Abstract

Five trisaccharide derivatives designed for detailed exploration of the acceptor specificity of glycosyltransferases involved in termination of *N*-acetyllactosamine-type structures have been synthesized: β-D-Gal *p*-(1 → 4)-β-D-Glc *p*NAc-(1 → 2)-α-D-Man *p*-(1 → O)$(CH_2)_7CH_3$ (**1**), 4-deoxy-β-D-Gal *p*-(1 → 4)-β-D-Glc *p*NAc-(1 → 2)-α-D-Man *p*-(1 → O)$(CH_2)_7CH_3$ (**2**), 4-*O*-methyl-β-D-Gal *p*-(1 → 4)-β-D-Glc *p*NAc-(1 → 2)-α-D-Man *p*-(1 → O)$(CH_2)_7CH_3$ (**3**), 4-deoxy-4-fluoro-β-D-Gal *p*-(1 → 4)-β-D-Glc *p*NAc-(1 → 2)-α-D-Man *p*-(1 → O)$(CH_2)_7CH_3$ (**4**), and β-D-Glc *p*-(1 → 4)-β-D-Glc *p*NAc-(1 → 2)-α-D-Man *p*-(1 → O)$(CH_2)_7CH_3$ (**5**). A general disaccharide acceptor octyl 3,4,6-tri-*O*-benzyl-2-*O*-(3,6-di-*O*-benzyl-2-deoxy-2-phthalimido-β-D-glucopyranosyl)-α-D-mannopyranoside was synthesized by condensation of 4-*O*-acetyl-3,6-di-*O*-benzyl-2-deoxy-2-phthalimido-α,β-D-glucopyranosyl trichloroacetimidate with octyl 3,4,6-tri-*O*-benzyl-α-D-mannopyranoside, followed by deacetylation. 2,3,4,6-Tetra-*O*-acetyl-α-D-galactopyranosyl trichloroacetimidate and 2,3,4,6-tetra-*O*-acetyl-α-D-glucopyranosyl trichloroacetimidate were used as the gly-

cosyl donors in the syntheses of **1** and **5**. The modified galactosyl derivatives required subtle anomeric activation. Suitable donors for **2** turned out to be 2,3,6-tri-*O*-acetyl-4-deoxy-α-D-*xylo*-hexopyranosyl trichloroacetimidate and ethyl 2,3,6-tri-*O*-acetyl-4-deoxy-1-thio-α,β-D-*xylo*-hexopyranoside; for **3**, ethyl 2,3,6-tri-*O*-acetyl-4-*O*-methyl-1-thio-α,β-D-galactopyranoside; and for **4**, 2,3,6-tri-*O*-acetyl-4-deoxy-4-fluoro-α-D-galactopyranosyl trichloroacetimidate. It was concluded that thioglycosides were most appropriate for stereoselective coupling of activated synthons (carrying deoxy or *O*-methyl groups), whereas trichloroacetimidates gave high yields with deactivated (fluorine-containing) synthons. © 1996 Elsevier Science Ltd.

1. Introduction

Carbohydrate sequences located at the periphery of glycoconjugate glycans have been implicated in a variety of biological recognition phenomena, including cell–cell, receptor–ligand, and host–pathogen interactions, or tumour progression and metastasis [1–4]. The biosynthesis of these carbohydrate ligands requires the action of many distinct glycosyltransferases, which are highly specific for acceptor substrates and the type of linkage formed in the product [5]. A thorough analysis of the substrate specificity can be attained by using modified oligosaccharides, probing the contribution of individual hydroxyl groups in recognition and binding. Usually, the substrate specificity of glycosyltransferases is studied with the smallest active acceptor and their derivatives (see for example ref. [6]). However, a number of these enzymes have been shown to interact with parts of the acceptor structure remote from the site of glycosylation (see for example ref. [7]). These findings prompted a detailed exploration of the binding features of glycosyltransferases using modified acceptors beyond the minimal recognition structure, at the interface of a biologically relevant and synthetically feasible approach.

