On foot templates and root templates

René Kager

0. Introduction

Many languages impose prosodic restrictions on the shape of the (canonical) root. For example, restrictions may hold w.r.t. maximal root length (e.g. four syllables) or the distribution of quantity (e.g. vowel length occurs in even-numbered syllables). The notion of *canonical root* will be defined by frequency, (ir)regularity, repair, etc. The central claim of this paper is canonical roots are members of *template pools* (Kager 1994a). A template pool is the natural class of prosodic shape invariants that together characterize a morphological category. Template pools are defined in terms of metrical feet, and are maximally two feet long. As an example, consider the template pool of Japanese loan abbreviations (Itô 1992). This pool has two bimoraic feet [H] or [LL] as its maximum. Each template begins with a foot:

(1) a	Strict MinWd	Ft	LL	suto (raiki)	‘strike’
b	Loose MinWd	Ft+σ _μ	H+L	dai ya (moNdo)	‘diamond’
			LL+L	tere bi (zyoN)	‘television’
c	Compound	Ft+Ft	H+H	baa teN (daa)	‘bartender’
			H+LL	koN bini (eNsu)	‘convenience store’
			LL+H	ea koN (dishonaa)	‘airconditioner’
			LL+LL	asu para (gasu)	‘asparagus’

In contrast to the parametric approach of Kager (1994a), I will derive the notion of template pool from *foot alignment* constraints. McCarthy and Prince (1993) obtain prosodic minimality from $MCat = PrWd$, i.e. both edges of a morphological domain must coincide with edges of a $PrWd$. Prosodic maximality can be obtained likewise by constraining the distribution of feet within $MCat$, hence within $PrWd$. The idea is that some edge (L/R) of every foot must stand at some edge (L/R) of $MCat$. This is stated in the *asymmetrical* alignment constraint $ALIGN(Ft, Rt)$ (2a). Maximally two feet per $MCat$ can satisfy this requirement; therefore the highest level at which $MCat$ maximality may be imposed is what Kager (1994a) calls *Compound*. Sharpening the demands on foot distribution, all feet may be required to stand at a designated (i.e. *either L or R*) edge of $MCat$ (2b, c). This gives a $MCat$ in which a single foot stands at the designated edge, i.e. what Kager (1994a) calls *Loose MinWd*. Finally, *Smw* is the situation in which every foot is required to stand at the opposite edge as well.

- (2) a ALIGN (Ft, Rt): Some edge of every Ft coincides with some edge of a Rt.
 b ALIGN-L (Ft, Rt): The L-edge of every Ft coincides with the L-edge of a Rt.
 c ALIGN-R (Ft, Rt): The R-edge of every Ft coincides with the R-edge of a Rt.

When these constraints are permuted with PARSE ('input material must reoccur in the output'), a typology arises.

- (3) a PARSE > ALIGN (Ft, Rt) > ALIGN-L (Ft, Rt) > ALIGN-R (Ft, Rt)
 (No maximality of M_{Cat} observed.)
 b ALIGN (Ft, Rt) > PARSE > ALIGN-L (Ft, Rt) > ALIGN-R (Ft, Rt)
 (Maximal M_{Cat} is a left-headed Cpd.)
 c ALIGN (Ft, Rt) > ALIGN-L (Ft, Rt) > PARSE > ALIGN-R (Ft, Rt)
 (Maximal M_{Cat} is a left-headed Lmw.)
 d ALIGN (Ft, Rt) > ALIGN-L (Ft, Rt) > ALIGN-R (Ft, Rt) > PARSE
 (Maximal M_{Cat} is a Smw.)

Note that Japanese loan abbreviations can be characterised by ranking (3b):

(4) /asuparagasu/	ALIGN (Ft, Rt)	PARSE	ALIGN-L (Ft, Rt)	ALIGN-R (Ft, Rt)
([a.su].[pa.ra])		gasu	*	*
([a.su].pa)		ragasu!		*
([a.su])		paraga!su		
([a.su].[pa.ra].ga)	*!	su	*	*
([a.su].[pa.ra].[ga.su])	*!		**	**

This approach expresses implications within template pools that were predicted by Kager (1994a). *Vertical*: If Cpd occurs in the pool of some M_{Cat}, then Lmw and Smw should occur as well. If Lmw occurs in a pool then Smw should occur as well. *Horizontal*: If Cpd (e.g. H+LL) occurs in a pool, then other Cpds (e.g. LL+LL) should occur as well. If Lmw (e.g. H+L) occurs in a pool, then other Lmws (e.g. LL+L) should occur as well. *Asymmetrical*: If left-headed templates (e.g. H+L) occur in a pool, then right-headed templates (e.g. *L+H) should not occur, and vice versa.

