Abstract

The presence of potentially intramolecularly coordinating substituents in ligands can be an attractive alternative to steric bulk as an approach to stabilizing monomeric, solvent-free complexes of Lewis-acidic metal complexes. In addition, intramolecular coordination has proven to be a useful tool for the preparation of well-defined mixed-metal complexes. This paper gives an overview of the various types of ligands containing intramolecularly coordinating substituents that have been used in complexes with Group 3 and lanthanide metals. Emphasis is put on the synthesis of such complexes and on an analysis of the intramolecular

coordination present. Their (potential) applications as catalysts in organic transformations and as precursors for lanthanide-oxide-containing ceramics are described.

Keywords: Lewis-acidic metal complex; Intramolecular coordination; Ceramic; Group 3; Lanthanides

1. Introduction

The general interest in monomeric, solvent- and salt-free complexes of the lanthanides can be seen as a result of two separate lines of research. Firstly, in order to take full advantage of the Lewis-acidic properties of the lanthanide ions for organic transformations and/or catalysis, the lanthanide complexes should preferably be monomeric, solvent-free and contain available coordination sites. Secondly, lanthanide complexes that are to be used as precursors for lanthanide-oxide-containing ceramics that are prepared via metal–organic chemical vapor deposition (MOCVD) should preferably be monomeric and salt-free in order to obtain optimal vapor pressures.

One approach to prevent association of metal complexes is to introduce sterically bulky substituents on the ligands. For example, while lanthanide alkoxides² and phenolates are typically polymeric in structure [2], monomeric, solvent-free complexes have been reported that use sterically demanding monoanionic ligands like OCMet¹Pr [3] and OC₆H₂-¹Bu₂-2,6-Me-4 [4]. An attractive alternative to this approach is the introduction of potentially intramolecularly coordinating substituents on the ligands. When these substituents coordinate to the metal center, they combine steric shielding of the metal center with electron donation to the metal center. The latter reduces the Lewis acidity of the metal center and, in combination with the shielding effect, may prevent association of the complexes, and also retention of salt or donor molecules at the metal center. When the donor substituents are pendant, they still provide steric shielding of the metal center. These pendant substituents can also serve as Lewis basic functional groups and add reactivity to the complex or serve as anchoring places for other metal complexes. This last option, which was recently also put forward by Anwender et al. [5], can be of great value in, for example, the preparation of heterometallic catalysts or heterometallic precursors for high-temperature superconductors [6].

During the last 15 years there has been an increase in the interest in potentially intramolecularly coordinating substituents in combination with the Lewis-acid lanthanide ions. The following paragraphs give an overview of the literature concerning this subject.

2. Cyclopentadienyl-based ligands (Table 1)

Only in the last decade has attention been focused on donor-substituted derivatives of the cyclopentadienyl ligand, which is traditionally used in lanthanide chemistry.

² For a review on lanthanide alkoxide chemistry up to 1990, see Ref. [1].

This attention has been partly academic (stabilization of low coordination numbers) and partly directed towards the stabilization of hydride species that are of interest with respect to catalytic hydrogenation reactions.

2.1. Complexes of bridged dicyclopentadienyl ligands

The first complexes of type I to be synthesized were the monomeric monochloride complexes $[\text{O}(\text{CH}_2\text{CH}_2\text{C}_5\text{H}_4)_2]\text{LnCl}$ (1; Ln is Y, Nd, Gd, Ho, Er, Yb, Lu) [7], which were prepared by reaction of LnCl_3 with one equivalent of $[\text{O}(\text{CH}_2\text{CH}_2\text{C}_5\text{H}_4)_2]\text{Na}_2$ at -20°C in THF. These complexes were reported to be much more stable towards air and moisture than the corresponding Cp_2LnCl [8] (Cp is C_5H_5) and $[\text{CH}_2(\text{CH}_2\text{CH}_2\text{C}_5\text{H}_4)_2]\text{LnCl}$ [9] complexes. Evidence for coordination of the oxygen functionality to the lanthanide centers was obtained from IR measurements, which show a shift of the C–O–C stretching vibration to lower frequency relative to that in the starting disodium complex $[\text{O}(\text{CH}_2\text{CH}_2\text{C}_5\text{H}_4)_2]\text{Na}_2$. In addition, XPS measurements showed a decrease in the binding energies of the lanthanide atoms, while the binding energies of oxygen increase, consistent with coordination of oxygen to the lanthanide centers. In combination with NaH, $[\text{O}(\text{CH}_2\text{CH}_2\text{C}_5\text{H}_4)_2]\text{YCl}$ was shown to be an effective catalyst for the hydrogenation of hexenes at 45°C under 1 atm of H_2 . The activity decreased in the order 1-hexene > 2-hexene \gg cyclohexene, but the complex was more reactive than Cp_2YCl and required a smaller excess of NaH [10].

Substitution of chloride by cyclopentadienyl [11], hydride [12] and 1,3-dimethylpyrazolate [13], using the corresponding sodium reagents in THF, has been reported for these complexes. For the cyclopentadienyl complexes $[\text{O}(\text{CH}_2\text{CH}_2\text{C}_5\text{H}_4)_2]\text{Ln}(\text{C}_5\text{H}_3\text{R})$ (2: R is H, Ln is Y, Nd, Gd, Er, Yb, Lu; 3: R is Me, Ln is Y, Yb), η^5 -coordination of the cyclopentadienyl was deduced from NMR and IR data for the complexes, as well as from their lack of reactivity towards CCl_4 (the latter selectively attacks $[\text{CH}_2(\text{CH}_2\text{C}_5\text{H}_4)_2]\text{Ti}(\eta^1\text{-C}_5\text{H}_5)_2$ to give $[\text{CH}_2(\text{CH}_2\text{C}_5\text{H}_4)_2]\text{TiCl}_2$ [14]).

The dimeric hydride complexes $\{[\text{O}(\text{CH}_2\text{CH}_2\text{C}_5\text{H}_4)_2]\text{Ln}(\mu\text{-H})\}_2$ (4; Ln is Y, Gd, Er, Yb, Lu) [12] are very sensitive towards air and moisture, soluble in THF, but insoluble in hydrocarbons at room temperature. These complexes react with 1-hexene to give the corresponding hexyl complexes, which can subsequently be hydrolyzed

to give hexane. The yield of hexane was found to depend on the reaction temperature, the concentration of the hydrides and on the lanthanide metal. In addition, the yield of hexane increased dramatically on the addition of a fourfold excess of NaH [12]. The hydride complexes **4** also react with the (acidic) hydrogen of terminal alkynes with formation of the corresponding alkynide complex and H₂ [12]. The system {[O(CH₂CH₂C₅H₄)₂]YH}₂/NaH (1:20 molar ratio) effectively reduces organic halides, with the rate depending on the position of the halogen atom (*p*-bromotoluene > *m*-bromotoluene > *o*-bromotoluene) as well as on the bond energy of the C–X bond (R–I > R–Br ≫ R–Cl, R–F). This system is also able to reduce organic bromides catalytically [12].

The 1,3-dimethylpyrazolate complexes [O(CH₂CH₂C₅H₄)₂]Ln(N₂C₃HMe₂) (**5**; Ln is Y, Lu) are highly sensitive towards air and moisture, and the products of their partial hydrolysis [O(CH₂CH₂C₅H₄)₂]Ln (μ-N₂C₃HMe₂)(μ-OH)Ln [O(CH₂CH₂C₅H₄)₂] (**6**; Ln is Y, Lu) were the first complexes of type **I** to be crystallographically characterized. The X-ray structures of these two complexes show nine-coordinate yttrium and lutetium centers as a result of intramolecular coordination of the oxygen functionality to the metal [13].

With a furyl moiety bridging the two cyclopentadienyl ligands (**1b**), the dimeric complexes {[C₄H₂O(CH₂C₅H₄)₂-2,5]Ln(μ-Cl)}₂ (**7**; Ln is Y, Nd, Sm, Yb) [15] were obtained, following a synthetic procedure similar to that used for complexes **1**. These air- and moisture-sensitive complexes decompose on heating before sublimation. Efforts to obtain similar complexes for the early lanthanides La and Pr were unsuccessful. The dimeric nature of the complexes follows from their mass spectra, and may be ascribed to the somewhat shorter ring-bridging linker in **1b** as compared to **1a**. This leads to a smaller bite angle for the dicyclopentadienyl ligand. Proof for intramolecular coordination of the furyl oxygen to the lanthanide metals was obtained from IR and XPS measurements. The complexes were transformed in situ to the corresponding hydrides {[C₄H₂O(CH₂C₅H₄)₂-2,5]Ln(μ-H)}₂ (**8**; Ln is Y, Nd, Sm, Yb) using NaH, and these were applied as catalysts in the reduction of 1-octene (low activity) and in the dechlorination of benzyl chloride (high activity). The catalytic activities were compared to those of other complexes of ring-linked dicyclopentadienyl ligands [15].

In addition to the bridging ether function, bridging nitrogen donors have also been used. Complexes {[MeN(CH₂CH₂C₅H₄)₂]Ln(μ-Cl)}₂ (**9**; Ln is Y, Nd, Sm, Yb) [16] were synthesized using a procedure similar to that for complexes **1**, and evidence for intramolecular coordination of the amino functionality to the lanthanide metals was obtained from NMR and IR data. In contrast to the monomeric structures of complexes **1**, these complexes were found to be dimeric chloride-bridged species (mass-spectral data). This is in accord with the softer character of the amino donor in complexes **9** as compared with the oxygen donor in complexes **1**.

Similarly, complexes {[C₅H₃N(CH₂C₅H₄)₂-2,6]Ln(μ-Cl)}₂ (**10**; Ln is Y, Pr, Nd, Sm, Dy, Er, Yb, Lu) [17], containing a bridging pyridine (**1c**) are also dimeric (mass-spectral data). Evidence for intramolecular coordination of the pyridine functionality in these complexes was again obtained from XPS measurements. Preliminary experiments showed complexes **8** to be active catalysts in the reduction of 1-hexene by

Fig. 1. Schematic representation of the proposed structure of complex **11**.

LiAlH₄ Reaction of three equivalents of the starting $[\text{C}_5\text{H}_3\text{N}(\text{CH}_2\text{C}_5\text{H}_4)_2\text{-2,6}]\text{Na}_2$ with two equivalents of $\text{PrCl}_3 \cdot (\text{THF})_x$ gave rise to the formation of $[\text{C}_5\text{H}_3\text{N}(\text{CH}_2\text{C}_5\text{H}_4)_2\text{-2,6}]_3\text{Pr}_2$ (**11**) which was proposed to contain the third ligand in a bridging fashion: $\text{Pr}(\eta^5\text{-C}_5\text{H}_4\text{CH}_2\text{-2-(C}_5\text{H}_3\text{N)-6-CH}_2\text{C}_5\text{H}_4\text{-}\eta^5\text{)Pr}$, see Fig. 1.

Type III
substituted ferrocenyl ligands

2.2. Complexes of donor-substituted cyclopentadienyl ligands

Both Ln(III) and Ln(II) complexes of type II ligands have been synthesized using oxygen and nitrogen donor substituents. Complexes $[(\text{MeOCH}_2\text{CH}_2\text{C}_5\text{H}_4)_2\text{Ln}(\mu\text{-Cl})]_2$ (**12**; Ln is La, Pr, Nd) [18] and $(\text{Me}_2\text{NCH}_2\text{CH}_2\text{C}_5\text{H}_4)_2\text{LnCl}$ (**13**; Ln is Nd [19], Lu [20]) were synthesized by reaction of LnCl_3 with two equivalents of $(\text{DoCH}_2\text{CH}_2\text{C}_5\text{H}_4)\text{Na}$ (Do is OMe, NMe₂) at room temperature in THF, and of both types of complexes X-ray structures have been reported. In the dimeric, chloride-bridged solid-state structure of $[(\text{MeOCH}_2\text{CH}_2\text{C}_5\text{H}_4)_2\text{LaCl}]_2$ [18] the ether substituents coordinate to the lanthanum metal to which the cyclopentadienyl ligand is η^5 -bonded, leading to formally ten-coordinate lanthanum centers. ¹H NMR measurements showed that also in solution the ether functions are coordinating to the metal center.

