair the quality of life of those infected with viral hepatitis.

P1276
VITAMIN D SUPPLEMENTATION FOR CHRONIC LIVER DISEASE – A COCHRANE HEPATO-BILIARY GROUP SYSTEMATIC REVIEW

G. Bjelakovic[1,2], D. Nikolova[2], M. Bjelakovic[3], C. Gluud[2]. *[1]Department of Internal Medicine – Gastroenterology and Hepatology, Medical Faculty, University of Nis, Nis, Republic of Serbia, [2]The Cochrane Hepato-Biliary Group, Copenhagen Trial Unit, Centre for Clinical Intervention Research, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark; [3]Institute of Anatomy, Medical Faculty, University of Nis, Nis, Republic of Serbia*
E-mail: goranb@junis.ni.ac.rs

Background and Aims: Vitamin D deficiency seems common in patients with chronic liver disease. Our aim was to assess the effects of vitamin D supplementation in patients with chronic liver disease.
Methods: We searched databases until Feb 2014 for randomised clinical trials that compared vitamin D3 (cholecalciferol), vitamin D2 (ergocalciferol), 1α-hydroxyvitamin D (alfacalcidol), 25-hydroxyvitamin D (calcidiol), or 1,25-dihydroxyvitamin D (calcitriol) supplementation at any dose, duration, and route of administration versus placebo or no intervention in patients with any chronic liver disease. We conducted meta-analyses, using intention-to treat. We used risk ratios (RR) and risk difference (RD) for dichotomous outcomes, and mean difference for continuous outcomes, all with 95% confidence intervals (CI).
Results: Six randomised trials with 325 participants provided data for analyses. All trials were with high risk of bias. Vitamin D supplementation had no significant effect on all-cause mortality (RD 0.01, 95% CI −0.02 to 0.04; 6 trials, 325 participants) (vitamin D3 800 to 2,000 IU; vitamin D2 14,286 to 21,429 IU; calcitriol 0.25 to 1 μg daily) or on liver-related mortality (RR 1.62, 95% CI 0.08 to 34.7; 1 trial, 18 participants). Vitamin D3 had no significant effect on rapid virological response (RR 0.24, 95% CI 0.01 to 4.58), but showed significant beneficial effect on early (RR 0.09, 95% CI 0.03 to 0.25) and sustained virological response (RR 0.23, 95% CI 0.11 to 0.52) in the two trials with 122 chronic hepatitis C patients. Calcitriol had no significant effect on acute cellular rejection in liver transplant recipients (RR 0.33, 95% CI 0.04 to 2.62; 1 trial, 75 participants). Vitamin D2 had no significant effect on liver function tests in patients with alcoholic cirrhosis (1 trial, 18 participants).
Conclusions: The lack of sufficient number of trials and sample size, low quality and paucity of data prevents us from drawing firm conclusions regarding effects of vitamin D supplementation on the meta-analysed outcomes in chronic liver disease patients. Vitamin D supplements have no statistically significant effects on survival, liver-related mortality, adverse events, the number of patients with rapid virological response, or acute cellular rejection in liver transplant patients, but data were sparse. Vitamin D3 might improve early and sustained virological response in chronic hepatitis C patients. Further trials with low risks of systematic and random errors seem warranted.

P1277

SCREENING FOR VIRAL HEPATITIS AMONG MIGRANTS IN THE EU: WHAT LESSONS CAN WE LEARN FROM POOR RESPONSE TO A PILOT TRIAL USING GP REGISTERS?

J. Kunkel[1], L. Sweeney[2], A. Falla[3], I. Veldhuijzen[3], G.R. Foster[1].
[1]Hepatology, [2]Queen Mary University of London, London, United Kingdom; [3]Infectious Disease Control, Municipal Public Health Service, Rotterdam, Netherlands
E-mail: j.kunkel@qmul.ac.uk

Background and Aims: Effective treatments for chronic infection with hepatitis B and C virus (HBV, HCV) are available. However, many infected individuals remain undiagnosed and cannot benefit from treatment. In particular migrants may be difficult-to-reach due to language and cultural barriers. The HEPscreen Project aimed to test different ways of screening migrants for viral hepatitis. Here we evaluate the benefits of a pilot study of general practitioner (GP) based testing for viral hepatitis in East London.
Methods: Registers of two GP practices in East London were screened for migrants at risk of viral hepatitis. African, South Asian and Turkish patients were selected as 'at-risk' ethnicities. Patients were included if they were aged 18 and over, had registered with the GP in the last 5 years and did not have known infection with HBV or HCV. Identified patients were sent invitation letters with information sheets in their main language and asked to attend the practice for testing. Half of the patients were additionally invited for HIV testing to investigate the influence on uptake. Subsequently, two focus groups were held with African and Turkish individuals who had not taken part in the pilot. The setup of the pilot and possible reasons for non-attendance were discussed.
Results: A total of 560 patients were invited, 200 African, 170 South Asian and 190 Turkish. Overall uptake was poor, with only 6 African, 3 South Asian and 4 Turkish patients attending for testing (2.3%). No infected patients were found and the pilot was stopped prematurely due to insufficient uptake. This prevented a formal analysis of the benefit or harm of including HIV testing in the program but of note 9 patients who were invited for hepatitis only testing attended compared to 4 patients for HIV and hepatitis testing. The focus groups highlighted a number of general and specific barriers to testing: relationship with GPs, attitude towards research studies, low levels of awareness of hepatitis B and C, sensitivity around their community being targeted for health screening, fear, and tone and content of the invitation letter and information sheet. The inclusion of HIV testing in the invitation was expected to reduce uptake.
Conclusions: GP registers in the UK can identify migrants at risk of viral hepatitis but a number of barriers need to be recognised and overcome if this is to be a cost effective intervention.

P1278

EFFECTS OF "CHRONIC HEPATITIS PATIENTS INFORMATION AND MORALE MEETINGS" ON PATIENT COMPLIANCE AND TREATMENT SUCCESS

O. Sezgin[1], E. Altıntaş[1], E. Üçbilek[1], F. Ateş[1], S. Yaraş[1], B. Sarıtaş[1], M.K. Aydın[1]. *[1]Gastroenterology, Mersin University School of Medicine, Mersin, Turkey*
E-mail: drorhansezgin@gmail.com

Background and Aims: Chronic hepatitis causes patients and their relatives to worry about their health and future, to feel isolated from the environment, to develop feelings of abandonment and affects their psychological state negatively. These negative factors prevent proper diagnosis and treatment. That's why, we organize "hepatitis patients information and morale meetings" to inform the patients and their relatives about hepatitis, to correct misconceptions and to improve their relationship with treatment team since 2007 in Mersin. These meetings are arranged twice a year in spring and autumn. About 150 patients with chronic hepatitis and their relatives are invited to each meeting. Meetings are informal and start at 10:30 with brunch on Sunday. All participants are encouraged to actively participate and join the conversation. To evaluate the efficiency of meetings and level of knowledge before and after the meeting quantitatively, we provided a survey with patients at two meetings of last year.
Methods: Patients were asked to fill a questionnaire before and after the meetin
Results: A total of 205 interviews were completed. Half of the participants were male, mean age was 47. 41% of participants were primary school graduates, 43% of them attended the meeting before. 59% of them had chronic HBV, 39% of them had chronic HCV. 59% of them had comorbidity. 13% of participants stated that they were excluded by their relatives after illness. 29% of participants were afraid of having a chronic disease and liver cirrhosis. 25% of them were worried about having a difficult to treat, contagious disease. 95% of the patients stated that they felt better after meetings, and negative psychological effect of disease decreased after meetings (5.9/10 to 7.1/10). They became more optimistic, they understood that it was a treatable disease and there is a group of doctors who care about them. They felt informed and their level of information rised from 6.3/10 to 8.6/10 and this increment was statistically significant ($p = 0.001$). Some of the patients stated that they used their drug regularly after the meeting. 99% of patients and their relatives wanted the meetings to continue and recommended to other patients.
Conclusions: These meetings had positive effects on their psychological state and level of knowledge about disease. This would increase their faith and their desire to continue treatment

P1279

MORTALITY, PREMATURE DEATH AND DIRECT COSTS ASSOCIATED WITH LIVER DISEASE IN PORTUGAL

S. Vítor[1], R.T. Marinho[1], J. Gíria[2]. *[1]Gastrenterologia e Hepatologia, Hospital de Santa Maria, [2]Direcção Geral de Saúde, Lisboa, Portugal*
E-mail: sivvitor@gmail.com

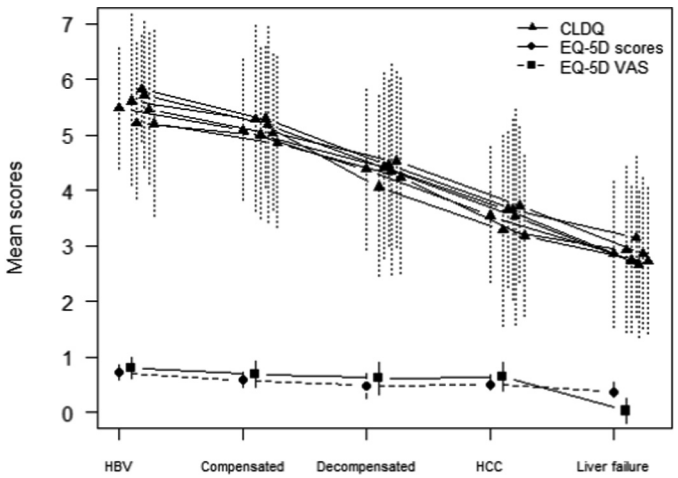
Background and Aims: Health professionals have recognized liver disease as a common cause of morbidity and mortality in Portugal. However, few studies have estimated the socioeconomic impact of these disorders. Our study aims to determine the number of hospital discharges and admissions, mortality, premature death and costs associated with liver disease from the perspective of the National Health Service in Portugal.
Methods: A descriptive, retrospective analysis of data from 97 hospitals between 2000 and 2008 and mortality data for 2011 collected from the Portuguese National Institute of Statistics (Instituto Nacional de Estatística [INE]). The 9th and 10th revisions of the International Classification of Diseases were used to establish diagnoses. Demographic data, average length of stay (ALOS), in-patient mortality and direct costs associated with hospital admissions and liver transplant were compared for the most common liver diseases. Based on national mortality data from people aged 70 years-old and younger (INE 2011), we estimated years of potential life lost index (YPLL) and compared liver disease with other conditions.
Results: The annual mean number of discharges for liver disease was 11,503 between 2000 and 2008. Most cases of liver disease were diagnosed in men (70.4%) and the prevalence of liver disease peaked in patients aged from 20 to 64 years (60.7%). Alcoholic cirrhosis was the most frequent liver-disease diagnosis (30.0%). The mean ALOS was 10 days and the mortality rate was 13%. Daily direct hospital costs ranged from €450 per patient for chronic hepatitis B infection to €1163 for chronic hepatitis C infection. In 2008, costs associated with liver transplantation were €15,259,275. The mortality rate for all liver diseases was 13 per 100,000 inhabitants in Portugal. Liver disease imposed the third greatest burden based on the YPLL in 2011. This YPLL result exceed these

attributed to certain conditions such as cerebrovascular diseases and some malignant neoplasms.
Conclusions: Liver disease imposes a considerable social and economic burden on Portugal. Our results suggest that educational, legislative and therapeutic interventions to prevent morbidity, mortality and premature death from liver disease are urgently required to minimise the economic and clinical burdens.

P1280
THE DYNAMICS IN GENERAL AND LIVER DISEASE SPECIFIC ASPECTS OF QUALITY OF LIFE AMONG PATIENTS WITH CHRONIC LIVER DISEASE IN YUNNAN, CHINA

Y. Che[1]. [1]*The First Peoples' Hospital of Kunming City, Kunming City, China*
E-mail: cheyanhu22@hotmail.com

Background and Aims: *Background:* Patients with chronic liver diseases (CLD) may compromise their health related quality of life (HRQoL). Hepatitis B virus (HBV) infection has long been the leading cause of CLD including liver cancer and cirrhosis. Knowledge on different symptom profiles of CLD help to develop comprehensive treatment and patient care plans.
Objective: To access the facets of HRQoL in chronic liver diseases throughout the spectrum of severity of the disease.
Methods: A cross-sectional study was conducted in the First Affiliated Hospital of Kunming Medical University in Yunnan province of China. Both out- and inpatients undergoing treatment protocols for different HBV related liver disease states were consecutively collected from December 2012 to June 2013. ANOVA was used to compare the mean scores of EQ-5D and chronic liver disease questionnaire (CLDQ) among 5 disease groups. The relationship between demographic variables predicting global CLDQ scores and the domains of CLDQ was analysed.
Results: A total of 1040 patients including 520 without complication, 91 with compensated cirrhosis, 198 with decompensated cirrhosis, 131 with HCC and 100 with liver failure were recruited. All domains of CLDQ, the means of EQ-5D value and EQ VAS exhibited significant decline with worsening of disease severity from uncomplicated HBV to liver failure. The multivariate regression demonstrated the reduction of mean scores of CLDQ domain at advanced stage. Patients with liver failure and HCC had more HRQoL impairment than other disease states. No effect of patient gender was found. Patient age was associated with 'fatigue' and 'worry' domains ($p = 0.006$; $p = 0.004$) but not with other domains and global scores of CLDQ and ED-5D.
Conclusions: The HRQoL in chronic hepatitis B patients has been greatly affected by disease states. The success of care for HBV-related diseases should consider not only in the outcomes of treatment strategies but also in improving patient's wellbeing.



P1281
HEPATOLOGICAL MANIFESTATION OF DENGUE VIRAL FEVER – A CLINICO BIOCHEMICAL STUDY IN ADULT PATIENTS

D. Chowdhury[1], P. Bardhan[2]. [1]*Gastroenterology, Sahara Hospital and Vivekananda Polyclinic & Institute of Medical Sciences,* [2]*Family Medicine, Vivekananda Polyclinic & Institute of Medical Sciences, Lucknow, India*
E-mail: ddebge@rediffmail.com

Background and Aims: Dengue is a common arboviral infection of tropics and sub tropics transmitted globally and is becoming a major international health concern. Adult data of liver involvement in dengue fever are scarce. The aim of this study was to determine the frequency and pattern of hepatic manifestation in Dengue fever.
Methods: A retrospective study of 48 patients of serologically confirmed dengue fever from two centres was done. All the patients had liver involvement either in the form of elevated transaminases, jaundice, increased prothombin time and or ascites. These patients were admitted during the recent outbreaks of 2013 and 2014.
Results: Of the 48 patients 37 were male and 11 female (M:F = 3.4:1). Mean age: 32.6 (range 16–60). Mean platelet count was 45.98×10^9/L (range: $10–160 \times 10^9$). Fever was present in all. Pain abdomen in 26 (54.2%), vomiting in 18 (37.5%). Melena was seen in 10 (20.8%) and 2 patients had encephalopathy. Clinical jaundice was observed in 7 (14.5%), ascites in 6 (12.5%), hepatomegaly in 28 (58.3%). 10 (20.8%) patients had hyperbilirubinemia (Ser Bil >2). AST and ALT was elevated in all the patients. Mean AST and ALT levels were 402.6 and 225.6 IU/ml respectively. ALT was two to five times elevated in 22 (45.8%) and more than five times elevated in 12 (25%). AST elevation was more than ALT in 40 (83.3%) patients. AST:ALT ratio more than 2 was observed in 17 (35.4%) patients. Serum Alkaline Phosphatase level was elevated in 21 (43.8%). Prothrombin time more than 3 s was observed in 9 (18.8%). Hypoalbuminemia (Ser Alb <3) was present in 19 (39.6%). Mean Ser albumin – 3.02 g/dl. Arterial ammonia was elevated in the 2 patients who developed encephalopathy. Ultrasonography revealed ascites in 20 patients which was mostly minimal to mild in quantity, hepatomegaly in 18 and splenomegaly in 6 patients. 5 (10.4%) patients developed Acute liver failure. Two patients died due to acute liver failure.
Conclusions: Dengue hepatitis manifest as fever, abdominal pain, hepatomegaly, thrombocytopenia, transaminase rise mainly preferential elevation of AST, with or without jaundice and minimal to mild ascites in majority. Acute liver failure may occur. Level of thrombocytopenia is not associated with disease progression.

P1282
WHAT IS NEEDED TO CONTROL HEPATITIS C (HCV) IN DIFFERENT EPIDEMIOLOGICAL SETTINGS?

H. Woodall[1], N. Martin[2], T. Hallett[3], G. Cooke[3], M. Hickman[1], P. Vickerman[1]. [1]*University of Bristol,* [2]*University of Btristol, Bristol,* [3]*Imperial College, London, United Kingdom*
E-mail: peter.vickerman@bristol.ac.uk

Background and Aims: Hepatitis C is a mojor cause of global mortality. There are scalable tools to combat HCV, including harm reduction interventions for people who inject drug (PWID), procedures to minimise medical risk, and new highly effective HCV treatments. We use modelling to consider how combination interventions could bring HCV mortality and incidence down to low levels in three epidemic scenarios
Methods: A model of HCV transmission was developed considering HCV transmission amongst PWID and due to unsafe medical procedures. The model was parameterised for three epidemiological scenarios, with all having a PWID chronic HCV prevalence of 60% and overall HCV chronic prevalence of either 1, 3 or 5%. The impact of different interventions were modelled incrementally,

firstly harm reduction (HR – opiate substitution therapy and needle and syringe provision, each at 50% coverage and 50% efficacy), then a 75% reduction in transmission risk due to unsafe medical procedures (MR), and lastly three HCV treatment scenarios of either all cirrhotics treated each year, or treatment of 10% of all infected per yr but either distributed to just non-PWID or all infecteds

Results: For the 1, 3 or 5% overall HCV chronic prevalence epidemic scenarios, PWID contributed 90, 32 or 20% of new incident HCV infections but a smaller proportion of prevalent infections. Results suggest that HR can have substantial impact (50%) on preventing onwards transmission in settings driven by PWID, but will have smaller impact (10%) in settings with substantial iatrogenic transmission. In these settings, reductions in iatrogenic transmission are crucial for reducing incidence. HCV treatment is required to quickly reduce HCV mortality, and can reduce HCV incidence if targeted to sub-groups driving transmission. In PWID-driven epidemics, this means targeting HCV treatment towards PWIDs to reduce incidence but non-PWID to reduce mortality as few PWID are cirrhotic. In non-PWID driven epidemics, treatment of cirrhotics will immediately prevent HCV mortality and may reduce HCV incidence. Treatment of PWID will have a smaller impact on transmission in these scenarios because they contribute less to transmission

Conclusions: A halving in new infections could be achieved rapidly (10 yrs) based on scaled-up harm reduction to 50% of PWID and 75% reduced risk of medical exposure. A halving in deaths by 2030 could also be achieved if 10% of the chronically infected population are treated annually, with greater impact if cirrhotics are prioritized

P1283
HEALTH RELATED QUALITY OF LIFE IN CIRRHOTIC PATIENTS IN AUSTRIA

A. Pickl[1], B. Hofmann-Bichler[1], R. Buder[2], P. Piringer[2], K. Lenz[2].
[1]Palliative Care, [2]Internal and Intensive Care Medicine & Palliative Care, Konventhospital Barmherzige Brueder Linz, Linz, Austria
E-mail: kurt.lenz@meduniwien.ac.at

Background and Aims: The majority of patients with chronic liver disease are living with the disease rather than dying from it. A number of systemic symptoms have been recognized that can occur at any point in the natural history of the disease and which can be associated with functional impairment and reduced quality of life.

Aim of the study: Health related impairment of quality of life in an Austrian group of patients with cirrhosis

Methods: 50 consecutive unselected hospitalized patients (43 men and 7 women; age 58.26+11.39 years) with a diagnosis of advanced chronic liver disease (Child–Pugh Score 9.62+1.92). A sociodemographic questionnaire included marital state, religion, life style variables, level of education and present working status. For the evaluatation of the impairment of quality of life the german version of the Chronic Liver Disease Questionnaire (CLDQ-D), and the Hospital Anxiety and Depression Score (HADS-D) was used as well as the questionnaire in "Resources in Sexuality and Partnership" (R-S-P). For correlations between severity of liver disease and impairment of different qualities of life, Spearman's rank correlation coefficients were calculated.

Results: See the table.

Conclusions: All HRQL domain scores were declined in our cirrhotic patients, as compared to published data of healthy persons. These findings are similar to results found in different European and US populations. Since sexuality and partnership is not included in the classical quality of life scores, but is known to be relevant in cirrhotics, we performed in addition a questionnaire concerning sexuality and partnership. All domain scores were as well declined compared to published normal values, with the largest difference in tenderness and love. An influence of the severity of liver disease on quality of life, could be seen in total CLQD, and in the subset of fatigue, but not in the anxiety and depression score, and not in the sexuality and partnership questionnaire.

Questionnaire	Score, mean±SD	Correlation with Child–Pugh score
CLDQ-D		
Total	4.77±1.13	p = 0.037
Abdominal symptoms	5.02±1.71	p = 0.066
Fatigue	3.66±1.60	p = 0.045
Systemic symptoms	5.11±1.32	p = 0.580
Activity	4.77±1.62	p = 0.066
Emotional function	5.11±1.25	p = 0.167
Worry	4.85±1.53	p = 0.221
R-S-P		
Total	58.57±19.13	p = 0.292
Physical feeling	12.77±5.14	p = 0.235
Tenderness	9.42±5.14	p = 0.061
Desire	16.1±7.26	p = 0.611
Love	8.1±3.36	p = 0.068
Communication	12.65±5.36	p = 0.471
HADS-D		
Anxiety	6.2±3.77	P = 0.204
Depression	6.24±4.36	P = 0.321

P1284
ESTABLISHMENT OF AN INTERDISCIPLINARY ONLINE EXPERT-FORUM (INXFO) SPECIALIZED IN HIV AND HEPATITIS IN GERMANY – UP-DATE 2014

N. Hanhoff[1], P. Braun[2], P. Ingiliz[1], T. Kümmerle[1], S. Preis[1], J. Rockstroh[1], E. Wolf[2], C. Wyen[3], L. Meemken[1], INXFO. *[1]INXFO GbR, [2]INXFO, [3]GbR, Cologne, Germany*
E-mail: L.Meemken@inxfo.de

Background and Aims: The continuous progress being made in the diagnosis and treatment of HIV and hepatitis have led to an increasing complexity in the management of these infections. In response, INXFO was founded as an internet-based forum for health care providers to obtain anonymous, case-specific, free-of-charge and independent recommendations from an interdisciplinary team of experts.

Methods: INXFO went on-line in April 2012 (www.inxfo.de). After an initial, free online registration, health care providers present their case and ask their question(s) by filling in a template. The question is directed to at least one expert team-member specialized in that field, who can provide a response or obtain more information from the user. Every answer of an expert is checked by a second expert prior to release. The team of experts consists of the following specialties: cardiology, dermatology, endocrinology, gynecology, hepatology, HIV-treatment and resistance, immunology, infectious diseases, internal medicine, lipidology, microbiology, nephrology, neurology, oncology, pediatrics, pharmacy, psychiatry and virology.

Results: In 2014 (Jan-Nov), 112 questions concerning the management of complex cases were answered by INXFO, which is comparable to 2013 (n = 113). Most frequently, questions were directed at pharmacy (55.4%, an increase from 32.7% in 2013), infectious diseases (15.2%) and virology (12.5%). Drug interactions was the most common topic (35.1%), followed by co-morbidities and side effects (16.7%), therapy failure (12.3%) and hepatitis (10.5%). 71.1% of cases were reported to be HIV-infected and 5.3% and 14.9% with hepatitis B and C respectively. Questions regarding hepatitis C-infected patients as well as those directed at pharmacy nearly doubled from 2013, possibly reflecting the availability of new direct acting antivirals used in the treatment of hepatitis C.