In a first approach, we focus on sialyltransferases, since sialic acids occur at the non-reducing termini of many glycans and are considered to be 'key' determinants in the regulation of many cell-surface recognition phenomena [8]. Recent studies with a purified rat-liver Gal-β-(1 → 4)-GlcNAc α-(2 → 6)-sialyltransferase revealed that the enzyme, though specific for the β-(1 → 4) linkage of the penultimate sugar in the *N*-acetyllactosamine epitope in glycoprotein N-glycans [9], tolerated some modifications in the accepting terminal monosaccharide, producing varying yields of oligosaccharides [10,11]. In β-D-Hex*p*-(1 → 4)-β-D-Glc*p*NAc-(1 → O)CH_3 the enzyme transferred Neu5Ac from CMP-Neu5Ac to the primary hydroxyl group of Hex, where Hex was Gal, GalNAc, Glc, GlcNAc, or Man [10]. These results indicated that some of the hydroxyl groups of the terminal monosaccharide are of minor importance for effective sialylation, a phenomenon that has been further explored in the present study. To this end, a number of modified trisaccharides of the type D-Hex*p*-(1 → 4)-β-D-Glc*p*NAc-(1 → 2)-α-D-Man*p*-(1 → O)$(CH_2)_7CH_3$, representing a complete branch of an *N*-acetyllactosamine glycan, have been synthesized chemically. These compounds all contain an octyl aglycon to facilitate the determination of kinetic parameters using the so-called Sep-Pak assay [12]. In this paper, the synthesis of β-D-Gal*p*-(1 → 4)-β-D-Glc*p*NAc-(1 → 2)-α-D-Man*p*-(1 → O)$(CH_2)_7CH_3$ (**1**) and a first series of analogues is described, wherein

HO-4 of terminal galactopyranose was replaced by hydrogen (**2**), methoxy (**3**), or fluorine (**4**) functions, or epimerized (**5**).

2. Results and discussion

For the syntheses of **1–5**, all containing the element → 4)-β-D-Glc*p*NAc-(1 → 2)-α-D-Man*p*-(1 → O)$(CH_2)_7CH_3$, a general strategy was aimed at the preparation of the disaccharide acceptor octyl 3,4,6-tri-*O*-benzyl-2-*O*-(3,6-di-*O*-benzyl-2-deoxy-2-phthalimido-β-D-glucopyranosyl)-α-D-mannopyranoside (**11**), followed by elongation at HO-4′ using suitably modified glycosyl donors. This would allow the chemical modification (i.e., the 4-deoxygenation, the 4-*O*-methylation, and the 4-fluorination) to be carried out at the level of galactose, to minimize the number of protective groups that might interfere. Some of the modifications (particularly deoxygenation) turned out to give rise to an increase in reactivity at the anomeric center, necessitating the selection of a glycosyl donor of suitable reactivity.

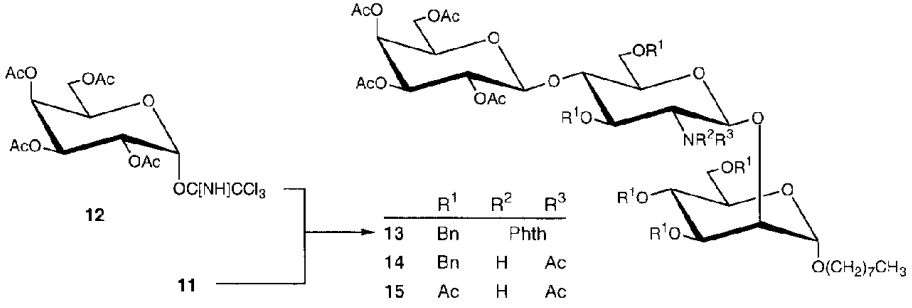
For the synthesis of the general disaccharide acceptor **11**, the mannosyl acceptor **9** was synthesized *via* a silver triflate promoted condensation of 2-*O*-acetyl-3,4,6-tri-*O*-benzyl-α-D-mannopyranosyl chloride (**7**) [13] with 1-octanol in 1:1 nitromethane–toluene (→ **8**, 53%), followed by Zemplén deacetylation (→ **9**, 88%). Condensation of **9** with 4-*O*-acetyl-3,6-di-*O*-benzyl-2-deoxy-2-phthalimido-α,β-D-glucopyranosyl trichloroacetimidate (**6**) [14] in CH_2Cl_2, using boron trifluoride etherate as a catalyst, gave **10** (90%), which was deacetylated to afford **11** (80%).