When the chloride ion in complexes **12** is replaced by the larger iodine, the complexes are monomeric: $(\text{MeOCH}_2\text{CH}_2\text{C}_5\text{H}_4)_2\text{LnI}$ (**14**; Ln is Y, La [21], Yb [22]). Intramolecular coordination of the methoxy substituents in complexes **14** was observed by IR and NMR spectroscopy (Ln is Y, La) and the monomeric structure was suggested by mass spectroscopy (Ln is Y, La) and firmly established by X-ray

structure analysis (Ln is Y, La, Yb). The structures of all three complexes show both ether substituents to coordinate to the metal centers, resulting in formal nine-coordination. Replacement of methoxy by sterically more demanding dimethylamino substituents as in complexes **13** also prevents dimerization of the resulting complexes, as shown by the monomeric solid-state structure of $(\text{Me}_2\text{NCH}_2\text{CH}_2\text{C}_5\text{H}_4)_2\text{NdCl}$ [19]. In this complex, coordination of both amino functionalities to neodymium also leads to formal nine-coordination.

Reaction of $[(\text{MeOCH}_2\text{CH}_2\text{C}_5\text{H}_4)_2\text{LnCl}]_2$ with NaBH_4 at room temperature in THF leads to the formation of $(\text{MeOCH}_2\text{CH}_2\text{C}_5\text{H}_4)_2\text{LnBH}_4$ (**15**; Ln is La, Pr, Nd, Sm, Gd) [23]. According to both MS data and the solid-state structures of the complexes with Ln as Pr, Nd, the larger bulkiness of BH_4^- compared to Cl^- (in complexes **12**) makes these complexes monomeric. Reaction of $[(\text{MeOCH}_2\text{CH}_2\text{C}_5\text{H}_4)_2\text{LnCl}]_2$ with NaH in THF at room temperature affords the hydride complexes $[(\text{MeOCH}_2\text{CH}_2\text{C}_5\text{H}_4)_2\text{Ln}(\mu\text{-H})]_2$ (**16**; Ln is Y, La, Pr, Ho) [24], which were reported to be much more soluble in THF than their unsubstituted C_5H_5 analogs, but insoluble in aliphatic solvents at room temperature. Their mass spectra and the X-ray structure of the Y-complex showed that these complexes are dimeric in structure. IR measurements showed two separate C–O–C stretching vibrations, which is in accord with the X-ray structure of $[(\text{MeOCH}_2\text{CH}_2\text{C}_5\text{H}_4)_2\text{YH}]_2$ that shows the ether functionality of one of the two cyclopentadienyl ligands to be coordinated to yttrium in the solid state. As a result of partial hydrolysis during crystallization, complex $[(\text{MeOCH}_2\text{CH}_2\text{C}_5\text{H}_4)_2\text{Ho}(\mu\text{-OH})]_2$ (**17**) was obtained, and the X-ray structure of this complex also shows the coordination of only one ether functionality, though the second remains pendant [24].

Up to now complexes $[(\text{MeOCH}_2\text{CH}_2\text{C}_5\text{H}_4)_2\text{Ln}(\text{THF})]^+[\text{Co}(\text{CO})_4]^-$ (**18**; Ln is Sm, Yb) are the only cationic complexes containing donor-substituted cyclopentadienyl ligands reported [25]. These complexes could be synthesized both by metathesis of $[(\text{MeOCH}_2\text{CH}_2\text{C}_5\text{H}_4)_2\text{LnI}]$ with $\text{K}[\text{Co}(\text{CO})_4]$ in addition to one-electron oxidation of divalent $(\text{MeOCH}_2\text{CH}_2\text{C}_5\text{H}_4)_2\text{Ln}(\text{THF})$ (vide infra) with $\text{Co}_2(\text{CO})_8$. The X-ray structure of the Yb complex showed **18** to exist as discrete cations and anions, with both ether functionalities coordinating to the ytterbium center in the cation. Together with the additional coordination of one THF solvent molecule, this amounts to a coordination number of nine for the ytterbium ion.

The triscyclopentadienyl complexes $(\text{MeOCH}_2\text{CH}_2\text{C}_5\text{H}_4)_3\text{Ln}$ (**19**; Ln is Nd [19], La, Pr [26], Sm [22]), synthesized similarly to complexes **12** and **13**, are monomeric, with two of the three available ether functionalities coordinating to the metal centers as shown by both low-temperature ^1H NMR spectra and the solid-state structure of the praseodymium [26] and samarium [22] complexes. The third ether function remains pendant. Also in this case, substitution of methoxy for dimethylamino as in complexes $(\text{Me}_2\text{NCH}_2\text{CH}_2\text{C}_5\text{H}_4)_3\text{Ln}$ (**20**; Ln is La, Nd) [19,20] leads to additional steric crowding around the lanthanide centers. In the solid-state structure of $(\text{Me}_2\text{NCH}_2\text{CH}_2\text{C}_5\text{H}_4)_3\text{Nd}$ [20] only one of the three donor substituents coordinates to the neodymium, the other two remaining pendant, as opposed to two of the three in complexes **19**. As a result of the somewhat larger ionic radius of La^{3+} as compared to Nd^{3+} , a second amino substituent is able to approach the lanthanum center in

($\text{Me}_2\text{NCH}_2\text{CH}_2\text{C}_5\text{H}_4$)₃La, although the La–N distance for this additional interaction in the solid state is very long (3.688(5) Å; cf. 2.898(6) Å for the ‘normal’ La–N distance in this complex, which itself is long when compared to other La–N interactions) [20]. These effects of steric crowding are even stronger for the smallest lanthanide, lutetium, where the tri-substituted complex is not formed using the reaction conditions for the preparation of complexes **19**, and ($\text{Me}_2\text{NCH}_2\text{CH}_2\text{C}_5\text{H}_4$)₂LuCl is obtained instead [20].

In addition to these trivalent lanthanide complexes, divalent lanthanide complexes of type **II** have also been reported for samarium and ytterbium. These complexes were prepared by reaction of the sodium or potassium salts of the ligands with LnI_2 in THF solution at room temperature. For complexes ($\text{MeOCH}_2\text{CH}_2\text{C}_5\text{H}_4$)₂Ln (Ln is Sm, Yb) (**21**) [27] and ($\text{Me}_2\text{NCH}_2\text{CH}_2\text{C}_5\text{Me}_4$)₂Sm (**22**) [28] intramolecular coordination of the donor substituents was established by NMR spectroscopy and also found in the X-ray structures of ($\text{MeOCH}_2\text{CH}_2\text{C}_5\text{H}_4$)₂Yb·THF and the calcium analog of **22**. For complexes [$\text{C}_5\text{H}_4\text{N}-2-(\text{CH}_2)_n\text{CMe}_2\text{C}_5\text{H}_3\text{R}$]₂Yb ($n=0, 1$; R is H, SiMe₃) (**23**) intramolecular coordination of the 2-pyridyl donor in the solid state was established from X-ray structures (for $n=0$, R is H; for $n=1$, R is SiMe₃) [29].

Thus far, only one report has appeared on complexes of type **III**. Complexes containing the monoanionic, ferrocene-based ligand [$(\text{C}_5\text{H}_5)\text{Fe}(\text{C}_5\text{H}_3\text{CH}_2\text{NMe}_2)]^-$ (FcN) were synthesized by reacting LnCl_3 (Ln is La, Ce, Pr, Nd, Yb) or Cp_2LnCl (Sm, Er, Yb) with the lithium complex (FcN)Li in THF at room temperature [30]. Reaction of LnCl_3 with three equivalents of (FcN)Li afforded the heterometallic salt-containing and solvent-containing complexes (FcN)₃Ln·LiCl·THF (**24**; Ln is Ce, Pr, Nd). Only for ytterbium could the salt-containing and solvent-free tris complex (FcN)₃Yb (**25**) be obtained, while with LaCl_3 such a complex was not formed and (FcN)₂LaCl (**26**) was obtained instead. Reaction of Cp_2LnCl with one equivalent of (FcN)Li afforded the mixed-ligand complexes $\text{Cp}_2\text{Ln}(\text{FcN})(\text{THF})_n$ (**27**; Ln is Sm: $n=1$; Ln is Er: $n=0$). In contrast, reaction of [Cp_2YbCl]₂ with one equivalent of (FcN)Li gives $\text{CpYb}(\text{FcN})_2$ (**28**) as the sole product.

3. Alkyl-, aryl- and pyridyl-based ligands (Table 2)

3.1. Complexes of donor-substituted aryl ligands

Among the first ligands in organolanthanide chemistry containing donor substituents were those that contained a Ln–C σ -bond and were derived from alkyl-, aryl- and 2-pyridyl ligands.

Table 2
Lanthanide complexes of alkyl-, aryl- and pyridyl^a based ligands containing intramolecularly coordinating substituents

Complex	Lanthanide metals ^a	Ln–Do bond lengths (Å)	Ligand type	Ref.
29 (C ₅ H ₅) ₂ Ln[C ₆ H ₄ (CH ₂ NMe ₂) ₂]	Sc, Y	Y–N: 2.43(2), 2.54(2) ^b	IV	[31, 32]
30 (C ₈ H ₈)Ln[C ₆ H ₄ (CH ₂ NMe ₂) ₂](THF)	Er, Lu	Lu–N: 2.479(6)	IV	[33, 34]
31 Ln[C ₆ H ₄ (CH ₂ NMe ₂) ₂] ₃	Er, Yb, Lu	Lu–N: 2.588(5), 2.468(6), 2.478(5)	IV	[34, 36]
32 (C ₅ Me ₅)Ln[C ₆ H ₄ (CH ₂ NMe ₂) ₂] ₂	Y	Y–N: 2.568(5), 2.506(6)	IV	[37, 38]
33 Cp*Ln[C ₆ H ₄ -2-CH ₂ NMe(μ-CH ₂)] [μ-C ₆ H ₄ -2-CH ₂ NMe(μ-CH ₂)] LnCp*-(THF) ^c	Y	Y–N: 2.405(6), 2.403(6)	—	[38]
34 {LnCl ₂ [C ₆ H ₃ (CH ₂ NMe ₂) ₂]-2.6}[μ-Cl][μ-Li(THF) ₂] ₂	Y, Lu	Lu–N: 2.623(5)	IV	[39]
35 Ln(μ-Cl)[C ₆ H ₃ (CH ₂ NMe ₂) ₂]-2.6](CH ₂ SiMe ₃)	Lu	Lu–N: 2.60(2), 2.541(19)	IV	[39]

^a Underlining indicates that a crystal structure is available. ^b Two crystallographically inequivalent molecules. ^c Cp* = C₅Me₅. ^d Insertion products of this complex have not been included in this table (see text for reference). ^e Estimate, owing to disorder.

All complexes of type IV reported thus far have been synthesized by reaction of a lanthanide chloride species with the aryl lithium complex $\text{Li}[\text{C}_6\text{H}_4(\text{CH}_2\text{NMe}_2)_2]$ in THF and the earliest report dates back to 1978 [31]. The mono(aryl) complexes $\text{Cp}_2\text{Ln}[\text{C}_6\text{H}_4(\text{CH}_2\text{NMe}_2)_2]$ (**29**; Ln is Sc [31], Y [32]) (synthesized from Cp_2LnCl) are monomeric, very air- and moisture-sensitive, and soluble in both aromatic and ethereal solvents. The solid-state structure of the yttrium complex contains two crystallographically independent molecules in the asymmetric unit and shows the amino substituent to coordinate to the metal center, resulting in a coordination number of seven [32]. In the mono(aryl) complexes $(\eta^8\text{-C}_8\text{H}_8)\text{Ln}[\text{C}_6\text{H}_4(\text{CH}_2\text{NMe}_2)_2](\text{THF})$ (**30**; Ln is Er, Lu (X-ray)) the amino substituent also coordinates to the lanthanide center, leading to a monomeric complex with coordination number eight [33,34]. These complexes are soluble in THF, but only slightly in aromatic solvents. The lutetium complex $(\eta^8\text{-C}_8\text{H}_8)\text{Lu}[\text{C}_6\text{H}_4(\text{CH}_2\text{NMe}_2)_2](\text{THF})$ was tested for hydrogenolysis with molecular hydrogen, reaction with CO, and insertion of simple olefins as well as for the reaction with internal alkynes like 1-(trimethylsilyl)propyne [34]. However, it only showed reactivity similar to that of Cp_2LnR (R is alkyl) in its metallation of terminal alkynes like 3,3-dimethyl-1-butyne, with formation of $(\eta^8\text{-C}_8\text{H}_8)\text{Lu}(\text{C}\equiv\text{C}^t\text{Bu})$ [35]. In the reaction with CO, an unidentifiable mixture of products was observed. The observed (lack of) reactivity was attributed to steric saturation of the complex.