1. Prosodic constraints on root shapes

Below I will discuss canonical root shapes of five East Australian languages: Yidij (Dixon 1977), Wargamay (Dixon 1981), Mbabařam (Dixon 1991), Gumbayngir (Eades 1979) and Uradhi (Crowley 1983). All are genetically related, and interesting variations occur in root shapes and stress. I will show that canonical roots in all five languages form template pools of the maximal type 'Compound' in the typology of M_{Cats} in (3). I will also show that for each language, the foot required for its *stress* pattern mirrors the foot required for its root definition (grammars are *prosodically coherent* in the terminology of Drescher and Lahiri 1991). Also, *extrametricality* and

catalexis, if required for stress, are mirrored in canonical root shape. Finally, the alignment of stress feet with PrWd edge is mirrored by L/R-headed root templates.

An important issue, which will not be fully resolved here, is that of the level at which constraints on canonical roots take effect. Often root-based constraints seem to be violated at the level of the word. E.g. in Yidij long vowels only occur in even-numbered root syllables, while within a word odd-numbered root syllables may be long by pre-suffixal lengthening, cf. *wuŋabaa-ji-ŋ* ‘hunt-:ji-PRES’. Similarly, the Uradhi root contains maximally one long vowel, but again word-level pre-suffixal lengthening may lead to two long root vowels, cf. *taaraa-namu* ‘reef-GEN’. Here a ‘domains’ approach might be contrasted with a ‘stratal’ approach. Under the former, constraints on roots are evaluated at word level in terms of root-prosody alignment constraints. It is significant that in both examples given above the ‘misbehaved’ long vowel stands at the edge of the root, where it could be analysed as bi-morphemic. Under the ‘stratal’ approach of Lexical Phonology, the lexicon is sub-divided into *strata*, including root, stem and word. In *Optimality Theory* each stratum may define its own ranking of constraints (McCarthy and Prince 1993a). Canonical root shapes are defined by a set of ranked constraints on the output of the earliest lexical stratum - before derivation nor affixation has taken place. Still, root-level constraints may be shared with other lexical levels. For example, Gumbayngir root-level constraints are active at word-level, where they both trigger and constrain a length shift.

A crucial property of all languages to be discussed below is that their roots may occur as stems or even words in isolation, where they mark the *absolute* case. For all languages except Yidij, the prosodic shape of the root in its word-level isolation form is highly similar to its canonical shape. Transparency of canonical root shapes at word level may be a factor enhancing the rôle of root-based constraints in these languages. (Conversely we would expect root constraints to be much less apparent in languages in which each root is obligatorily inflected by non-zero material.)

2. Yidij

Below the distribution of 836 roots in Dixon’s (1977) vocabulary of Yidij is given, per prosodic type, by descending frequency:

(5) Type Number Example

LL	590	gala ‘spear’, gugaŋ ‘large guanna’
LLL	219	/gindanu/ [gindaan] ‘moon’, /gudaga/ [gudaaga] ‘dog’
LLLL	12	ɟulugunu ‘black myrtle tree’, yingilibiy ‘bee’
LH	11	durguu ‘mopoke owl’, giŋaa ‘vine species’
LLLLL	2	/jilibugabi/ [jilibugaabi] ‘next day’
LHLL	1	waŋaaba ‘white apple tree’
LLLH	1	galambaŋaa ‘march fly’

Note that Yidj has no monosyllabic roots, L nor H. Furthermore, vowel length contrasts are restricted to *even-numbered* syllables of roots. (We will return to the absence of LHL below.) As Dixon (1977:86) observes, there is no theoretical reason why we should not have an odd-syllabled root ending in a long vowel, e.g. LLH, as this length would surface in inflected words with an even number of syllables, e.g. CvCvCvv-*gu*. (Below the relevance of syllable number will be clarified.) And no roots have length in the initial syllable (e.g. *HL, *HLL), since initial length never surfaces in even-numbered words. Finally, the only two LLLLL roots may well be morphologically complex (e.g. *filibugabi* ‘next day’, cf. *jili* ‘eye’, *buga* ‘night’).