Conclusions: Considering the complexity of HIV and hepatitis treatment, an interdisciplinary online expert-forum is a valuable tool for discussion of individual cases. A steady number of incoming questions suggests an awareness and acceptance of INXFO. The next

step will be a 'conversation-function' within the forum to allow online discussion of cases and the responses/recommendations provided by the experts.

FORECASTING THE DISEASE BURDEN OF CHRONIC HEPATITIS C IN RUSSIA

V. Chulanov[1,2], O. Sagalova[3], N. Blokhina[4], N. Mamonova[2], E. Nurmukhametova[4], N. Pimenov[1], A. Rakhmanova[5], H. Razavi[6], K. Razavi-Shearer[6], A. Shevaldin[7], E. Chesnokov[8], S. Sokolov[8], E. Strebkova[9], O. Znoiko[10], I. Shestakova[10,11]. *[1]Reference Center for Viral Hepatitis, [2]The Clinical Diagnostics and Research Center, Central Research Institute of Epidemiology, Moscow, [3]Infectious Diseases Department, Clinic of the South Urals State Medical University, Chelyabinsk, [4]Hospital of Infectious Diseases #1, Moscow, [5]The St. Petersburg City AIDS Center, St. Petersburg, Russia; [6]Center for Disease Analysis, Louisville, Colorado, United States; [7]Department of Infectious and Parasitic Diseases with Immunoprophylaxis, St Petersburg Polyclinic 74, St. Petersburg, [8]Tyumen Regional State Autonomous Healthcare Institution "Consulting and Diagnostic Centre", Tyumen, [9]Samara State Medical University (SamSMU), Samara, [10]Department of Infectious Diseases and Epidemiology, Moscow State University of Medicine and Dentistry (MSUMD), [11]Ministry of Health of the Russian Federation, Moscow, Russia*
E-mail: vladimir.chulanov@pcr.ru

Background and Aims: Estimated number of individuals with chronic hepatitis C (CHC) in Russia is 4,161,700; however, few are aware of their condition (1,789,500 diagnosed by 2012) and even fewer are treated (5,500 in 2010). This analysis projected future disease burden and developed four treatment scenarios to control CHC related disease burden in Russia.

Methods: Using a modelling approach, the hepatitis C virus (HCV) infected population and future disease progression was quantified. Baseline variables included: viraemic prevalence, age and gender distribution, diagnosis rate, treatment rate, disease progression and sustained virologic response (SVR) rates. Data were collected from the literature and through expert interviews.

Results: The number of prevalent HCV infections is projected to increase 36% by 2030. In addition, the number of individuals with decompensated cirrhosis, hepatocellular carcinoma (HCC) and liver related deaths (LRD) are estimated to increase 175%, 205% 220% and 215%, respectively. There are an estimated 236,000 new infections annually.

If SVR is increased, but the number of treated patient stays the same and treatment is restricted to individuals with a fibrosis stage of ≥F1 (as today), then there was only a 1% decrease in the number of HCC cases, LRD, and decompensated cirrhosis by 2030. Restricting the treatment to ≥F3 will lead a 4–5% reduction in morbidity and mortality.

Combining prevention with treatment resulted in the most substantial impact. Reducing annual incidence to 96,000 in 12 years as well as increasing treatment to 123,800 with high SVR therapies resulted in a 40% reduction in viraemic individuals. Additionally, HCC cases, liver related deaths and decompensated cirrhosis decreased by 65%, 68% and 74%, respectively.

Delaying prevention and treatment by two years resulted in a reduction in viraemic individuals, HCC cases, liver related deaths and decompensated and compensated cirrhosis by 34%, 54%, 57% and 64%, respectively. In addition, the delayed scenario resulted in an estimated 20,000 more liver related deaths.

Conclusions: A substantial reduction in CHC related disease burden is possible with increases in SVR and treatment numbers while lowering the number of new HCV infections. These results could inform the development of effective disease management in Russia.

P1286

LOW PREVALENCE OF POSITIVE VIRAL SEROLOGY FOR HBV AND HCV AMONG A GENERAL DUTCH ELDERLY POPULATION: RESULTS FROM THE ROTTERDAM STUDY

E.P. Plompen[1], R. Maan[1], R.J. de Knegt[1], P. Taimr[1], A. Hofman[2], B.H. Stricker[2], S. Darwish Murad[1], H.L. Janssen[1,3]. *[1]Gastroenterology and Hepatology, [2]Epidemiology, Erasmus MC University Medical Center, Rotterdam, Netherlands; [3]Liver Centre, Toronto Western & General Hospital, University Health Network, Toronto, Canada*
E-mail: e.plompen@erasmusmc.nl

Background and Aims: Worldwide the prevalence of chronic HBV infection is approximately 7%, whereas the prevalence of chronic HCV infection is 3%. Recently, screening for HCV among babyboomers was implemented in the United States. In the Netherlands, prevalence of HBV and HCV is much lower (0.24% for chronic HBV and 0.22% for chronic HCV infection), with a higher prevalence among first-generation migrants. Therefore we assessed the prevalence of HBsAg and anti-HCV positivity in the Rotterdam Study, a population-based cohort consisting of elderly participants of almost exclusively Caucasian ethnicity.

Methods: The Rotterdam Study is a large population-based cohort study of subjects ≥45 years at start of the study. Screening for HBV and HCV was performed with an anti-HCV ECLIA (Cobas®, Roche) and HBsAg ECLIA (Cobas®, Roche). Liver fibrosis was assessed with transient elastography (Fibroscan, Echosens®).

Results: In total, 6036 participants were included in this study. Mean age was 69.5±9.0 years and 43.1% were male. Median ALT was 19 (15–24) U/L. At abdominal ultrasonography, steatosis was present in 35.6%. Median liver stiffness (LS) (n = 4284) was 4.8 (3.9–5.9) kPa. In the total cohort, anti-HCV was positive in 34 participants (0.56%) and HBsAg positivity was observed in 12 participants (0.20%). Borderline positivity was encountered in 8 (0.13%) and 7 (0.12%) patients for anti-HCV and HBsAg respectively. Prevalence of positive viral serology in babyboomers (born 1945–1965, n = 2635) was 0.38% for HCV and 0.30% for HBV. Mean age of the 45 participants with positive viral serology in the total cohort was 71.1±8.3 years and 62.2% were male (vs 42.9% in those without positive viral serology, p = 0.009). Median ALT was 20 (16–25) U/L. Steatosis was present in 40%. Median LS (n = 31) was 5.6 (4.2–6.4) kPa vs 4.8 (3.9–5.9) kPa in those without positive viral serology (p = 0.013). Two participants (6.5%) had LS ≥9.5 kPa. Three participants (6.8%) with positive serology were of non-caucasian ethnicity compared to 4.8% in the total cohort. Ten (22.2%) participants had diabetes mellitus, this prevalence was 12% in the total cohort (p = 0.035).

Conclusions: The occurrence of positive viral serology for hepatitis B and C in a general elderly Western population, including almost exclusively participants of Caucasian ethnicity, was very low with a prevalence of 0.2% and 0.6% respectively. Therefore, screening for HBV and HCV in the general Caucasian elderly population, including babyboomers, in the Netherlands should not be recommended.

P1287

PHYLOGENETIC ANALYSIS OF AN EPIDEMIC OUTBREAK OF ACUTE HEPATITIS C IN HIV-INFECTED PATIENTS BY MASSIVE SEQUENCING

N. Caro Pérez[1], M. Martinez-Rebollar[2], J. Gregori[3,4], J. Quer[3], P. González[1], M. Gambato[1], H. Visser[2], J.I. Esteban[3], J. Mallolas[2], X. Forns[1], S. Pérez-del-Pulgar[1], M. Laguno[2], Liver Unit, Hospital Clínic, IDIBAPS, CIBERehd, Barcelona, Spain. *[1]Liver Unit, Hospital Clínic, IDIBAPS, CIBERehd, [2]Infectious Diseases Unit, Hospital Clínic, IDIBAPS, [3]Liver Unit, Vall d'Hebron Institut de Recerca-Hospital Universitari Vall d'Hebron, CIBERehd, Barcelona, [4]Roche Diagnostics SL., Sant Cugat del Vallès, Barcelona, Spain*
E-mail: caro@clinic.ub.es

Background and Aims: The incidence of acute hepatitis C among HIV-infected men who have sex with men (MSM) has significantly

increased in recent years. This increase may be due to factors such as high HCV viral load in blood and semen, sex with risk of mucosal damage, a higher number of sexual partners, presence of concomitant ulcerative sexually transmitted diseases and the use of recreational drugs. The aim of our study was to investigate the dynamics of HCV transmission in an outbreak of acute hepatitis C in HIV-infected MSM in Barcelona.

Methods: Between 2008 and 2013, 113 cases of acute hepatitis C in HIV-infected MSM were diagnosed in the Infectious Diseases Unit, Hospital Clínic, Barcelona. Phylogenetic analysis of the HCV NS5B gene was performed in a total of 70 patients. Viral RNA was extracted from serum samples collected from each patient at the time of diagnosis. Massive sequencing was performed using the Roche 454 GS Junior platform. To define possible transmission networks, phylogenetic trees and multidimensional scaling maps were constructed from genetic distance matrices (Da).

Results: At the time of diagnosis of acute hepatitis C, 53 of the 70 (76%) patients included in the study were receiving antiretroviral therapy. HIV viral load was undetectable in 48 patients (69%) and the mean CD4 cell count was 923 cells /ul. HCV viral load was 6.37 log IU/mL (range 3.73–6.99). Thirty-five of 53 (66%) patients treated with pegIFN and ribavirin achieved a sustained virological response. The prevalence of HCV genotypes was: 4d 51% (n = 36), 1a 40% (n = 28), 1b 7% (n = 5) and 3a 1% (n = 1). Phylogenetic analysis showed the existence of at least 13 monophyletic groups: 5 of genotype 1a, 2 of genotype 1b and 6 genotype 4d. Molecular analysis showed that the genetic distances between genotype 4d viruses (Da 5.42) were significantly lower than those of the subtypes 1a (Da 18.50, $p < 2.2 \times 10^{-16}$) and 1b (Da 15.25, $p < 1.1 \times 10^{-6}$). This result may suggest the existence of a single source of infection for genotype 4d and different sources for subtypes 1a and 1b.

Conclusions: HCV infection spreads rapidly among HIV-infected MSM through a local network in Barcelona. The implementation of public health campaigns and preventive measures, as well as treatment interventions with the new direct-acting antivirals will allow the development of strategies to reduce the HCV transmission of HCV within these high-risk groups.

E-mail: allama5@hotmail.fr

Background and Aims: To clarify the epidemiology of BCS in France on a large population basis.

Methods: For year 2010, 48 French liver units were asked to record prospectively and retrospectively adult in- and out-patients excluding known cirrhotic patients, hepatocellular carcinoma (HCC). Incidence and prevalence were calculated using the 2010 national census excluding 3 regions that did not provide exhaustive answers. Mortality and survival rates were calculated from incident cases. Clinical and laboratory data (including non questionable risk factors for venous thromboembolism) were collected.

Results: 270 patients were recorded. 90 were excluded (6 <18 yrs, 25 non-residents, 35 misdiagnosed, 10 missing files, 17 duplicates). There were 28 incident cases. Estimated incidence was 0.65 per million (pmi) in year 2010, and prevalence 4.02 pmi. 70% were women, mean age 39±1 years. Time from first symptoms to diagnosis was <7 days in 9%, and >1 month in 48%. At presentation, 73% of patients had ascites, 71% hepatomegaly, 69% abdominal pain, 55% oesophageal varices, 50% splenomegaly, and 28% a factor V <50%. Risk factors were myeloproliferative diseases (MPD) in 46% (polycythemia vera 61%, essential thrombocythaemia 28%, latent MPD 10% and myelofibrosis 1%), oral contraceptives in 33%, factor V Leiden in 15% and a local factor in 7.4%. Platelet counts were >450,000/mm^3 in 78% of MPD patients. MPD was known but untreated prior to BCS in 9/72 patients No risk factor was identified in 23% of patients and ≥2 risk factors in 24%. BMI was higher in the group without cause (25.8 kg/m^2 vs 23.5 kg/m^2, p = 0.018). Within the first year, refractory ascites occurred in 24% of cases, variceal bleeding in 10% of cases. There were 8 HCC in a mean delay of 11.2±4.2 years. Half interventional treatments were performed within the first year (15% TIPS, 13% angioplasty and 5% liver transplantation). Angioplasty, TIPS/LT one-year free survival were respectively 81.2±7.6% and 79.6±8.1%. 50% of deaths occurred the first month. In October 2014 mean survival rate was 3.5±0.4 years and global SR 69.2±9.1%.

Conclusions: In France, incidence and prevalence of BCS were at least 0.65 pmi and 4.02 pmi, respectively, in 2010, close to previous European reports. Overall mortality was higher than expected based on the data from expert referral centers. In half the patients, diagnosis is delayed beyond 1 month. Reducing this delay might be a target for improving the outcome.

P1289

UNDERSTANDING AND PREVENTING THE HCV EPIDEMIC AMONG MEN WHO HAVE SEX WITH MEN IN THE UK: A MATHEMATICAL MODELLING ANALYSIS

N.K. Martin[1], M. Hickman[1], M. Nelson[2], A. Thornton[3], C. Sabin[3], S. Lattimore[4], T.C.S. Martin[5], G.S. Cooke[6], V. Delpech[4], M. Ruf[7], H. Price[8], E.C. Thomson[6,9], P. Vickerman[1]. *[1]University of Bristol, Bristol, [2]Chelsea and Westminster Hospital, [3]University College London, London, [4]Public Health England, Colindale, [5]Kings College London, [6]Imperial College London, [7]Gilead Sciences, London, [8]Mid Essex Hospital Services NHS Trust, Chelmsford, [9]MRC University of Glasgow Centre for Virus Research, Glasgow, United Kingdom*
E-mail: natasha.martin@bristol.ac.uk

Background and Aims: There is an emerging hepatitis C virus (HCV) epidemic among HIV-positive men who have sex with men (MSM). Recent UK reports indicate declines in primary and reinfection HCV incidence, despite an expanding epidemic. We use a mathematical model to understand potential drivers of recent incidence declines and predict the impact of HCV prevention interventions, including HCV interferon-free direct acting antivirals (DAAs).

Methods: A dynamic deterministic HCV transmission and treatment model among HIV-positive MSM was developed and calibrated to UK data on HCV Ab+ seroprevalence (2004–2011, UK Collaborative HIV Cohort [UK CHIC]), primary incidence (2002–2012, Public Health England), and rates of reinfection (2005 and 2011, Chelsea and Westminster Hospital cohort). Based on data, we model HCV treatment rates of 39%/22% treated within 1 year of an acute/chronic diagnosis, respectively, and 1–6%/yr thereafter (UK CHIC). We assume historic interferon-based SVR rates of 80%/40% in the acute/chronic stage, respectively, and 90% with DAAs from 2015. The model was used to understand observed declines in incidence and project the epidemic with: (a) current levels of risk and treatment (status quo), (b) double treatment rates, (c) double treatment and halved risk from 2015 (combination prevention), and (d) no treatment or historic risk reduction (counterfactual).

Results: Recent declines in primary incidence and reinfection rates suggest a 70% reduction in transmission risk from 2008–2012, with model projections indicating this will result in HCV Ab+ seroprevalence plateauing at 9% and a slight fall in chronic RNA+ prevalence to 7% among HIV+ MSM by 2025 (Figure 1a,b). Without HCV treatment or risk reductions, seroprevalence could have been 12% in 2014, rising to 14% by 2025. Doubling HCV treatment could reduce chronic prevalence from 8% to 6% over a decade, with incidence and chronic prevalence a relative 12% less than the status quo in 2025 (Figure 1b,c). Combination prevention could reduce chronic prevalence by over a third (to 5%, a quarter lower than the status quo in 2025) and reduce primary and reinfection incidence by 55–60% by 2025 (Figure 1a–d).

Conclusions: Past treatment and risk reductions in the last 6 years may have averted an expanding HCV epidemic among HIV+ MSM in the UK. Combination prevention including HCV treatment and behavioural interventions could halve incidence within a decade. Further research should identify high risk individuals to focus intervention strategies for maximum impact.

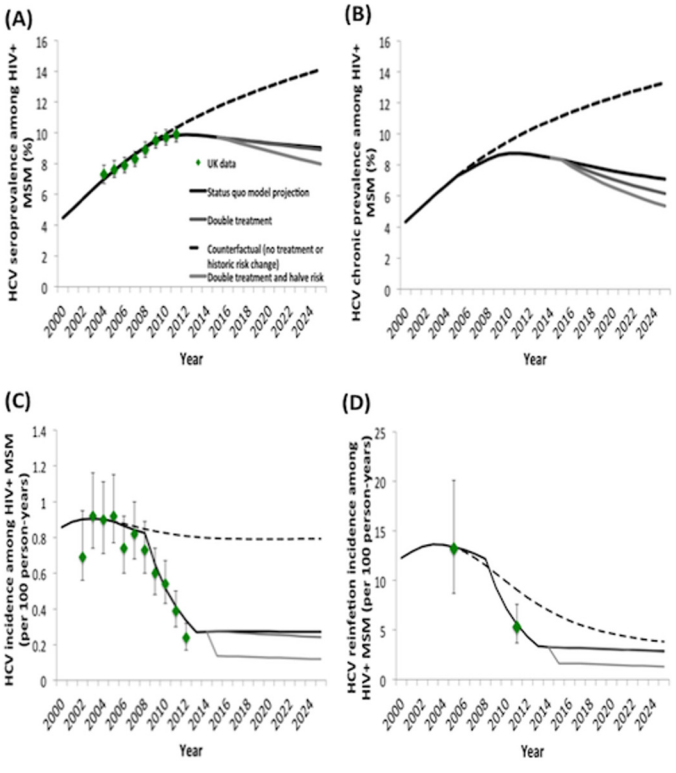

Figure 1. Model projections of the HCV epidemic among HIV-positive MSM in the UK. (A) HCV seroprevalence (Ab+); (B) HCV chronic (RNA+) prevalence; (C) HCV incidence and (D) HCV reinfection incidence. Black lines show status quo projections (continued treatment and historic risk reductions with no change since 2012), dark grey lines show double treatment from 2015, light grey lines show double treatment and halved risk from 2015, and black dashes show counterfactual of no treatment or historic risk reductions.

P1291

INCIDENCE OF BUDD CHIARI SYNDROME (BCS): AN EXHAUSTIVE NATIONWIDE FRENCH STUDY

M. Allaire[1], N. Goutte[2], N. Bendersky[3], O. Farges[4], A. Plessier[3], R. Morello[1], G. Delaval[1], T. Dao[1], D. Valla[3], I. Ollivier-Hourmand[1]. *[1]Service d'Hépato-gastroentérologie, CHU, CAEN, [2]Service d'Hépato-gastroentérologie, Université Paris VII, Inserm U773, [3]Service d'Hépato-gastroentérologie, [4]Service de Chirurgie hépato-bilaire, Université Paris VII, Inserm U773, CHU Beaujon, CLICHY, France*
E-mail: allama5@hotmail.fr

Background and Aims: To evaluate exhaustive incidence of BCS in France.

Methods: BCS were screened from 2007 to 2012 in French healthcare databases using their unique identifier number and the ICD-10-CM Version 2010 codes. Incident-cases were defined by the entry point as a first admission in 2012, and excluded when admission pattern was not related to BCS, or Arnold Chiari Syndrome (ACS) suspected. Mortality and incidence were calculated using the 2012 national census. Demographic data, primary and secondary risk factors, patient's location, the type and annual BCS-caseload of the centers where patients were first managed, were retrieved. Annual BCS-caseload of centers were stratified by: <5 patients/year, 5–15 patients/year, >15 patients/year.

Results: For year 2012, 258 BCS incident-cases were identified. 25 (9 ACS) were excluded. Global and primary BCS incidences were respectively 3.5 and 0.75 per million inhabitants (pmi). Patients were first managed in public sector 53.7%, university public sector 27.9%, private center 13.7% and charitable hospital 4.7%. Primary BCS were mostly first admitted in university public sector (56%). After adjusting for potential confounders, the mortality (9.8%) was only significantly influenced by age (adjusted OR = 1.031 [1.006–1.056], p = 0.008). Primary BCS mortality was 6%. Mean age was 56.1 yrs (±21) (10.3% <18) and 55.5% were male. No risk factor (RF) was identified in 32.2% and ≥2 risk factors in 13.3%. RF were inflammatory diseases 12%, alcoholic and viral cirrhosis excluding HCC 9.4%, secondary hepatic tumor (SHT) 9%, hepatocellular carcinoma (HCC) 8.1%, liver graft complications 6.4%, primary hepatic tumor excluding HCC 4.3%, mechanic or traumatic factors involving inferior vena cava 3%. Other RF were hypercoagulable state such as cancer excluding SHT 12%, myeloproliferative

diseases (MPD) 8.6%, other coagulation disorders 4.7%, pregnancy complications 3% and rare diseases 2.6%. Among the 50 primary BCS, mean age was 43.8 yrs (±20) (3 <18) and 64% were female. RF were inflammatory diseases 36%, MPD 28%, other coagulation disorders 16%, pregnancy complications 14%, rare diseases 12% and mechanic or traumatic factors involving inferior vena cava 6%.
Conclusions: In France in 2012, exhaustive incidence of BCS was 3.5 pmi. This study confirms that incidence of primary BCS is low, close to expert centers' evaluation in 2010.

P1292
INCIDENCE OF HEPATITIS C IN AN EUROPEAN LOW THRESHOLD METHADONE PROGRAM

M.J. Silva[1], P. Lopes[2], D. Carvalho[1], C. Pereira[2], E. Belo[2], R. Coutinho[2], F. Calinas[1]. *[1]Gastroenterology Department, Central Lisbon Hospital Centre, [2]Ares do Pinhal – NGO – Low threshold methadone program, Lisbon, Portugal*
E-mail: mariojorgesilva01@gmail.com

Background and Aims: Data on incidence of hepatitis C virus (HCV) infection in Europe are sparse. Where documented, injecting drug use is a major transmission route for HCV infections.
We aimed to estimate the incidence of HCV infection in an ambulatory medical and psychosocial program with low threshold methadone administration in Lisbon, Portugal (LTMP-Lx).
Methods: At LTMP-Lx, serological status for HCV and human immunodeficiency virus (HIV) are collected prospectively from every individual in the cohort. Negative serologies are repeated annually during follow-up. Drug use and other risk behaviors are accessed during periodical consultations within the program. We analyzed serologies from individuals entering the program between 2001 and 2013, and estimated the incidence of HCV seroconversion in the whole cohort and its subgroups. Statistical analysis was performed with Microsoft Office® Excel 2007 and STATA® 12.1.
Results: During the 12 years of observation, 5038 individuals in the program were tested for HCV antibodies. A total of 1032 individuals – 801 (77.6%) males, median age at program entry 35 [18; 63] years, 173 (16.8%) have ever injected drugs – had a baseline negative HCV serology and at least one further serology. Of those, 85 (8.2%) had a positive HIV baseline serology.
Ninety-one individuals (8.8%) seroconverted for HCV, during 3852.5 person-years (PY) [HCV seroconversion incidence 2.36/100PY (95% CI 1.92–2.90/100PY)].
Seroconversion incidence was 2.22/100PY (95% CI 1.75–2.81/100PY) among males, 2.93/100PY (1.95–4.41/100PY) among females; 7.59/100PY (95% CI 5.13–11.23/100PY) among HIV positive and 1.88/100PY (95% CI 1.47–2.39/100PY) among HIV negative individuals. Incidence was 0.78/100PY (95% CI 0.53–1.15/100PY) among individuals with non-injecting drug use in their lifetime and 12.15/100PY (95% CI 9.53–15.49/100PY) among individuals who ever injected drugs.
Conclusions: At this european low threshold methadone administration program, HCV seroconversion incidence is low in non-injecting drug users and is significantly higher among injecting drug users and HIV positive individuals.