The homoleptic complexes $\text{Ln}[\text{C}_6\text{H}_4(\text{CH}_2\text{NMe}_2)_2]_3$ (**31**; Ln is Er, Yb, Lu) are also monomeric, soluble in aromatic and ethereal solvents, and slightly soluble in aliphatic solvents [34,36]. The X-ray structure of the lutetium complex shows all amino substituents to be coordinated to lutetium, leading to a coordination number of only six for lutetium in this complex [36]. The reactivity of the lutetium complex $\text{Lu}[\text{C}_6\text{H}_4(\text{CH}_2\text{NMe}_2)_2]_3$ resembles that of $(\eta^8\text{-C}_8\text{H}_8)\text{Lu}[\text{C}_6\text{H}_4(\text{CH}_2\text{NMe}_2)_2](\text{THF})$ (vide supra) with the addition that in the reaction with 3,3-dimethyl-1-butyne the insertion product 2-[*o*-(dimethylamino)methyl]phenyl-3,3-dimethylbutenyl is isolated in addition to the expected *N,N*-dimethylbenzylamine [34,36].

Another route to mixed cyclopentadienyl-aryl complexes is the reaction of $\text{Y}[\text{C}_6\text{H}_4(\text{CH}_2\text{NMe}_2)_2]_3$ with $\text{C}_5\text{Me}_5\text{H}$ (Cp^*H) to give $\text{Cp}^*\text{Y}[\text{C}_6\text{H}_4(\text{CH}_2\text{NMe}_2)_2]_2$ (**32**) and *N,N*-dimethylbenzylamine [37,38]. The solid-state structure of this 14-electron complex shows it to be monomeric, with both amino substituents coordinating to yttrium [38]. However, the two Y–N dative bonds differ substantially (2.568(5) and 2.506(6) Å) and further inspection of the molecular structure shows close Y–H (3.00(6) and 3.13(9) Å) and Y–C (3.202(8) Å) contacts with one of the aminomethyl groups, providing evidence for Y–C–N and Y–C–H agostic interactions. Probably as a result of these interactions, thermolysis of **26** leads to C–H activation in one of the aminomethyl groups, giving $\text{Cp}^*\text{Y}[\text{C}_6\text{H}_4\text{-2-CH}_2\text{NMe}(\text{CH}_2\text{-}\mu)]_2[\mu\text{-C}_6\text{H}_4\text{CH}_2\text{NMe}(\text{CH}_2\text{-}\mu)_2]\text{YCp}^*(\text{THF})$ (**33**) exclusively (see Fig. 2) [38].

The dimeric ‘ate’-complexes $\{\text{LuCl}_2[\text{C}_6\text{H}_3(\text{CH}_2\text{NMe}_2)_2\text{-2,6}](\mu\text{-Cl})[\mu\text{-Li}(\text{THF})_2]\}_2$ (**34**; Ln is Y, Lu), synthesized by reaction of LnCl_3 with $\text{LiC}_6\text{H}_3(\text{CH}_2\text{NMe}_2)_2\text{-2,6}$ in THF at room temperature, appear to be excellent precursors for the synthesis of reactive lanthanide dialkyl complexes [39]. Intramolecular coordination of both amino substituents to the metal center was indicated by ^1H

Fig. 2. Schematic representation of complex 33.

NMR and observed in the solid-state structure of the lutetium complex (see Fig. 3). Reaction of **34** (Ln is Lu) with one equivalent of $\text{LiCH}_2\text{SiMe}_3$ in THF at -78°C afforded dimeric $\text{Lu}(\mu\text{-Cl})[\text{C}_6\text{H}_3(\text{CH}_2\text{NMe}_2)_2\text{-2,6}](\text{CH}_2\text{SiMe}_3)$ (**35**) [39]. As already indicated by ^1H NMR, the solid-state structure of this complex shows it to contain the bis(*ortho*)-amino aryl ligand in its pseudo-facial coordination mode (see Fig. 3). Reaction of this complex with an additional equivalent of $\text{LiCH}_2\text{SiMe}_3$ in THF at -78°C gave rise to the formation of the dialkyl complex $\text{Lu}[\text{C}_6\text{H}_3(\text{CH}_2\text{NMe}_2)_2\text{-2,6}](\text{CH}_2\text{SiMe}_3)_2$ (**36**) [39]. Complexes **35** and **36** are unstable in hexane solution and decompose with formation of tetramethylsilane (TMS). This loss of TMS takes place from complex **36** (which is also formed from **35** through a disproportionation reaction) and probably involves formation of an intermediate unstable carbene species $[\text{C}_6\text{H}_3(\text{CH}_2\text{NMe}_2)_2\text{-2,6}]\text{Lu}=\text{CHSiMe}_3$. The corresponding yttrium alkyl complexes are even more unstable and could not be isolated.

Although complexes **31** could not be obtained for the early lanthanides, reaction of $(\text{C}_5\text{H}_5)_3\text{La}\cdot\text{THF}$ with one equivalent of $\text{LiC}_6\text{H}_3(\text{CH}_2\text{NMe}_2)_2\text{-2,6}$ in THF at room temperature afforded the monomeric complex $(\text{C}_5\text{H}_5)_2\text{La}[\text{C}_6\text{H}_3(\text{CH}_2\text{NMe}_2)_2\text{-2,6}]$ (**37**) [40]. This complex also contains the bis(*ortho*)-amino aryl ligand in its pseudo-facial coordination mode in the solid state (see Fig. 4), leading to two inequivalent cyclopentadienyl ligands and a formal coordination number of nine. In solution, NMR data indicate a symmetric structure, probably as a result of low-energy fluxional processes. Complex **37** is soluble in aromatic solvents and THF, and reacts with proton donors with initial loss of the bis(*ortho*)-amino aryl ligand.

Fig. 3. Schematic representations of complexes **34** and **35**, showing the pseudo-facial coordination of the bis(*ortho*)-amino aryl ligand in the latter.

Fig. 4. Schematic representation of complex 37.

3.2. Complexes of pyridyl ligands

Complexes of type V can be obtained through C–H activation of pyridine by $(\eta^5\text{-C}_5\text{Me}_5)_2\text{LnR}$ (for Ln is Lu, R is H, Me [41]; for Ln is Sc, R is H, Me, C_6H_5 , $\text{CH}_2\text{C}_6\text{H}_5$ [42]; and for Ln is Y, R is H, Me, $\text{CH}_2(\text{SiMe}_3)_2$ [43,44]). This C–H activation is thought to be an intramolecular process, taking place after initial coordination of pyridine to form $(\eta^5\text{-C}_5\text{Me}_5)_2\text{LnR}\cdot(\text{pyridine})$ [41–43]. From the X-ray structure of $(\eta^5\text{-C}_5\text{Me}_5)_2\text{Sc}(\text{C}_5\text{H}_4\text{N})$ (38) [41], which contains a disordered pyridyl group with estimated Sc–C and Sc–N bond lengths of 2.20 and 2.14 Å, respectively, it appears that a description in terms of an $\eta^2\text{-C,N}$ interaction is more realistic than intramolecular coordination of the pyridine nitrogen. The reactivity of $(\eta^5\text{-C}_5\text{Me}_5)_2\text{Y}(\text{C}_5\text{H}_4\text{N})$ (38) was examined in detail [44], and the complex was found to decompose at elevated temperatures with formation of 2,2'-bipyridine through C–C coupling. Mono-insertion products were found in the reaction of 38 with ethylene, propylene and 2-pentyne, leading to lanthanide alkyl complexes with intramolecular coordination (type VI). With terminal alkynes, transmetalation to give the acetylides $(\eta^5\text{-C}_5\text{Me}_5)_2\text{Y}(\text{C}\equiv\text{CR})$ (cf. complexes 30 and 31) was the dominant reaction. Interestingly, reaction of 35 with CO resulted in the formation of the enolate complex $[(\eta^5\text{-C}_5\text{Me}_5)_2\text{Y}][\mu\text{-}\eta^2\text{:}\eta^2\text{-OC(2-NC}_5\text{H}_4)_2]$ (39) depicted in Fig. 5, which was crystallographically characterized [44].

Fig. 5. Schematic representation of complex 39.

3.3. Complexes of donor-substituted alkyl ligands

In addition to the complexes of type VI obtained by insertion of alkenes or alkynes in the Y–C bond of $(\eta^5\text{-C}_5\text{Me}_5)_2\text{Y}(\text{C}_5\text{H}_4\text{N})$ (vide supra), some alkyl ligands containing amino, arseno or phosphino donor groups have been applied in lanthanide chemistry. The ‘ate’-complexes $\text{Li}_3[\text{Ln}(\text{CH}_2\text{CH}_2\text{CH}_2\text{NMe}_2)_3\text{Cl}_3](\text{THF})_x$ (**40**; Ln is La ($x=2$), Pr ($x=0.5$), Er ($x=0$)) were prepared by reaction of three equivalents of the lithium alkyl with LnCl_3 in THF at room temperature [45]. The use of six equivalents of lithium alkyl does not lead to complexes $\text{Li}_3[\text{LnR}_6]$ (**41**) for Ln is La, Pr, Er, but for Ln is Ce a complex with this stoichiometry is indeed formed. The La and Pr complexes were reported to be insoluble in THF after their isolation from this solvent. The cyclopentadienyl lanthanide alkyl complexes $(\text{C}_5\text{H}_5)_2\text{Lu}(\text{CH}_2\text{CH}(\text{R})\text{CH}_2\text{NMe}_2)\text{Cl}(\text{THF})_2$ (**42**; R is H, Me) were prepared by metathesis of $(\text{C}_5\text{H}_5)_2\text{LuCl}_2(\text{THF})_3$ with one equivalent of the appropriate lithium alkyl in THF [46]. The X-ray structure of complex **42** with R is Me shows the amino substituent to coordinate to lutetium, resulting in a seven-coordinate metal center. The related complexes $(\text{C}_5\text{H}_5)_2\text{Lu}(\text{CH}_2\text{CH}(\text{R})\text{CH}_2\text{NMe}_2)$ (**43**; R is H, Me) were prepared by a one-pot synthesis in THF from LuCl_3 , NaCp and $\text{LiCH}_2\text{CH}(\text{R})\text{CH}_2\text{NMe}_2$ in a molar ratio 1:2:1 [47]. The intramolecular coordination of the amino substituent in **43** for R is H was established from a crystal structure determination. Interestingly, the one-pot procedure takes a different course in the presence of CO_2 with the formation of the yttrium carboxylate $(\text{C}_5\text{H}_5)_2\text{Y}(\eta^2\text{-O}_2\text{CCH}_2\text{CH}_2\text{CH}_2\text{NMe}_2)$. In this complex the bidentate bonding of the carboxylate moiety results in the amino functionality remaining pendant, as shown by the X-ray structure of the complex (Y–N: 4.99 Å) [47].

The only known complexes using a soft arseno donor substituent, $(\text{C}_5\text{H}_5)_2\text{Lu}[\text{CH}_2\text{CH}_2\text{CH}_2\text{As}(\text{R}')_2]_2$ (**44**; R' is Me, ^tBu), were synthesized by reaction of $\text{CpLu}(\text{OSO}_2\text{CF}_3)_2(\text{THF})_n$ with two equivalents of $\text{ClMg}(\text{CH}_2)_3\text{As}(\text{R}')_2$ in THF [46]. However, there is no direct evidence for the intramolecular coordination of the arseno substituents to lutetium, which was postulated by analogy to $(\eta^5\text{-C}_5\text{Me}_5)_2\text{Y}[\text{C}_6\text{H}_4(\text{CH}_2\text{NMe}_2)_2]_2$ (**32**).

The first reported phosphine-stabilized lanthanide complex, $(\text{C}_5\text{H}_5)_2\text{Lu}(\text{CH}_2)\text{PMe}_2$ (**45**), was synthesized by reaction of $(\text{C}_5\text{H}_5)_2\text{LuCl}(\text{THF})$ with $\text{Li}(\text{CH}_2)\text{PMe}_2$ in THF at -30°C [48]. Intramolecular coordination of the phosphine donor to lutetium, with formation of a three-membered ring, was postulated on the basis of ^1H and ^{13}C NMR data, although formation of a six-membered ring as a result of dimerization could not be excluded. Complex **45** was reported to be toluene soluble.