Turning to (word-level) stress and length, we find an interesting correlation with canonical root shape. In odd-numbered words, long vowels only occur in even-numbered syllables. Actually, the penult of an odd-numbered word always contains a long vowel by *Penultimate Lengthening* (Dixon 1977:43). Such words have iambic feet [LH], [LL] throughout. Final vowels outside a foot are apocopated except when an illegal coda would result (6d) - *Final Syllable Deletion* (Dixon 1977:58).

(6)	a	/gudaga/	[gu.dáa].ga	‘dog-ABS’
	b	/gali-ŋu/	[ga.lí:ŋ]	‘go-PAST’
	c	/maʃinda-ŋunda/	[ma.ʃín].[da.ŋúun]	‘walk up-DAT SUB’

Kirchner (1990) argues that *Penultimate Lengthening* is a compensatory effect that is triggered by *Final Syllable Deletion*, which is in its turn driven by the preference for all syllables to be parsed into disyllabic feet (Dixon 1977:41), i.e. PARSE- σ .

(7)	/gali-ŋu/	[(ga.lí:ŋ)<u>]
		\
	μμ μ	μ μ μ

When the underlying form has no long vowels, and an even number of syllables, all feet in the word are balanced trochees [LL] (8a-d). When a long vowel occurs in an even-numbered syllable, feet are iambic throughout the word (8e-f). Finally, when the word contains a special suffix that induces length in the preceding syllable, long vowels occur in odd-numbered syllables, with trochaic feet [LL] or [HL] (8g-h):

(8)	a	/waʃil/	[wá.ʃil]	‘doorway-ABS’
	b	/gudaga-ni/	[gú.da].[gá.ni]	‘dog-GEN’
	c	/wawal-ŋunda/	[wá.wal].[ŋún.da]	‘see-DAT SUB’
	d	/maʃinda-ŋal-ŋunda/	[má.ʃin].[dá.ŋal].[ŋún.da]	‘walk up-COM-DAT SUB’
	e	/durguu/	[dur.gúu]	‘mopoke owl-ABS’
	f	/durguu-nu-la/	[dur.gúu].[nu.lá]	‘mopoke owl-GEN-LOC’
	g	/gali-ŋal-:ʃi-ŋ/	[gá.li].[ŋáa.ʃiŋ]	‘go-COM-:ʃi-PRES’
	h	/wuŋaba-:ʃi-ŋunda/	[wú.ŋa].[báa.ʃi].[ŋún.da]	‘hunt-:ʃi-COM-DAT SUB’

We find that stress feet at word level are strictly disyllabic [LL], [LH], or [HL], excluding *[H]. Iambic [LL] occurs under pressure of prominence harmony only (Dixon 1977:41, McCarthy and Prince 1986). However the unbalanced trochee [HL] *never occurs in roots* - its only source is pre-suffixal length. (If roots such as HL would occur, we would expect even-numbered forms with trochaic stress, cf. 8g-h). Accordingly the root stratum strictly enforces the *optimal feet* [LL] and [LH], in a template pool *Cpd-Left*:

- (9) a Smw ([LL]) ([LH])
 ([ga.la]) ([dur.guu])
 b Lmw ([LL]+L) *([LH]+L)
 ([gu.da].ga) (*gap, see below*)
 c Cpd ([LL]+[LL]) ([LH]+[LL]) ([LL]+[LH]) ([LH]+[LH])
 ([ma.raŋ].[gar.ga]) ([bu.raa].[ba.di]) ([ga.lam].[ba.ɾaa]) (*gap*)

Note that the root level does not require exhaustive parsing of syllables by disyllabic feet, in contrast to the word level. We find that root structure is, on the one hand, more restrictive than word structure in disallowing [HL] feet, but on the other hand less restrictive, in allowing for Lmw.

Let us now turn to the puzzling absence of LHL roots. No trisyllabic roots occur whose second syllable length surfaces in even-numbered case forms. E.g. given an LHL root */*gudaagu*/, we might expect a quadrisyllabic case form */*gu.dáa*].[*ga.ní*]. However, the only attested type of form is [*gú.da*].[*gá.ni*]. Reduplication is another source of evidence for lack of LHL roots, since putative length is not copied along, cf. /*waguʃa*/ [*wagúuʃa*] ‘man-ABS’, [*wagú*=*wagúuʃa*] */*wagúu*=*wagúuʃa*] ‘lots of men-ABS’ (Dixon 1977:69). The absence of LHL roots may be due to the fact that the effect of *Penultimate Lengthening* is abstracted away from the underlying root.