The synthesis of trisaccharide **1** involved galactosylation of **11** with 2,3,4,6-tetra-*O*-acetyl-α-D-galactopyranosyl trichloroacetimidate (**12**) [15] in CH_2Cl_2 as a first step, using trimethylsilyl triflate as a catalyst, to afford **13** (94%). Dephthaloylation of **13** with hydrazine monohydrate in aqueous ethanol, followed by *N*,*O*-acetylation, gave **14** (80%), but the use of ethylenediamine [16] in 1-butanol improved the yield of this step from 80% to 95%. Catalytic hydrogenation of **14** over 10% Pd–C and subsequent *O*-acetylation (→ **15**, 97%) and *O*-deacetylation afforded, after purification on Bio-Gel P-2 and lyophilization, **1** (94%). The *O*-acetylation step at the final stage of the deprotection sequence was carried out to allow a good chromatographic purification, ensuring a high purity of the deprotected structure. The ^{1}H NMR structural-reporter-group data of **1** are presented in Table 1. It should be noted that the propyl [17], aminohexyl [18], and 8-methoxycarbonyloctyl [11] analogues of **1** have been described previously.



Since it is known that deoxyglycosyl donors are more reactive than the parent saccharides [19,20], several donors were examined for their suitability in the preparation of trisaccharide **2**, containing a 4-deoxy-D-galactosyl (systematic name: 4-deoxy-D-*xylo*-hexosyl) group. To this end, benzyl 2,3,6-tri-*O*-benzyl-β-D-galactopyranoside (**16**) [21] was chosen as a precursor for the donors **22**, **23**, **24**, and **26**. As a first step, **16** was converted into the methyl xanthate **17**, which was reduced with tributyltin hydride (→ **18**, 82% from **16**), and then hydrogenolyzed over 10% Pd–C (→ **19**) and acetylated, to afford **20** (86% from **18**). Selective deacetylation of **20** (→ **21**) and treatment with trichloroacetonitrile in the presence of 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) gave imidate **22** (63% from **20**). Treatment of **20** or **25**, obtained by conventional benzoylation (benzoyl chloride, pyridine) of **19**, with hydrogen bromide in acetic acid gave bromides **23** (93%) and **26** (82% from **19**). An anomeric mixture (α:β = 1:6) of ethyl thioglycosides (**24**, 70%) was obtained from **20** by a boron trifluoride etherate catalyzed

reaction with EtSH. The glycosylation behaviour of the bromides **23** and **26**, examined towards the corresponding allyl glycoside analogue of acceptor **11**, revealed that these donors produced mixtures (presumably of trisaccharide derivatives) which could not be separated (unpublished data). Therefore, **23** and **26** were not further investigated. The glycosylation of **11** with imidate **22** in CH_2Cl_2 at −30 °C, using trimethylsilyl triflate as a catalyst, resulted in the formation of pure **27** (74%). It should be noted that the donor reagent was added dropwise to a solution of acceptor (**11**) and the catalyst in this reaction, requiring a 2.5-fold excess of **22**. Alternatively, the use of thioglycosides **24** (1.3 equiv) in CH_2Cl_2 at 0 °C, with *N*-iodosuccinimide–triflic acid as a promoter, gave **27** in high yield (81%) without the necessity of a reversed addition of reagents. Deprotection of **27** (→ **28**, → **29**, → **2**), in an analogous way to that indicated for **13**, using hydrazine monohydrate as a dephthaloylation reagent, afforded **2** in an overall yield of 75%. For ^{1}H NMR data, see Table 1.