4. Alkoxide-, phenolate-, thiolate- and siloxide-based ligands (Table 3)

4.1. Complexes of monoanionic, bi- and tridentate ligand systems

As a result of the interest in the possible use of lanthanide chelate complexes in optical maser (laser) devices in the early 1960s [49], a number of lanthanide com-

^a Underlining indicates that a crystal structure is available. ^b n = : L = 1,10-phenanthroline, 2,2-bipyridine; n = 2: L = quinoline, pyridine. ^c Average of Yb–C bond lengths in single η⁶-arene interaction. ^d Average value. ^e R¹ = H, ‘Bu, ‘Pr; R² = ‘Bu, ‘Pr. ^f ε_{cac} = acetylacetonate. ^g thd = 2,2,6,6-tetramethyl-3,5-heptanedione. ^h hfd = 1,1,1,5,5,5-hexafluoroacetylacetonate. ⁱ Hbdmap = 1,3-bis(dimethylamino)propan-2-ol.

plexes of type **VIIb** using salicylaldehyde (2-(CHO)C₆H₄OH; Hsal) were prepared and characterized mainly for their optical properties.

The insoluble complexes Ln(sal)₃ (**47**; Ln is La, Ce, Pr, Nd, Sm, Eu) were prepared by reacting LnCl₃ with three equivalents of Na(sal) in a water/alcohol mixture [50]. Although intramolecular coordination of the aldehyde carbonyl to the lanthanide metal would be expected on the basis of the absence of additional ligands (elemental analyses were satisfactory), the frequency of the carbonyl stretching vibration appeared to be insensitive to the nature of the lanthanide metal. In addition, complexes Ln(sal)₃(L)_n (**48**; Ln is La, Pr, Nd, Sm, Eu, Tb; for *n*=1, L is 1,10-phenanthroline, 2,2'-bipyridine; for *n*=2, L is quinoline, pyridine) are readily formed in the presence of additional nitrogen ligands [51].

The steric unsaturation in complexes **47** is further illustrated by the isolation of the tetrakis(salicylaldehydato) complexes M[Y(sal)₄] (**49**; M is Li, Na) [52]. In agreement with the synthesis of **47**, Na[Y(sal)₄] was prepared by reaction of Y(sal)₃ with another equivalent of Na(sal), using salicylaldehyde itself as solvent; the lithium complex could be synthesized in one step. For complexes **49**, the observation of a single phenolate C–O stretching vibration in the IR spectra is strong evidence that all four ligands coordinate in a bidentate fashion [52]. When the insolubility of complexes **47** in polar solvents like water is taken into account, a polymeric structure for these complexes appears likely.

As the synthesis of well-defined 8-quinolinolate complexes (**VIIa**) of the lanthanides starting from Ln(NO₃)₃ in acetic acid failed [53], complexes (C₅H₅)₂Ln(8-OC₉H₆N) (**50**) and (C₅H₅)Ln(8-OC₉H₆N)₂ (**51**) (Ln is Nd, Yb) were synthesized from (C₅H₅)₃Ln and 8-hydroxyquinoline in THF at room temperature [54]. The same procedure using 2-aminophenol (**VIIb**; Do is NH₂), resulted in the formation of complexes (C₅H₅)₂Ln(OC₆H₄NH₂-2) (**52**) and (C₅H₅)Ln(OC₆H₄NH₂-2)₂ (**53**) (Ln is Nd, Yb) [54]. Both IR and XPS spectral data for complexes **50**–**53** provide proof for intramolecular coordination of the nitrogen functionalities to the lanthanide centers in these complexes. In addition, cryoscopic measurements showed the complexes to exist as monomers in solution. The complexes were reported to disproportionate into the homoleptic complexes at moderately high temperatures (below 300°C) as a result of the high transferability of the cyclopentadienyl ligands. Mass-spectral data showed the ytterbium complexes to be thermally more stable than the

corresponding neodymium complexes. This was attributed to the smaller ionic radius of Yb^{3+} as compared to Nd^{3+} , leading to a stronger Ln–ligand bond.

A relatively uncommon form of intramolecular coordination was observed for $\text{Yb}(\text{OC}_6\text{H}_3\text{Ph-2,6})_3$ (**54**) in the solid state, where one of the *ortho*-phenyl substituents has an η^6 -arene interaction with the ytterbium center (**VIIIb**; Do is $\eta^6\text{-C}_6\text{H}_5$), as depicted in Fig. 6 [55]. Identical complexes were also prepared for the lanthanides Nd, Er, and Lu, but no information on the coordination geometry of the ligands could be obtained from IR or NMR data. The η^6 -arene interaction is undoubtedly a result of the electronic unsaturation of the ytterbium ion in the solvent-free tris-phenolate complex. This is illustrated by the fact that the complex is prepared by drying under vacuum of $\text{Yb}(\text{OC}_6\text{H}_3\text{Ph-2,6})_3(\text{THF})_2$.

The unique heterometallic complexes $\{\text{ClLn}[\text{OC}_6\text{H}_2(\text{CH}_2\text{NMe}_2)_2\text{-2,6-Me-4}]\text{Na}\}$ (**55**; Ln is Y, Lu) of type VII were obtained by reaction of LnCl_3 with three equivalents of $\text{NaOC}_6\text{H}_2(\text{CH}_2\text{NMe}_2)_2\text{-2,6-Me-4}$ in THF at room temperature [56,57]. The crystal structure of the lutetium complex shows it to consist of the chloride, lutetium and sodium atoms, lying on a pseudo-threefold axis, with the three phenolate ligands bridging the lutetium and sodium atoms (see Fig. 7). The phenolate ligands each coordinate with one amino substituent to lutetium and with the other to sodium, resulting in a complex with screw-type chirality. Complexes **55** are soluble in hexane, aromatic solvents and THF. Low-temperature NMR studies (^1H and ^{13}C) have shown that the structure in solution closely resembles that in the solid state. The self-assembly of complexes **55** is described in terms of positive cooperativity in

Fig. 6. Schematic representation of complex **54**.

Fig. 7. Schematic representations of the heterometallic complexes **55** and **56**.

binding of the chloride and sodium ions [56,57]: coordination of chloride anion to the unsaturated metal tris-phenolate $\text{Ln}[\text{OC}_6\text{H}_2(\text{CH}_2\text{NMe}_2)_2\text{-2,6-Me-4}]$ leads to preorganization of available binding sites in the resulting anion for coordination of sodium cation.

This positive cooperativity is also the driving force for the self-assembly of the (hetero)trimetallic complex $\{\text{ClY}[\text{OC}_6\text{H}_4(\text{CH}_2\text{NMe}_2)_2\text{-2}]_3\text{Y}[\text{OC}_6\text{H}_4(\text{CH}_2\text{NMe}_2)_2\text{-2}]_3\text{Na}\}$ (**56**) [57]. This complex was obtained in quantitative yield following the procedure described above for complexes **55**, but using $\text{NaOC}_6\text{H}_4(\text{CH}_2\text{NMe}_2)_2$. The solid-state structure of **56** shows it to contain one group of three phenolate ligands bridging the two yttrium atoms, with their amino substituents coordinated to the yttrium bearing the chloride. The second group of three phenolate ligands bridges the other yttrium and the sodium atom, with their amino substituents coordinated to sodium (see Fig. 7). The complex shows structural characteristics that closely resemble complexes **55** and contains two shells of screw-type chirality, which have opposite senses of rotation. Using ^{89}Y NMR, an ^{89}Y – ^{89}Y coupling of 0.4 Hz was observed [57]. In combination with ^1H and ^{13}C NMR data, this showed that the solid-state structure is retained in solution. Complex **56** is soluble in aromatic solvents and THF, but only very slightly soluble in hexane. Complexes **55** and **56** provide new leads for the preparation of heterometallic precursors for the preparation of lanthanide-containing ceramics, as well as a new type of coordination polymer.

In an attempt to avoid the inclusion of salt, observed in complexes **55** and **56**, and possibly obtain complexes with available binding sites, the salt-free lanthanide precursors $\text{Ln}[\text{N}(\text{SiMe}_3)_2]_3$ were used. From the reaction of these precursors with four equivalents of the parent phenols $\text{HOC}_6\text{H}_2(\text{CH}_2\text{NMe}_2)_2\text{-2,6-Me-4}$ and $\text{HOC}_6\text{H}_4(\text{CH}_2\text{NMe}_2)_2$, complexes $\text{Ln}[\text{OC}_6\text{H}_2(\text{CH}_2\text{NMe}_2)_2\text{-2,6-Me-4}]_3[\text{OC}_6\text{H}_2(\text{CH}_2\text{NMe}_2)_2(\text{CH}_2\text{N}(\text{H})\text{Me}_2)\text{-6-Me-4}]$ (**57**; Ln is Y, La) and $\text{Ln}[\text{OC}_6\text{H}_4(\text{CH}_2\text{NMe}_2)_2]_3[\text{OC}_6\text{H}_4(\text{CH}_2\text{N}(\text{H})\text{Me}_2)_2]$ (**58**; Ln is Y, La), respectively, were obtained [58]. The X-ray structure of complex **58** (Ln is La) shows it to contain three bidentate O,N-bonded phenolate ligands and one neutral phenol. This neutral phenol is bonded in its zwitterionic form: attached to the metal center through its phenolate oxygen and with its protonated amino substituent involved in a strong $\text{N-H}\cdots\text{O}$ hydrogen bridge (see Fig. 8). The strong similarities between the NMR data

Fig. 8. Schematic representations of complexes **57** and **58**, showing the $\text{N-H}\cdots\text{O}$ bridges.

a hard donor substituent like oxygen, as in complexes of the simple alkoxide ligand $(\text{OCH}_2\text{CH}_2\text{OMe})^-$ invariably leads to oligomeric structures. For example, the solid-state structure of $[\text{Y}(\mu_2, \eta^2\text{-OCH}_2\text{CH}_2\text{OMe})_2(\mu_1, \eta^1\text{-OCH}_2\text{CH}_2\text{OMe})]_{10}$ (**64**) is a cyclic decamer [63]. This complex, which could be prepared both by direct attack of the alcohol on metallic Y turnings or by alcoholysis of $\text{Y}_5\text{O}(\text{O}^i\text{Pr})_{13}$ [64], was found to be highly soluble, but air-sensitive and non-volatile. An oligomeric structure is also present in the mixed-ligand complex $\text{Y}_3(\mu_3, \eta^2\text{-OCH}_2\text{CH}_2\text{OMe})_2(\mu_2, \eta^2\text{-OCH}_2\text{CH}_2\text{OMe})_2(\mu_2, \eta^1\text{-OCH}_2\text{CH}_2\text{OMe})\text{-(acac)}_4$ (acac is acetylacetonate) (**65**), which was obtained in an attempt to prepare a pre-ceramic mixed-metal complex by mixing $\text{Cu}(\text{acac})_2$ (three equivalents) with **64** [65]. Such mixed-metal complexes could be obtained by mixing **64** with $[(\text{thd})\text{Cu}(\text{OCH}_2\text{CH}_2\text{OMe})]_4$ or $[(\text{hfd})\text{Cu}(\text{OCH}_2\text{CH}_2\text{OMe})]_4$ (thd is 2,2,6,6-tetramethyl-3,5-heptanedionate; hfd is 1,1,1,5,5,5-hexafluoroacetylacetonate) to give complexes $(\text{thd})_4\text{Cu}_3\text{Y}(\text{OCH}_2\text{CH}_2\text{OMe})_5$ (**66**) and $[(\text{hfd})_2\text{CuY}(\text{OCH}_2\text{CH}_2\text{OMe})_3]_2$ (**67**), respectively [66]. Complex $(\text{hfd})_2(\text{thd})_2\text{YCu}_2(\text{OCH}_2\text{CH}_2\text{OMe})_3$ (**68**) was obtained when in situ prepared “ $[(\text{hfd})_2\text{Y}(\text{OCH}_2\text{CH}_2\text{OMe})]_n$ ” was mixed with $[(\text{thd})\text{Cu}(\text{OCH}_2\text{CH}_2\text{OMe})]_4$. Complex **65** was reported to be soluble in both aliphatic and aromatic solvents [65]. Complexes **66** and **68** are soluble in polar, aromatic and aliphatic solvents, as well as in the parent alcohol $\text{HOCH}_2\text{CH}_2\text{OMe}$, while complex **67** is only very slightly soluble in THF, CHCl_3 and aromatic solvents [66]. The X-ray structures of the heterometallic complexes **66** and **67** show the alkoxide ligand to be present both with the ether substituent pendant and coordinated to copper or yttrium.