P1293
RESULTS OF A GLOBAL SURVEY OF HEPATITIS C PATIENTS: THE IMPACT OF INFECTION, THE EXPERIENCE OF THE PATIENT PATHWAY AND THE BARRIERS TO, AND SIGNIFICANCE OF, A CURE

C. Gore[1], M. Peck-Radosavljevic[2], B. Taylor[1]. *[1]World Hepatitis Alliance, London, United Kingdom; [2]Department of Gastroenterology and Hepatology, Medical University of Vienna, Vienna, Austria*
E-mail: admin@worldhepatitisalliance.org

Background and Aims: Somewhere between 80 and 150 million people are living with hepatitis C so a survey was conducted to establish the impact on their lives, socially, economically, physically and psychologically, the impact of being cured of the virus and the experience of the patient pathway.
Methods: A questionnaire was developed with input from both patients and physicians and distributed during 2014 to patients online and in physical form through patient organisations and physician associations. It was available in 35 languages. Most questions were multiple choice, but those addressing the barriers to, and impact of, a cure were free text.
Results: Half or more of respondents said that living with hepatitis C had a significant or very significant negative impact on their emotional life (romantic or family relationships), on their physical health and particularly on their psychological well-being. Around one third felt that it had negatively impacted their education or career prospects and a similar proportion had not told even their close family about their status. Half felt that nurses did not understand this impact and a third that doctors did not. Of those that knew about hepatitis before their diagnosis a tiny minority had heard about it through government awareness campaigns and only a third were tested at their own or their doctor's initiative. Of those who told their doctor about hepatitis C symptoms, two-thirds were not offered a test. Half of respondents were unsatisfied with the information given to them on diagnosis. Almost all respondents had tried herbal remedies to help with their hepatitis C, most either to slow disease progression or to ameliorate the symptoms. The key barrier for people in addressing their hepatitis C was treatment, either access to it or the side effects of interferon-based therapy. The predominant description of the impact of achieving a cure was 'life'.
Conclusions: Living with hepatitis C has a major impact on all aspects of a person's life but patients do not perceive that healthcare workers, especially nurses appreciate this. The provision of information prior to diagnosis, especially from governments, as well as on diagnosis clearly needs to be improved. Equally, treatment needs to move rapidly to interferon-free regimens and access assured for all, as this will remove the two key barriers for patients. This is particularly important because for patients a cure is not seen as a 'nice-to-have'; it means 'life'.

Clinical trials in progress

P1309
A RANDOMIZED, OPEN-LABEL, MULTICENTER, CONTROLLED STUDY TO ASSESS SAFETY AND EFFICACY OF ELAD® HUMAN CELL-BASED BIO-ARTIFICIAL LIVER SUPPORT SYSTEM (ELAD®) IN SUBJECTS WITH ALCOHOL-INDUCED LIVER DECOMPENSATION (AILD)

R.A. Ashley[1], J. Stange[2], A.J. Henry[3], Z. Li[1]. *[1]Research & Development, [2]Medical Affairs, [3]Clinical Operations, Vital Therapies, Inc., San Diego, United States*
E-mail: rashley@vitaltherapies.com

Background and Aims: Treatment options for patients with AILD are limited, leading to significant morbidity and mortality. ELAD® is designed to provide liver support continuously for up to 5 days to a subject with compromised liver function and allow time for the native liver to regenerate by circulating patient plasma through a hollow fiber cartridge containing metabolically active, immortalized VTL C3A human liver cells. Based on preliminary findings from a subset of subjects with AILD enrolled in a prior Phase 2 study (VTI-206), the aim is to provide data on the safety and clinical utility of ELAD in a larger, prospectively defined population with AILD. The

primary endpoint will evaluate overall survival of subjects with a clinical diagnosis of AILD up to at least Study Day 91. The secondary objectives are to determine the proportion of survivors at Study Days 28 and 91. Exploratory objectives are to evaluate the ability of ELAD to stabilize liver function, measured using the Model of End-stage Liver Disease (MELD)-based time to progression (TTP) up to Study Day 91, and the proportion of progression-free survivors (PFS) up to Study Days 28 and 91.

Methods: Eligibility requirements were established in order to replicate the AILD population in VTI-206 as follows:

Key inclusion criteria:

1. Age ≥18 years;
2. Total bilirubin ≥8 mg/dL;
3. A clinical diagnosis of AILD, based upon evidence (by lab test, medical history, or family interview) of a clinical judgment of a temporal (6 weeks or less) and causal relationship between use of alcohol and this onset of symptoms;
4. Subjects meeting inclusion criteria 1 through 3 will be classified as having either:
   a. Severe acute alcoholic hepatitis (AAH), with:
      i. Medical history of alcohol abuse; AND
      ii. Maddrey score of ≥32; AND
      iii. AAH documented by either:
         1. Confirmatory liver biopsy, OR
         2. Two or more of the following:
            a. Hepatomegaly,
            b. AST > ALT,
            c. Ascites,
            d. Leukocytosis (WBC count above lab normal at site), OR
   b. Alcohol-induced decompensation of chronic liver disease that is not acute alcoholic hepatitis as defined above), with:
      i. MELD score of 18–35; AND
      ii. Underlying chronic liver disease documented by:
         1. Liver biopsy, AND/OR
         2. Laboratory findings, AND/OR
         3. Medical history;
5. Not eligible for liver transplant during this hospitalization.

Key exclusion criteria:

1. Platelets <40,000/mm^3, INR >3.5;
2. Chronic renal failure;
3. MELD score >35;
4. Septic shock, major hemorrhage, spontaneous bacterial peritonitis with uncontrolled systemic infection, hemodynamic instability;
5. Significant concomitant disease;
6. Previous liver transplant;
7. Have a Do Not Resuscitate or a Do Not Intubate (DNR/DNI).

Target age based on the VTI-206 population is 45–55 and baseline target MELD is 27–29 for the current study. A total of 200 evaluable subjects meeting these requirements will be randomly assigned in a 1:1 ratio to receive either standard of care treatment for AILD plus treatment with the ELAD System (ELAD group) or standard of care of treatment for AILD alone (Control group). ELAD treatment will take place for a maximum of five 24-hour periods unless the discontinuation criteria are met. It was anticipated that enrollment would take approximately 2 years.

Results: The first subject was enrolled in March 2013 and as of November 12, 2014, 175 subjects have been enrolled in 51 clinical sites in the United States, Europe and Australia. Based on data captured as of this date in the Electronic Data Capture system for the study, major demographics/baseline variables include: Age (45.16±10.10, n = 174), MELD (27.23±3.94, n = 172), Maddrey (73.15±25.39, n = 173), bilirubin (24.79±9.39 mg/dL, n = 173), INR (2.04±0.52, n = 172), creatinine (0.99±0.74 mg/dL, n = 172), PT (22.42±5.30 seconds, n = 173).

Conclusions: Trial enrollment has proceeded in accord with anticipated timelines. Average age and MELD at baseline are within the trial target ranges established during VTI-206.

P1310

ADJUVANT CHEMOTHERAPY WITH GEMCITABINE AND CISPLATIN COMPARED TO OBSERVATION AFTER CURATIVE INTENT RESECTION OF CHOLANGIOCARCINOMA AND MUSCLE INVASIVE GALLBLADDER CARCINOMA (ACTICCA-1) – A RANDOMIZED, MULTIDISCIPLINARY, MULTINATIONAL PHASE III TRIAL

H. Wege[1], D. Arnold[2], W.O. Bechstein[3], J. Bridgewater[4], D. Goldstein[5], L.H. Jensen[6], S. Kasper[7], H.J. Klümpen[8], V. Kunzmann[9], U. Lindig[10], A.W. Lohse[1], B. Nashan[1], J. Primrose[11], M. Rentsch[12], J. Shannon[13], M. Sinn[14], K.H. Weiss[15], A. Stein[1].

E-mail: hwege@uke.de

Background and Aims: Despite complete resection, disease free survival (DFS) of patients with cholangiocarcinoma (CCA) is less than 65% after 1 year and not more than 35% after 3 years. For muscle invasive gallbladder carcinoma (GBCA) prognosis is even worse, with an overall survival (OS) of only 30% after 3 years. Thus, evaluation of adjuvant chemotherapy (CTx) in biliary tract cancer (BTC) in a large randomized trial is urgently warranted.

Methods: ACTICCA-1 is a randomized, multidisciplinary, multinational phase III investigator initiated trial (EudraCT number 2012–005078–70). With respect to data obtained in the ABC-02 trial, we selected the combination of cisplatin and gemcitabine for 24 weeks as investigational treatment. Based on adjuvant trials in pancreatic cancer (e.g. ESPAC IV) with a comparable postoperative recovery time, inclusion of patients within a maximum interval of 16 weeks between surgery and start of CTx was chosen. Due to the different prognosis and treatment susceptibility of muscle invasive carcinoma, two separate cohorts for CCA and GBCA were included to capture the expected treatment effects. Randomization will be stratified for lymph node status for both cohorts and localization for CCA. The primary endpoint is DFS and secondary endpoints include OS, safety and tolerability of adjuvant CTx, quality of life, and patterns of disease recurrence. For CCA, DFS 24 months post surgery (DFSR@24) is expected to be 40% without CTx. Adjuvant gemcitabine and cisplatin should increase DFS@24 to 55% to be regarded as clinically relevant. With a power of 80% and a significance level of 5%, 271 evaluable study patients have to be followed for 24–28 months to observe 166 events. For GBCA, adjuvant CTx should increase DFSR@24 from 35% to 55% to be relevant; thus, 154 evaluable study patients have to be monitored for 24–28 months to observe 90 events. In both cohorts, randomization will be 1:1 with adjuvant CTx for 24 weeks and imaging every 12 weeks. In 2014, the study has been started in Germany (funded by the Deutsche Krebshilfe and supported by medac GmbH). Site activation in Germany will continue in 2015. Furthermore, the Netherlands (funded by the Dutch Cancer Society), Australia, Denmark and the United Kingdom (funded by Cancer Research UK) will join in 2015.

Conclusions: The randomized, multinational, multidisciplinary phase III ACTCCA-1 trial will establish the role of adjuvant CTx

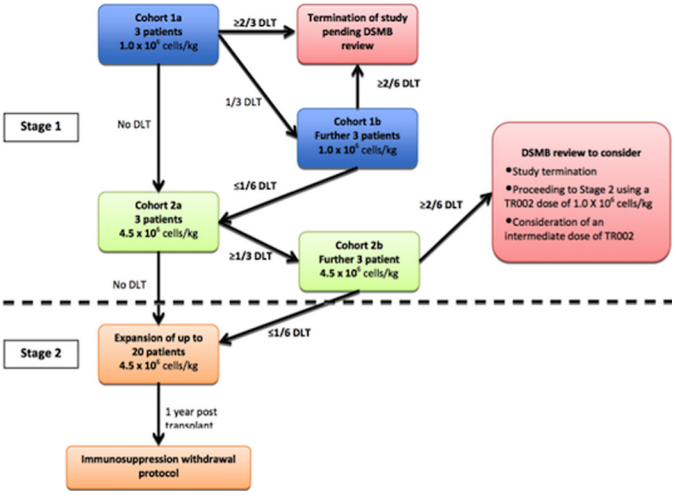
with gemcitabine and cisplatin in comparison to observation in patients with BTC.

P1311

THRIL; PILOT STUDY EVALUATING THE SAFETY AND EFFICACY PROFILE OF REGULATORY T CELL THERAPY IN LIVER TRANSPLANT RECIPIENTS

G.P. Whitehouse[1,2], N. Safinia[1], I. Rebollo-Mesa[1], K. Lowe[1], S. Thirkell[1], L. Fry[1], A. Androulidakis, M. Martinez-Llordella[1], A. Hope[1], V. Aluvihare[2], C. Fisher[1], R. Lechler[1], N. Heaton[2], G. Lombardi[1], A. Sanchez-Fueyo[1,2]. *[1]MRC Centre for Transplantation, King's College London, [2]Institute of Liver Studies, King's College Hospital, London, United Kingdom*
E-mail: gav@doctors.org.uk

Background and Aims: Protracted immunosuppression following liver transplantation is accompanied by significant morbidity and mortality and negatively impacts on the long term survival of liver transplant recipients. A proportion of liver transplant recipients develop a state of 'operational' tolerance and can discontinue all immunosuppressive treatment without undergoing rejection. However, this phenomenon is exceedingly rare over the first years after transplantation. $CD4^+CD25^+FOXP3^+$ regulatory T cells (Tregs) are ideal candidates for therapeutic strategies aimed at inducing tolerance in organ transplantation, but the evidence for the use and efficacy of Treg therapy in this setting is absent.
ThRIL is the first combined Phase I/IIa clinical trial of Treg immunotherapy worldwide in the setting of liver transplantation. Stage 1 will evaluate the safety and dose limiting toxicities of TR002 administration to adult de novo primary liver transplant recipients. Stage 2 will evaluate the efficacy of TR002 administration in allowing the complete discontinuation of immunosuppressive therapy.
Methods: A single site, open-label, uncontrolled, phase I/IIa clinical trial in subjects undergoing liver transplantation, in which liver transplant recipients will receive a single infusion of an in vitro expanded autologous regulatory T cell therapy (TR002). Participants will be adults on the King's College Hospital liver transplant waiting list with chronic liver disease and no history of autoimmunity or active HCV infection. Recipient blood will be collected immediately before transplantation for TR002 manufacture. Participants will receive immunosuppression with rATG in addition to Prednisolone and Tacrolimus. Conversion to Sirolimus based immunosuppression will occur at 8 weeks post-transplantation.



In Stage 1, two cohorts of three evaluable patients will be recruited, with cohort 1 receiving a low dose TR002 infusion (1.0×10^6 cells/kg) and cohort two receiving a higher dose TR002 infusion (4.5×10^6 cells/kg) at week 13. The number of dose limiting toxicities up to one month after cell infusion will determine the requirement to expand cohort 1 and/or 2 to six patients as shown in the figure. Protocol liver biopsies will be performed at week 13 and 52. In stage 2, a maximum of 20 patients who have received the highest tolerated dose of TR002 will initiate gradual immunosuppression discontinuation at 12 months. Drugs will be withdrawn over a 6 month period, and patients will be followed until month 24.

P1312

ALFAPUMP SYSTEM VERSUS TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT AND PARACENTESIS IN THE TREATMENT OF ASCITES. A MULTICENTRE RANDOMISED CONTROLLED STUDY (AGUA-TRIAL)

C. Engelmann[1], O. Brosteanu[2], H. Tenckhoff[1], J. Babatz[3], F. Lammert[4], M. Manns[5], I. Schiefke[6], T. Bruns[7], C. Trautwein[8], S. Zeuzem[9], U. Treichel[10], R. Jalan[11], T. Berg[12]. *[1]Division of Gastroenterology and Hepatology, University Hospital Leipzig, [2]Centre of Clinical Trials, University Leipzig, Leipzig, [3]Medizinische Klinik I, Universitätsklinikum Carl Gustav Carus, Dresden, [4]Klinik für Innere Medizin II – Gastroenterologie und Endokrinologie, Universitätsklinikum des Saarlandes, Homburg, [5]Klinik für Gastroenterologie, Hepatologie und Endokrinologie, Medizinische Hochschule Hannover, Hannover, [6]Klinik für Gastroenterologie und Hepatologie, Klinikum St. Georg, Leipzig, [7]Gastroenterologie, Hepatologie und Infektiologie, Universitätsklinikum Jena, Jena, [8]Klinik für Gastroenterologie, Stoffwechselerkrankungen und Internistische Intensivmedizin, Uniklinik Aachen, Aachen, [9]Medizinische Klinik I, Universitätsklinik Frankfurt am Main, Frankfurt am Main, [10]Innere und Allgemeinmedizin, Kreiskrankenhaus Hagenow, Hagenow, Germany; [11]UCL Institute for Liver and Digestive Health, Royal Free Hospital, London, United Kingdom; [12]Division of Gastroenterologie and Hepatology, University Hospital Leipzig, Leipzig, Germany*
E-mail: Cornelius.Engelmann@medizin.uni-leipzig.de

Background and Aims: Ascites represents a complication of liver cirrhosis that becomes refractory to medical treatment in 5–10% of patients. The treatment of choice is repeated paracentesis or the implantation of a transjugular intrahepatic portosystemic shunt (TIPS). However, complications such as bleedings, hepatic encephalopathy and liver failure limit applicability of TIPS. The alfapump® system from Sequana Medical is a device implanted at subcutaneous level, which is able to move the ascitic fluid from the peritoneal cavity to the urinary bladder. Usually the device is implanted in patients with advanced stages of liver cirrhosis if TIPS is contraindicated. However, complications like renal insufficiency and infections largely result from this late disease stage.
Aim: The purpose of the Agua-Trial is to evaluate the efficacy of the alfapump in patients with cirrhosis presenting with recurrent or refractory ascites. Two patient populations are studied with different aims:

1. patients with indication to TIPS – the aim is to show that alfapump is non-inferior to TIPS in reducing of the need for paracenteses.
2. patients with contraindication to TIPS – the aim is to show that alfapump is superior to repeated paracenteses, reducing the need for paracenteses.

Methods: Agua-Trial is a prospective, randomized, open multicenter international trial consisting of two sub-studies with 200 patients in part 1 and 60 patients in part 2. The main inclusion criteria are: age >18 years, liver cirrhosis, refractory or recurrent ascites, written informed consent. For sample size calculation an average number of paracenteses per quarter of 0.817 for alfapump and 1.17 for TIPS and a power of 90% was assumed.
For both sub-studies, the primary endpoint is the average number of paracenteses per quarter (three months) documented over 4 quarters (12 months). Secondary objectives include treatment related complications, transplant-free survival, need for albumin

substitution and quality of life. Patients will be followed-up for 24 months, with the primary endpoint being assessed after 12 months. The trial will start in 2015.
Conclusions: Agua-Trial is the first large-sale clinical trial to evaluate the efficacy as well as the complications of alfapump in comparison with TIPS in patients with recurrent or refractory ascites qualifying for both treatments. Agua-Trial will provide important information about the clinical course of this condition and may have significant impact on treatment strategies in these patients

P1313
WTX101–201: PHASE 2 STUDY OF BIS-CHOLINE TETRATHIOMOLYBDATE IN NEWLY DIAGNOSED WILSON DISEASE PATIENTS

K.H. Weiss[1], F. Askari[2], P. Ferenci[3], A. Czlonkowska[4], J. Bronstein[5], D. Clark, J. Hansson, M. Schilsky[6]. *[1]Dept. of Internal Medicine IV, University Hospital Heidelberg, Heidelberg, Germany; [2]Internal Medicine, University of Michigan, Ann Arbor, United States; [3]Dept. of Gastroenterology, University Hospital Vienna, Vienna, Austria; [4]Institute of Psychiatry and Neurology, Medical University, Warsaw, Poland; [5]Department of Neurology, UCLA School of Medicine, Los Angeles, [6]Division of Digestive Diseases and Section of Transplantation and Immunology, Yale New Haven Medical Center, New Haven, United States*
E-mail: karl-heinz_weiss@med.uni-heidelberg.de

Background and Aims: Wilson Disease (WD) is a rare autosomal-recessive disorder of impaired hepatic copper excretion caused by mutations in the ATP7B gene, resulting in copper accumulation in various organs, including the liver and the brain. WTX101 (bis-choline tetrathiomolybdate) is a novel de-coppering agent with a unique mechanism of action (MoA) in development for treatment of WD. WTX101 targets improved control of Cu due to the rapid formation of irreversible Cu-tetrathiomolybdate-protein complexes leading to a rapid de-coppering without mobilizing free Cu that could cause tissue toxicity, including neurological deterioration. Tetrathiomolybdate has been studied in several clinical trials in WD patients using ammonium tetrathiomolybdate. The study will evaluate if individualised BID oral dosing of WTX101 with an up-titration design in the initial de-coppering phase is safe and efficacious in lowering free copper levels (NCC, adjusted for plasma Mo concentration) as well as maintaining these lowered free copper levels using QD dosing. It will also provide data on additional free Cu endpoints, 24-hour urinary copper and neurological outcome with the UWDRS.
Methods: This is a Phase 2, open-label, non-controlled, 24 week study conducted in the EU and US. An individualised WTX101 dosing regimen is administered with PPI in newly diagnosed symptomatic (neurological, stable hepatic or combined) WD patients aged 18 and older with elevated NCC levels who have been treated for ≤28 days with chelation therapy or zinc therapy. Eligible subjects will receive WTX101 as out-patients at doses ranging from 30–300 mg per day along with omeprazole 20 mg per day. The primary endpoint is the proportion of patients who achieve normalised levels of NCC (≤2.3 μM) or reach a reduction of at least 25% in NCC. Secondary endpoints include safety and tolerability, change in and time to normalisation of NCC levels, copper endpoints (exchangeable copper, profiling of Mo/Cu/Protein tripartite complex species, and 24-hour urinary copper), hepatic status with ALT, AST, INR and bilirubin measurement, neurological assessment (UWDRS), psychiatric assessment (MINI Tracking), clinical symptom status (CGI) and QOL/PRO endpoints (EQ5D, MMAS-8, TSQM). PK of WTX101 will be measured by plasma total and free elemental Mo.
Conclusions: The unique mode of action suggests that WTX101 may be an effective treatment option for WD patients having a lower potential for neurologic deterioration while once daily dosing offers improve compliance.

P1314
GRANULOCYTE COLONY STIMULATING FACTOR (G-CSF) TO TREAT ACUTE-ON-CHRONIC LIVER FAILURE: A MULTICENTER RANDOMIZED TRIAL (GRAFT STUDY)

C. Engelmann[1], O. Brosteanu[2], H. Tenckhoff[1], K. Splith[3], M. Schmelzle[3,4], T. Berg[1]. *[1]Gastroenterologie, Section of Hepatology, University Hospital Leipzig, [2]Center for Clinical Trials, [3]Translational Centre for Regenerative Medicine (TRM), University of Leipzig, [4]Department of Visceral, Transplantation, Thoracic and Vascular Surgery, University Hospital Leipzig, Leipzig, Germany*
E-mail: Cornelius.Engelmann@medizin.uni-leipzig.de

Background and Aims: ACLF is a condition with dismal prognosis, for which apart from OLT no therapeutic options exist. A treatment approach that helps to recover from this acute intercurrent event and hereby improves the very poor short-term survival would be of major clinical importance. Recently two small randomised trials have shown the potential of G-CSF in this patient population markedly improving patients' outcome. However, these results need to be confirmed in a large multicenter trial.
Aim: The purpose of the GRAFT Study is to evaluate the efficacy of G-CSF in patients with ACLF.
Methods: GRAFT Study is a prospective and open multicenter trial randomizing 292 patients with ACLF in two arms. All patients will receive standard of care according to current guidelines. Patients in the experimental arm receive in addition twelve doses of G-CSF (5 μg/kg daily) administered subcutaneously on day 1–5, then every 3rd day until day 26. Inclusion criteria are: age >18, ACLF according to the diagnostic criteria of the CANONIC Study and written informed consent. We aim to detect an absolute difference of 20% in transplant-survival at day 90. With these assumptions, a total of 262 patients have to be analysed to achieve a power of 90% at a significance level of 5% using a two-sided log-rank test. Due to the short observation period for the primary endpoint, we expect a drop-out rate not exceeding 10%. Taking this into account, 292 patients will be randomized. The primary endpoint is the transplant-free survival up to 90 days. Secondary objectives include the overall survival, complications of ACLF, rate of infections, liver function and the duration of hospital stay. Patients will be followed-up for 12 months. The trial will start in 2015.
Conclusions: GRAFT Study is the first large-scale clinical trial evaluating the efficacy as well as the safety of G-CSF in patients with ACLF. GRAFT Study will provide important information about the clinical course of this condition and may have significant impact on treatment strategies in these patients.