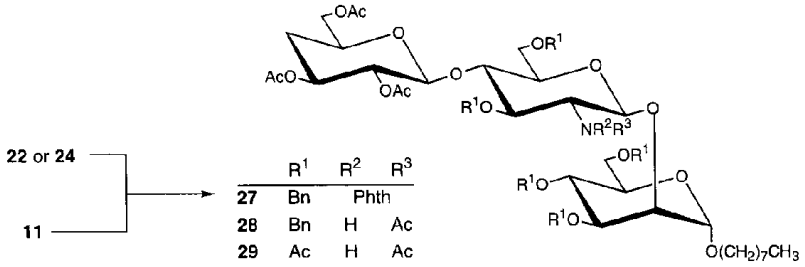
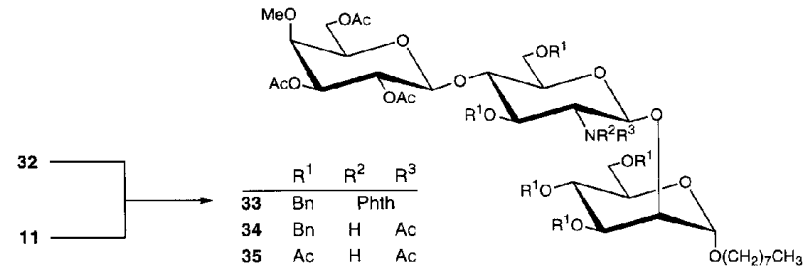
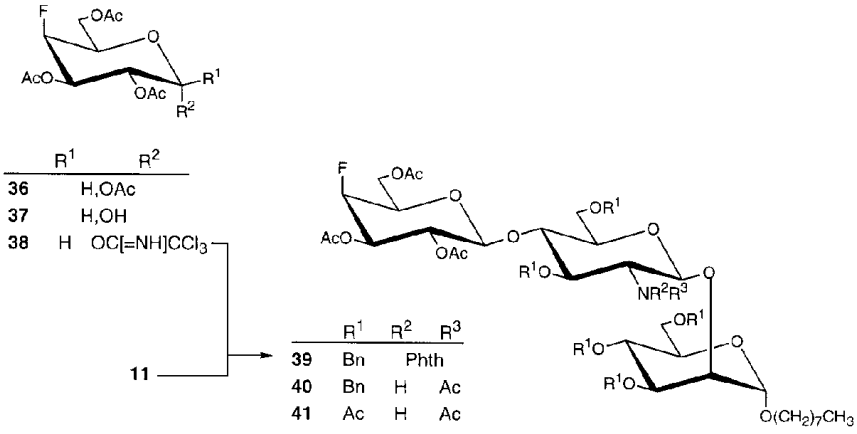
In the synthesis of trisaccharide derivative **3**, a 4-*O*-methyl-D-galactosyl donor was required for glycosylation of **11**. Preliminary experiments (data not shown) with the allyl glycoside analogue of **11** indicated that the presence of the methyl group enhanced the reactivity at the anomeric center of the galactose residue, leading to a loss of stereoselectivity. For example, the use of 2,3,6-tri-*O*-acetyl-4-*O*-methyl-α-D-galactopyranosyl trichloroacetimidate as a donor with either trimethylsilyl triflate or boron trifluoride etherate as a catalyst proved to be unsuitable for the exclusive formation of a β linkage.

A reversed addition of reagents was not attempted, since this would require a relatively large excess of the donor reagent. Instead, in view of the efficacy of thioglycosides **24** in the stereoselective glycosylation of **11**, the synthesis of thioglycosides **32** was planned, starting from compound **16**. Methylation (MeI, NaH) of **16** afforded crystalline **30** (86%), which was debenzylated and then acetylated to afford **31** (97%). Treatment of **31** with EtSH in the presence of boron trifluoride etherate gave an anomeric mixture (α:β = 1:2) of ethyl thioglycosides (**32**, 73%). Coupling of **11** with **32** in CH_2Cl_2 at 0 °C, using *N*-iodosuccinimide–triflic acid as a promoter, gave the expected β-linked trisaccharide **33** in high yield (85%). Deblocking of **33** (→ **34**, → **35**, → **3**) as indicated for **13**, using hydrazine monohydrate as the dephthaloylation reagent, yielded **3** in an overall yield of 62%. For ^{1}H NMR data, see Table 1.