3. Wargamay

Consider the distribution of 917 roots in the Wargamay vocabulary (Dixon 1981):

(10) Type	Number	Example
LL	489	bada ‘dog’, gawal ‘call’
LLL	268	gagara ‘cane dilly-bag’, girawan ‘scrub hen’
LLLL	69	gayambula ‘white cockatoo’, jígubina ‘falling star’
HL	58	wiigi ‘no good’, muugil ‘freshwater black bream’
HLL	17	giibaɾa ‘fig tree’, giirigin (proper name)
H	15	yaa ‘top of a tree’, jiin ‘eyebrow’
LLLLL	1	burayŋjubaɾa (proper name)

4. Mbabařam

Next consider the distribution of 332 roots in Mbabařam vocabulary (Dixon 1991):

(13) Type	Number	Example
LL	169	muga ‘aunt’, wuřgun ‘young boy’
L	94	mba ‘belly’, bib ‘breast’
LLL	30	agařu ‘to scratch’, yaraman ‘horse’
H	19	bii ‘ear’, wiit ‘head hear’
LH	17	abuu ‘ground’, nambuut ‘big brown snake’
HL	2	nɔɔmbi ‘big red wallaroo’, ŋɔɔlmbu ‘small’
LLLL	1	řarabulgan ‘Mount Mulligan’ (loan)

On the whole, Mbabařam roots are much shorter than Yidij or Wargamay roots. Monomoraic (‘sub-minimal’) roots L are not only allowed, but quite numerous. Also roots exceeding three syllables are rare. Vowel length contrasts are almost restricted to monosyllables and to the second syllable of disyllabic roots (i.e. *LHL).

Shortness of the canonical root is closely related to the stress pattern through the notion of *catalexis*, as I will now show. Mbabařam stress is complex and lexically variable. Heavy syllables are always stressed (14a-b). An initial /a/ never bears main stress, which usually falls on the second syllable (14b-d). Disyllabic full-vowel roots stress are stressed on the second syllable (14g-h), or the initial syllable (14 i-j). Most trisyllabic full-vowel roots are stressed on the second syllable (14k-l), some on the final syllable with an initial secondary stress (14m-n):

(14) a	nambúur (snake)	e	řibú	‘no good’	i	řambářa	‘nulla nulla’
b	abúu ‘ground’	f	miřál	‘lip’	j	malgářir	‘very big’
c	abář ‘sister’	g	búmba	‘ashes’	k	gùriřál	‘eaglehawk’
d	aráman ‘woomera’	h	láŋgil	‘light’	l	gùludún	‘dove’

Accordingly, the stress foot is the *moraic trochee*, with optional *mora catalexis*. Catalexis is a segmentally empty mora at the right edge of the root (Kiparsky 1991, Kager 1995), making a final light syllable count as heavy (hence ‘L⁺’). The foot is right-aligned in the root. The root template pool is *Cpd-Right* modulo μ catalexis.

(15) a	Smw	94	([L ⁺])	mbá	
		12	([LL])	búmba	
		19	([H])	bíi	
	bLmw	152	(L+[L ⁺])	řibú	93 of which (a+[L ⁺]) (e.g. abář)
		23	(L+[LL])	yuwágil	10 of which (a+[LL])(e.g. aráman)
		17	(L+[H])	muřáal	10 of which (a+[H]) (e.g. abúu)
	c Cpd	5	([LL]+[L ⁺])	gùludún	
		1	([LL]+[LL])	řàrabúlgan	

We are now able to state the distribution of initial /a/: its syllable must occupy the ‘adjunct’ (pre-head) position in Lmw. Under this analysis, only four roots resist a ‘canonical’ analysis. They are: *àrɨŋgúl* ‘kite hawk’ (which has initial /a/ in non-adjunct position); *nɔ́mbɪ* ‘big red wallaroo’ and *ɨɔ́mbu* ‘small’, both of which have the left-headed Lmw structure [H]+L; and *mbábaraŋam* (language name), which also has a left-headed Lmw structure [LL]+L.

Furthermore, attested roots have gaps as compared to predictions of the template pool. Absence of noncatalectic Cpd ([LL])+(H) must be an accidental gap. The fact that no Cpd has a heavy initial foot (e.g. ([H])+(L⁺), ([H])+(LL), ([H])+(H)), may well be due to clash avoidance.