Other examples of well-characterized pre-ceramic mixed-metal complexes have been obtained by using 1,3-bis(dimethylamino)propan-2-ol (Hbdmap; **VIIIc**) as a cross-linker. The heterometallic complex $\text{LnCu}_2(\text{bdmap})_3(\text{O}_2\text{CCF}_3)_4$ (**69**; Ln is La, Nd) and $\text{Cu}_3(\text{bdmap})_3(\text{O}_2\text{CCF}_3)_2[\text{Y}_2(\text{bdmap})_2(\text{O}_2\text{CCF}_3)_6]$ (**70**) were obtained from pre-ceramic mixtures of $\text{Ln}(\text{O}_2\text{CCF}_3)_3(\text{H}_2\text{O})_4$, $\text{Ba}(\text{O}_2\text{CCF}_3)_2$, $\text{Cu}_2(\text{O}_2\text{CCF}_3)_4(\text{H}_2\text{O})_2$ and Hbdmap and could also be synthesized independently by reaction of LnCl_3 , CuCl_2 , $\text{Ag}(\text{O}_2\text{CCF}_3)$, $\text{Cu}(\text{OCH}_3)_2$ and Hbdmap in THF [67]. The X-ray structures of complex **69** (Ln is La) and **70** show the bis(amino)alkoxide to bridge two (different) metal atoms, with the amino substituents each coordinating to one of these metal centers (see Fig. 9). The $\text{YBa}_2\text{Cu}_3\text{O}_{7-x}$ powder obtained from

Fig. 9. Schematic representations of complex **69** and the cation (middle) and anion (right) of complex **70**, showing the coordination geometries of the bdmap ligand. Other ligands have been omitted for clarity.

the pre-ceramic mixture (using acetate instead of trifluoroacetate) was reported to have an onset superconducting temperature of 92 K [67].

By reacting optically active (*R*)-(+)-, or (*S*)-(–)-isobutylacetate (iba) with Cp_3Yb in CH_2Cl_2 at -40 to -70°C , the dimeric complexes $[\text{Cp}_2\text{Yb(iba)}]_2$ (**71**) were obtained [68]. IR measurements showed the presence of intramolecular coordination of the carbonyl oxygen to ytterbium, while mass spectra indicated a dimeric, alkoxide-bridged structure. The X-ray structure of the *R* complex shows the isobutylacetate ligands to bridge the two ytterbium ions in a dinuclear arrangement, with the carbonyl oxygens each coordinating to one of the ytterbium ions. The resulting rigid dinuclear complexes **71** were reported to display notable *f-f* circular dichroism.

In the first of only two reports so far on complexes of donor-substituted siloxide complexes, bulky substituents are present on silicon in addition to the amine donor substituent (**IXa**), to effect monomeric structures by analogy to complexes **59–63**. Complexes $\text{Ln}\{\text{OSi}(\text{}^t\text{Bu})_{3-n}[(\text{CH}_2)_3\text{NMe}_2]_n\}_3$ (**72**; for $n=1$, Ln is Y, Ce; for $n=2$, Ln is Y) were synthesized by reaction of $\text{Ln}[\text{N}(\text{SiMe}_3)_2]_3$ with the appropriate silanol (three equivalents) at room temperature in toluene and subsequently recrystallized from toluene/hexane mixtures [69]. The solid-state structure of $\text{Y}[\text{OSi}(\text{}^t\text{Bu})_2(\text{CH}_2)_3\text{NMe}_2]_3$ shows two amino substituents to be coordinated to yttrium, resulting in a coordination number of only five, and the third amino substituent remains pendant. In solution, rapid exchange between coordinated and pendant amino substituents leads to the observation of only one set of signals for the ligands by NMR (^1H and ^{29}Si). When four equivalents of the silanol are used during the synthesis, the zwitterionic tetrakis(siloxide) complexes $\text{Ln}[\text{OSi}(\text{}^t\text{Bu})_2(\text{CH}_2)_3\text{NMe}_2]_3 [\text{OSi}(\text{}^t\text{Bu})_2(\text{CH}_2)_3\text{NHMe}_2]$ (**73**; Ln is Y, Yb) are obtained, in which the proton counterion is present as an $\text{N-H}\cdots\text{N}$ bridge between two pendant amino substituents. However, as a result of the steric bulk of the four siloxide ligands, the other two amino substituents are also pendant in the solid-state structure of the ytterbium complex. In solution, an equilibrium was observed between complexes **73** on one hand and the free silanol in combination with the tris(siloxide) complexes **72** on the other hand.

The arylsiloxide complex $\text{Y}[\text{OSi}(\text{}^t\text{Bu})(\text{C}_6\text{H}_4\text{CH}_2\text{NMe}_2)_2][\text{N}(\text{SiMe}_3)_2]_2$ (**74**) was prepared by a procedure similar to that for **72** and **73**, but now using only one equivalent of the silanol at reflux temperature in toluene [70]. The complex shows

complex fluxional behavior in solution as observed by NMR spectroscopy (^1H and ^{29}Si), but in the temperature range of -40 to $+50^\circ\text{C}$, coordination of one of the two available amino substituents is observed. This was confirmed by the X-ray structure of the complex, which shows one of the amino substituents to coordinate to yttrium, while the second remains pendant. Together with the two amido ligands, this amounts to a coordination number of only four, which is stabilized by the steric bulk of both the siloxide and amido ligands. Reaction of **74** with two equivalents of $\text{HOC}_6\text{H}_3^t\text{Bu}_{2,6}$ at reflux temperature in toluene afforded the bis-phenolate $\text{Y}[\text{OSi}^t\text{Bu}(\text{C}_6\text{H}_4\text{CH}_2\text{NMe}_2)_2][\text{OC}_6\text{H}_3^t\text{Bu}_{2,6}]_2$ (**75**), which was prepared as a precursor for yttrium dialkyl complexes [70]. In an attempt to prepare these dialkyl complexes by reacting **75** with two equivalents of neosilyl lithium, loss of only one phenolate ligand led to the complex $\{\text{Y}[\text{OSi}^t\text{Bu}(\text{C}_6\text{H}_4\text{CH}_2\text{NMe}_2)_2][\text{OC}_6\text{H}_3^t\text{Bu}_{2,6}](\text{CH}_2\text{SiMe}_3)_2\}^- \text{Li}^+$ (**76**) [70]. On account of its solubility in toluene and the bulk of the ligands, a monomeric structure was reported to be likely for this complex. However, the presence of two signals in the ^{89}Y spectrum of **76** (about 2:1 relative intensity) at -70°C in toluene is indicative of aggregation.

The bimetallic complexes $[(\text{C}_5\text{H}_5)\text{Fe}(2-(\text{CH}_2\text{NMe}_2)\text{C}_6\text{H}_3\text{S})]_{3-n}\text{YbCl}_n$ (**77**; $n=0, 1$) of type X are soluble in aromatic solvents and were synthesized from YbCl_3 and the lithium thiolate at room temperature in THF [71]. NMR data indicated that in the tris(ferrocenylthiolate) complex only two amino substituents are coordinated to the metal center, one remaining pendant.

4.2. Complexes of acyclic, polydentate ligand systems (Table 4)

In addition to the monoanionic, potentially bidentate ligands mentioned thus far in this paragraph, mono-, di- and trianionic polydentate ligands have also been applied in lanthanide chemistry. The lanthanide complexes of bis-salicylaldehyde ethylenediamine (salen, R is H; busalen, R is ^tBu ; **XIa**) and bis-salicylaldehyde *o*-phenylenediamine (salphen, **XIb**) have the composition $[\text{Ln}_2\text{L}_3](\text{C}_2\text{H}_5\text{OH})_n$ (for L is salen (**78**): $n=0$, Ln is La, Pr, Nd, Er, Yb; $n=2$, Ln is Y, Sm, Gd; $n=3$, Ln is Dy; for L is busalen (**79**): $n=0$, Ln is Pr, Nd, Sm, Eu, Gd, Ho; for L is salphen (**80**): $n=$

0, Ln is La, Pr, Nd), with the exception of cerium(IV) complexes, which have $\text{Ce}(\text{L})_2$ stoichiometry (L is salen (**81**), busalen (**82**)) [72,73]. Complexes **78–80** were prepared by addition of $\text{Ln}(\text{NO}_3)_3$ to a solution of the ligand (H_2salen , $\text{H}_2\text{busalen}$ or $\text{H}_2\text{salphen}$) in ethanol [72], methanol [74], acetone [73] or DMF [52] at 55–80°C, followed by the addition of a base (ammonia gas, aqueous ammonia [72], triethylamine [52]). The cerium(IV) complexes **81** and **82** could be prepared by using either $(\text{NH}_4)_2\text{Ce}^{\text{IV}}(\text{NO}_3)_6$ or $\text{Ce}^{\text{III}}(\text{NO}_3)_3 \cdot (\text{H}_2\text{O})_6$. The busalen complexes **79** are, as a result of the presence of the *tert*-butyl substituents, soluble in CHCl_3 . All other complexes are crystalline, melt with decomposition above 260°C (**80**), 280°C (**81**) or 300°C (**78**) and are soluble in dimethylformamide (DMF), but insoluble in common organic solvents. $\text{Ce}(\text{salphen})_2$ (**83**) was prepared in a procedure similar to that for **81**, using DMF as the solvent, from which it could also be crystallized [75]. The crystal structure of this complex shows the Ce(IV) center to be sandwiched between the two salphen ligands, with all anionic oxygen and neutral nitrogen donor sites coordinated to the metal center, resulting in formal eight-coordination (see Fig. 10).

Despite several attempts, no crystals suitable for X-ray analysis could be obtained thus far for complexes **78–80**, and, although structures have been proposed on the basis of the composition and spectroscopic data for these complexes and the structure of complex **83** [52,72,73], the matter remains unresolved. Complexes $\text{M}[\text{Ln}(\text{salphen})_2]$ (**84**; M is Li, Na, K, Cs; Ln is Y, La, Gd, Yb) were prepared by two different procedures, depending on both the lanthanide and alkali metals [52]: (i) addition of $\text{Ln}(\text{NO}_3)_3 \cdot (\text{DMSO})_n$ (Ln is Y, La, Gd, Yb) to a solution of $\text{H}_2\text{salphen}$ in dimethyl sulfoxide (DMSO), followed by addition of MOH (M is Li, Na, K, Cs), or (ii) addition of *o*-phenylenediamine to a solution of $\text{M}[\text{Ln}(\text{sal})_4]$ (M is Li, Na; Ln is Y) in DMSO. The lithium and cesium salts are only slightly soluble in DMSO, except for $\text{Li}[\text{La}(\text{salphen})_2]$, which is soluble in DMSO, as are the sodium and potassium salts. On the basis of similarities of the spectroscopic data for complexes **84** and the Ce(IV) complex **83**, the structure of the $[\text{Ln}(\text{salphen})_2]^-$ anion in **84** was proposed to be similar to the solid-state structure of **83** [52].

Reaction of the potentially dianionic, pentadentate 2,6-pyridinediylbis[*N*-(2-hydroxyphenylaldimine)] (H_2L^1) or 2,5-pyrrolediylbis[*N*-(2-hydroxyphenylaldimine)] (H_2L^2) with $\text{Ln}(\text{NO}_3)_3$ in refluxing methanol in the absence of a

Fig. 10. Schematic representation of $\text{Ce}(\text{salphen})_2$ (**83**).

base, was reported to afford lanthanide complexes of the mono-deprotonated ligands (**XIc**): $\text{Ln}(\text{HL}^1)(\text{NO}_3)_2 \cdot (\text{H}_2\text{O})_n$ (**85**; $n=1$: Ln is Pr, Gd, Dy, Er, Yb; $n=2$: Ln is Y, La, Ce) [76], $\text{Ln}(\text{HL}^2)(\text{NO}_3)_2 \cdot (\text{H}_2\text{O})_n$ (**86**; $n=1$: Ln is Pr, Gd, Dy, Er; $n=2$: Ln is Sc, Y, La) and the Ce(IV) complex $\text{Ce}(\text{HL}^2)(\text{NO}_3)_3 \cdot (\text{H}_2\text{O})_2$ (**87**) [77]. In these complexes no interaction of the pyridine and pyrrole nitrogen atoms with the lanthanide centers was observed. IR data for the complexes indicate that the second acidic hydrogen is involved in hydrogen bonding and, based on the structure of the ligand, probably held in between the two phenolate oxygen atoms (see **XIc**). Complexes **85** are soluble in water and DMF, and decompose between 210 and 325°C. Complexes **86** and **87** are slightly soluble in DMF, DMSO and nitrobenzene, and decompose between 230 and 340°C.