P1315
DESIGN OF THE INCA TRIAL (IMPACT OF NOD2 GENOTYPE-GUIDED ANTIBIOTIC PREVENTION ON SURVIVAL IN PATIENTS WITH LIVER CIRRHOSIS AND ASCITES): PROSPECTIVE, DOUBLE-BLIND, RANDOMISED CLINICAL TRIAL EVALUATING THE IMPACT OF GENOTYPE-STRATIFIED CARE

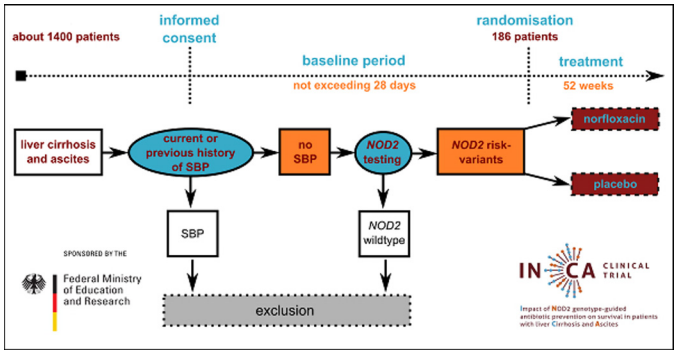
M. Casper[1], M. Mengel[2], C. Fuhrmann[2], E. Herrmann[3], M. Reichert[1], B. Appenrodt[1], F. Grünhage[1], F. Lammert[1]. *[1]Department of Medicine II, Saarland University Medical Center, Homburg, [2]Study Center Bonn, University Hospital Bonn, Bonn, [3]Institute for Biostatistics and Mathematical Modelling, Goethe University Hospiatl, Frankfurt, Germany*
E-mail: markus.casper@uks.eu

Background and Aims: Patients with liver cirrhosis suffer from a highly elevated risk to develop bacterial infections that significantly decrease survival rates. One of the most relevant infections is spontaneous bacterial peritonitis (SBP). Recently, we reported that *NOD2* germline variants are associated with the development of infectious

complications and mortality in patients with cirrhosis (Appenrodt et al., 2010; Lutz et al., 2014). The *aim* of the INCA trial is to investigate whether survival of this genetically defined high-risk group of patients with cirrhosis characterised by the presence of *NOD2* variants is improved by primary antibiotic prophylaxis of SBP.

Methods: The INCA trial is a double-blind and placebo-controlled clinical trial with two parallel treatment arms (arm 1: norfloxacin 400 mg once daily; arm 2: placebo once daily; 12 months treatment and observational period). Balanced randomisation of 186 eligible patients with stratification for the protein content of the ascites (<15 vs. ≥15 g/l) and the study site is planned. As a multicentre national study patients are recruited at at least 13 centres throughout Germany. Key inclusion criterion is the presence of a *NOD2* risk variant in patients with liver cirrhosis who developed ascites, the most important exclusion criteria are a current SBP or previous history of SBP and any long-term antibiotic prophylaxis (Figure 1). The primary endpoint is overall survival after 12 months of treatment. Secondary objectives are to evaluate whether the frequencies of SBP and other clinically relevant infections necessitating antibiotic treatment as well as the total duration of unplanned hospitalisation due to cirrhosis differ in both study arms. Recruitment has started in March 2014. The study is registered in the German Clinical Trials Register (DRKS00005616).

Conclusions: Preventive strategies are required to avoid life-threatening infections in patients with liver cirrhosis, but unselected use of antibiotics can trigger resistant bacteria and worsen outcome. Thus, individualised approaches that direct intervention only to patients with the highest risk are urgently needed. This trial meets this need by suggesting stratified prevention based on genetic risk assessment. The INCA trial is among the first studies aiming to rapidly transfer and validate information on individual genetic risk into clinical decision algorithms for patients with end-stage liver disease.



P1316

EFFECTS OF LONG-TERM ADMINISTRATION OF MIDODRINE AND ALBUMIN IN THE PREVENTION OF COMPLICATIONS IN PATIENTS WITH CIRRHOSIS ON WAITING LIST FOR LIVER TRANSPLANTATION. A RANDOMIZED, MULTICENTER, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL. MACHT STUDY

E. Sola[1], M. Simon Talero[2], M. Martin-Llahi[3], J. Castellote[4], A. Nazar[1], C. Solè[1], M. Ventura[5], R. Cela[1], N. Fabrellas[6], M. Torrens[7], E. Lopez[1], G. de Prada[1], P. Huelin[1], P. Suñé[8], M. Guevara[1], X. Xiol[9], V. Vargas[5], V. Arroyo[1], P. Gines[1]. *[1]Liver Unit, Hospital Clinic, [2]Hepatology, Vall d'Hebron, [3]Gastroenterology, Hospital Moises Broigges, [4]Hepatology, Hospital de Bellvitge, [5]Hepatology, Hospital Vall d'Hebron, [6]Universitat de Barcelona, [7]Hospital Vall d'Hebron, Barcelona, Spain; [8]Farmacia, Hospital Vall d'Hebron, [9]Hepatology, Hospital Bellvitge, Barcelona, Spain*
E-mail: pgines@clinic.ub.es

Background and Aims: Patients with cirrhosis awaiting liver transplantation frequently develop complications of the disease that increase mortality in the waiting list. Many of these complications are related to an impairment of circulatory function that causes effective hypovolemia. The hypothesis of the study is that the administration of midodrine, an oral vasoconstrictor, associated with albumin, may improve circulatory function and prevent complications of cirrhosis while awaiting for transplantation.

Endpoints: The primary endpoint of the study is to evaluate the incidence of complications (kidney failure, hepatic encephalopathy, hyponatremia, bacterial infections and gastrointestinal bleeding) in patients with cirrhosis and ascites awaiting liver transplantation. Secondary end points are: control of ascites, relationship between development of complications and activity of vasoconstrictor systems (renin, aldosterone, norepinephrine) and cytokines (TNF, IL6, IL10), quality of life, presence and outcome of minimal hepatic encephalopathy (MHE), and survival.

Study design: Randomized, multicenter, double-blind, placebo-controlled trial that will include 194 patients with cirrhosis and ascites awaiting liver transplantation. Inclusion criteria are patients with cirrhosis and ascites just enrolled in the waiting list for liver transplantation. Exclusion criteria include patients with HIV infection, TIPS and patients with contraindications for midodrine (i.e., arterial hypertension, heart disease). Included patients are randomized to receive treatment with midodrine (15–30 mg/day) associated with intravenous albumin (40 g/15days) (treatment group) or placebo (saline and placebo tablets; placebo group). Randomization will be 1:1 between groups. Randomization will be stratified according to the inclusion center and to the presence of kidney failure at inclusion (defined as serum creatinine >1.2 mg/dL). Treatment will be administered during one year or until liver transplantation. Liver and kidney function tests, vasoconstrictor systems and cytokines will be determined at baseline and at months 1, 3, 6, 12. At study inclusion neuropsychological test (PHES score) will be performed to diagnose MHE. This test will be repeated at months 3, 6, 12. Finally, quality of life questionnaires will be performed at baseline and at months 3, 6, 12. During follow-up the number of paracenteses required and the development of complications of cirrhosis will be recorded

P1317

EFFICACY OF URSODEOXYCHOLIC ACID AS A VOLUME REDUCING TREATMENT FOR SYMPTOMATIC POLYCYSTIC LIVER DISEASE: AN INTERNATIONAL, MULTICENTER, RANDOMIZED CONTROLLED TRIAL

H.M. D'Agnolo[1], T.J. Gevers[1], I. Riaño[2], L. Bujanda[2], B. Takkenberg[3], U. Beuers[3], J.M. Banales[2], J.P. Drenth[1]. *[1]Department of Gastroenterology and Hepatology, Radboud university medical center, Nijmegen, Netherlands; [2]Department of Liver and Gastrointestinal Diseases, Biodonostia Research Institute – Donostia University Hospital, University of the Basque Country (UPV/EHU), IKERBASQUE, CIBERehd, San Sebastián, Spain; [3]Department of Gastroenterology and Hepatology, Amsterdam Medical Centre, Amsterdam, Netherlands*
E-mail: hedwig.dagnolo@radboudumc.nl

Background and Aims: A large proportion of patients with polycystic liver disease (PLD) due to autosomal dominant polycystic kidney disease (ADPKD) or autosomal dominant polycystic liver disease (ADPLD) suffer from symptomatic hepatomegaly. Conventional invasive therapies may cause serious complications and have high recurrence rates. Medical treatment with somatostatin analogues that aim to diminish increased intracellular cAMP levels in polycystic cholangiocytes, show modest beneficial effects and considerable side effects. The bile acid ursodeoxycholic acid (UDCA) is FDA-approved for the treatment of the most common cholestatic liver disease, primary biliary cirrhosis. Experimental evidence suggests that UDCA reduces cystogenesis in a rodent model of PLD by restoring diminished intracellular free calcium

levels in polycystic cholangiocytes. We hypothesized that UDCA may be effective in reducing total liver volume (TLV) in PLD patients.

Methods: This international, multicenter, randomized, controlled clinical trial evaluates the effect of 24 weeks of UDCA as a volume reducing treatment. Eligible patients are symptomatic PLD patients that have a TLV ≥2500 mL. Primary outcome is change in TLV determined by CT volumetry. Secondary outcomes are change in symptoms and health-related quality of life. Moreover, safety and tolerability of the drug will be assessed. Patients will be randomized through a 1:1 allocation. The intervention group receives UDCA 15–20 mg/kg/day for 24 weeks, the control group will receive standard care. 34 patients will be included for a power of 80% (alpha 0.05) to detect a change in difference in TLV of at least 4% in favor of the UDCA-treated group.

Conclusions: Treatment of PLD with UDCA appears promising based on experimental observations. A 4% difference in TLV in favor of UDCA treatment versus standard care would indicate comparable efficacy of UDCA to that of somatostatin analogues at lower costs, less side effects and contra-indications and a more acceptable route of admission. In case of a positive result, further research should focus on the molecular mechanism of action of UDCA in PLD, dose-response relationship and combination therapy of somatostatin analogues with UDCA to evaluate synergistic effects.

P1318

PHASE I DOSE ESCALATION STUDY OF THE SAFETY, IMMUNOREGULATORY ACTIVITY, PHARMACOKINETICS, AND PRELIMINARY ANTITUMOR ACTIVITY OF NIVOLUMAB IN ADVANCED HEPATOCELLULAR CARCINOMA IN PATIENTS WITH OR WITHOUT CHRONIC VIRAL HEPATITIS

B. Sangro[1], A.B. El-Khoueiry[2], T.S. Crocenzi[3], T.H. Welling III[4], W. Feely[5], J.A. Anderson[5], C. dela Cruz[5], I. Melero[1]. *[1]Clinica Universidad de Navarra and CIBEREHD, Pamplona, Spain; [2]University of Southern California Norris Comprehensive Cancer Center, Los Angeles, [3]Providence Cancer Center, Portland, [4]University of Michigan, Ann Arbor, [5]Bristol-Myers Squibb, Princeton, United States*
E-mail: bsangro@unav.es

Background and Aims: Sorafenib is the standard of care and sole option for patients with advanced hepatocellular carcinoma (HCC) who are not candidates for curative resection or other hepatic regional therapies. The immune checkpoint inhibitor, programmed death-1 (PD-1), reduces immune response to tumor cells when the PD-1 receptor interacts with its ligands, PD-L1 and PD-L2, to down-regulate T-cell activation [1]. HCC overexpressing PD-L1 is aggressive with a poor prognosis [2]. Nivolumab, a fully human IgG4 monoclonal antibody, blocks interaction between PD-1 and its ligands and has demonstrated antitumor activity in solid tumors [3] and hematologic malignancies [4]. This study (CA209-040/NCT01658878) will evaluate the safety and antitumor activity of nivolumab in patients with advanced HCC with or without chronic viral hepatitis.

Methods: This open-label, 3-arm, dose escalation study will enroll patients with advanced histologically confirmed HCC, ECOG PS of 0 or 1 and Child–Pugh Class B7 or less who are not candidates for surgery or locoregional therapies and had progressive disease on or were intolerant of at least 1 prior therapy or refused sorafenib. Patients with encephalopathy, prior or current clinically significant ascites, recent variceal bleeding, or co-infection with either hepatitis B and C or hepatitis B and D are ineligible. Study arm assignment is dependent on HCC risk factors: no active hepatitis virus infection (non-viral HCC); chronic hepatitis C (HCC-HCV); chronic hepatitis B (HCC-HBV). Nivolumab dose levels for non-viral HCC and HCC-HCV patients are 0.3, 1, 3 and 10 mg/kg. HCC-HBV patients' dose escalation levels are 0.1, 0.3, 1, 3, and 10 mg/kg. Dose escalation will proceed independently in each arm (3+3 design). Nivolumab will be administered as a 1 hour infusion on days 1, 15, and 29 of each 6-week cycle for up to 2 years. In the dose expansion phase, 200 additional patients will receive nivolumab: 100 non-viral HCC and 50 HCC-HCV patients at the 3 mg/kg dose and 50 HCC-HBV patients at 3 mg/kg or the maximum tolerated dose. Primary endpoints are incidence of worst adverse events and incidence of clinical laboratory test abnormalities. Secondary endpoints include assessments of nivolumab antitumor activity, pharmacokinetics and immunogenicity.

ALFAPUMP® SYSTEM VERSUS LARGE VOLUME PARACENTESIS IN THE TREATMENT OF REFRACTORY ASCITES. A MULTICENTER RANDOMISED CONTROLLED STUDY

D. Adebayo[1], C. Bureau[2], D. Valla[3], M. Peck-Radosavljevic[4], A. McCune[5], V. Vargas[6], P. Angeli[7], S. Whittaker[8], R. Jalan[1]. *[1]UCL Institute of Hepatology, Royal Free Hospital, London, United Kingdom; [2]Service d'hépato-gastroentérologie, CHU Toulouse, Toulouse, [3]Hépatologie, Hôpital Beaujon, Clichy, France; [4]Dept. of Gastroenterology & Hepatology, Medizinische Universität Wien, Wien, Austria; [5]Department of Hepatology, Bristol Royal Infirmary, Bristol, United Kingdom; [6]Servei de M. Interna-Hepatologia, Hospital Vall d'Hebron, Barcelona, Spain; [7]Facoltà di Medicina e Chirurgia, Università degli Studi di Padova, Padova, Italy; [8]Clinical Affairs, Sequana Medical, Zurich, Switzerland*
E-mail: steve.whittaker@sequanamedical.com

Background and Aims: Refractory ascites (RA) develops in 10% of patients with advanced cirrhosis and is associated with poor prognosis. Management is large volume paracentesis (LVP) with albumin substitution. LVP severely affects quality of life, has a deleterious effect on nutrition, may be complicated by circulatory dysfunction and does not improve survival. TIPS (transjugular intrahepatic portosystemic shunt) is an alternative, but is associated with a high risk of hepatic encephalopathy and is contraindicated in advanced disease. A novel, implantable, programmable device (alfapump® system [AP] from Sequana Medical) moves ascites to the urinary bladder from where it is excreted naturally. The aim of this study is to compare AP and LVP in the management of RA in patients not suitable for TIPS.

Methods: Multi-center, open, RCT with RA & cirrhosis, randomised to AP or LVP. Follow-up is 12 months with a primary end-point of paracentesis-free survival (PFS). Secondary end-points include: cirrhosis-related complications, nutritional effects, quality of life, and survival. Exclusion criteria include: GI bleed ≤7 days, Serum Cr ≥2 mg/dl, platelet count <40,000, recurring SBP or UTI, loculated ascites, HCC (outside Milan criteria), and obstructive uropathy.

Data from a previous study (Pioneer) were used to estimate PFS for LVP and AP at 3 and 6 months post-implant. Sample size calculations were performed at a significance level of 5% and a power of 90%. Assuming a ratio of median PFS between groups is 2.5, for comparison at 3 months 60 subjects would be required, for comparison at 6 months 56 subjects would be sufficient.

Descriptive analysis will be performed for basal and post-basal measures. Variables will be described using means, medians, standard deviation, 95% confidence interval, minimum and maximum values. Changes will be analyzed using Student's t-test. In the case of variables with non-normal distribution, analysis will be done using nonparametric tests. The safety of the dispositive will be evaluated using a description of Serious Adverse Events.

Results: Table 1 summarises the trial activity across sites thus far.

Enrolment Target 60, Pre-screened 191, Consented 73, Screened 68, Screen Failures 14, Randomised 52, AP Group 24, LVP Group 27, Ongoing 18, Complete 10, Withdrawn 23, Lost to Follow-up 0.
Conclusions: The results of this trial are eagerly awaited and will provide the first randomised controlled evidence for the use of the AP as a possible treatment strategy for patients with RA.

P1320
EARLY EVEROLIMUS-BASED TACROLIMUS REDUCTION IN DE NOVO LIVER TRANSPLANT RECIPIENTS: DESIGN AND BASELINE DATA FROM HEPHAISTOS STUDY

B. Nashan[1], P. Schemmer[2], F. Braun[3], M. Dworak[4], P. Wimmer[4], H. Schlitt[5], for the Hephaistos study. *[1]Department of Hepatobiliary Surgery and Visceral Transplantation, University Medical Centre Hamburg-Eppendorf, Hamburg, Germany; [2]Department of General, Visceral and Transplant Surgery, University Hospital Heidelberg, Heidelberg, Germany; [3]Department of General Surgery and Thoracic Surgery, University Hospital SchleswigüHolstein, Kiel, Germany; [4]Novartis Pharma GmbH, Nürnberg, Germany; [5]Department of Surgery, University Hospital Regensburg, Regensburg, Germany*
E-mail: nashan@uke.de

Background and Aims: Everolimus (EVR) might provide protection against viral replication, malignancy, and progression of fibrosis, apart from preventing nephrotoxicity by facilitating calcineurin inhibitor (CNI; tacrolimus [TAC]) reduction. Here we present the design and baseline data from the Hephaistos study evaluating the beneficial effects of early initiation of EVR in *de novo* liver transplantation recipients (LTxR).
Methods: Hephaistos is a 12-month (mo), multi-centre, open-label, controlled study aiming to randomise 330 *de novo* LTxR (1:1 ratio; 7–21 days post-transplantation) to receive EVR (C0 3–8 ng/mL) with reduced (r) TAC (C0 <5 ng/mL), or standard (s) TAC (C0 6–10 ng/mL) (Figure). Patients will receive induction therapy, mycophenolate mofetil, TAC, and corticosteroids as per local practice during run-in period. Randomisation is stratified by HCV status and lab MELD scores at transplantation. The primary objective of the study is to exhibit superior eGFR (MDRD-4 formula) with EVR+rTAC vs sTAC at month 12. Secondary objectives are to assess: the incidence of composite of treated biopsy proven acute rejection (tBPAR), graft loss, or death; the incidences of components of the composite efficacy endpoint; renal function by eGFR using various formulae (MDRD4, Nankivell, Cockcroft–Gault, CKD-EPI and Hoek formulae); incidence of proteinuria; incidence of AEs and serious AEs; incidence and severity of CMV and HCV infections and HCV-related fibrosis.

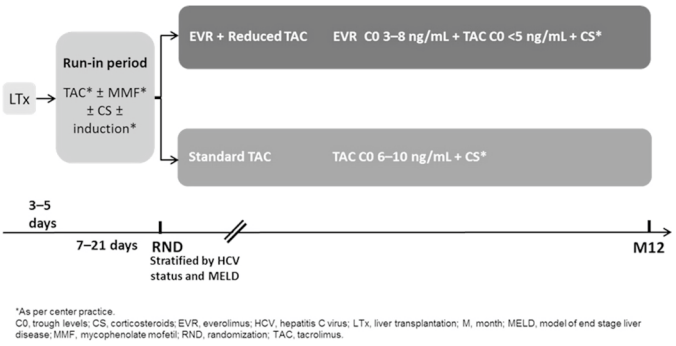

Figure: Hephaistos Study design.

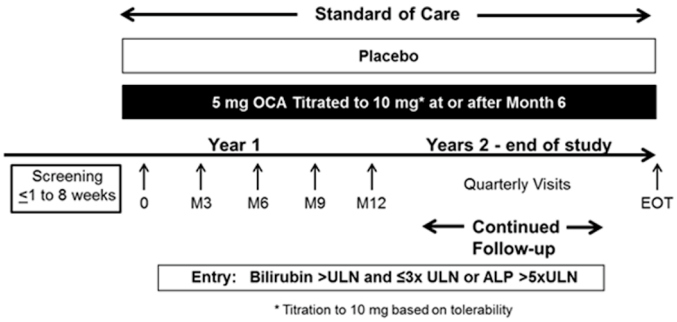
Results: Hephaistos is an ongoing study recruiting LTxR at 15 centres across Germany. Currently 359 LTxR are screened and of these 156 patients are randomized (78 in each arm). At baseline, mean age (54.04 vs 54.21), male gender (77.8% vs 62.5%), Caucasian (100% vs 95.8%) and mean BMI (26.01 vs 26.81) were similar in EVR+rTAC and sTAC regimens respectively.

Conclusions: Hephaistos study aims to demonstrate benefits of early initiation of EVR+rTAC vs sTAC regimen by evaluating the renal function, efficacy, and safety particularly from recurrence of HCC, HCV and CMV.

P1321
A PHASE 3B, DOUBLE BLIND, PLACEBO CONTROLLED STUDY EVALUATING THE EFFECT OF OBETICHOLIC ACID ON CLINICAL OUTCOMES IN SUBJECTS WITH PRIMARY BILIARY CIRRHOSIS AT ELEVATED RISK OF PROGRESSION TO LIVER TRANSPLANT OR DEATH

K. Lindor[1,2], B. Hansen[3], R. Pencek[4], R. Hooshmand-Rad[4], T. Marmon[4], L. MacConell[4], D. Shapiro[4], D. Jones[5]. *[1]Dept of Gastroenterology and Hepatology, Mayo Clinic, Rochester, [2]Arizona State University, Phoenix, United States; [3]Gastroenterology and Hepatology, Erasmus MC University Medical Center, Rotterdam, Netherlands; [4]Clinical Development, Intercept Pharmaceuticals, Inc., San Diego, United States; [5]Institute of Cellular Medicine, Newcastle University, Newcastle-upon-Tyne, United Kingdom*
E-mail: rpencek@interceptpharma.com

Background and Aims: Primary biliary cirrhosis (PBC) is an autoimmune cholestatic liver disease that leads to cirrhosis, transplantation and/or death. While transplant-free survival is the best demonstration of clinical benefit, slow disease progression makes this end point challenging. The hepatobiliary damage and secondary loss of function with PBC is reflected by increased plasma alkaline phosphatase (ALP) and bilirubin, respectively, which correlate with disease progression (Lammers 2014). Obeticholic acid (OCA) is in late-phase development for PBC. In the POISE trial after 12 months of OCA therapy, 46% [OCA Titration] and 47% [OCA 10 mg] of subjects met the primary composite endpoint of ALP <1.67×ULN *and* ≥15% ALP reduction *and* normal bilirubin compared to 10% of placebo subjects. This ongoing confirmatory Phase 3b study will evaluate OCA compared to placebo, standard of care continued, on major clinical outcomes.
Methods: 350 subjects with PBC at elevated risk for complications based on event rate predictions from the Global PBC group defined as ALP >5×ULN or bilirubin >ULN to ≤3×ULN will be randomized 1:1 to OCA or placebo. OCA dosing will initiate at 5 mg and after 6 months titrated to 10 mg based on tolerability. Given the inherent difficulties of a long-term placebo-controlled study in a rare disease both a placebo and a historical control are included. Total treatment duration is determined by the time to accrue the needed number of total primary events with a minimum 6 year follow-up expected. Should event rate accrual prove unfeasible due to challenges (enrollment or retention), randomization will stop and eligible subjects enrolled in open-label OCA treatment and comparisons made to matched historical controls.