5. *Gumbayŋgir*

The distribution of 473 roots in the Gumbayŋgir vocabulary (Eades 1979) is below:

(16) *Type Number Example*

HL	126	<i>miimi</i> ‘mother’, <i>jaawan</i> ‘pheasant’, <i>yiila</i> ‘to cook’
LL	108	<i>baga</i> ‘knee’, <i>badaɟ</i> ‘rat, mouse’, <i>bira</i> ‘to dig’
LH	80	<i>duluu</i> ‘ankle’, <i>babaar</i> ‘club’, <i>bagii</i> ‘to burn’
LLL	71	<i>bulari</i> ‘two’, <i>balawir</i> ‘flying fox’, <i>bagulwa</i> ‘to slay’
LHL	36	<i>guluura</i> ‘bone’, <i>ɨaluŋgir</i> ‘clever man’, <i>baguuli</i> ‘to lie down’
H	20	<i>juum</i> ‘smoke’, <i>pa</i> ‘to see’ (irregular)

V N Part

HLL	8	5	2	1	<i>juuliyam</i> ‘fig’, <i>paagili</i> ‘to find’, <i>guuɟulaw</i> ‘tomorrow’
LLLL	8	2	6	-	<i>maranɟarga</i> ‘spider’, <i>bilagara</i> ‘to run’
LHLL	2	1	1	-	<i>wuruuŋga</i> ‘salt water oak tree’, <i>buraabadi</i> ‘to return’

We first observe that the minimal root is bimoraic (The exception *bu(m)* ‘to hit’ always surfaces as a bimoraic stem by an augment, e.g. imperative *bum-a*). Second, no adjacent heavy syllables occur (e.g. *HH, *HHL). Third, vowel length does not occur outside the first two root syllables. (e.g. *LLH, *LLHL, *HLHL). Fourth, a closer look at roots of the shapes LLLL, HLL, and LHLL reveals that almost all are verbs. One of the two nominal HLL roots (*gaagup-ga* ‘fig tree’) has the ‘tree suffix’ *-ga*, which also occurs in three out of six LLLL nominal roots (*balawun-ga* ‘ti-tree’, *barigir-ga* ‘ironbark tree’, *gayabar-ga* ‘boxtree’), and the single nominal LHLL root (*wuruuŋga-ga* ‘salt water oak tree’), although no meaningful roots can be identified as bases. Two more LLLL nominal roots are semi-compounds (e.g. *galam=bila* ‘Coff’s harbour’, cf. *galaamga* ‘oak tree’, Eades 1979:354). Finally, no roots longer than four syllables occur (two apparent exceptions *yariyapini* ‘Yarihapini Mountain’ and *jinanɟubala* ‘to kick’ are arguably morphologically complex, Eades 1979:265).

The question then is: can the canonical root shapes (those above the bar in 16) all be captured by a single root formula? Let us first look into the stress pattern. Stress falls on a heavy syllable (17a-d). When there are no heavy syllables, stress is initial and optionally on the second syllable of words longer than two syllables (17e-f):

- (17) a [júum] ‘smoke’ e [ná.mi] ‘woman’
 b [míi].mi ‘mother’ f [gá.lu].gun **or** [ga.lú].gun ‘one’
 c [ŋa.líi] ‘ldu inc S,A’
 d [ŋa.lúuŋ].gir ‘clever man’

That is, the stress foot is minimally bimoraic and maximally disyllabic, with vowel length aligning with right edge of foot: the ‘uneven iamb’ [H], [LH], [LL]. The actual choice between trochaic [LL] and iambic [LL] depends on rhythm. That is, default prominence in [LL] feet is trochaic, but *lapse avoidance* in trisyllabic words causes optional second syllable stress, with [LL]. We then arrive at a template pool *Cpd-Left* for verbal roots, and *Lmw-Left* for nominal roots:

- (18) a Smw ([H]) ([LL]) ([LH])
 (N, V) ([juum]_N) ([na.mi]_N) ([ba.gii]_V)
 b Lmw ([H]+L) ([LL]+L) ([LH]+L)
 (N, V) ([mii].mi)_N ([ba.gul].wa)_V ([ŋa.luun].gir)_N
 c Cpd ([H]+[LL]) ([LL]+[LL]) ([LH]+[LL])
 (V) ([naa].[gi.li])_V ([bi.la].[ga.ra])_V ([bu.raa].[ba.di])_V

As Wargamay, Gumbayngir has a number of unattested compound templates:

- (19) a *([H]+[H]) c *([LL]+[H]) e *([LH]+[H])
 b *([H]+[LH]) d *([LL]+[LH]) f *([LH]+[LH])

Absence of these root shapes can be explained as in Wargamay. No vowel length occurs outside the first two syllables because of converging stress requirements that both outrank PARSE, i.e. (a) a constraint that heavy syllables must be main-stressed, and (b), a constraint that the initial foot must be main-stressed.