Trianionic polydentate ligands are very rare in lanthanide chemistry, but of interest with respect to their potential application as magnetic resonance contrasting agents, for which purpose water-soluble, neutral complexes are required [78]. Complexes $\text{Ln}(\text{trac})$ (**88**; trac is tris(3-aza-4-methyl-6-oxohept-4-en-1-yl)amine; Ln is La, Sm, Er, Yb), $\text{Ln}(\text{hatren})$ (**89**; hatren is tris(((2-oxobenzyl)imino)ethyl)amine; Ln is La, Sm, Yb) and $\text{Ln}(\text{datren})$ (**90**; datren is tris(((2-oxo-4,5-dimethylbenzyl)imino)ethyl)amine; Ln is La, Sm, Yb) (**XId–XIe**) were synthesized by reaction of $\text{Ln}[\text{N}(\text{SiMe}_3)_2]_3$ with the appropriate trisalkoxide or trisphenol in THF at room temperature [79]. Complexes **88–90** are very unstable towards moisture and strong σ -donor solvents like DMSO and pyridine; this was attributed to either metal-enhanced hydrolysis of the ligand in water or solvent competition. The solubility of the complexes in THF decreases in the order $\text{Ln}(\text{trac}) \gg \text{Ln}(\text{hatren}) > \text{Ln}(\text{datren})$. Complexes **88** for Ln is Sm, Er and Yb are thermally robust and sublime intact. The crystal structure of $\text{Yb}(\text{trac})$ shows all seven donor sites of the trianionic ligand to coordinate to the ytterbium center in a monocapped distorted octahedron with the apical amino functionality capping the face formed by the three imine functionalities (see Fig. 11) [79].

Similar complexes that are stable towards hydrolysis were obtained by reduction of the imine $\text{HC}=\text{NR}$ functionality (in complexes **XIe**) to the more stable amine $\text{CH}_2\text{-NH(R)}$ functionality (in complexes **XIf**). These amine phenolate complexes

Fig. 11. Schematic representations of the monomeric complexes **88–90** and the dimeric complexes **91–93**, showing the arrangement of the neutral and anionic donor atoms around the metal centers.

$[\text{Ln}(\text{L}^3)]_2$ (**91**; L^3 is tris(((2-oxobenzyl)amino)ethyl)amine; Ln is Y, La, Pr, Nd, Gd, Dy), $[\text{Ln}(\text{L}^4)]_2$ (**92**; L^4 is tris(((2-oxo-5-chlorobenzyl)amino)ethyl)amine; Ln is La, Gd) and $[\text{Ln}(\text{L}^5)]_2$ (**93**; L^5 is tris(((2-oxo-5-bromobenzyl)amino)ethyl)amine; Ln is La, Nd, Gd) were prepared by reaction of $\text{Ln}(\text{NO}_3)_3$ with the appropriate amine phenol ligands (H_3L^3 , H_3L^4 or H_3L^5) in methanol/water or methanol/chloroform/water in the presence of a base [80]. These complexes are insoluble in common organic solvents. In contrast to the imine phenolate complexes **88–90**, the amine phenolate complexes **91–93** are dimeric species, as was indicated by the FAB mass spectra of the complexes and firmly established by the crystal structure of $[\text{Gd}(\text{L}^3)_2](\text{CHCl}_3)_2$. This structure shows that each heptadentate ligand coordinates with all donor sites to one gadolinium and bridges with one phenolate oxygen to the other gadolinium center, resulting in two eight-coordinate metal centers (see Fig. 11). Apparently, the more flexible ligand backbone, as compared to the imine complexes **88–90**, reduces the steric shielding of the lanthanide ions and results in the observed formation of dimeric species. This is supported by the characterization of the monomeric complex $\text{Gd}(\text{L}^6)$ (**94**; L^6 is tris(((2-oxo-3-methoxybenzyl)amino)ethyl)amine), a small amount of which could be obtained pure in the initial stage of the reaction of $\text{Gd}(\text{NO}_3)_3$ with H_3L^6 in methanol/chloroform/water in the presence of six to eight equivalents of NaOH [81]. Further work-up of the reaction mixture afforded a mixture of **94** and $[\text{Gd}(\text{H}_3\text{L}^6)_2](\text{NO}_3)_3$. The FAB mass spectra confirmed that **94** is a monomeric species, which can be attributed to increased (as compared with **91–93**)

Type XI
(continued)

acyclic, polydentate alkoxide- and phenolate-based ligands

steric shielding of the metal center by the *ortho*-methoxy substituents. No analytically pure complexes similar to **94** could, however, be isolated for Ln is Pr, Nd and Yb.

Another example of a trianionic ligand is represented by L^7 (**XIg**), where the three phenolate oxygen donors are held in much closer proximity than in complexes **88–94** (**XId–XIi**). Complexes $Ln(L^7)(H_2O)_n$ (**95**; Ln is La, Pr, Sm, Gd, Dy, Yb) were prepared by reaction of H_3L^7 with the appropriate lanthanide nitrate in the presence of three equivalents of a base (LiOH) [82]. It was recognized that pentacoordination of the ligand to the lanthanide centers is difficult in view of the ligand backbone, and, even if this does occur, the limited number of solvent molecules present still indicates that oligomerization probably takes place. Unfortunately, no further data were reported.

DMSO-soluble complexes of L^8 (**XIh**), general formula $Ln(L^8)(NO_3)_2X$ (**96**; Ln is Pr, X is MeOH; Ln is La, Nd, X is H_2O), were prepared by a template procedure, involving low-temperature (0°C) acid-catalyzed condensation of 2,6-diformyl-*p*-cresol and triethylenetetramine (1:2 ratio) with Ln^{3+} as the template [83]. As a result of the mild acidic conditions, the non-condensed carbonyl function has been acetalized. The X-ray structure of $Pr(L^8)(NO_3)_2 \cdot (MeOH)$ shows the ligand to be oxygen-bonded, with all four nitrogen donor functionalities coordinating to the lanthanide center. In combination with two bidentate coordinating nitrate anions and a coordinating molecule methanol, this amounts to a ten-coordinate metal center.

Complexes $[(R,R)-L^9]LnI$ (**97**; **XIi**), prepared by reaction of $[(R,R)-L^9]Li_2$ with SmI_3 in THF, appear to be excellent catalysts for asymmetric Meerwein–Ponndorf–Verley reductions [84]. For example, the reduction of simple aryl methyl ketones using **97** (Ln is Sm) gave the (*R*)-alcohols with enantiomeric excesses of 92% or more. Optimal selectivities were found with Ln is Tb, Sm, Nd, while elements with either larger or smaller ionic radii gave lower enantioselectivities. Non-linear effects were observed with respect to the correlation of the e.e. of the catalyst and the e.e. of the corresponding product, which was interpreted as an indication for aggregation of the catalyst in solution [84].

4.3. Complexes of macrocyclic ligand systems (Table 5)

The preparation and elucidation of the structure of both homo- and heterodinuclear lanthanide complexes³ of macrocycles (Mcs) is of particular interest with respect to lanthanide metal-to-metal interactions [86] (cross-relaxation processes) [87a,88] and their applications in lasers [87], phosphors [89], extractive metallurgy [90,91] and NMR tomography [78a], for the characterization of complex biomolecules [92], and for the preparation of atomically homogeneous precursors for oxides with well-defined electronic characteristics [93].

³ For an exhaustive review on lanthanide (and actinide) complexes of macrocyclic ligands, see Ref. [85a]. For a review including lanthanide complexes of both macrocyclic and compartmental ligands, see Ref. [85b].

cyclic, polydentate phenolate-based ligands

Mc¹: R = (CH₂)₂NH(CH₂)₂NH(CH₂)₂; R' = Me.

Mc²: R = (CH₂)₂O(CH₂)₂O(CH₂)₂; R' = Cl.

Mc³: R = (CH₂)₂O(CH₂)₂O(CH₂)₂; R' = Me.

Mc⁴: R = (CH₂)₂NH(CH₂)₂; R' = Cl.

Mc⁵: R = (CH₂)₂S(CH₂)₂; R' = Cl.

Complexes of dianionic phenolate-based macrocycles can either be synthesized via

- (i) a template procedure: condensation of 2,6-diformyl-4-R'-phenol and the appropriate poly- or diamine with Ln³⁺ as the template [90,94,95], or
- (ii) by reaction of the preformed ligand with a lanthanide salt in the presence of a base [82,95].

Some of complexes Ln₂(Mc¹)(X)_{4-n}(OH)_n·(H₂O)_m (**98**; X is NO₃, ClO₄; n = 0, 1, 2; Ln is La–Nd, Sm–Lu) were obtained in two different forms, depending on the work-up employed; as a yellow or orange microcrystalline precipitate or as a flaky off-white crystalline precipitate [94]. As the off-white complexes were increasingly difficult to prepare with decreasing Ln³⁺ radius, a coordination geometry as represented by **B** (see Fig. 12) was tentatively proposed for these complexes. The coordination geometry represented by **A** was tentatively proposed for the orange compounds. Using the macrocycle Mc², both the homodinuclear complexes Ln₂(Mc²)(NO₃)₄·(H₂O)_n (**99**; n = 1: Ln is La, Sm, Eu, Dy; n = 2: Pr, Gd, Tb) and the heterodinuclear complexes LnLn'(Mc²)(NO₃)₄·(H₂O)_n (**100**; LnLn' is LaSm, LaEu, LaGd, LaTb, LaDy, GdEu, GdTb, DyEu, DyGd, EuTb) were obtained [95]. These complexes are slightly soluble in chloroform, dichloromethane and methanol, and soluble in warm DMSO. The heterodinuclear complexes were prepared by stepwise addition of the lanthanide nitrates and Ln:Ln' stoichiometries of 99:1 (Ln is Gd or Tb, Ln' is Eu; Ln is Gd, Ln' is Tb) and 50:50 (all combinations) were studied.

From both emission spectra and luminescence it was concluded that complexes

Fig. 12. The two different coordination geometries proposed for dinuclear lanthanide complexes of macrocycles.

99 and **100** are isostructural. The absence of metal–metal interactions, as concluded from the magnetic moments of the heterodinuclear complexes, indicates that the two metal ions are held far apart in their coordination environment, with no bridging heteroatom between them. This would point to a structure resembling **A** in Fig. 12. However, for the complexes $\text{Ln}_2(\text{Mc}^3)(\text{NO}_3)_4(\text{H}_2\text{O})$ (**101**; Ln is La, Pr, Nd, Sm, Eu, Gd, Tb) of the closely related macrocycle Mc^3 (Mc^2 and Mc^3 differ only by the para-substituent on the aromatic nucleus) metal–metal interactions were observed and the crystal structure of the bis-gadolinium complex has the structure represented by **B**, with both phenolate oxygen atoms bridging between the two metal centers [90].

With the smaller macrocycles Mc^4 and Mc^5 the mononuclear complexes $\text{Ln}(\text{Mc}^4)(\text{NO}_3)(\text{H}_2\text{O})_n$ (**102**; Ln is Gd ($n=4$), Dy ($n=3$)) and $\text{Ln}(\text{Mc}^5)(\text{NO}_3)(\text{H}_2\text{O})_n$ (**103**; Ln is La ($n=4$), Dy ($n=2$)) were obtained [96]. These complexes are best synthesized by reaction of the freshly prepared ligand with the appropriate lanthanide nitrate in the presence of a base. Both ligands contain two separate pockets (analogous to the larger macrocyclic ligands mentioned above) and may be expected to be able to accommodate two lanthanide ions. However, no experiments in this direction have been mentioned for the dianionic ligands.

Type XII

cyclic, polydentate phenolate-based ligands

Mc⁶: R = $(\text{CH}_2)_2\text{O}(\text{CH}_2)_2\text{O}(\text{CH}_2)_2$; R' = Me

Mc⁷

Because small changes in a ligand can have a significant effect on the molecular recognition process, the influence of (partial) reduction of the imine groups in Mc^3 to amine groups as in Mc^6 was also investigated [91]. Although reduction of metal-free H_2Mc^3 by a normal sodium tetrahydroborate procedure was expected to give a macrocycle with all imine groups reduced to amine groups, addition of $\text{Ln}(\text{NO}_3)_3(\text{H}_2\text{O})_n$ to the tetrahydroborate reduction product did not afford the expected bis-lanthanide complexes. However, if the mixture was allowed to stand, large crystals of complexes $\text{Ln}_2(\text{Mc}^6)(\text{NO}_3)_4(\text{MeOH})_{1.2}$ (**104**; Ln is La, Pr, Nd, Eu, Tb) were deposited [91]. These complexes apparently result from selective oxidation, in the presence of the lanthanide ions, of two of the four amine groups in the all-amine macrocycle to give the asymmetric chelate Mc^6 . Allowing the tetrahydroborate solutions to stand without the addition of lanthanide salts appeared to lead to

oxidation of all amine groups. These observations indicate that lanthanide complexes of macrocyclic amines are considerably less stable than those of macrocyclic imines [91].