EOT = end of treatment; M = month; UDCA = ursodeoxycholic acid; ULN = upper limit of normal

Figure 1. Schematic diagram, Study 747-302.

Results: The primary composite endpoint includes: death; liver transplant; model of end stage liver disease (MELD) score ≥15; hospitalization (defined by stay ≥24 hours) for new onset or

recurrence of: variceal bleed; encephalopathy; spontaneous bacterial peritonitis; uncontrolled ascites; hepatocellular carcinoma. 121 events provides 80% power to demonstrate a significant difference between OCA and placebo on time to liver-related outcomes, including all-cause mortality.
Conclusions: This study is designed to confirm the clinical benefit of OCA when added to standard of care. The design integrates a specific PBC patient population, event rate estimates, and end points from recent studies that correlate liver biochemistry with clinical outcomes.

P1322
CONTRAST (SONZOID)-ENHANCED US AS A SCREENING TOOL FOR HEPATOCELLULAR CARCINOMA IN CIRRHOSIS: AN EXPLORATORY CLINICAL TRIAL (SCAN TRIAL)

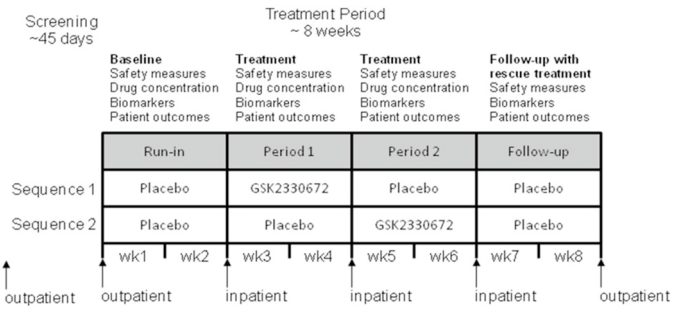
M.-S. Park, J. Park[1], S. Lee[2], W. Chung[3], J. Lee[1]. *[1]Radiology, Seoul National University, [2]Radiology, Asan medical center, [3]Radiology, Samsung medical center, Seoul, Korea, South*
E-mail: radpms@yuhs.ac

Background and Aims: US has been used as the standard examination for HCC surveillance for it's noninvasiveness, convenience, and relatively lower price. However, the detection rate of early-stage HCC is low (63% of sensitivity), and more optimal surveillance tool is required to upgrade the detection rate while maintaining advantages of the US. Sonazoid, a recently developed new US contrast agent, enables not only the vascular phase imaging but also the Kupffer phase imaging with long-time window up to 3 hours. Several papers reported that Sonazoid is effective in characterizing focal liver lesions, grading histologic differentiation of HCC, guiding radiofrequency ablation or operation, and detecting small HCCs. However, it has not been generally implemented as a surveillance tool.
This study aimed to investigate the detection rate of early-stage HCC (BCLC 0/A) and the false referral rate when the Sonazoid contrast-enhanced US is used as a screening test in the high-risk group of HCC and to compare B-mode US and Sonazoid-US by intra-individual comparison.
Methods: This is a prospective, multi-center, explanatory, single group clinical trial to sound out the possibility prior to the fully randomized assessment study on the efficiency of the Sonazoid contrast-enhanced US in the HCC screening (NCT02188901). The patients fulfilling the following eligibility criteria will be included: (1) The high-risk group of the HCC scheduled to take the surveillance ultrasonography; (2) No prior HCC; (3) Cirrhosis related to HBV, HCV, and stage 4 primary biliary cirrhosis; (4) No contradiction to Sonazoid. The subjects will undergo the routine surveillance program (B-mode US) as planned and then kupffer phase image will be obtained between 10 and 30 minutes after the Sonazoid injection. The Liver US reporting and data system will be additionally prepared and implemented.
To obtain 80% statistical power with a 2-sided α equal to 0.05 and 10% drop-out rate, under the assumption of HCC incidence at very high risk group= 5%, sensitivity of G-US=63%, sensitivity of S-US=94%, 2262 patients per group are needed for a randomized controlled trial. In this exploratory trial, we will enroll 20% of S-US group (452 patients).
Results: In progress.
Conclusions: In progress.

P1323
A STUDY TO EVALUATE THE SAFETY, TOLERABILITY, PHARMACOKINETICS AND PHARMACODYNAMICS OF REPEAT DOSES OF GSK2330672 ADMINISTRATION IN SUBJECTS WITH PRIMARY BILIARY CIRRHOSIS AND SYMPTOMS OF PRURITUS

V.S. Hegade[1], S. Kendrick[1,2], R. Dobbins[3], J. Storey[2], S.R. Miller[2], G.F. Mells[4], G. Alexander[5], G. Hirschfield[6], D.E. Jones[1], on behalf of UK-PBC Consortium. *[1]Institute of Cellular Medicine, Newcastle University, Newcastle, [2]GSK Medicines Research Centre, Stevenage, United Kingdom; [3]GlaxoSmithKline (GSK), Research Triangle Park, NC, United States; [4]Academic Department of Medical Genetics, University of Cambridge, [5]Hepatology, Addenbrooke's Hospital, Cambridge, [6]Centre for Liver Research, Institute of Biomedical Research, University of Birmingham, Birmingham, United Kingdom*
E-mail: vinod.hegade@ncl.ac.uk

Background and Aims: Pruritus is a common symptom of cholestatic liver diseases such as primary biliary cirrhosis (PBC). There is a strong need for newer, safe and effective treatments for cholestatic pruritus. Bile acids have been proposed as potential pruritogens in cholestatic diseases. The ileal bile acid transporter (iBAT) expressed in the distal ileum, plays a key role in the enterohepatic circulation of bile acids. Pharmacological inhibition of iBAT is expected to interrupt enterohepatic recirculation, reduce bile acid concentrations in the liver and systemic circulation, resulting in improvement in pruritus.
The aims of this study are to administer oral GSK2330672 for 14 days to patients with PBC treated with ursodeoxycholic acid (UDCA) to: (1) investigate the safety and tolerability compared with placebo, (2) evaluate the effects on subjects' experience of pruritus, (3) evaluate effect on total serum bile acid concentrations and serum markers of bile acid synthesis and (4) study the effect on steady-state pharmacokinetics of UDCA. Additional exploratory analyses will be performed to identify potential biomarkers associated with PBC symptoms.
Study design: This is a UK multicentre, phase II, randomized, double-blind, placebo-controlled crossover trial recruiting patients with PBC and symptoms of pruritus. Patients must be on stable dose of UDCA or have demonstrated intolerance to UDCA. The total duration of subject participation will be up to 14 weeks. The participating centres include Newcastle, Birmingham and Cambridge.
The main inclusion criteria are: (1) male or female aged 18–75 years, (2) proven or likely PBC [based on serum alkaline phosphatase (AP), serology and/or liver biopsy], (3) screening AP value <10× upper limit of normal (ULN), (4) severe symptoms of pruritus that significantly impact daily life and have proven refractory after at least one previous therapy or unresolved symptoms with use of a single antipruritic agent or seeking treatment for pruritus that is newly diagnosed or previously untreated.



The Figure shows the study design. Eligible patients will participate in a 2-week placebo run-in period to assess compliance with study procedures and to record baseline symptoms on electronic diaries. Subjects will be randomized in a crossover fashion (Sequence 1/

Sequence 2) to receive placebo or GSK2330672 treatment during two consecutive 2-week study periods.

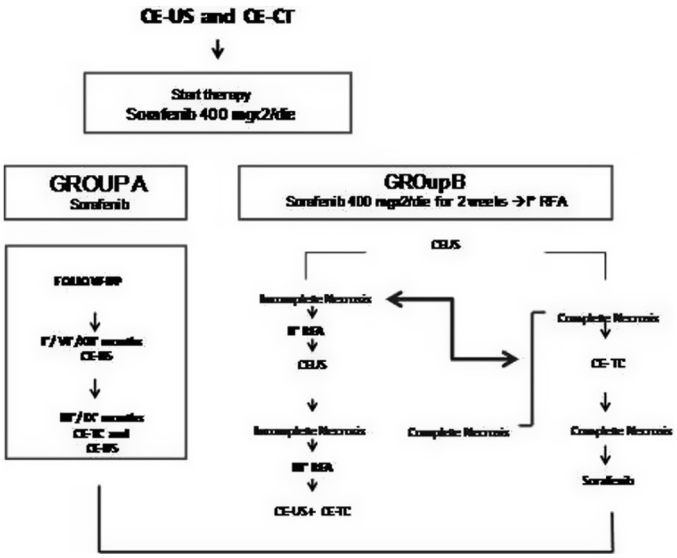
THE HOME STUDY (HOME MONITORING IN ENCEPHALOPATHY): RATIONALE AND STUDY DESIGN
J.G. Orr[1,2], M. Hudson[1,2], C.J. McNeil[1], D.E. Jones[1]. [1]*Instiute of Cellular Medicine, Newcastle University,* [2]*Liver Unit, Freeman Hospital, Newcastle upon Tyne, United Kingdom*
E-mail: james.orr@ncl.ac.uk

Background and Aims: Overt Hepatic Encephalopathy (HE) affects 30–45% of patients with cirrhosis. It is associated with severely impaired Health Related Quality of Life (HRQOL), likely impacted by the unpredictability of relapses and high hospital admission rates. First line treatment is usually with the non-absorbable disaccharide lactulose, however compliance with this drug can be poor. A system enabling home monitoring and remote management of HE has been developed as part of the EC FP7 project, d-LIVER. The HoME study is a pilot study of this system, primarily addressing patient acceptability.
Methods: A system was developed including software to be used by patients on a 10′ tablet-PC at home with wireless connectivity to the hospital. An electronic Number Connection Test (eNCT), based on the established paper NCT, and a stool frequency enquiry are carried out daily. Based on these parameters lactulose dosage is adjusted, if necessary. When there is evidence of deterioration despite appropriate treatment the health professional is alerted to take further action.
Results: Normative data for the eNCT showed a close correlation between the paper-based NCT and the eNCT (Pearson's 0.724, $p < 0.005$). The HoME study will include 20 patients aged 18 years or older with cirrhosis who have had an inpatient admission with overt HE, treated with lactulose. Patients are recruited while inpatients and require to have capacity to provide written informed consent. All patients undergo formal psychometric testing for HE at baseline [including the Psychometric Hepatic Encephalopathy Score (PHES)]. Patients are randomised to 6 months of management directed either by the new system or by the current standard of care (10 patients in each). Patients in the home monitoring group are asked to complete the eNCT and stool frequency enquiry daily with the primary outcome measure being patient acceptability at two, four and six months. Secondary outcome measures in the home monitoring group are completion rate and rate of change of therapy. In addition, HRQOL data (SF-36, SFLDQOL, PBC-40), health economics data, admission rates and HE recurrence rates are collected in both groups.
Conclusions: The HoME study evaluates the d-LIVER system for home monitoring in HE for the first time. The primary outcome is patient acceptability. Secondary outcomes, such as HRQOL and readmission rates, are unlikely to reach statistical significance in this study, but will inform the design of future larger scale trials of the system.

P1325
EFFICACY AND SAFETY OF COMBINED SEQUENTIAL TREATMENT WITH RFA AND SORAFENIB IN PATIENTS WITH HCC IN INTERMEDIATE STAGE INELIGIBLE FOR TACE: A PROSPECTIVE RANDOMIZED OPEN STUDY
G. de Stefano[1], V. Iodice[1], G. Signoriello[2], U. Scognamiglio[1], N. Farella[1]. [1]*AORN Ospedali dei Colli, Napoli,* [2]*SUN Napoli – Dipartimento Salute Mentale, Servizio Statistica Medica, Naples, Italy*
E-mail: giordest1@virgilio.it

Background and Aims: TACE is the gold standard for intermediate hepatocellular carcinoma (BCLC-B, HCC). Patients (pts) who have contraindications or are not eligible to TACE are candidates for sorafenib. Aim of the present study is to verify the efficacy and safety of a combined treatment Sorafenib + radiofrequency ablation (RFA) in patients with intermediate HCC (BCLC-B) not eligible to TACE.
Methods: The present prospective randomized open-label study is expected to enroll 124 pts with BCLC-B, HCC (3–5 HCCs nodules ≥3 cm ≤5 cm), Child–Pugh A, age <80 years, not eligible to TACE or who refused TACE and were not eligible for surgical resection. Pts will be randomized 1:1 into two treatment arms: Group A, sorafenib (800 mg/day); Group B, combined sequential treatment sorafenib + RFA. Group B will start sorafenib for 2 weeks; then sorafenib is stopped from the 15th to the 19th day, to allow RFA scheduled on the 17th day. Pts will undergo CEUS to assess the extent of necrosis and withdrawals chemistry 24 hours after RFA. In case of incomplete necrosis, two days after RFA, pts will start again sorafenib at full dose for 11 days; then suspend the molecule two days before the II sitting RFA and resume it after only two days from the procedure itself (possible up to 3 sessions of RFA, in each session will be treated maximum 2 nodules or a single nodule up to 5 cm size). Seven days after the last RFA therapeutic efficacy will be evaluated with CEUS and three-phase contrast-enhanced (CE) spiral CT. In case of complete necrosis, pts will resume sorafenib two days after the RFA. The therapeutic efficacy will be evaluated in Group A and in Group B with CE-CT and CE-US 3 months after the start of treatment. The primary endpoint was overall survival. Secondary objectives: validation of CEUS in the evaluation of treatment efficacy RFA; safety and efficacy of the combination Sorafenib + RFA in pts with HCC BCLC-B. Sample size has been calculated by assuming a proportion of survival after 16 months of 50% in arm A and 75% in arm B, with a predicted percentage of drop-out of 5%. The time of expected enrollment is 12 months to make a comparison with the log rank test, with an α error of 0.05 and a power of 80%. Forty events are needed equal to a total sample size of 124 patients (62 patients per treatment group). Randomization will be performed with a list of *a priori* sample prepared in sealed envelopes opaque.
EuDRACT number: 2014–003925–16. Protocol Code Number: 054.



P1326

PASIREOTIDE IN ADDITION TO ASPIRATION SCLEROTHERAPY TO IMPROVE TREATMENT OF LARGE SYMPTOMATIC HEPATIC CYSTS: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL

T.F. Wijnands[1], T.J. Gevers[1], L.J. Schultze Kool[2], J.P. Drenth[1].
[1]*Gastroenterology and Hepatology,* [2]*Radiology, Radboud University Medical Center, Nijmegen, Netherlands*
E-mail: titus.wijnands@radboudumc.nl

Background and Aims: Aspiration sclerotherapy (AS) is a therapeutical option for large symptomatic hepatic cysts. However, inadequate cyst reduction following AS is frequently reported. Strong post-procedural cyst fluid secretion by cholangiocytes, lining the epithelium of the hepatic cyst, seems to be associated with lower reduction rates. Previous studies showed that somatostatin analogues curtail cyst cholangiocyte fluid production. We hypothesize that combining the long-acting somatostatin analogue pasireotide (SOM230) with AS will decrease post-procedural fluid reaccumulation resulting in more effective hepatic cyst reduction.

Methods: This is a single center, randomized, double-blind, placebo-controlled clinical trial. Patients with a large (>5 cm) symptomatic hepatic cyst are eligible for inclusion. A total of 34 patients will be randomized in a 1:1 ratio. All patients will undergo AS, comprising percutaneous cyst aspiration followed by instillation of 100% ethanol (ratio of 10%, never exceeding 50 mL) for 10 minutes. In the active arm, patients receive a pasireotide 60 mg injection two weeks prior and two weeks following AS. Controls receive placebo injections at corresponding intervals. Primary endpoint is the proportional cyst diameter reduction four weeks after AS measured by ultrasonography. Diameter reduction at 12 and 24 weeks after AS will be measured as secondary outcomes. Symptomatic relief will be assessed with a standardized, 7-point scale questionnaire and health-related quality of life will be evaluated using the generic short-form health survey (SF-36). Finally, safety and tolerability will be assessed.

Results: Registration: ClinicalTrials.gov: NCT02048319, January 6, 2014; EudraCT: 2013–003168–29, August 16, 2013

Conclusions: In this trial we investigate the additional effect of pasireotide to AS. By curtailing post-procedural cholangiocyte fluid reaccumulation we aim to optimize efficacy of cyst regression ultimately leading to better symptomatic relief and reduced recurrence rates.

P1327

ATTIRE: ALBUMIN TO PREVENT INFECTION IN CHRONIC LIVER FAILURE

L. China[1], J. Fullerton[1], M. George[1], S. Skene[1], Z. Shabir[1], D. Gilroy[1], A. O'Brien[1], on behalf of the ATTIRE Study Investigators. [1]*University College London, London, United Kingdom*
E-mail: louise.china@ucl.ac.uk

Background and Aims: Patients with cirrhosis are at a greatly increased risk of severe bacterial infection with survival directly related to extra-hepatic organ dysfunction. A defective innate immune response is considered to underlie this risk. There is however no medical strategy to restore immune competence in these patients.

Elevated circulating Prostaglandin E_2 (PGE_2) levels contribute to immune suppression in acutely decompensated (AD) cirrhosis. PGE_2 is more bioavailable because of decreased serum albumin levels in AD patients as albumin binds PGE_2. The binding capacity of endogenous albumin is also known to be defective in cirrhosis. Human Albumin Solution (HAS), a safe and common intervention, could thus be repurposed as an immune restorative drug in AD patients.

The primary aim of ATTIRE is to determine if raising serum albumin to >30 g/L in patients with decompensated cirrhosis will decrease rates of infection, extra hepatic organ dysfunction and death.

Methods: All patients admitted to hospital with acute onset or worsening of complications of cirrhosis, 18–75 years old, predicted hospital admission >5 days, serum albumin <30 g/L, randomised within 72 hours of hospital admission.

Exclusion Criteria: HIV, advanced HCC, predicted survival <48 hrs, severe cardiac dysfunction.

Stage 1 is a feasibility study (n = 80). All patients will be given daily 20% HAS according to a suggested protocol dependent on serum albumin. This will determine if patient's serum albumin can be maintained at >30 g/L.

Stage 2 is a multicenter open label randomised controlled trial (n = 880). Patients will be randomised to daily 20% HAS to target a serum albumin of 35 g/L OR standard of care for maximum of 14 days.

The composite primary endpoint within the intervention period has 3 components:

1. Noscomial Infection indicated by any new (or change in) prescribed antibiotics.
2. Extra Hepatic Organ Dysfunction.
   - RENAL: Serum creatinine increases by ≥50% compared to randomization value
   - CEREBRAL: Development of grade III or IV encephalopathy (Westhaven criteria)
   - CIRCULATORY: Decrease in MAP to <60 mmHg or initiation of inotropic support
   - RESPIRATORY: any single point increase in SpO_2/FiO_2 ratio in defined criteria
3. Death.

Conclusions: ATTIRE is a large UK multicenter RCT that will evaluate the impact of albumin on rates of infection, extrahepatic organ dysfunction and death in AD patients. EudraCT 2014-002300-24. Visit www.attiretrial.com for more information.

P1328

RITPBC: B-CELL DEPLETING THERAPY (RITUXIMAB) AS A TREATMENT FOR FATIGUE IN PRIMARY BILIARY CIRRHOSIS: STUDY PROTOCOL FOR A RANDOMISED CONTROLLED TRIAL

L. Jopson, J.L. Newton[1], D. Howel[2], J. Palmer[3], J. Isaacs[3], J. Qian[4], J. Wilkinson[4], A. Blamire[3], A. Floudas[3], D.E. Jones[3]. [1]*Institute of Health and Ageing,* [2]*Institute of Health and Society,* [3]*Institute of Cellular Medicine,* [4]*Newcastle Clinical Trials Unit, Newcastle University, Newcastle, United Kingdom*
E-mail: laura.jopson@ncl.ac.uk

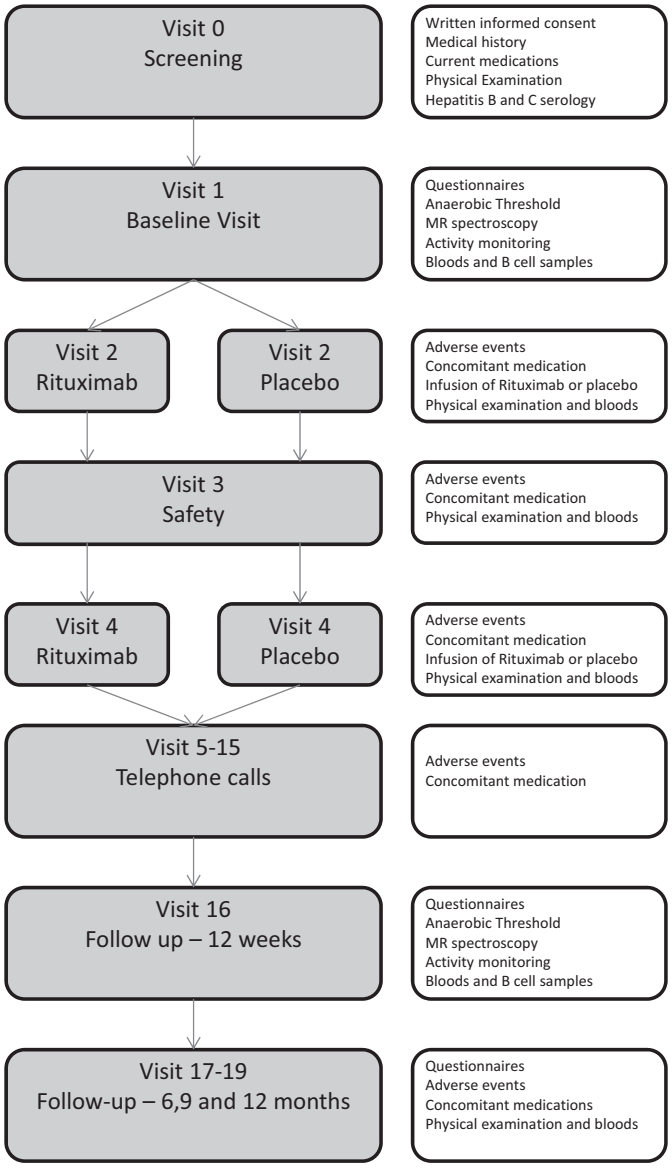
Background and Aims: Primary Biliary Cirrhosis (PBC) is an autoimmune liver disease with 45% of patients experiencing clinically significant fatigue. Fatigue often has a negative impact on quality of life, particularly when it results in social isolation. Fatigue is highlighted by patients as a priority for research and patient support groups were involved in the design and development of this trial. Mechanistic studies have led to the hypothesis that AMA and its activity against PDC results in muscle bio-energetic abnormalities by over-utilisation of anaerobic pathways. B-cell depleting agents could therefore be a potential treatment for fatigue in PBC. Pilot studies of Rituximab have shown an improvement in fatigue but were powered for biochemical endpoints rather than symptoms.