The interest of Gumbayngir resides in the fact that HLL is avoided in ‘derived’ nouns. If an inflectional suffix is added to a (vowel-final) HL nominal root, vowel length obligatorily shifts from the first to the second syllable.

- (20) *Base* *Inflected form*
 a waŋŋji waŋŋji-gu ‘dog-DAT’ (*waŋŋji-gu)
 guuru guuru-la ‘black-LOC’ (*guuru-la)
 b niigar niigar-gu ‘man-DAT’ (*nigaar-gu)

(23)	a	[á.ma]	‘person’	e	a.[ðáa]	‘hole’
	b	[tú.ɣu].<βa>	‘cigarette’	f	a.[máa].<ka>	‘message stick’
	c	u.[kú.ma].<la>	‘sweet potato’	g	[áa.ni].<ma>	‘to do’
	d	ay.pa.[rúm.pi].<wa>	‘sparrowhawk’	h	al.[ɣúu.ma].<la>	‘child’

Accordingly, the template pool is Cpd-Right, modulo σ_μ extrametricality. There are two restrictions. The minimal root is disyllabic. Moreover, no long vowels may appear in the non-head foot (of a Cpd template).

(24)	a	Smw	([H]) (*Min 2 σ)	([LL]) ([á.ma])	([HL]) (*E.m. parse)
	b	Lmw	(L+[H]) (a.[ðáa])	(L+[LL]) (*E.m. parse)	(L+[HL]) (*E.m. parse)
	c	Cpd	([LL]+[H]) ([a.ðu].<ðáa])	([LL]+[LL]) (*E.m. parse)	([LL]+[HL]) (*E.m. parse)

(25) Extrametrical analysis:

a	Smw	([H]) <L> ([máa]).<ru>	([LL]) <L> [tú.ɣu].<βa>	([HL]) <L> ([áa.ni]).<ma>
e	Lmw	(L+[H]) <L> (a.[máa]).<ka>	(L+[LL]) <L> (u.[kú.ma]).<la>	(L+[HL]) <L> (al.[gúu.ma]).<la>
f	Cpd	([LL]+[H]) <L> ([yu.ku].[tíi]).<na>	([LL]+[LL]) <L> ([ay.pa].[rúm.pi]).<wa>	([LL]+[HL]) <L> (<i>accidental gap?</i>)

As in Wargamay, minimal discrepancies arise between the templatic analysis of Cpd roots and their reported stress pattern, which is apparently single-stressed.

Note that the root templates HLL and LHLL, which are based on the unbalanced trochee [HL], are in fact marginal. This observation matches the universal tendency to avoid unbalanced trochees, cf. Hayes (1995). (The Atampaya dialect is the most restrictive since it has no HLL nor LHLL roots at all.) Interestingly Uradhi enforces this restriction at the *root level* rather than at the word level. This can be concluded from two pre-lengthening suffixes (genitive *-:namu* and reciprocal *-:niβa*), which derive words ending in HLL. An interesting example is the genitive of the HL root *taara* ‘reef’, *táaráanamu*, a double-stressed HHLL sequence with two long vowels in adjacent syllables. No root in Uradhi contains adjacent long-voweled syllables, while a final sequence HLL in roots is rare.

Let us now turn to the dialectal variation, which this analysis can describe by two minimal differences. First, the fact that HLL and LHLL roots are restricted to the Angkamuthi and Yadhaykenu dialects is captured by strictly bimoraic feet [H], [LL] in this dialect. Second, the fact that final root syllables cannot contain long vowels in

the Atampaya dialect. For this dialect, all root-final syllables (light and heavy) are extrametrical, while in Angkamuthi and Yadhaykenu only light syllables are so.

7. Conclusions

We have found that for all languages discussed, canonical root shapes (maximal size and position of length) can be captured by template pools. And for all languages, the foot required in root shape agrees with the stress foot. Prosodic coherence was even enhanced by correspondence (in root shape and stress pattern) of *extrametricality* (Uradhi) and *catalexis* (Mbabařam). However, there appears to be no full isomorphy between stress feet and ‘templatic’ feet in some languages (Wargamay, Uradhi) in which the template pool functions as ‘analytic’ only.