The crystal structure of $\text{Pr}_2(\text{Mc}^6)(\text{NO}_3)_4 \cdot (\text{MeOH})_{1.2}$ is similar to that of the bis-gadolinium complex **101** (see representation **B** in Fig. 12) with the praseodymium ions bridged by the two phenolates and each coordinated by an imine nitrogen, an amine nitrogen and two oxygen atoms in one chain of the macrocycle. Two bidentate coordinated nitrate groups complete the coordination sphere on each praseodymium, leading to ten-coordinate metal centers. In addition to the homodinuclear complexes **104**, also heterodinuclear complexes $\text{LnLn}'(\text{Mc}^6)(\text{NO}_3)_4 \cdot (\text{MeOH})_{1.2}$ (**105**; LnLn' is $\text{La}_{0.97}\text{Tb}_{0.03}$, $\text{La}_{0.89}\text{Eu}_{0.11}$) were prepared [91]. For these complexes, enrichment of La^{3+} from $\text{La}_{0.8}\text{Tb}_{0.2}$ in the reaction mixture to $\text{La}_{0.97}\text{Tb}_{0.03}$ in the crystalline product was observed, indicating that macrocycle Mc^6 can act as a selective dinucleating agent. However, no enrichment of either lanthanide ion was observed in the LaEu complex.

The trinuclear macrocyclic complexes $\text{Ln}_3(\text{Mc}^7)(\text{OH})_2(\text{NO}_3)_4 \cdot (\text{H}_2\text{O})_n$ (**106**; Ln is La, Pr, Eu, Gd; $n = 4-7$) and $\text{Ln}_3(\text{Mc}^7)(\text{OH})(\text{NCS})_5 \cdot (\text{H}_2\text{O})_7$ (**107**; Ln is La, Pr, Eu, Gd) were prepared by template condensation of 2,6-diacetylpyridine with 1,3-diaminopropane-2-ol in refluxing methanol with $\text{Ln}(\text{NO}_3)_3 \cdot (\text{H}_2\text{O})_n$ and $\text{Ln}(\text{NCS})_3 \cdot (\text{H}_2\text{O})_n$, respectively, as the template [97]. The X-ray structure of $\text{La}_3(\text{Mc}^7)(\text{OH})_2(\text{NO}_3)_4 \cdot (\text{H}_2\text{O})_4$ shows the three lanthanide ions to form an approximately equilateral triangle ($\text{La} \cdot \text{La} \approx 4 \text{ \AA}$) with a $\mu_3\text{-OH}^-$ bridging between the lanthanide ions. In order to study possible metal-metal interactions a number of mixed La/Gd complexes were also prepared, but apparently not analyzed with respect to their actual structure. In any case, no conclusions could be drawn from ESR measurements with respect to metal-metal interactions.

4.4. Complexes of compartmental ligand systems

Another class of ligands that is especially suited for accommodating two (different) metal centers, are the so-called compartmental ligands [98] (CLs, type **XIII**), which contain two different coordination pockets [85b].

Type XIII
compartmental phenolate-based ligands

The first complexes of this type were the heterobimetallic complexes $\text{Ln}(\text{OH})\text{M}(\text{CL}^1)(\text{H}_2\text{O})_n$ (**108**; for M is Ni(II): Ln is La, Nd, Eu, Ho, Yb, Lu; for M is Cu(II): Ln is La, Nd, Eu, Ho, Yb) [99]. These complexes were synthesized by deprotonation of complexes $\text{M}(\text{H}_2\text{CL}^1)$ with LiOH in a pyridine/ethanol mixture, followed by the addition of the appropriate lanthanide nitrate. The complexes were reported to be only sparingly soluble or even insoluble in common solvents, with the exception of pyridine or similar coordinating solvents. Previous studies had shown that the Cu(II) and Ni(II) ions occupy the internal N_2O_2 pocket, leaving the outer O_2O_2 pocket for the lanthanide ions. Coordination of the lanthanide ions was established from IR data, and electronic spectra showed that the internal divalent cations are unaffected by the presence of the lanthanide ion in the adjacent O_2O_2 compartment. The closely related complexes $\text{Ln}(\text{NO}_3)\text{Ni}(\text{CL}^2)(\text{H}_2\text{O})_n$ (**109**; Ln is La, Pr, Eu) have also been reported, in addition to the mononuclear complexes $\text{Ln}(\text{CL}^2)(\text{NO}_3)(\text{H}_2\text{O})_n$ (**110**; Ln is La, Ce, Pr, Nd, Sm, Eu) and $\text{Ln}(\text{CL}^3)(\text{NO}_3)(\text{H}_2\text{O})_n$ (**111**; Ln is La, Ce, Pr, Nd, Sm) [100]. The absence of the O–H and the presence of the N–H stretch vibration in the IR showed the lanthanide ions to occupy the outer O_2O_2 pocket in the mononuclear complexes **110** and **111**. Complexes of the dianion of 2-propionoacetylphenol (pap²⁻), $\text{Ln}_2(\text{pap})_2(\text{NO}_3)(\text{OH})(\text{H}_2\text{O})_n$ (**112**; Ln is La ($n=2$), Pr ($n=6$), Eu ($n=3$)) were assigned a structure resembling that of complexes **108–111** by analogy to their transition metal analogs [100]. However, the low apparent coordination numbers (even including crystal water), as well as the possibility of dehydration mentioned for complexes **108**, make a simple monomeric structure of complexes **108–111** and a dimeric structure for complexes **112** rather unlikely. Unfortunately (or consequently), the complexes were reported to be too involatile for mass-spectral studies [100].

The mixed Cu(II)–Ln(III) complexes $[\text{CuLn}(\text{CL}^4)\text{X}]_2(\text{solv})_n$ (**113**; Ln is Y, La; X is Cl, NO_3 ; solv is H_2O , MeOH; $n=1-4$) were prepared by a procedure similar to that reported for complexes **108**, using methanol as the solvent [101]. The X-ray structure of $[\text{CuY}(\text{CL}^4)(\text{NO}_3)(\text{DMSO})]_2(\text{DMSO})_2$ shows the complex to be dimeric in the solid state, with each yttrium occupying the outer O_2O_2 pocket of one ligand and coordinated by one oxygen atom of the O_2O_2 pocket of the other ligand, leading to a bridging Y_2O_2 unit. The coordination geometry around each yttrium is completed by a bidentate coordinated nitrate anion and one DMSO molecule, leading to two eight-coordinate yttrium centers. In analogy to complexes **108** and **109**, the Cu(II) ions occupy the inner N_2O_2 pockets. These complexes are of interest for the development of new routes for the preparation of mixed oxides for ceramic superconductor synthesis: thermogravimetric measurements showed that decomposition of the complexes eventually gave $\text{CuLn}_2\text{O}_4 + \text{CuO}$ [101].

The acyclic dianionic ligands CL^5 and CL^6 are precursors for the cyclic ligands Mc^4 and Mc^5 respectively [96], and should in principle be able to accommodate two metal centers. However, only the mononuclear complexes $\text{Ln}(\text{LC}^5)(\text{NO}_3)(\text{H}_2\text{O})_n$ (**114**; $n=1$: Ln is La, Gd; $n=2$: Dy) and $\text{Ln}(\text{CL}^6)(\text{NO}_3)(\text{H}_2\text{O})_n$ (**115**; Ln is La ($n=3$), Dy ($n=2$)) have been reported [96]. Whether the lanthanide ion occupies the inner $\text{N}_2\text{O}_2\text{Do}$ (Do is S, NH) pocket or the outer O_2O_2 pocket could not be

Type XIII
(continued)
compartmental phenolate-based ligands

CL⁵: Do = NH.
CL⁶: Do = S.

CL⁷: Do = N(CH₂)₁₁Me; Y = COO.
CL⁸: Do = N(CH₂)₁₁Me; Y = O.
CL⁹: Do = NH; Y = COO.
CL¹⁰: Do = NH; Y = O.
CL¹¹: Do = S; Y = O.

established from the IR data. Homo- and heterodinuclear complexes could be obtained by replacing the neutral aldehyde substituents in CL⁵ and CL⁶ by anionic substituents as in the ligands CL⁷–CL¹¹. The homodinuclear complexes Ln₂(O₄N₂Do)X₂·(solv)_n (**116**: O₄N₂Do is CL⁷; Ln is La, Pr, Nd, Sm–Dy, Yb; X is NO₃, Cl; solv is H₂O; **117**: O₄N₂Do is CL⁸; Ln is La; X is NO₃; solv is H₂O; **118**: O₄N₂Do is CL⁹; Ln is La, Sm; X is NO₃, Cl; solv is H₂O, MeOH; **119**: O₄N₂Do is CL¹⁰; Ln is Eu, Tb; X is NO₃; solv is H₂O; **120**: O₄N₂Do is CL¹¹; Ln is La; X is NO₃; solv is MeOH) were prepared by a template procedure, analogous to the lanthanide complexes of macrocycles (*vide supra*) [102]. The long aliphatic chains present on the ligand in complexes **116** and **117** were introduced in an attempt to increase the solubility of these complexes in organic solvents, but probably as a result of oligo- or polymerization this was not successful [102].

IR data for the only mononuclear complex that could be isolated, La(H₂O₄N₂Do)(NO₃) (**121**; O₄N₂Do is CL⁷), showed the lanthanide ion to occupy the outer O₂O₂ pocket [102], analogous to complexes **110** and **111**. The heterobimetallic complexes LnLn'(O₄N₂Do)(NO₃)₂·(solv)_n (**122**; O₄N₂Do is CL¹⁰; LnLn' is LaEu, EuTb; solv is H₂O; **123**: O₄N₂Do is CL¹¹; LnLn' is LaTb; solv is MeOH) were prepared by a stepwise procedure: to the in situ prepared ligand, Ln(NO₃)₃·(H₂O) is added with formation of Ln[H₄(O₄N₂Do)](NO₃)₃, followed by successive addition of four equivalents of LiOH and Ln'(NO₃)₃·(H₂O) [102]. The homogeneity and metal ratio in these complexes were established by electron microscopy in combination with X-ray fluorescence analysis. It was reasoned that the complexes are most probably dimeric in structure, analogous to the CuY complex **113**. There were indications for metal–metal interactions through the bridging atoms in the complex Gd₂(O₄N₂Do)(NO₃)₂·(H₂O)₄.

5. Miscellaneous (Table 6)

Although a wide range of lanthanide chelate complexes of (poly)carboxylic acids containing donor functionalities [(poly)aminepolycarboxylates] have been studied, most attention has been paid to formation constants in aqueous solution, and to heats and entropies of formation [103]. Relatively little is known of the actual structures of most of these complexes [103] and they have therefore been excluded from this overview.

An exception is made for the lanthanide complexes of pyridine-2,6-dicarboxylate (pdc) and thiophene-2,5-dicarboxylate (tdc) (XIV). Complexes $\text{Ln}(\text{pdc})(\text{Hpdc})(\text{H}_2\text{O})_n$ (**124**; Ln is La ($n=6$), Gd ($n=8$), Dy ($n=6$)) and $\text{Na}_3[\text{Ln}(\text{pdc})_3](\text{H}_2\text{O})_m$ (**125**; Ln is La, Gd, Dy) were prepared by reacting $\text{Ln}(\text{NO}_3)_3$ with H_2pdc in water in the presence of NaOH with Ln/ H_2pdc /NaOH molar ratios of 1:3:6 and 1:2:4, respectively [104]. While complexes **125** are soluble in cold water, complexes **124** are only soluble in hot water. Both types of complexes behave as electrolytes, indicating that even complexes **124** dissociate in solution. The crystal structure of $[\text{La}(\text{pdc})(\text{Hpdc})(\text{H}_2\text{O})_2](\text{H}_2\text{O})_4$ shows both ligands to coordinate in a tridentate fashion, with one carboxyl group bridging to a second lanthanum, forming a polymeric chain. Two coordinated water molecules complete the coordination sphere around lanthanum, leading to a nine-coordinate metal center. With thiophene-2,5-dicarboxylate, complexes $\text{Ln}_2(\text{tdc})_3(\text{H}_2\text{O})_n$ (**126**; Ln is La, Gd, Dy) and $\text{Ln}(\text{tdc})(\text{OH})(\text{H}_2\text{O})$ (**127**; Ln is Sm, Gd) were obtained, which were insoluble in common organic solvents [104].