Methods: RITPBC is an MRC and NIHR Efficacy and Mechanism Evaluation Programme (EME) funded project. It is a phase II, single-centre, randomised controlled, double blinded trial comparing Rituximab with placebo in fatigued Primary Biliary Cirrhosis patients. 78 patients with PBC and clinically significant fatigue will be randomised to receive two infusions of Rituximab or placebo. Fatigue severity will be assessed by the PBC-40, a patient-derived, disease specific, fully validated, quality of life measure.

The trial aims to assess whether Rituximab improves fatigue in PBC, the safety and tolerability and the sustainability of any beneficial actions. The primary outcome will be an improvement in fatigue

domain score of the PBC-40 evaluated at 12 weeks. Secondary outcome measures include novel MRI techniques to assess muscle bioenergetic function, physical activity, anaerobic threshold, liver biochemistry and quality of life measures.

Conclusions: This is a landmark trial as it is the first randomised controlled trial to investigate a therapeutic agent as a treatment for fatigue in PBC. The protocol describes a model for fatigue trials including trial endpoints and sample size calculations which will be transferrable to future trials of fatigue both in PBC and in other disease areas. The trial protocol is innovative as it utilises novel MRI techniques as an outcome measure. Recruitment strategies utilising the UK-PBC MRC trials platform have been implemented in RITPBC, these methods have the potential to revolutionise the way trials are conducted in rare diseases. Recruitment started in October 2012 and to date, 38 patients have been recruited, making it the largest biologicals trial in liver disease.



P1329

A PLACEBO CONTROLLED SINGLE CENTRE DOUBLE BLIND RANDOMISED TRIAL TO INVESTIGATE THE EFFICACY OF RIFAXIMIN IN IMPROVING SYSTEMIC INFLAMMATION AND NEUTROPHIL MALFUNCTION IN PATIENTS WITH CIRRHOSIS AND CHRONIC HEPATIC ENCEPHALOPATHY ('RIFSYS')

V.C. Patel[1], D.L. Shawcross[1]. [1]*Institute of Liver Studies, King's College London School of Medicine at King's College Hospital Foundation NHS Trust, London, United Kingdom*
E-mail: vishal.patel@nhs.net

Background and Aims: Hepatic encephalopathy (HE) is a devastating complication of cirrhosis which portends a poor prognosis without liver transplantation. It results from a dysfunctional gut–liver–brain axis and historically therapies have primarily targeted gut ammonia metabolism. The non-absorbable gut-selective antibiotic rifaximin-α is efficacious in chronic HE reducing recurrent overt episodes and improving cognitive function in minimal HE. Rifaximin-α has broad antimicrobial spectrum and may inhibit division of urea-deaminating bacteria, thereby reducing gut ammonia production. However, recent studies have failed to demonstrate a convincing reduction in blood ammonia and the specific mechanism of action of rifaximin-α has yet to be elucidated. Neutrophil dysfunction is recognised in cirrhosis as predisposing to infection and organ dysfunction, and may also have a more direct pathogenic role in HE. A therapeutic strategy utilizing rifaximin-α to modulate gut bacteria could potentially lower gut-derived systemic inflammation, endotoxemia, neutrophil dysfunction, and organ dysfunction improving outcomes and prolonging transplant-free survival.

Methods: An investigator-initiated randomised placebo-controlled single centre double blind study [ClinicalTrials.gov ref: NCT 02019784] has therefore been designed to examine the impact of rifaximin-α 550 mg (TARGAXAN) bid for 90 days on parameters of immune and gut dysfunction in patients with liver cirrhosis experiencing chronic HE. Patients with cirrhosis presenting with chronic persistent overt HE (≥ grade 1) or with ≥2 episodes of overt HE in the previous 6 months will be recruited.

Primary end point: To test if rifaximin-α reduces neutrophil spontaneous oxidative burst *ex vivo* in patients with cirrhosis and chronic HE after 30 days.

Secondary end points: To test if rifaximin-α reduces the development of systemic inflammation, organ failure and improves survival over 90 days. This will include analyses for intestinal permeability and microbiota, alterations in faecal biomarkers, plasma and urine metabolic profiling, markers of bacterial translocation (blood bacterial DNA quantification) and neutrophil dysfunction (including toll-like receptor 4 expression). 50 participants will be randomised on 1:1 basis to either Rifaximin-α or placebo with 90 days treatment duration with assessments at baseline (day 0) prior to initiation of medication, 30 and 90 days.

Results: Trial recruitment closes Nov 2015 with anticipated publication of data mid-2016.

P1330

HIGH DOSE STEROIDS VERSUS INTRAVENOUS IMMUNOGLOBULIN PLUS STEROIDS IN OPERATED BILIARY ATRESIA PATIENTS

T.Y. Abdelghaffar[1], A.A. Eldesokey. [1]*Pediatric Hepatology, Ainshams University – Pediatric Hospital, Cairo, Egypt*
E-mail: megoo78@gmail.com

Introduction: Biliary atresia (BA) is the most prevalent cause of liver-related death in children and the most frequent indication for liver transplantation in the pediatric population. Recently, Davenport et al. found that the use of prednisolone significantly improved early post-operative liver biochemistry (especially at the higher dose), and increased the proportion of infants who cleared their jaundice at 6 months post-KPE.

The actual primary target(s) of IVIG in autoimmune disease are still unclear. IVIG may work via a multi-step model where the injected IVIG first forms a type of immune complex in the patient (Clynes, 2005). Once these immune complexes are formed, they interact with activating Fc receptors on dendritic cells which then mediate anti-inflammatory effects helping to reduce the severity of the autoimmune disease or inflammatory state (Siragam et al., 2006). IVIG may also regulate the immune response by reacting with a number of membrane receptors on T cells, B cells, and monocytes *that are pertinent to autoreactivity and induction of tolerance to self* (Bayry et al., 2003).

Aim: Evaluating the effect of administrating IV IG plus high dose steroids post-KP on the outcome of operated BA patients and comparing it with the use of post-KP high dose steroids alone.

Methods: The study population consists of two main groups:

Group A: This group will include 30 post-KP BA patients and this group will be given oral prednisolone on the following regimen: On day 5–9 postoperative, prednisolone 5 mg/kg/day. On day 10–14 postoperative, prednisolone 4 mg/kg/day. On day 15–19 postoperative, prednisolone 3 mg/kg/day. On day 20–24 postoperative, prednisolone 2 mg/kg/day. On day 25–29 postoperative, prednisolone 1 mg/kg/day. On day 30–32 postoperative, hydrocortisone 2.5 mg/kg/dose twice daily. On day 33–35 postoperative, hydrocortisone 2.5 mg/kg/dose once daily.

Group B: This group will include 30 post-KP BA patients and this group will be given oral prednisolone on the same previous regimen plus two doses of IV IG 1 g/kg/dose on day 1 and 30 postoperative.

According to the one year postoperative outcome, patients will be classified into two groups: good outcome group (well colored stool and total bilirubin <2.0 mg/dL) and bad outcome group (persistent clay-colored or pale stool, rapidly progressive disease, the incidence of death due to the liver disease or total bilirubin ≥2 mg/dL).

P1331

PHASE 3B STUDIES TO ASSESS LONG-TERM CLINICAL OUTCOMES IN HCV GT1-INFECTED PATIENTS TREATED WITH OMBITASVIR/PARITAPREVIR/RITONAVIR AND DASABUVIR WITH OR WITHOUT RIBAVIRIN

E.O. Dumas[1], J. Enejosa[1], G. Ball[1], Y.B. Hu[1], M. Co[1], R. Kumar Pothacamury[1], Y. Liu[1], N. Shulman[1], T. Podsadecki[1]. [1]*AbbVie Inc., North Chicago, United States*
E-mail: douglas.dylla@abbvie.com

Background and Aims: Curing HCV infection has been demonstrated to reduce the risk of progression to cirrhosis, liver decompensation, hepatocellular carcinoma (HCC), and mortality. The objectives of these phase 3b studies are to evaluate the effect of sustained virologic response at post-treatment week 12 (SVR12) on the progression of liver disease for 5 years following treatment with the interferon (IFN)-free three direct-acting antiviral (3D) regimen of ombitasvir/paritaprevir (identified by AbbVie and Enanta, co-administered with ritonavir) and dasabuvir with or without ribavirin (RBV) in HCV genotype (GT) 1-infected patients.

Methods: TOPAZ-I and -II are phase 3b, open-label, non-randomized, multicenter trials will enroll approximately 2250 patients (pts): 1650 pts from about 200 sites representing 29 countries outside the United States (TOPAZ-I; NCT02219490), and approximately 600 pts from roughly 50 sites in the United States (TOPAZ-II; NCT02167945). Study participants will include HCV GT1-infected pts with or without prior IFN/RBV treatment experience, including pts with compensated cirrhosis. Patients with GT1b infection and no cirrhosis will receive the 3D regimen without RBV for 12 weeks; GT1b pts with cirrhosis will receive 3D+RBV for 12 weeks. Patients with GT1a infection without cirrhosis and GT1b pts with cirrhosis will receive 3D+RBV for 12 weeks. Patients with GT1a infection will be treated with 3D+RBV for 12–24 weeks. Broad inclusion criteria will allow enrollment of pts with no upper limit on age, BMI, or ALT/AST levels and include pts with creatinine clearance ≥30 mL/min, albumin ≥2.8 g/dL, and platelet count ≥25,000 cells/mm^3.

TOPAZ-I and -II share a primary endpoint evaluating the effect of SVR12 on the incidence of all-cause death, liver-related death, liver decompensation, liver transplantation, HCC, and the composite of any of these clinical outcomes. Additional endpoints include: the percentage of pts achieving SVR12 for each study ITT population; long-term liver fibrosis progression measured by transient elastography (TOPAZ-I only); mean change from baseline in patient-reported quality of life and fatigue assessed by the SF-36v2 survey and FACIT-F questionnaire, respectively; and adherence to study drugs during the treatment period (TOPAZ-II only). Safety and tolerability will be assessed by monitoring adverse events, physical examinations, clinical laboratory tests, and vital signs.

P1332

THE ASTRAL STUDIES: EVALUATION OF SOF/GS-5816 SINGLE TABLET REGIMEN FOR THE TREATMENT OF GENOTYPE 1–6 HCV INFECTION

T. Asselah[1], M. Charlton[2], J. Feld[3], G.R. Foster[4], J. Mcnally[5], D.M. Brainard[5], J.G. McHutchison[5], A. Mangia[6], M. Sulkowski[7], S. Zeuzem[8]. [1]*University Paris Diderot, INSERM U773, Paris, France;* [2]*Intermountain Medical Center, Murray, United States;* [3]*Toronto Western Hospital, Toronto, Canada;* [4]*Queen Mary University of London, London, United Kingdom;* [5]*Gilead Sciences, Inc., Foster City, United States;* [6]*Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Italy;* [7]*Johns Hopkins University, Baltimore, United States;* [8]*Johann Wolfgang Goethe University, Frankfurt, Germany*
E-mail: john.mcnally@gilead.com

Background and Aims: GS-5816 is a second-generation NS5A inhibitor that has potent in vitro antiviral activity across all HCV genotypes. The co-administration of sofosbuvir (SOF) and GS-5816 for 12 weeks without ribavirin (RBV), was well-tolerated and resulted in high SVR12 in patients with genotype 1–6 HCV infection in Phase 2 studies.

Methods: The Phase 3 ASTRAL program comprises 4 clinical studies evaluating the safety and efficacy of treatment with a fixed dose combination (FDC) of SOF/GS-5816 (400 mg/100 mg) in patients with genotype 1–6 HCV infection, including including those with prior treatment failure and cirrhosis, and also patients with decompensated cirrhosis.

Results: The ASTRAL-1 study (NCT02201940) is a double-blind, placebo-controlled study that will randomize 600 treatment-naïve and treatment-experienced patients with and without compensated cirrhosis with genotype 1–6 HCV infection in a 5:1 ratio to SOF/GS-5816 or placebo for 12 weeks. The study is being conducted at 81 sites in Belgium, Canada, France, Germany, Hong Kong, Italy, United Kingdom and the United States.

The ASTRAL-2 study (NCT02220998) is an open-label, active-comparator study that will randomize 240 treatment-naïve and treatment-experienced patients with and without compensated cirrhosis with genotype 2 HCV infection (1:1) to SOF/GS-5816 for 12 weeks or SOF+RBV for 12 weeks. The study is being conducted at 51 sites in the United States.

The ASTRAL-3 study (NCT02201953) is an open-label, active-comparator study that will randomize 500 treatment-naïve and treatment-experienced patients with and without compensated cirrhosis with genotype 3 HCV infection (1:1) to SOF/GS-5816 for 12 weeks or SOF+RBV for 24 weeks. The study is being conducted at 76 sites in Australia, Canada, France, Germany, Italy, New Zealand, United Kingdom and the United States.

The ASTRAL-4 study (NCT02201901) is an open-label study that will randomize 225 patients with genotype 1–6 HCV infection with Child–Pugh–Turcotte (CPT) class B cirrhosis (1:1:1) to SOF/GS-5816 for 12 weeks, SOF/GS-5816+RBV for 12 weeks or SOF/GS-5816 for 24 weeks. The study is being conducted at 50 sites in the United States.

Conclusions: The ASTRAL clinical program will evaluate SOF/GS-5816 in more than 1000 patients with genotype 1–6 HCV infection including patients with advanced liver disease. If successful, SOF/GS-5816 will provide a simple, highly effective, well tolerated, pangenotypic single tablet regimen (STR) for the treatment of HCV infection globally.

P1333
A RANDOMIZED, DOUBLE-BLIND STUDY OF THE EFFECTS OF OMEGA-3 FATTY ACIDS (OMEGAVEN™) ON OUTCOME AFTER MAJOR LIVER RESECTION

M. Linecker[1], P. Limani[1], F. Botea[2], I. Popescu[2], R. Alikhanov[3], M. Efanov[3], I. Khatkov[3], D. Raptis[1], C. Tschuor[1], B. Beck Schimmer[4], J. Bonvini[4], A. Wirsching[1], P. Kron[1], K. Slankamenac[1], B. Humar[1], R. Graf[1], H. Petrowsky[1], P.A. Clavien[1]. *[1]Visceral and Tranplant Surgery, University Hospital Zurich, Zurich, Switzerland; [2]Surgery, Fundeni Institute Bucharest, Bucharest, Romania; [3]Liver and Pancreatic Surgery, Moscow Clinical Scientific Center, Moscow, Russia; [4]Anesthesiology, University Hospital Zurich, Zurich, Switzerland*
E-mail: Michael.Linecker@usz.ch

Background and Aims: The body is dependent on the exogenous supply of omega-3 polyunsaturated fatty acids (n3-PUFA). These essential fatty acids are key players in regulating metabolic signaling but also exert anti-inflammatory and anti-carcinogenic properties. The liver is a major metabolic organ involved in fatty acid metabolism. Under experimental conditions n3-PUFA exert beneficial effect on hepatic steatosis, regeneration and inflammatory insults such as ischemic injury after surgery. Some of these effects have also been observed in human subjects. However, it is unclear, whether perioperative application of n3-PUFA is sufficient to protect the liver from ischemic injury. Therefore, we designed a randomized controlled trial (RCT) assessing n3-PUFA (pre-) conditioning strategies in patients scheduled for liver surgery.

Methods: The Omegaven™ trial is a multi-centric, double-blind, randomized, placebo-controlled trial applying two single doses of Omegaven™ or placebo on 258 patients undergoing major liver resection. Primary endpoints are morbidity and mortality one month after hospital discharge, defined by the Clavien-Dindo classification of surgical complications as well as the Comprehensive Complication Index (CCI). Secondary outcome variables include length of Intensive Care Unit (ICU) and hospital stay, postoperative liver function tests, fatty acid and eicosanoid concentration, inflammatory markers in serum and in liver tissue. An interim analysis is scheduled after the first 30 patients.

Conclusions: Long-term application of n3-PUFA have a beneficial effect on metabolism and hepatic injury. Patients often require surgery without much delay, thus long-term n3-PUFA uptake is not possible. Also, lack of compliance may lead to incomplete n3-PUFA substitution. Hence, perioperative application of Omegaven™ may provide an easy and controllable way to ensure hepatic protection.

P1334
A MULTICENTRE, RANDOMISED, OPEN-LABEL STUDY COMPARING THE EFFICACY AND SAFETY OF TWO DOSES OF DOXORUBICIN TRANSDRUG™ TO BEST STANDARD OF CARE IN PATIENTS WITH ADVANCED HEPATOCELLULAR CARCINOMA (HCC) AFTER SORAFENIB. THE RELIVE STUDY

E-mail: b.vasseur@onxeo.com

Background and Aims: Doxorubicin Transdrug (DT) is a nanoparticular formulation of doxorubicin shown preclinically to bypass the multidrugresistance to chemotherapy and improve the biodistribution of doxorubicin into the liver and tumor cells. In a previous study in HCC patients, DT was shown to increase overall survival but pulmonary toxicity prevented its use by intraarterial route. DT is currently under evaluation using the IV route in a phase III trial in patients previously progressive under sorafenib (NCT01655693).

Methods: The ReLive study is a randomized, 3 parallel arms, open-label study with stratification on geographic regions. Patients with advanced HCC having received at least one prior treatment including sorafenib, with Child–Pugh A to B7 cirrhosis, ECOG <2

Table (abstract P1333).

Sponsor investigator	Prof. Pierre-Alain Clavien, MD PhD
Study product	Omegaven™, 100 ml intravenously administered at the evening before and during liver resection.
Primary endpoint	Postoperative morbidity and mortality determined by the Clavien–Dindo classification of surgical complications and the Comprehensive Complication Index (CCI) 1 month after hospital discharge.
Secondary endpoints	
Main center	Serum samples: postoperative peak AST and ALT, fatty acids and n3-PUFA concentration, inflammatory markers. Liver biopsy: histology (necrosis, apoptosis), inflammatory markers, hepatic fatty acid and n3-PUFA content
Main center and external centers	Duration of hospitalization and ICU stay. Hematology: hemoglobin, hematocrit, leukocytes, platelets, INR. Chemistry: triglycerides, bilirubin, AST, ALT, ALKP, creatinine, CRP
Methodology	Randomized, double-blind, placebo controlled
Clinical phase	Phase III (new indication for Omegaven™)
Study duration	3 years (start July 2013)
Study centers	Multi-center (Zurich, Bucharest, Moscow)
Number of subjects	258 patients
Main inclusion criteria	Adults (over 18 years) requiring liver resection of at least 1 segment or multiple wedge resections (≥3); no coagulopathy (INR ≤1.2, platelets ≥150,000×10^3/μl)
Main exclusion criteria	Liver resections <1 segment, wedge resections (<3); coagulopathy (INR >1.2, platelets <150,000×10^3/μl); hypertriglyceridemia (>5.0 mmol/l); liver cirrhosis; severe renal failure (estimated GFR <30 ml/min/1.73 m^2); pregnancy.
ClinicalTrials.gov	ID: NCT01884948

and adequate cardiac and pulmonary functions are eligible.
Patients receive DT 20 mg/m^2, DT 30 mg/m^2 or best standard of care (BSC). DT is administered through a slow 6 hours intravenous infusion every 4 weeks until progression or toxicity. In control group, patients are treated according to centre's usual practice.
Primary endpoint is overall survival (OS). Main secondary efficacy endpoints are response rate and progression-free survival according to RECIST 1.1 and centralized independent radiologic review. A pharmacokinetic study is performed in selected centers. An independent data safety monitoring board (DSMB) blindly reviews safety data every 6 months.
To demonstrate an OS superiority in comparing each DT groups versus BSC with a hazard ratio of 0.6, a sample size of 130 patients/group has been calculated with 90% power.
The study was initially conducted in limited centers in France to evaluate the safety of this new administration schedule. Safety analyses did not show pulmonary toxicity. The study was thus extended to Italy, Spain, Germany, Belgium, Austria, Hungary, USA and Russia. Additional sites in Australia, Turkey, Lebanon, Egypt and KSA will be open in 2015.
The first patient was included in June 2012. By mid December 2014, 136 patients have been randomized and 289 DT infusions administered in 75 patients. The last DSMB review recommended continuing the study without any modification.
Conclusions: Since approval of sorafenib, no other treatment has demonstrated a significant OS improvement. The aim of this phase 3 study is to evaluate whether a nanoformulation of systemic chemotherapy (doxorubicin) can improve the OS of advanced HCC patients after failure to one or more prior tyrosine kinase inhibitor treatments.

P1335

A RANDOMIZED, CONTROLLED PHASE III TRIAL OF SORAFENIB WITH OR WITHOUT CONVENTIONAL TRANSARTERIAL CHEMOEMBOLIZATION IN PATIENTS WITH ADVANCED HEPATOCELLULAR CARCINOMA (STAH)

J.-W. Park[1], Y.J. Kim[2], D.Y. Kim[3], S.H. Bae[4], J.E. Yeon[5], S.Y. Han[6], J.S. Hwang[7], Y.-J. Lee[8], J.Y. Cheong[9], O.S. Kwon[10], H.Y. Kim[11], H.C. Lee[12], J. Heo[13], B.H. Kim[1], S.W. Paik[14]. *[1]National Cancer Center, Korea, Goyang, [2]Seoul National University Hospital, [3]Severance Hospital, [4]The Catholic University Hospital of Korea, [5]Korea University Guro Hospital, Seoul, [6]Dong-A University Medical Center, Busan, [7]Keimyung University Dongsan Medical Center, Daegu, [8]Busan-Paik Hospital, Busan, [9]Ajou University Hospital, Suwon, [10]Gachon University Gil Hospital, Incheon, [11]Boramae Medical Center, [12]Asan Medical Center, Seoul, [13]Busan National University Hospital, Busan, [14]Samsung Medical Center, Seoul, Korea, South*
E-mail: jwpark@ncc.re.kr

Background and Aims: The conceptual advantage of a combination of transarterial chemoembolization (TACE) plus anti-angiogenic agents is the possible synergistic effect in patients with hepatocellular carcinoma (HCC). Positive results of two phase II studies combining TACE and sorafenib have been reported. The COTSUN study (NCT00919009) showed a promising time to progression in patients with advanced HCC. However, no study shows the additional effect of TACE with sorafenib treatment in patients with advanced HCC, particularly in patients with macrovascular invasion or extrahepatic metastasis.
Methods: STAH is a randomized, multi-center, open-labeled, phase III study in patients with advanced HCC. A total of 338 patients will be randomized (1:1) into 1 of the 2 treatment arms: sorafenib with (arm combination treatment; arm C) or without (arm sorafenib alone; arm S) conventional TACE (cTACE). Randomization will be stratified according to the modified International Union Against Cancer (mUICC) stage (III vs. IV), vascular invasion (none and Vp1–2 vs. Vp3–4 and any other presence), Child–Pugh score (5 vs. 6–7), and serum alpha-fetoprotein level (≥200 ng/mL vs. <200 ng/mL). The primary objective is to determine overall survival (OS) in the 2 arms. Assuming a median OS associated with sorafenib treatment of 9.5 months and a median OS associated with combination treatment of 13.0 months, 241 events will provide an 80% one-sided power with an α value of 0.05 to detect a difference in OS between the 2 groups.
The main inclusion criterion is advanced HCC (mUICC stage III, IVa, IVb) that is indicated for systemic chemotherapy as the treatment of choice according to the Korean guidelines. All eligible patients will take sorafenib (both arms) within 3 days after randomization, while patients in arm C will undergo the first cTACE within 14 days after randomization, with subsequent cTACE performed as needed according to re-determined criteria. Enrollment has begun February 2013 and two-hundred two patients (59.8% of the target population) have been enrolled in this study by 30 November 2014.
Clinical trial information: NCT01829035.