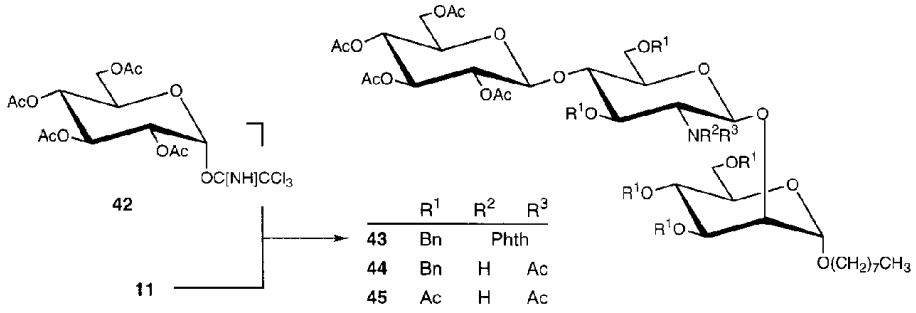




For the synthesis of the 4″-fluorinated trisaccharide **4**, galactosyl imidate **38** was prepared. Removal of the acetyl group at O-1 from 1,2,3,6-tetra-*O*-acetyl-4-deoxy-4-fluoro-α,β-D-galactopyranose (**36**) [22] with hydrazine acetate (→ **37**) and imidation using trichloroacetonitrile and DBU yielded **38** (63% from **36**). Coupling of **11** and **38** in CH_2Cl_2 at 0 °C, using trimethylsilyl triflate as a catalyst, gave **39** (93%). After deprotection of **39** (→ **40**, → **41**, → **4**) as described for **13**, using hydrazine monohydrate as the dephthaloylation reagent, compound **4** was obtained in an overall yield of 59%. For ^{1}H NMR data, see Table 1.



The synthesis of the glucose-containing trisaccharide analogue **5** was carried out by condensation of **11** with 2,3,4,6-tetra-*O*-acetyl-α-D-glucopyranosyl trichloroacetimidate (**42**) [15] in CH_2Cl_2 at 0 °C, in the presence of trimethylsilyl triflate, affording **43** (76%). This trisaccharide derivative was deprotected in a similar way as described for **13** (→ **44**, → **45**, → **5**), using ethylenediamine as the dephthaloylation reagent, to give **5** in an overall yield of 65%. For ^{1}H NMR data, see Table 1.



Summarizing the various coupling results, it can be concluded that thioglycosides were most appropriate for stereoselective coupling of activated synthons carrying deoxy or *O*-methyl groups, whereas trichloroacetimidates gave high yields with deactivated fluorine-containing synthons. A kinetic study of the transfer of Neu5Ac from CMP-Neu5Ac to the trisaccharides **1**–**5** as well as to a series of additional synthesized trisaccharides wherein Hex = 3-*O*-methyl-β-D-Gal, 3-deoxy-β-D-Gal, 3-deoxy-3-fluoro-β-D-Gal, 3-amino-3-deoxy-β-D-Gal, β-D-Gul, α-L-Alt, or β-L-Gal, by several purified and recombinant α-(2 → 6)- and α-(2 → 3)-sialyltransferases, will be reported elsewhere.

3. Experimental

General methods.—All solvents were distilled from appropriate drying agents. Reactions were monitored by TLC on Kieselgel 60 F_{254} (Merck) using solvent mixtures of appropriately adjusted polarity; solvent A = 4:2:2:1 1-butanol–EtOH–HOAc–H_2O. Compounds were visualized by charring with aq 50% sulfuric acid, after examination under UV light. In the workup procedures of reaction mixtures, organic solutions were washed with appropriate amounts of aqueous solutions as indicated, or with 8 mM phosphate buffer (pH 7.5), then dried ($MgSO_4$), and concentrated under reduced pressure at 20–40 °C. Column chromatography was performed on Kieselgel 60 F_{254} (70–230 mesh, Merck), unless otherwise stated. Optical rotations were determined for solutions in $CHCl_3$ unless otherwise stated, at 20 °C with a Perkin–Elmer 241 polarimeter, using a 10-cm 1-mL cell. ^{1}H NMR spectra were recorded with a Bruker AC 300 or AM 500 spectrometer; the values of δ_H are expressed in ppm relative to the signal for internal Me_4Si for solutions in $CDCl_3$, or by reference to acetone (δ 2.225) for solutions in D_2O. ^{13}C NMR spectra were recorded with a Bruker WP 200 (50 MHz) or a Varian Gemini-300 instrument (75 MHz); indicated values for δ_C are relative to the signal of $CDCl_3$ (δ 76.9). Microanalyses were carried out by the Mikroanalytisches Laboratorium of H. Kolbe (Mülheim an der Ruhr, Germany). Fast-atom-bombardment mass spectrometry (FABMS) was performed on a JEOL JMS SX/SX 102A four-sector mass spectrometer, operated at 10-kV accelerating voltage, equipped with a JEOL MS-FAB 10 D FAB gun operated at 10-mA emission current, producing a beam of 6-keV xenon atoms.

The stirring was continued for 1 h, MeI (0.53 mL, 8.5 mmol) was added, and after 30 min TLC (7:3 hexane–EtOAc) showed the formation of **17** (R_f 0.59). The mixture was diluted with CH_2Cl_2, washed with phosphate buffer, 0.2 M HCl, aq 10% $NaHCO_3$, and H_2O, then concentrated.