Some of the very few known examples of phosphine-stabilized complexes of Group 3 and lanthanide metals (see also complexes **45** and **59**) are the bis(amido-diphosphine) complexes (XV) $\text{LnCl}[\text{N}(\text{SiMe}_2\text{CH}_2\text{FR}_2)_2]_2$ (**128**: R is Me, Ln is Y, La, Lu; **129**: R is Ph, Ln is Y, La; **130**: R is ⁱPr, Ln is Y) [105]. These complexes were synthesized by reaction of LnCl_3 with two equivalents of $\text{MN}(\text{SiMe}_2\text{CH}_2\text{PR}_2)_2$ (M is Li (Ln is Y, Lu), K (Ln is La)) in THF at room temperature. The complexes are soluble in THF and aromatic and aliphatic solvents. Substitution of chloride in complexes **128** was only successful using PhLi or PhCH_2K for the yttrium and lutetium complexes, with formation of $\text{LnR}[\text{N}(\text{SiMe}_2\text{CH}_2\text{PMe}_2)_2]_2$ (**131**: R is Ph, Ln is Y, Lu; **132**: R is PhCH_2 , Ln is Y) [105c]. These complexes are thermally

Table 6
Lanthanide complexes of miscellaneous ligands containing intramolecularly coordinating substituents

Complex	Lanthanide metals ^a	Ln-Do bond lengths (Å)	Ligand type	Ref.
124 Ln(pdc)(Hpdc)·(H ₂ O) _n ^b	La, Dy (n = 6); Gd (n = 8)	La-N: 2.67 ^c	XIVa	[104]
125 Na ₃ [Ln(pdc) ₃]·(H ₂ O) _n ^b	La, Gd, Dy	—	XIVa	[104]
126 Ln ₂ (tdc) ₃ ·(H ₂ O) _n ^d	La, Gd, Dy	—	XIVb	[104]
127 Ln(tdc)(OH)·H ₂ O ^d	Sm, Gd	—	XIVb	[104]
128 LnCl[N(SiMe ₂ CH ₂ PMc ₂) ₂] ₂	Y, La, Lu	—	XV	[105]
129 LnCl[N(SiMe ₂ CH ₂ P(Ph) ₂) ₂] ₂	Y, La	—	XV	[105]
130 LnCl[N(SiMe ₂ CH ₂ P(Pr) ₂) ₂] ₂	Y	—	XV	[105]
131 LnPh[N(SiMe ₂ CH ₂ PMc ₂) ₂] ₂	Y, Lu	—	XV	[105c]
132 Ln[CH ₂ Ph][N(SiMe ₂ CH ₂ PMc ₂) ₂] ₂	Y	—	XV	[105c]
133 Ln[N(SiMe ₂ CHPMc ₂) ₂][N(SiMe ₂ CH ₂ PMc ₂) ₂]	Y, La, Lu	Y-P: 2.817(3), 2.896(3), 2.903(3), 3.005(3)	XV	[105c]
134 Ln[P(C ₆ H ₄ OMe-2) ₂] ₃ ·(C ₆ H ₅ Me) _n	Y (n = 0), La (n = 2)	—	XVI	[106]
135 Ln[N(Pr) ₂][P(C ₆ H ₄ OMe-2) ₂] ₂ ·(THF)(C ₆ H ₅ Me)	La	—	XVI	[106]
136 [N(Pr) ₂] ₂ Ln[μ-P(C ₆ H ₄ OMe-2) ₂] ₂ Li(THF)	La	La-O: 2.787(9)	XVI	[106]
137 (C ₅ Me ₃)Ln[S ₂ P(OMe) ₂] ₂	Sm	Sm-O: 2.645(3)	XVII	[107]
138 Ln(DAC)[N(SiMe ₃) ₂] ^e	Y, Ce, Sm	Y-O: 2.457(12), 2.467(11), 2.514(12), 2.590(12)	XVIII	[108]
139 Ln{μ-DAC}Ln[N(SiMe ₃) ₂] ₂ ^e	Yb	Yb-O: 2.49(2)–2.57(3)	XVIII	[108]
140 {Ln[N(SiMe ₃) ₂]} ₂ (μ-DAC) ^f	Yb ^g	—	XVIII	[108]
141 Ln(DAC)(CH ₂ SiMe ₃) ^f	Y	Y-O: 2.431(12), 2.442(13), 2.534(11), 2.622(11)	XVIII	[109]

^a Underlining indicates that a crystal structure is available. ^b pdc = pyridine-2,6-dicarboxylate. ^c No esd given. ^d tdc = thiophene-2,5-dicarboxylate. ^e DAC = deprotonated 4,13-diaza-18-crown-6. ^f As a result of extensive disorder, only the general structure is reported.

Fig. 13. Schematic structure of the cyclometallated complex **133**.

unstable, and undergo a cyclometallation reaction via abstraction of a methylene proton from the ligand backbone with liberation of benzene (complexes **131**) or toluene (complex **132**). In the case of reaction of the lanthanum complex $\text{LaCl}[\text{N}(\text{SiMe}_2\text{CH}_2\text{PMe}_2)_2]_2$ (**128**) with PhLi , only the cyclometallated complex was obtained. Coordination of the phosphine donor substituents to the lanthanide metals was established from ^1H , ^{13}C and ^{31}P NMR. All complexes are fluxional in solution at room temperature. At low temperature all four phosphine donors are coordinated to the metal center in the case of complexes **128**, **131** and **132**.

For the complexes with phenyl substituents on phosphorus (**129**), steric crowding results in one donor remaining pendant for the yttrium complex, while the larger ionic radius of La^{3+} appears to result in a monomer–dimer equilibrium at low temperature. The cyclometallated complexes $\text{Ln}[\text{N}(\text{SiMe}_2\text{CHPMe}_2)_2][\text{N}(\text{SiMe}_2\text{CH}_2\text{PMe}_2)_2]$ (**133**; Ln is Y, La, Lu) are also fluxional in solution at room temperature, and, at low temperature, coordination of all four phosphine donors was established by ^{31}P NMR for the yttrium and lutetium complexes. The crystal structure of $\text{Y}[\text{N}(\text{SiMe}_2\text{CHPMe}_2)_2][\text{N}(\text{SiMe}_2\text{CH}_2\text{PMe}_2)_2]$ also shows all four phosphine donors to be coordinated, resulting in a seven-coordinate metal center (see Fig. 13). Unfortunately, no reactivity was observed for the cyclometallated complexes: the cyclometallation is reversible at high temperatures under about 4 atm H_2 or D_2 , but the complexes only activate their own C–H bonds [105c].

Type XVI
donor substituted phosphide ligands

Type XVII
donor substituted dithiophosphate ligands

The only reported donor-substituted phosphide ligand used in lanthanide chemistry thus far is the bis(2-methoxyphenyl)phosphide ligand (**XVI**). The toluene-soluble complexes $\text{Ln}[\text{P}(\text{C}_6\text{H}_4\text{OMe-2})_2]_3 \cdot (\text{C}_6\text{H}_5\text{Me})_n$ (**134**; Ln is Y ($n=0$), La ($n=2$)) were prepared by reaction of $\text{Ln}[\text{N}(\text{iPr})_2]_3(\text{THF})$ with three equivalents of

Fig. 14. Schematic representation of complex 137.

$\text{P}(\text{C}_6\text{H}_4\text{OMe-2})_2\text{H}$ in toluene at room temperature [106]. Addition of one equivalent of $\text{P}(\text{C}_6\text{H}_4\text{OMe-2})_2\text{H}$ to $\text{La}[\text{N}(\text{tPr})_2]_3(\text{THF})$ also gave complex 134 as the only product, together with unreacted lanthanide amide. However, if the reaction is performed at 0°C , bright yellow crystals of $\text{La}[\text{N}(\text{tPr})_2][\text{P}(\text{C}_6\text{H}_4\text{OMe-2})_2]_2(\text{THF})(\text{C}_6\text{H}_5\text{Me})$ (135) are precipitated with virtually no formation of 134. Reaction of $\text{Li}\{\text{La}[\text{N}(\text{tPr})_2]_4\}$ with two equivalents of $\text{P}(\text{C}_6\text{H}_4\text{OMe-2})_2\text{H}$ gave good-quality crystals of $[\text{N}(\text{tPr})_2]_2\text{La}[\mu\text{-P}(\text{C}_6\text{H}_4\text{OMe-2})_2]_2\text{Li}(\text{THF})$ (136) [106]. The crystal structure of this complex shows the phosphide ligands to bridge La and Li through the phosphorus atom, with each of the methoxy substituents coordinating to one of the metal centers. The coordination sphere around lanthanum is completed by two dialkylamido groups, resulting in a relatively low coordination number of six.

Complex $(\text{C}_5\text{Me}_5)_2\text{Sm}[\text{S}_2\text{P}(\text{OMe})_2]_2$ (137), which was prepared by reaction of two equivalents of the divalent samarium complex $(\text{C}_5\text{Me}_5)_2\text{Sm}(\text{THF})_2$ with $[(\text{MeO})_2\text{P}(\text{S})\text{S}]_2$ at room temperature in toluene [107], is another example of the incorporation of potential donor sites in relatively simple ligands. The X-ray structure shows the *O,O'*-dimethyldithiophosphate ligands to be present in two different coordination geometries: two terminally ($\eta^2\text{-S,S}$)Sm bonded ligands with both methoxy substituents pendant and two bridging $\text{Sm}(\eta^2\text{-S,S}/\eta^1\text{-S})\text{Sm}$ ligands, each with one methoxy substituent coordinating to one of the samarium centers (see Fig. 14). Thus, the formal coordination number for the samarium centers is nine.

Type XVIII
deprotonated diazacrown ethers

Despite the fact that lanthanide complexes of both crown ethers and their N-substituted analogs (aza-crowns) have been extensively studied, to date only two reports on the use of deprotonated aza-crowns have appeared [108,109]. By reacting $\text{Ln}[\text{N}(\text{SiMe}_3)_2]_3$ with one equivalent of 4,13-diaza-18-crown-6 (H_2DAC ; XVIII) at

Fig. 15. Schematic representations of complexes **139** and **140**, containing the DAC ligand.

room temperature in toluene, complexes $\text{Ln}(\text{DAC})[\text{N}(\text{SiMe}_3)_2]$ (**138**; Ln is Y, Ce) were obtained [108]. NMR data for the yttrium complex indicate a monomeric structure, which was confirmed by the X-ray structure of the complex. The crystal structure shows the DAC ligand to span one hemisphere of the yttrium ion as a hexacoordinate ligand, with the bis(trimethylsilyl)amido ligand shielding the space above. Complexes **138** are moderately soluble in hexane and very soluble in THF, diethyl ether and toluene. Attempts to replace the amido ligand by phenolate or alkoxide ligands were not successful. Reaction of the divalent complex $\text{Yb}[\text{N}(\text{SiMe}_3)_2]_3(\text{Et}_2\text{O})_2$ with H_2DAC in a 2:3 ratio gave complex $\text{Yb}\{(\mu\text{-DAC})\text{Yb}[\text{N}(\text{SiMe}_3)_2]\}_2$ (**139**), while a 2:1 ratio afforded $\{\text{Yb}[\text{N}(\text{SiMe}_3)_2]\}_2(\mu\text{-DAC})$ (**140**) [108]. The X-ray structure of complex **139** shows each of the DAC ligands to be hexacoordinated to one ytterbium ion, which also bear one amido ligand each and are seven-coordinate. The third ytterbium ion is sandwiched between the two ligands and is only four-coordinate (see Fig. 15). NMR data and preliminary X-ray data for complex **140** show the DAC ligand in this case to act as a dinucleating ligand (see Fig. 15). The coordination sphere around each ytterbium is completed by an amido ligand, leading to the relatively low coordination number five.

Interestingly, reaction of divalent $\text{Sm}[\text{N}(\text{SiMe}_3)_2]_3(\text{THF})_2$ with H_2DAC in a 1:1 ratio afforded the trivalent complex $\text{Sm}(\text{DAC})[\text{N}(\text{SiMe}_3)_2]$ (**138**) [108]. Initial formation of divalent $\text{Sm}(\text{HDAC})[\text{N}(\text{SiMe}_3)_2]$, followed by reduction of the amine N–H bond, was proposed as a possible mechanism for the formation of **138**. Reaction of $\text{Y}(\text{CH}_2\text{SiMe}_3)_3(\text{THF})_2$ with H_2DAC at room temperature in toluene allowed for the isolation of the first alkyl derivative, $\text{Y}(\text{DAC})(\text{CH}_2\text{SiMe}_3)$ (**141**) [109]. The solid state structure of this complex resembles that of complex **138**. Complex **141** slowly decomposes in solution at room temperature, with formation of TMS. NMR data suggest that this decomposition involves metallation of the DAC ligand.