P1336

TREATMENT OF TYPE 1 HEPATORENAL SYNDROME WITH TERLIPRESSIN INFUSION ADJUSTED ACCORDING TO HEMODYNAMIC RESPONSE. THE AMELIORATE STUDY

P. Huelin[1], E. Rodriguez[1], M. Poca[2], M. Martin-Llahi[3], C. Elia[1], R. Moreira[1], C. Solè[1], I. Cirera[4], J. Sanchez[5], V. Vargas[6], G. Soriano[7], V. Arroyo[1], E. Sola[1], P. Gines[1]. *[1]Liver Unit, Hospital Clinic, [2]Liver Unit, Hospital de Sant Pau, [3]Gastroenterology, Hospital Moises Broigges, [4]Hepatology, Hospital del Mar, BArcelona, [5]Dept of Hepatology, Hospital Parc Tauli, Sabadell, [6]Hepatology, Hospital Vall d'Hebron, [7]Hepatology, Hospital de Sant Pau, Barcelona, Spain*
E-mail: pgines@clinic.ub.es

Background and Aims: First-line treatment for type 1 hepatorenal syndrome (HRS) is currently based on terlipressin administered as intravenous bolus associated with albumin. There are data showing a direct relationship between increase in mean arterial pressure (MAP) during treatment and response to therapy. However, terlipressin dose is adjusted according to changes in serum creatinine. Recent studies suggest that terlipressin administered as continuous infusion could be more effective and with less side effects. The hypothesis of the study is that terlipressin administred as continuous infusion and with an early dose adjustment according to hemodynamic response could improve the efficacy and safety of treatment in type 1 HRS.
Endpoints: Primary endpoint is to evaluate the effects of treatment with terlipressin infusion with dose adjusted according to hemodynamic response in type 1 HRS. Secondary endpoints are: to identify predictive factors of response to therapy and assess adverse events.
Study design: Proof-of-concept, prospective, multicenter study that will include 40 patients with cirrhosis and type 1 HRS. Exclusion criteria are hepatocellular carcinoma beyond Milan criteria, advanced extrahepatic diseases or contraindications to receive terlipressin. Patients will receive terlipressin administered as continuous infusion and albumin at standard doses. Dose of terlipressin will be adjusted according to hemodynamic response (increase ≥10 mmHg in MAP with respect to pretreatment value) and to changes in serum creatinine. Initial terlipressin dose is 2 mg/day. MAP will be monitored every 8 h and serum creatinine will be determined daily. Terlipressin dose will be increased 2 mg every 8 h until an increase in MAP >10 mmHg with respect to pretreatment value or a decrease >25% in serum creatinine with respect to previous value are achieved. Maximum dose of terlipressin is 12 mg/day. Treatment will be maintained until resolution of type 1 HRS or maximum of 14 days. Complete response will be defined as a decrease in serum creatinine <1.5 mg/dL. Partial response will be defined as a 50% reduction in serum creatinine with final value >1.5 mg/dL. Liver and circulatory function (renin, noradrenaline) will determined at baseline and days 3 and 7.

Urinary biomarkers will be measured and analyzed for their relationship with response to therapy. The development of adverse events will be recorded.

P1337

RANDOMIZED TRIAL WITH RIFAXIMIN IN LIVER CIRRHOSIS. EFFECTS ON THE HAEMODYNAMIC AND INFLAMMATORY STATE

N. Kimer[1,2], J.S. Pedersen[1], S. Møller[2], A. Krag[3], F. Bendtsen[1].
[1]Gastrounit, medical division, [2]Department of Clinical Physiology and Nuclear Medicine, Centre of Diagnostic Imaging and Research, Copenhagen University Hospital Hvidovre, Hvidovre, [3]Department of Gastroenterology and Hepatology, Odense University Hospital, University of Southern Denmark, Odense, Denmark
E-mail: nina.kimer@regionh.dk

Background and Aims: Bacterial infections occur frequently in cirrhosis, often triggering complications to decompensated cirrhosis. Bacterial translocation from the gut has been hypothesized to worsen the haemodynamic derangement and trigger infections in the cirrhotic patient and affect the risk of complications to cirrhosis. Rifaximin is applied in the treatment and prophylaxis of hepatic encephalopathy and known to affect both aerobe and anaerobe bacteria in the intestinal lumen. In this trial we aim to investigate the pathophysiological mechanisms of rifaximin on the bacterial translocation and evaluate the effects on splanchnic and systemic haemodynamics and inflammation in the cirrhotic patient.
Methods: Between January 2013 and December 2015 a randomized, double blind, placebo controlled trial will be performed. Inclusion criteria are cirrhotic Child-Turcotte class B or C patients and ascites present on ultrasound within the past three months and a hepatic venous pressure gradient (HVPG) above10 mmHg. Exclusion criteria are Child-Turcotte score above 12, infection, renal failure, and overt hepatic encephalopathy. The patients will be randomized to receive either oral rifaximin, 1100 mg/day or identical placebo for 28 days. The investigational programme includes measurements of HVPG, cardiac output, plasma volume, glomerular filtration rate (GFR) as measured by Cr-51-EDTA, full biochemical evaluation, continuous reaction times and psychometric hepatic encephalopathy score. All measurements will be performed at baseline and repeated at day 29. Patients are followed for at least six months, until death or end of trial. Data will be compared over time and between groups. Rates of complications and survival will be calculated. Primary outcome measures are effect on HVPG and GFR. Secondary outcome measures include, but are not limited to, effect on systemic vascular resistance, haemodynamic and inflammatory markers, biochemistry, state of hepatic encephalopathy, complication rates and survival.
Results: Data will be analyzed January 2016.
Conclusions: Until now there are no conclusive data on the effects of rifaximin on the haemodynamics and the inflammatory state in cirrhosis. We expect that the results of the present trial will significantly contribute to reveal these important clinical questions.

P1338

AN INTERNATIONAL OBSERVATIONAL STUDY TO ASSESS THE USE OF SORAFENIB AFTER TRANSARTERIAL CHEMOEMBOLIZATION (TACE) IN PATIENTS WITH HEPATOCELLULAR CARCINOMA (HCC): OPTIMIS

M. Peck-Radosavljevic[1], J.-L. Raoul[2], H.C. Lee[3], M. Kudo[4], K. Nakajima[5], A.-L. Cheng[6]. *[1]Institut Paoli-Calmettes, Marseille, France; [2]Medical University of Vienna, Vienna, Austria; [3]Asan Medical Center, Seoul, Korea, South; [4]Kinki University School of Medicine, Osaka, Japan; [5]Bayer HealthCare Pharmaceuticals, Whippany, United States; [6]National Taiwan University Hospital, Taipei City, Taiwan*
E-mail: markus.peck@meduniwien.ac.at

Background and Aims: TACE is currently recommended for the treatment of patients with intermediate-stage HCC (Barcelona Clinic Liver Cancer [BCLC] stage B). However, it remains unclear which patients are most likely to benefit from TACE, or when TACE should be stopped and alternative treatments considered. Currently there is no globally accepted clinical algorithm for TACE use. The multikinase inhibitor sorafenib is the only systemic therapy currently approved for the treatment of unresectable HCC.
Methods: Patients aged ≥18 years, with histologically/cytologically documented or radiographically diagnosed HCC classified as BCLC stage B or higher, with a life expectancy of ≥8 weeks, and for whom a decision to treat with TACE has been made at the time of study enrollment (one prior TACE treatment is allowed if performed at the same center and all required data about the procedure are available), are eligible. Treatment decisions made before a patient is enrolled, and during the observation period, must be according to investigators' regular practice. Exclusion criteria include any systemic anti-cancer therapy prior to the first TACE, or participation in an interventional study of locoregional or systemic therapy. The primary objective is evaluation of overall survival in patients who received sorafenib subsequent to TACE non-eligibility (early sorafenib) compared with those who did not (non-early sorafenib). The non-early sorafenib group includes patients who did not receive sorafenib or who received it at a later point. Secondary objectives include progression-free survival, time to progression, tumor response, and safety. Planned enrollment is approximately 1600 patients from about 30 countries across Europe, Latin America, and Asia-Pacific, and from Canada. One interim analysis is planned once 500 patients have been observed for at least 6 months. Final analysis will be performed once the last enrolled patient has been followed for 18 months, has been lost to follow-up, or has died. The study began in October 2013 and 737 patients have been enrolled as of November 2014.
ClinicalTrials.gov identifier: NCT01933945.

P1339

EVALUATING THE EFFICACY AND SAFETY OF EVEROLIMUS WITH REDUCED TACROLIMUS VERSUS STANDARD TACROLIMUS IN LIVING DONOR LIVER TRANSPLANT RECIPIENTS: H2307 STUDY DESIGN

C. Sips[1], K.S. Suh[2], J.W. Joh[3], T. Yoshizumi[4], W.C. Lee[5], Y. Genyk[6], E.-D. Martzloff[1], Z. Wang[1], P. Lopez[1], D. Grant[1], for the H2307 Study Group. *[1]Novartis Pharma AG, Basel, Switzerland; [2]Seoul National University Hospital, Seoul National University, College of Medicine, Seoul, Korea, South; [3]Samsung Medical Center, SungKyunKwan University School of Medicine, Seoul, Korea, South; [4]Kyushu University Hospital, Fukuoka-city, Japan; [5]LinKou Chang Gung Memorial Hospital, Taoyuan, Taiwan; [6]University of Southern California, Los Angeles, United States; [7]Toronto General Hospital, Toronto, Canada*
E-mail: carole.sips@novartis.com

Background and Aims: Living donor liver transplantation (LDLT) is a valuable option for mitigating the shortage of organs. Little data exists from randomised clinical studies evaluating the effect of different immunosuppressive regimens in LDLT recipients.

H2307 is the first study to evaluate the efficacy and safety of everolimus (EVR) + reduced tacrolimus (rTAC) vs standard TAC (TAC-C) in LDLT recipients. Here, we present the baseline data from the study.

Methods: H2307, an ongoing 24-month (mo), multicentre (38 active sites across 14 countries), controlled study aims to randomise adult LDLT recipients in a 1:1 ratio to receive EVR (C0 3–8 ng/mL) + rTAC (C0 3–5 ng/mL) or TAC-C (6–10 ng/mL) after entering a 30-day run-in period with TAC (5–15 ng/mL) +/− mycophenolate mofetil +/− anti-IL2 induction and steroids (Figure). Randomisation is stratified based on hepatocellular carcinoma (HCC) at time of LT. HIV-negative status and known HCV and HBV status are the key inclusion criteria; exclusion criteria are HCV-negative subjects receiving transplant from HCV positive donor, MELD score >35 within 1 mo prior to transplantation, and HCC patients with extra-hepatic spread or macrovascular invasion. Study objectives are composite efficacy failure (treated biopsy proven acute rejection, graft loss or death), evolution of renal function from randomisation to month 12 and month 24, and the incidence of adverse events. Specific objectives include incidence and time to HCC recurrence, evolution of HCV viral load and allograft regeneration.

Results: Around 43 LDLT recipients (male: 67.4%, Asian: 76.7%, age <60 years: 69.8%) are enrolled to the H2307 study as of 10 December 2014. Major end stage diseases leading to transplantation are HCC (34.9%) and HBV (27.9%). At baseline, mean age was 53.1 years, eGFR (mean±SD) was 112.2±36.6 mL/min/1.73 m^2, and model end-stage liver disease score (mean±SD) was 13.3±5.0.

Conclusions: H2307 is the first randomised, multicentre study in LDLT recipients, evaluating the efficacy and safety of EVR+rTAC vs TAC-C.

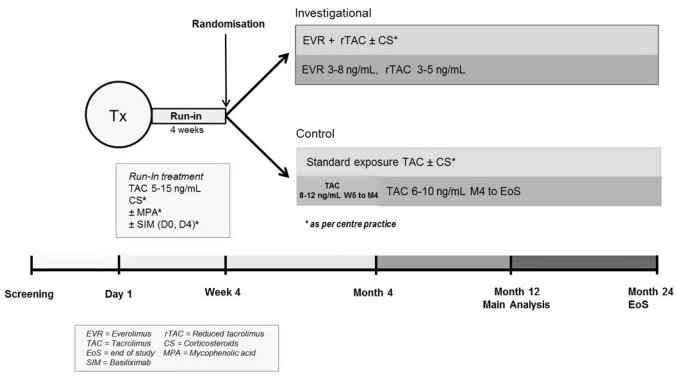

Figure: H2307 Study design.

ASSESSING NUTRITION THROUGH OBSERVATION IN EARLY CIRRHOSIS OF THE LIVER: A NURSE LED PILOT STUDY

A. Ghezzi[1], P. Crick[1], M. Taylor[2], M. Abraham[3], N. Guha[4], G. Aithal[4].
[1]Health and Social Care, University of Derby, Derby, [2]School of Nutrition, University of Nottingham, [3]Dietetics, Nottingham University Hospitals, [4]NIHR Nottingham Digestive Diseases Biomedical Research Unit, University of Nottingham, Nottingham, United Kingdom
E-mail: antonella.ghezzi@nottingham.ac.uk

Background and Aims: Prevalence of malnutrition in patients with cirrhosis has been reported to be high and it has major implications on morbidity and mortality in these group of patients. Malnutrition in cirrhosis still remains underdiagnosed and undertreated in routine clinical practice.

Aims:

1. To perform nutritional assessment of patients with compensated cirrhosis using validated tools.
2. To evaluate the effect of a personalised dietary intervention on the nutritional status of patients.

Methods: The Research Nurse will identify malnourished patients from a cohort of patients with Child–Pugh A cirrhosis using a combination of handgrip strength <30 kg/F + Mid-arm muscle circumference (MAMC) <23 cm and subjective global assessment tool. All patients will undergo anthropometric measurements, blood/urine biochemistry, chronic liver disease questionnaire (CLDQ) to evaluate quality of life and Dual Energy X-ray absorptiometry (DEXA) at baseline and 6 months following the intervention.

Participants: 21 patients with Child–Pugh A cirrhosis (based on histology or combination of clinical + non invasive markers) meeting the criteria of malnutrition.

Exclusions: Liver cancer, portal/splenic vein thrombosis, on-going alcohol abuse and uncontrolled diabetes.

Intervention: Dieticians will evaluate individual's nutritional requirements which will be used to develop a personalised dietary intervention. The effect of the intervention will be evaluated at 6 months follow-up.

Primary Outcome: Improvement from baseline in the protein compartment and fat free mass on DEXA scan.

Secondary Outcomes: Improvements in CLDQ, grip strength and MAMC post intervention; compliance with dietary intervention.

Results: We will describe the prevalence of malnutrition based on the parameters that are evaluated in the study cohort. We will analyse the primary and secondary outcomes as the changes in the nutritional parameters assessed prior to and after 6 months of dietary intervention.

We will present our results at the International Liver Congress 2015.

Conclusions: This nurse-led project will highlight the importance of a multi-disciplinary approach to liver care and the relevance of nutritional assessment and dietary interventions in this specific group of patients.

P1341

PERFORM: AN IMAGING STUDY OF ARTERIAL BLOOD FLOW TO LIVER METASTASES BEFORE AND AFTER SELECTIVE INTERNAL RADIOTHERAPY

H.S. Winter[1], E. Hill[1], N. Syed[1], D. Chung[1], J. Franklin[2], J. Statham[3], J. Lee[2], N. Weir[4], G. Weir[4], E. Brown[4], J. Mills[5], S. Anthony[3], D. Patel[4], P. Boardman[3], E. Anderson[3], F. Gleeson[2], R. Sharma[1], Department of Oncology, University of Oxford. *[1]Oncology, [2]Radiology, University of Oxford, [3]Radiology, Churchill Hospital NHS, Oxford, [4]Radiology, NHS Lothian Hospitals, Edinburgh, [5]Oncology, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom*
E-mail: helen.winter2@oncology.ox.ac.uk

Background and Aims: Colorectal cancer (CRC) is the third most common malignancy worldwide. The leading cause of death from this disease is progression of liver metastases. Selective internal radiotherapy (SIRT) involves the injection of yttrium-90 resin microspheres directly into hepatic arterial vessels to deliver radiotherapy to primary and secondary liver malignancies. Our research programme is focussed on drugs which can alter arterial blood flow to tumours. Since deposition of microspheres depends on flow characteristics, we decided to evaluate perfusion Computed Tomography (pCT) before and after SIRT. The aim of PERFORM is to show that imaging evaluation of arterial blood flow is an essential component of patient assessment prior to liver-directed arterial therapy.

Methods: In 58 patients due to receive systemic chemotherapy for liver metastases, and in patients due to receive the same chemotherapy plus SIRT, pCT liver scans are performed at 4 timepoints: pre-chemotherapy, after one cycle of chemotherapy (2 days before SIRT), 12 days post-SIRT and 40 days post-SIRT. A metastasis measuring 1–4 cm is selected on a pre-contrast CT study for dynamic imaging after pump-injection of iodinated contrast.

Data are analysed on GE Advantage Workstation (GE CT Perfusion 4D). Analysis involves motion correction and image co-registration
Results: At 3 participating sites, 29 participants have been recruited. Feasibility analysis of 25 pCT studies acquired from the first 7 patients treated with SIRT has shown a metastasis suitable for analysis on all studies. In 22/25 studies, dual-input pharmacokinetic modelling of tumour Blood Flow, Blood Volume, Mean Transit Time and Hepatic Arterial Fraction has been successfully performed.
Conclusions: We have demonstrated the feasibility of performing pCT scans before and after SIRT at 4 timepoints and the ability to derive reproducible data from those scans. These data will be used to measure changes in perfusion parameters after chemotherapy to optimise the delivery of SIRT. Regarding the assessment of baseline arterial flow characteristics for patient selection for SIRT, the feasibility of performing both pCT and dynamic contrast enhanced MRI at the same timepoint for exchange of information between imaging modalities will be explored.

P1342
PROSPECTIVE REAL WORLD OUTCOMES STUDY OF HE PATIENTS' EXPERIENCE ON RIFAXIMIN-α (PROSPER): AN OBSERVATIONAL STUDY AMONG 550 PATIENTS

H. Sodatonou[1], A. Krag[2], R. Jalan[3], P. Conway[4], J. Pilot[5], A. Radwan[1]. *[1]Medical Affairs, Norgine, Uxbridge, United Kingdom; [2]Department of Gastroenterology and Hepatology, Odense University Hospital, University of Southern Denmark, Odense, Denmark; [3]University College London, Royal Free London, London, [4]Global Market Access, [5]Clinical Development, Norgine, Uxbridge, United Kingdom*
E-mail: ssheikh@norgine.com

Background and Aims: Rifaximin-α is indicated in Europe for prevention of recurrent episodes of overt hepatic encephalopathy (HE) in patients ≥18 years old. Its efficacy was confirmed in a randomized controlled trial (Bass et al. NEJM 2010); rifaximin 550 mg b.i.d. reduced the relative risk of recurrence of HE and hospitalisation by 58% and 50%, respectively (absolute risk reduction 24% and 9%, respectively). To translate this 'efficacy' into 'effectiveness', real world data are needed. The aim of this study is to monitor the clinical effectiveness of rifaximin-α and its impact on health care resources in Europe and Australia.
Methods: This is an observational, multicentre study with 550 patients. Inclusion criteria: adults with a diagnosis of liver cirrhosis and one confirmed HE event within the past 12 months, which can include the index event. Exclusion criteria: prior treatment with rifaximin-α, contraindications to the use of rifaximin-α, hepatocellular carcinoma, inability to give informed consent or West Haven score of ≥2 at the point of study entry. Timing of recruitment: patients can enter into this study from the point of hospital discharge up to 8 weeks after hospital discharge. Study Design: patients will be followed up prospectively for 24-months. Patients will either be managed with rifaximin-α (treatment group) or not managed with rifaximin-α (control group) in the prospective phase. The treating physician will decide the allocation of treatment according to local practice. The study will also have a retrospective part, in which clinical information from medical records for the prior 12 months will be obtained. Primary endpoint: the number and duration of hospitalisation. Secondary endpoints will include mortality rate, incidence of other cirrhosis complications, 30-day readmission rate, accident and emergency visits, primary care contacts and quality of life.
Results: Initial analyses will be performed after 12 months of data collection. Full dataset should be available for analysis by July 2018.
Conclusions: Currently, there are little data on the 'effectiveness' of secondary prophylaxis and the impact on health care resource used in Europe and Australia with rifaximin-α. Therefore, the findings of this study may provide important real world evidence. Furthermore, the data could potentially provide a better understanding of the burden and natural history of HE, and variability in disease management in individual units.
PROSPER is sponsored by Norgine.

P1343
PHASE I DOSE-ESCALATION STUDY EVALUATING THE SAFETY AND PHARMACOKINETICS OF ORAL ARTESUNATE IN PATIENTS WITH ADVANCED HEPATOCELLULAR CARCINOMA (DESPARTH TRIAL)

Y.-P. Vandewynckel[1], K. Rombauts[2], X. Verhelst[1], L. Van Bortel[3], B. De Spiegeleer[4], A. Geerts[1], H. Van Vlierberghe[1]. *[1]Department of Hepatology and Gastroenterology, Ghent University, Ghent, [2]The Anticancer Fund, Strombeek-Bever, [3]Clinical pharmacology and pharmacotherapy, [4]Laboratory of Drug Quality & Registration, Faculty of Pharmaceutical Sciences, Ghent University, Ghent, Belgium*
E-mail: yvespaul.vandewynckel@ugent.be

Background and Aims: Artemisinins are safe and effective FDA-approved antimalarial drugs. Recent studies have suggested that artemisinins also exert anti-angiogenic and cytotoxic effects on human cancer cells. Dihydro-artemisinin, the main active metabolite of artemisinins, has been demonstrated to exhibit antitumour effects toward various types of human cancers, including liver, lung, breast (clinical trial running) and pancreatic cancer. Artesunate is a water-soluble semisynthetic artemisinin with improved pharmacokinetic properties. We previously reported the antitumour effect of Artesunate in the diethylnitrosamine-induced mouse model for HCC, together with its effect on angiogenesis and multidrug resistance.
Methods: An investigator-initiated single-center phase I dose-escalation study evaluating the safety and pharmacokinetics of oral Artesunate in patients with advanced HCC was designed and is now recruiting. Advanced HCC patients with Child–Pugh class not higher than B7 are included when sorafenib is stopped due to intolerance or therapeutic failure or when sorafenib is contraindicated or refused. Approximately 16 patients will be enrolled in this trial.
The first patient will receive 200 mg Artesunate once-daily for 14 days. If no dose-limiting toxicity (DLT) is observed after 14 days, the next patient will start at a daily dose of 300 mg Artesunate. If no DLT is observed after 14 days, a cohort of 3 patients will receive 400 mg once-daily for 14 days. For each subsequent cohort of 3 patients 200 mg will be added to the dose, until maximum tolerated dose (MTD) is determined. Treatment will continue until both radiologic and symptomatic progression are reached, adverse reactions requiring discontinuation of study treatment occur, or mortality.
Plasma concentrations of Artesunate will be determined by ultra-performance liquid chromatography tandem mass-spectrometry. Pharmacokinetic parameters that will be measured are C_{max}, C_{min}, T_{max}, and AUC.
Results: The primary objectives are to assess the safety, estimate the MTD, and characterize the pharmacokinetics of Artesunate in HCC patients with mild impaired liver function.
The secondary objectives are to evaluate the time to tumor progression, overall survival and quality of life based on the Functional Assessment of Cancer Therapy Hep-30 scale.
Conclusions: Since Artesunate could represent a novel drug in the treatment of advanced HCC, determination of the MTD in this patient population is primordial.

P1344

DETERMINING THE HEPATIC CYST PENETRATION OF CEFAZOLIN AND FACTORS AFFECTING PENETRATION, AN EXPLORATIVE STUDY

M.A. Lantinga[1], T.F. Wijnands[1], R.H. te Morsche[1], D.M. Burger[2], J.P. Drenth[1]. *[1]Gastroenterology and Hepatology, [2]Pharmacy, Radboud university medical center Nijmegen, Nijmegen, Netherlands*
E-mail: marten.lantinga@radboudumc.nl

Background and Aims: Hepatic cysts are fluid-filled cavities located in the liver parenchyma. With aspiration sclerotherapy (AS) hepatic cysts are drained and flushed with a sclerosing agent. AS results in cyst volume reduction and is indicated in patients with a symptomatic dominant hepatic cyst. Cyst infection, either spontaneous or following AS, is a severe complication as it frequently requires hospitalization, long-term antibiotics or invasive treatment. Cefazolin prophylaxis is given to prevent cyst infection following AS. Evidence that antibiotics reach adequate intracystic concentrations is lacking. Our primary objective is to determine cefazolin penetration into hepatic cysts. Secondary objective is to identify factors affecting antibiotic penetration and to evaluate the association between antibiotic penetration and development of AS-induced cyst infection.
Methods: We aim to include nine subjects (aged ≥18 years) who will be treated by AS. Prior to AS, patients receive a single dose of cefazolin (intravenous infusion 1000 mg in 1 hour). We will collect blood following cefazolin infusion to determine the peak cefazolin blood concentration (μg/ml). The cyst aspirate concentration of cefazolin (μg/ml) will be measured in cyst fluid obtained during AS. Simultaneously, we will perform a second blood withdrawal during AS to determine the blood concentration of cefazolin (μg/ml). Cyst aspirate and blood concentrations of cefazolin will be measured using high-performance liquid chromatography (HPLC). Primary endpoint is hepatic cyst penetration of cefazolin defined as the ratio (%) of cyst aspirate concentration (μg/ml) to blood concentration (μg/ml) of cefazolin. Secondary study parameters are location and volume of the aspirated hepatic cyst, cyst fluid and blood parameters, and development of clinical signs indicating AS-induced cyst infection.
Conclusions: This study investigates the hepatic cyst penetration of cefazolin and factors that affect cyst penetration.

P1345

A RANDOMIZED, OPEN-LABEL STUDY TO EVALUATE EFFICACY AND SAFETY OF OMBITASVIR/PARITAPREVIR/RITONAVIR CO-ADMINISTERED WITH RIBAVIRIN IN ADULTS WITH GENOTYPE 4 CHRONIC HEPATITIS C INFECTION AND CIRRHOSIS

T. Asselah[1], T. Hassanein[2], R.B. Qaqish[3], J.J. Feld[4], C. Hezode[5], S. Zeuzem[6], P. Ferenci[7], T. Pilot-Matias[3], Y. Yu[3], N. Goethe University, Frankfurt, Germany; [7]Medical University Vienna, Vienna, Austria*
E-mail: kristina.kligys@abbvie.com

Background and Aims: Hepatitis C virus (HCV) infection is a global health problem, with over 170 million individuals chronically infected worldwide. HCV genotype 4 (GT4) represents approximately 20% of global HCV infection. Although GT4 infection is more common in the Middle East and sub-Saharan Africa, with globalization, GT4 is now seen in many other countries. Combinations of direct-acting antiviral agents (DAAs) targeting different steps of viral replication have the potential to significantly improve HCV treatment. In a Phase 2b study (PEARL-I), a sustained virologic response rate 12 weeks post-treatment (SVR12) of 100% was achieved among both treatment-naïve and prior peginterferon (pegIFN) and ribavirin (RBV) experienced HCV GT4-infected patients without cirrhosis. These patients were treated for 12 weeks with the 2DAA IFN-free regimen of ombitasvir (OBV), a NS5A inhibitor, plus paritaprevir (formerly ABT-450, a NS3/NS4A protease inhibitor, identified by AbbVie and Enanta co-dosed with ritonavir [PTV/r]) and RBV. Furthermore, a Phase 3 study (TURQUOISE-II) in HCV GT1-infected patients with cirrhosis demonstrated high efficacy and good tolerability of OBV/PTV/r with dasabuvir and RBV. The current study will evaluate the efficacy and safety of co-formulated OBV/PTV/r with RBV in HCV GT4-infected patients with compensated cirrhosis.
Methods: This Phase 3, randomized, open-label, multinational study (NCT 02265237) will enroll 160 HCV GT4-infected treatment-naïve or IFN/RBV or pegIFN/RBV (pegylated-interferon alfa-2a or alfa-2b) treatment-experienced patients with compensated cirrhosis. Patients are randomized 1:1 to receive co-formulated OBV/PTV/r co-administered with weight based RBV for 12 or 16 weeks. The primary objectives of the study are to assess the safety of the 2DAA regimen and to compare the proportion of patients achieving SVR12 (HCV RNA <lower limit of quantification) with the 2DAA regimen to the historical SVR12 rate for HCV GT4-infected patients treated with pegIFN/RBV. The secondary objectives are to compare SVR12 rates between the 12 and 16 week treatment arms, and to assess in each treatment arm the percentage of patients with on-treatment virologic failure and the proportion of patients with post-treatment relapse within 12 weeks following the end of treatment. The study will also include exploratory pharmacokinetic, resistance and pharmacogenomics analyses. The study opened in October 2014 and is currently enrolling patients in North America and Europe.

P1346

STUDY PROTOCOL FOR A PARTLY RANDOMISED, OPEN-LABEL PHASE IIA TRIAL OF ONCE-DAILY SIMEPREVIR COMBINED WITH SOFOSBUVIR FOR THE TREATMENT OF HCV GENOTYPE 4-INFECTED PATIENTS WITH OR WITHOUT CIRRHOSIS (OSIRIS)

M. El Raziky[1], M. Gamil[2], R. Hammad[3], M.S. Hashem[4], M. Hassany[3], M. Khairy[1], A. El Sharkawy[1], A. Gomaa[4], S. Keim[5], G. Van Dooren[2], R. DeMasi[6], I. Lonjon-Domanec[7], W. Doss[3], I. Waked[8]. *[1]Cairo University, Cairo, Egypt; [2]Janssen Infectious Diseases BVBA, Beerse, Belgium; [3]National Hepatology and Tropical Medicine Research Institute, Cairo, [4]National Liver Institute, Menoufiya, Egypt; [5]Janssen-Cilag Portugal, Lisbon, Portugal; [6]Janssen Research & Development LLC, Titusville, United States; [7]Janssen-Cilag, Paris, France; [8]National Liver Institute, Cairo, Egypt*
E-mail: maelraziky@yahoo.com

Background and Aims: HCV genotype 4 is mainly found in the Middle East and Africa, but it is beginning to spread to Europe. Although direct-acting antiviral agents are revolutionising treatment of hepatitis C, HCV genotype 4-infected patients have been under-represented in large multicentre clinical studies. Simeprevir is an inhibitor of HCV NS3/4A protease effective against HCV genotype 4. Sofosbuvir is a nucleotide NS5B polymerase inhibitor also effective against HCV genotype 4. This trial will evaluate efficacy and safety of 8 or 12 weeks' treatment with once-daily simeprevir and sofosbuvir for HCV genotype 4-infected patients in Egypt.
Methods: OSIRIS (Optimize Simeprevir In a Regimen Including Sofosbuvir), is a Phase IIa, partly randomised, multicentre open-label trial (NCT02278419). Sixty HCV genotype 4-infected, treatment-naïve or experienced adult patients with baseline HCV RNA >10,000 IU/mL and compensated liver disease will be enrolled.

Forty patients without cirrhosis will be randomised (1:1) to receive oral simeprevir (TMC435) 150 mg qd combined with sofosbuvir 400 mg qd for either 8 (Group A1) or 12 weeks (Group A2) (Figure). Randomisation will be stratified by prior treatment experience and METAVIR score (Stratum 1: treatment naïve and F0–F2; Stratum 2: treatment-experienced and/or F3). A further 20 patients with cirrhosis will receive the regimen for 12 weeks (Group B).

The primary objective is to determine the efficacy of this regimen, assessed by the percentage of patients with HCV RNA IL28B genotype, and demographic/baseline characteristics. The lower limit of the 95% confidence interval (CI) of the overall SVR12 rate will be compared against composite historical control rates; superiority will be concluded if the lower limit of the 95% CI is greater than the threshold. Secondary objectives include SVR at 4 and 24 weeks after end of treatment; relative efficacy of 8 versus 12 weeks' treatment; on-treatment virologic responses; frequency of treatment failure and relapse; and safety and tolerability of the regimen.

Conclusions: This study will evaluate the efficacy and safety of a once-daily regimen comprising simeprevir 150 mg qd plus sofosbuvir 400 mg qd for treatment of patients with HCV genotype 4 infection.

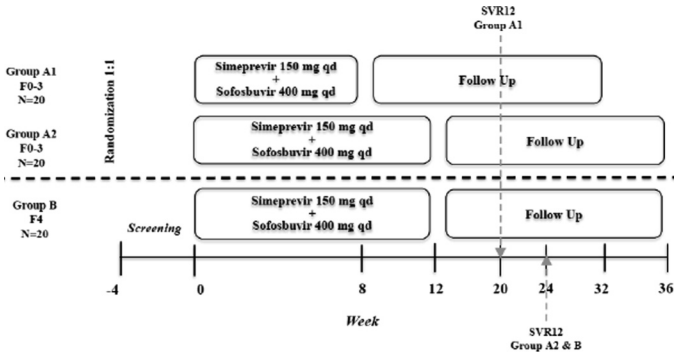

Figure: Randomisation. F0–3 and F4 refer to METAVIR fibrosis score. qd, once daily; SVR12, sustained virologic response at 12 weeks after end of treatment.

P1347

A PROSPECTIVE, MULTI-CENTRIC STUDY ABOUT DISEASE DEVELOPMENT FOR LIVER CIRRHOSIS PATIENTS WITH ACUTE DECOMPENSATION OR NON-CIRRHOTIC PATIENTS WITH ACUTE HEPATIC INJURY

H. Li[1], Chinese liver study group for ACLF. [1]*Gastroenterology, Renji Hospital, Shanghai Jiao Tong University, School of Medicine, Shanghai, China*
E-mail: haili_17@126.com

Background and Aims: Acute-on chronic liver failure (ACLF) is a distinct entity encompassing the acute deterioration of liver function culminating in multiple organ failure and high short-time mortality. Our Chinese single center 890 HBV cirrhotic patients with acute decompensation (AD) cohort data which be collaborated with and analyzed by CANONIC study group has been shown both HBV and alcoholic related ACLF belong to a homogenous disease entity. However, that conclusion still need to be confirmed by a prospective multi-centric study in HBV prevailing region.

Methods: 13 Chinese national wide liver centers which total beds are around 500 have been included. Continuous hospitalized patients with any etiology induced chronic liver disease (including both cirrhotic and non-cirrhotic) with AD or acute hepatic injury (aminotransferase >3NL) will be recruited from January to December 2015. Biochemical parameters, organ failure, mortality and liver transplantation rate will be collected at days 1, 4, 7, 14, 21 and 28 after enrollment. The patients will be continuously followed up once a month until the 24th month after hospital discharge. Because expecting for lacking of liver biopsy in most of the patients, both CT and FibroScan will be used for differentiating non-cirrhotic patients, especially for hepatitis with mild fibrosis patients from cirrhotic patients.

Results: 2500–3000 patients are planed to be recruited and followed-up in this study. Two different cohorts for ACLF patients with cirrhosis and acute deterioration patients with mild liver fibrosis (FibroScan value <8.5) will be identified. Disease severity, organ failure score and mortality will be compared between ACLF and non-ACLF cirrhotic patients (according to CLIF-C-OF score), or between ACLF cirrhotic and mild fibrosis with acute deterioration patients. The homogeneity for different etiological ACLF cirrhotic patients will be statistically calculated. Whether mild fibrosis with acute deterioration patients belong to the same disease entity with ACLF cirrhotic patients or to be a new disease entity will be identified in the study.

Conclusions: Different etiology related ACLF belong to a same disease entity and could share an universal diagnostic criteria, severity classification and prognostic models will be confirmed by this prospective multi-centric study. Whether non-cirrhotic patients with acute deterioration is a separated disease entity or a homogeneous entity with ACLF cirrhotic patients will be identified in this study.

P1348

RCT FOR ANTI-HEPATOFIBROTIC EFFECT OF A HERBAL DRUG (CGX)

H.G. Kim, D.S. Lee[1,2], C.G. Son. [1]*Department of Internal Medicine, Daejeon St. Mary's Hospital of Catholic University,* [2]*Liver & Immunology Research Center, Daejeon Oriental Hospital, Daejeon, Korea, South*
E-mail: ckson@dju.ac.kr

Background and Aims: The progress of hepatic fibrosis determines the clinical outcome of patients, but no therapeutics for this disease exists yet. CGX is a modification of a traditional Korean herbal medicine, which has a hsitory of the long clinial use for patients with various chronic liver inuries and multiple pharmacological results on anti-hepatofibrosis in animal models. CGX is now under clinical trial phase III for anti-hepatofibrosis therapeutic effect in South Korea.

Methods: The clinical study is a phase III trial of stratified randomized (intake antiviral drugs vs. no use), placebo controlled and double blind. 174 patients with chronic HBV, HBV or alcoholic injury are enrolled in 2 hospitals. All patients should have a moderate fibrosis score by 7< and 17 kPa of LSM using Fibroscan. They should not be in advanced fibrosis or cirrosis (ascites, esophageal varix, TB >3 mg/dl, AST, ALT > ULN > 5 folds, INR >2.0 or platelets <80,000/mm^3, BMI >30). Patients take a placebo or CGX (1 or 2 gram daily) for six months. The primary outcome is the changed value of LSM during 6 months. The secondary measurement includes the changed values of hyaluronic acid (HA), serum TGF-β1 and PDGF, AST to platelet ratio index (APRI), and QOL (SF-36) respectively.

Results: This RCT will be continue until June 2015 (From June 2013; RCT registration number is KCT0000773).

Conclusions: The objective of the present study is to present the overall status of a clinical evaluation for CGX, an herbal drug-derived anti-hepatofibrotic.

P1349

RANDOMISED PLACEBO-CONTROLLED TRIAL ASSESSING WHETHER PROBIOTIC SUPPLEMENTS AMELIORATE DEPRESSIVE SYMPTOMS IN PATIENTS WITH CHRONIC HEPATITIS C VIRUS INFECTION

C.S. Stokes[1], J.G. Schneider[1,2], P. Wilmes[3], F. Lammert[1]. [1]*Department of Medicine II, Saarland University Medical Center, Homburg, Germany;* [2]*Translational and Experimental Research Group, Luxembourg Centre for Systems Biomedicine,* [3]*Eco-Systems Biology Group, Luxembourg Centre for Systems Biomedicine, University of Luxembourg, Luxembourg, Luxembourg*
E-mail: caroline.stokes@uks.eu

Background and Aims: Patients with chronic hepatitis C virus (HCV) infection frequently present with co-morbid depression. The pathophysiology of depression is multifactorial, and intestinal microbiota have been reported to influence depressive symptoms. Studies in mice report specific strains of gut bacteria to positively influence brain neurotransmitters implicated in depression, such as GABA. A randomised placebo-controlled trial reported a probiotic supplement to alleviate psychological distress and depressive symptoms in otherwise healthy individuals (Messaoudi et al. Br J Nutr 2011).
Study aim: Given the high prevalence of depressive symptoms in patients with chronic HCV infection, this study assesses whether oral administration of select commensal bacteria modulates depressive symptoms and alters intestinal flora architecture in favour of increased lactobacillus and bifidobacterium in these patients. We hypothesised that probiotic supplementation reduces the severity of depressive symptoms.
Methods: A randomised, double-blind placebo-controlled study is being carried out in adults with chronic HCV infection and depression, that have been awaiting new DAA-based antiviral therapies. The intervention product contains two strains of lactic acid bacteria *Lactobacillus helveticus* and *Bifidobacterium longum*. Patients are randomly given the probiotic or identical placebo orally for 60 days. Patients are assessed using a validated self-report questionnaire (Beck Depression Inventory-II) for depressive symptoms at baseline, and after 30 and 60 days of treatment. Fecal samples collected during these time points enable us to characterise the microbial community using 16S rRNA pyrosequencing and to assess for changes in the gut microbiota in parallel to changes in depressive symptoms. Body composition using bioelectrical impedance analysis and other potential confounders such as dietary intake and physical activity are captured during all study time points, using food diaries and actigraphs.

LIVER AND SPLEEN STIFFNESS MEASUREMENT FOR PREDICTING VARICES BLEEDING AND PROGNOSIS IN RUSSIAN PATIENTS WITH HCV AND ALCOHOL RELATED CIRRHOSIS

E. Liusina, C.S. Pavlov[1], V.T. Ivashkin[1]. [1]*First Moscow State Medical University named after I.M. Sechenov, Moscow, Russia*
E-mail: eka-lusina@yandex.ru

Background and Aims: Hepatitis C viral infection and alcohol are the main ethiological factors of liver cirrhosis in Russia. The direct measurement of hepatic venous pressure gradient is the reference standard for detection of level of portal hypertension but it is expensive and invasive. Colecchia et al. in 2012 published a predictive model for HVPG values that included spleen (SS) and liver stiffness (LS) measured by transient elastography. In our study we tried to modify and study diagnostic test accuracy of this model in a Russian cohort of patients.
The aim of the study is to establish the diagnostic test accuracy of non-invasive liver and spleen stiffness measurement model for prognosis of bleeding from esophageal varices in HCV and alcohol-related cirrhosis.
Methods: A cohort of 100 consecutive patient with HCV and alcohol-related cirrhosis will be enrolled in the study and divided into two groups based on ethiology. After the study design: baseline blood test sampling, upper endoscopy for detecting esophageal varices, ultrasound, liver stiffness measurement with Fibroscan (LS), spleen stiffness measurement with Fibroscan (SS) will be performed at the same day. Abstinence will be recommended to all patients with alcoholic cirrhosis. HCV patients who meet inclusion criteria will be treated in clinical trials with different interferon-free AVT regimes. All baseline procedures will be repeated in 6–12 month after follow up. We register all clinical outcomes during follow-up period.
In this paper we report the data from 22 enrolled patients (15 patients with HCV-related cirrhosis, 7 patients with alcoholic cirrhosis).
Results: LS in the group with varices is significantly higher than in the group without ($p = 0.005$). Median of LS in varices group is 29.5 kPa (IQR 25–48) vs 18.5 kPa (IQR 16.9–21.8). No statistically significant differences between two groups when competed SS were found (small number of enrolled patients). Nevertheless the level of portal vein pressure calculated using the predictive model is significantly higher in varices group – 16.8 (IQR 11–23) vs 9.4 (IQR 7–13) respectively ($p = 0.009$). In addition a statistically significant difference observed when comparing LS in patients with alcohol-related cirrhosis [median LS 48 kPa (IQR 25–75)] with HCV-related group [median LS 21 kPa (IQR 16–27); $p = 0.004$].

AN OPEN-LABEL STUDY TO EVALUATE THE EFFICACY AND SAFETY OF CO-FORMULATED OMBITASVIR/PARITAPREVIR/RITONAVIR WITH RIBAVIRIN IN ADULTS WITH CHRONIC HCV GENOTYPE 4 INFECTION IN EGYPT

W. Doss[1], G. Esmat[2], R.B. Qaqish[3], I. Waked[4], G. Shiha[5], A. Yosry[2], J. King[3], C. Hall[3], N. Mobashery[3]. [1]*National Hepatology & Tropical Medicine Research Institute,* [2]*Cairo University, Cairo, Egypt;* [3]*AbbVie Inc, North Chicago, United States;* [4]*National Liver Institute, Menoufiya,* [5]*Egyptian Liver Research Institute And Hospital (ELRIAH), Dakahliah, Egypt*
E-mail: kristina.kligys@abbvie.com

Background and Aims: Hepatitis C virus (HCV) genotype (GT) 4 is responsible for almost 90% of HCV infections in Egypt. Although HCV GT4 infection is more common in the Middle East and sub-Saharan Africa, the prevalence of GT4 is increasing in Europe. The efficacy and safety of the direct acting antiviral agents (DAA) ombitasvir (OBV), a NS5A inhibitor and paritaprevir (formerly ABT-450, a NS3/4A protease inhibitor, identified by AbbVie and Enanta, co-dosed with ritonavir, PTV/r) with or without ribavirin (RBV) were studied in 135 patients with HCV GT4 infection without cirrhosis in the multicenter Phase 2b study, PEARL-I. SVR12 was 100% in both treatment naïve and prior interferon (IFN) and RBV experienced patients receiving OBV plus PTV/r with RBV for 12 weeks. The current trial will be the first to evaluate OBV/PTV/r with RBV in an exclusively Egyptian population of patients with and without cirrhosis.
Methods: This is a phase 3, open-label, multicenter study (NCT02247401). Approximately 160 treatment-naïve and prior pegIFN/RBV experienced patients with HCV GT4 infection will be enrolled at approximately 5 sites in Egypt. The enrolled population will consist of 100 patients without cirrhosis (50 treatment-naïve and 50 treatment-experienced) and 60 patients with compensated cirrhosis (at least 20 treatment-experienced patients). All non-cirrhotic patients will receive co-formulated OBV/PTV/r once-daily (25 mg/150 mg/100 mg) with weight based RBV for 12 weeks. Cirrhotic patients will be randomized 1:1 to OBV/PTV/r with weight based RBV for 12 or 24 weeks. All patients will be followed for 48 weeks after end of treatment. The primary objective of this

study is to assess the efficacy (proportion of patients with HCV RNA <lower limit of quantification 12 weeks after last dose of study drug) and safety of OBV/PTV/r with RBV among treatment-naïve and prior pegIFN/RBV experienced HCV GT4-infected patients without cirrhosis or with compensated cirrhosis. Secondary objectives of this study are to assess the proportions of patients in each treatment arm with on-treatment virologic failure and with post-treatment relapse within 12 weeks following the end of treatment. The study opened in October 2014.

EASL
The Home of Hepatology

EVENTS 2015

LIVER DISEASE IN RESOURCE LIMITED SETTINGS

Monothematic Conference
Bucharest, Romania
May 29-30

The EASL Monothematic Conference on Liver diseases in resource-limited settings is a very timely conference due to the greater than ever strain on healthcare budgets, the high incidence of liver diseases in resource-limited regions, and the fantastic new drug treatments that come at an incredible cost.

It is intended for those interested in bringing better care for liver patients to areas in need, and will be a time to discuss problems and find solutions on this topic.

The faculty will be a mix of high level liver experts as well as representatives from governmental and non-governmental organisations.

LIVER CIRRHOSIS AND COMPLICATIONS

Clinical School of Hepatology Course 24
Moscow, Russia
June 5-6

AUTOIMMUNE HEPATITIS

Monothematic Conference
London, United Kingdom
September 3-5

ADDRESSING END-STAGE LIVER DISEASE - A MULTIFACETED CHALLENGE

Special Conference
Glasgow, United Kingdom
September 25-27

MANAGEMENT OF CRITICALLY ILL CIRRHOTIC PATIENT

Clinical School of Hepatology Course 25
Barcelona, Spain
October 22-23

EASL MASTERCLASS

Milan, Italy
December 3-5

www.easl.eu/events
